**Remark 5.1.3.4.** Let $q : X \to S$ be a morphism of simplicial sets and let $e : x \to y$ be an edge of $X$. Suppose that $S$ is isomorphic to a left cone $K^q$ and that $q$ carries the vertex $x \in X$ to the cone point of $K^q$. Then $e$ is $q$-cartesian if and only if it is locally $q$-cartesian. Similarly, if $S$ is isomorphic to a right cone $L^q$ and $q$ carries the vertex $y \in X$ to the cone point of $L^q$, then $e$ is $q$-cocartesian if and only if it is locally $q$-cocartesian.

**Remark 5.1.3.5.** Suppose we are given a pullback diagram of simplicial sets

$$
\begin{array}{ccc}
X' & \longrightarrow & X \\
\downarrow & & \downarrow q \\
S' & \longrightarrow & S.
\end{array}
$$

Let $e'$ be an edge of the simplicial set $X'$, having image $e = f(e')$ in $X$. Then $e$ is locally $q$-cartesian if and only if $e'$ is locally $q'$-cartesian. Similarly, $e$ is locally $q$-cocartesian if and only if $e'$ is locally $q'$-cocartesian.
Example 5.1.3.6. Let \( q : X \to S \) be a morphism of simplicial sets and let \( e \) be an edge of \( X \) such that \( q(e) = \text{id}_s \) is a degenerate edge of \( S \). Suppose that the fiber \( X_s = \{s\} \times_S X \) is an \( \infty \)-category (this condition is satisfied, for example, if \( q \) is an inner fibration). The following conditions are equivalent:

- The edge \( e \) is locally \( q \)-cartesian.
- The edge \( e \) is locally \( q \)-cocartesian.
- The edge \( e \) is an isomorphism in the \( \infty \)-category \( X_s \).

To prove this, we can use Remark 5.1.3.5 to reduce to the situation where \( S = \{s\} \) consists of a single vertex. In this case, the edge \( e \) is locally \( q \)-cartesian if and only if it is \( q \)-cartesian, and locally \( q \)-cocartesian if and only if it is \( q \)-cocartesian (Remark 5.1.3.4). The desired result now follows from Example 5.1.1.4.

Proposition 5.1.3.7. Let \( q : X \to S \) be an inner fibration of simplicial sets and let \( \sigma : \Delta^2 \to X \) be a 2-simplex of \( X \), which we will depict as a diagram

\[
\begin{array}{ccc}
& y & \\
\downarrow^f & \downarrow^g & \\
x & h & z.
\end{array}
\]

- Suppose that \( g \) is \( q \)-cartesian. Then \( f \) is locally \( q \)-cartesian if and only if \( h \) is locally \( q \)-cartesian.
- Suppose that \( f \) is \( q \)-cocartesian. Then \( g \) is locally \( q \)-cocartesian if and only if \( h \) is locally \( q \)-cocartesian.

Proof. We will prove the first assertion; the proof of the second is similar. Using Remarks 5.1.1.11 and 5.1.3.5, we can replace \( q \) by the projection map \( \Delta^2 \times_S X \to \Delta^2 \), and thereby reduce to the case where \( S = \Delta^2 \) and \( q(\sigma) \) is the identity morphism \( \text{id}_{\Delta^2} \). In this case, both \( X \) and \( S \) are \( \infty \)-categories and the morphisms \( f \) and \( h \) are locally \( q \)-cartesian if and only if they are \( q \)-cartesian (Remark 5.1.3.4). The desired result now follows from Corollary 5.1.2.4.

Remark 5.1.3.8 (Uniqueness of Locally Cartesian Lifts). Let \( q : X \to S \) be an inner fibration of simplicial sets and let \( g : y \to z \) be a locally \( q \)-cartesian edge of \( X \). Suppose that \( h : x \to z \) is another edge of \( X \) satisfying \( q(h) = q(g) \). Set \( s = q(x) = q(y) \), and let
$X_s = \{s\} \times_S X$ denote the fiber of $q$ over the vertex $s$. Our assumption that $g$ is $q$-cartesian then guarantees that we can choose a 2-simplex $\sigma$ of $X$ satisfying

$$d_0(\sigma) = g \quad d_1(\sigma) = h \quad q(\sigma) = s_0(q(g)),$$

which we display informally as a diagram

```
    y
   / \  \\
  f   g  \\
 /     \  \\
x     h   z
```

here $f = d_2(\sigma)$ is a morphism in the $\infty$-category $X_s$. In this case, the following conditions are equivalent:

(1) The morphism $f$ is an isomorphism in the $\infty$-category $X_s$.

(2) The morphism $h$ is locally $q$-cartesian.

To see this, we can replace $q$ by the projection map $\Delta^1 \times_S X \to \Delta^1$, and thereby reduce to the case where $g$ and $h$ are both lifts of the unique nondegenerate edge of $S = \Delta^1$. In this case, the morphism $g$ is $q$-cartesian, and (1) is equivalent to the assertion that $f$ is locally $q$-cartesian (Example 5.1.3.6). The equivalence of (1) and (2) is now a special case of Proposition 5.1.3.7.

**Corollary 5.1.3.9.** Let $q : X \to S$ be an inner fibration of simplicial sets, let $z$ be a vertex of $X$, and let $e : s \to q(z)$ be an edge of $S$. Suppose that there exists a $q$-cartesian edge $g : y \to z$ of $X$ satisfying $q(g) = e$. Then any locally $q$-cartesian edge $h : x \to z$ satisfying $q(h) = e$ is $q$-cartesian.

**Proof.** By virtue of Remark 5.1.1.12, we may assume without loss of generality that $S$ is an $\infty$-category (or even a simplex). Applying Remark 5.1.3.8, we deduce that there is a 2-simplex of $X$ as depicted in the diagram

```
    y
   / \  \\
  f   g  \\
 /     \  \\
x     h   z
```

where $f$ is an isomorphism in the $\infty$-category $X$. Then $f$ is also $q$-cartesian (Proposition 5.1.1.8), so Corollary 5.1.2.4 guarantees that $h$ is $q$-cartesian. □
We now record an analogue of Proposition 5.1.2.1 for detecting locally cartesian edges.

**Notation 5.1.3.10.** Let \( q : X \to S \) be an inner fibration of simplicial sets, let \( y \) and \( z \) be vertices of \( X \) having images \( s = q(y) \) and \( t = q(z) \), and let \( \overline{e} : s \to t \) be an edge of \( S \). Recall that the relative morphism space \( \text{Hom}_X(y,z)_\overline{e} \) is defined to be the fiber product \( \text{Hom}_X(y,z) \times_{\text{Hom}_S(s,t)} \{ \overline{e} \} \) (Construction 4.6.1.13).

Let \( x \) be another vertex of \( X \) satisfying \( q(x) = s \), and let \( \sigma \) denote the image of \( \overline{e} \) under the degeneracy map \( \text{Hom}_S(s,t) \to \text{Hom}_S(s,s,t) \) (see Notation 4.6.8.1). It follows from Proposition 4.6.8.4 (and Example 4.6.1.15) that restriction along the inclusion \( \Lambda^2_1 \to \Delta^2 \) induces a trivial Kan fibration of simplicial sets

\[
\theta : \text{Hom}_X(x,y,z) \times_{\text{Hom}_S(s,s,t)} \{ \sigma \} \to \text{Hom}_X(y,z) \times \text{Hom}_X(x,y),
\]

where \( X_\sigma \) denotes the \( \infty \)-category given by the fiber \( \{ \sigma \} \times_S X \). In particular, the homotopy class \([\theta]\) is an isomorphism in the homotopy category \( \text{hKan} \). Combining the inverse isomorphism \([\theta]^{-1}\) with the restriction map \( \text{Hom}_X(x,y,z) \times_{\text{Hom}_S(s,s,t)} \{ \sigma \} \to \text{Hom}_X(x,z)_{\overline{e}} \), we obtain a composition law

\[
\circ : \text{Hom}_X(x,y)_{\overline{e}} \times \text{Hom}_X(x,y) \to \text{Hom}_X(x,z). 
\]

If \( e : y \to z \) is an edge of \( X \) satisfying \( q(e) = \overline{e} \), then the restriction of this composition law to \( \{ e \} \times \text{Hom}_X(x,y) \) determines a morphism of Kan complexes \( \text{Hom}_X(x,y) \xrightarrow{[e]} \text{Hom}_X(x,z)_{\overline{e}} \), which is well-defined up to homotopy.

**Proposition 5.1.3.11.** Let \( q : X \to S \) be an inner fibration of simplicial sets, and let \( e : y \to z \) be an edge of the simplicial set \( X \) having image \( \overline{e} : s \to t \) in \( S \). Then \( e \) is locally \( q \)-cartesian if and only if, for every object \( x \) of the \( \infty \)-category \( X_s \), the composition map

\[
\text{Hom}_X(x,y) \xrightarrow{[e]} \text{Hom}_X(x,z)_{\overline{e}}
\]

of Notation 5.1.3.10 is an isomorphism in the homotopy category \( \text{hKan} \).

**Proof.** Without loss of generality, we can replace \( q : X \to S \) by the projection map \( X \times_S \Delta^1 \to \Delta^1 \) and thereby reduce to the case where \( S = \Delta^1 \) and \( \overline{e} \) is the unique nondegenerate edge of \( \Delta^1 \). In this case, the edge \( e \) is locally \( q \)-cartesian if and only if it is \( q \)-cartesian, and the desired result is a special case of Corollary 5.1.2.3. \( \square \)

5.1.4 Cartesian Fibrations

We now introduce an \( \infty \)-categorical counterpart of Definition 5.0.0.3.

**Definition 5.1.4.1.** Let \( q : X \to S \) be a morphism of simplicial sets. We say that \( q \) is a **cartesian fibration** if the following conditions are satisfied:
(1) The morphism $q$ is an inner fibration.

(2) For every edge $\bar{e} : s \to t$ of the simplicial set $S$ and every vertex $z \in X$ satisfying $q(z) = t$, there exists a $q$-cartesian edge $e : y \to z$ of $X$ satisfying $q(e) = \bar{e}$.

We say that $q$ is a \textit{cocartesian fibration} if it satisfies condition (1) together with the following dual version of (2):

(2$'$) For every edge $\bar{e} : s \to t$ of the simplicial set $S$ and every vertex $y \in X$ satisfying $q(y) = s$, there exists a $q$-cocartesian edge $e : y \to z$ of $X$ satisfying $q(e) = \bar{e}$.

\textbf{Example 5.1.4.2.} Let $q : C \to D$ be a functor between ordinary categories. Then $q$ is a cartesian fibration (in the sense of Definition\textsuperscript{5.0.0.3}) if and only if the induced morphism of simplicial sets $N_\bullet(q) : N_\bullet(C) \to N_\bullet(D)$ is a cartesian fibration (in the sense of Definition\textsuperscript{5.1.4.1}). Similarly, $q$ is a cocartesian fibration if and only if $N_\bullet(q)$ is a cocartesian fibration of simplicial sets. See Corollary\textsuperscript{5.1.2.2}.

\textbf{Example 5.1.4.3.} Let $X$ be a simplicial set and let $q : X \to \Delta^0$ denote the projection map. The following conditions are equivalent:

\begin{itemize}
  \item The simplicial set $X$ is an $\infty$-category.
  \item The morphism $q$ is a cartesian fibration.
  \item The morphism $q$ is a cocartesian fibration.
\end{itemize}

\textbf{Remark 5.1.4.4.} Let $q : X \to S$ be a morphism of simplicial sets. Then $q$ is a cartesian fibration if and only if the opposite morphism $q^{\text{op}} : X^{\text{op}} \to S^{\text{op}}$ is a cocartesian fibration.

\textbf{Remark 5.1.4.5.} Let $q : X \to S$ be an inner fibration of simplicial sets and let $e$ be an edge of $X$. If $q$ is a cartesian fibration, then $e$ is $q$-cartesian if and only if it is locally $q$-cartesian (see Corollary\textsuperscript{5.1.3.9}). Similarly, if $q$ is a cocartesian fibration, then $e$ is $q$-cocartesian if and only if it is locally $q$-cocartesian.

\textbf{Remark 5.1.4.6.} Suppose we are given a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
X' & \xrightarrow{f} & X \\
\downarrow{q'} & & \downarrow{q} \\
S' & \xrightarrow{g} & S
\end{array}
\]

If $q$ is a cartesian fibration, then $q'$ is also a cartesian fibration. Moreover, an edge $e'$ of $X'$ is $q'$-cartesian if and only if $e = f(e')$ is a $q$-cartesian edge of $X$ (this follows from Remarks
Similarly, if \( q \) is a cocartesian fibration, then \( q' \) is also a cocartesian fibration (and an edge \( e' \) of \( X' \) is \( q' \)-cocartesian if and only if \( e = f(e') \) is a \( q \)-cocartesian edge of \( X \)).

**Proposition 5.1.4.7.** Let \( q : X \to S \) be a morphism of simplicial sets. Then \( q \) is a cartesian fibration if and only if, for every simplex \( \sigma : \Delta^n \to S \), the projection map \( q_\sigma : \Delta^n \times_S X \to \Delta^n \) is a cartesian fibration.

*Proof.* If \( q \) is a cartesian fibration, then Remark 5.1.4.6 guarantees that every pullback of \( q \) is a cartesian fibration. Conversely, suppose that for every \( n \)-simplex \( \sigma : \Delta^n \to S \), the projection map \( q_\sigma : \Delta^n \times_S X \to \Delta^n \) is a cartesian fibration. Applying this assumption in the case \( n = 1 \), we conclude that for every vertex \( y \in X \) and every edge \( \tau : x \to q(y) \) of \( S \), there exists a locally \( q \)-cartesian edge \( e : x \to y \) satisfying \( q(e) = \tau \). Moreover, Remark 4.1.1.13 guarantees that \( q \) is an inner fibration. It will therefore suffice to show that every locally \( q \)-cartesian edge \( e \) of \( X \) is \( q \)-cartesian. By virtue of Remark 5.1.1.12, it suffices to verify the analogous assertion for each of the projection maps \( q_\sigma : \Delta^n \times_S X \to \Delta^n \), which follows from Remark 5.1.4.5 (since \( q_\sigma \) is assumed to be a cartesian fibration).

**Proposition 5.1.4.8.** Let \( q : C \to D \) be a cartesian fibration of \( \infty \)-categories. Then \( q \) is an isofibration.

*Proof.* Suppose we are given an object \( Y \in C \) and an isomorphism \( \bar{\tau} : X \to q(Y) \) in the \( \infty \)-category \( D \). We wish to show that there exists an isomorphism \( e : X \to Y \) in the \( \infty \)-category \( C \) satisfying \( q(e) = \bar{\tau} \). Our assumption that \( q \) is a cartesian fibration guarantees that we can write \( \bar{\tau} = q(e) \), where \( e : X \to Y \) is a \( q \)-cartesian morphism of \( C \). Since \( \bar{\tau} = q(e) \) is an isomorphism, Proposition 5.1.1.8 guarantees that \( e \) is an isomorphism.

**Remark 5.1.4.9.** In the statement of Proposition 5.1.4.8, the hypothesis that \( C \) and \( D \) are \( \infty \)-categories is superfluous: we will later show that every cartesian fibration of simplicial sets is an isofibration (Corollary 5.7.7.5).

**Corollary 5.1.4.10.** Let \( q : X \to S \) be a morphism of simplicial sets, where \( S \) is a Kan complex. The following conditions are equivalent:

1. The morphism \( q \) is an isofibration.
2. The morphism \( q \) is a cartesian fibration.
3. The morphism \( q \) is a cocartesian fibration.

*Proof.* We will prove the equivalence (1) \( \iff \) (2); the equivalence (1) \( \iff \) (3) follows by a similar argument. The implication (2) \( \implies \) (1) is a special case of Proposition 5.1.4.8. For the converse, suppose that \( q \) is an isofibration. Then \( q \) is an inner fibration. To complete
the proof, we must show that for every vertex \( y \in X \) and every edge \( \bar{e} : \bar{x} \to q(y) \) of \( S \), we can write \( \bar{e} = q(e) \) for some \( q \)-cartesian edge \( e \) of \( X \). Since \( S \) is a Kan complex, \( \bar{e} \) is an isomorphism (Proposition 1.3.6.10). Our assumption that \( q \) is an isofibration then guarantees that we can write \( \bar{e} = q(e) \) for some isomorphism \( e : x \to y \) of \( X \). The edge \( e \) is automatically \( q \)-cartesian by virtue of Corollary 5.1.1.10.

**Proposition 5.1.4.11.** Let \( q : X \to S \) be a cartesian fibration of simplicial sets and let \( e \) be an edge of \( X \) such that \( q(e) = \text{id}_x \) is a degenerate edge of \( S \). Then \( e \) is \( q \)-cartesian if and only if it is an isomorphism in the \( \infty \)-category \( X_s = \{ s \} \times_S X \).

**Proof.** Combine Example 5.1.3.6 with Remark 5.1.4.5.

**Proposition 5.1.4.12.** Let \( q : X \to S \) be a cartesian fibration of simplicial sets and let \( \sigma : \Delta^2 \to X \) be a 2-simplex of \( X \), which we will depict as a diagram

\[
\begin{array}{ccc}
  & y & \\
 g & \downarrow & \downarrow f \\
 x & \quad h \quad & z
\end{array}
\]

Suppose that \( g \) is \( q \)-cartesian. Then \( f \) is \( q \)-cartesian if and only if \( h \) is \( q \)-cartesian.

**Proof.** Combine Proposition 5.1.3.7 with Remark 5.1.4.5.

**Proposition 5.1.4.13.** Let \( p : X \to Y \) and \( q : Y \to Z \) be cartesian fibrations of simplicial sets. Then:

- The composite morphism \( (q \circ p) : X \to Z \) is a cartesian fibration of simplicial sets.
- An edge \( e \) of \( X \) is \( (q \circ p) \)-cartesian if and only if \( e \) is \( p \)-cartesian and \( p(e) \) is \( q \)-cartesian.

**Proof.** It follows from Remark 4.1.1.8 that \( q \circ p \) is an inner fibration. Let us say that an edge \( e \) of \( X \) is special if \( e \) is \( p \)-cartesian and \( p(e) \) is \( q \)-cartesian. Remark 5.1.1.6 guarantees that every special edge of \( X \) is \( (q \circ p) \)-cartesian. Consequently, to prove the first assertion, it will suffice to verify the following:

\((*)\) For every edge \( \bar{e} : z' \to z \) of \( Z \) and every vertex \( x \in X \) satisfying \( z = (q \circ p)(x) \), there exists a special edge \( e : x' \to x \) of \( X \) satisfying \( \bar{e} = (q \circ p)(e) \).

To prove \((*)\), set \( y = p(x) \). Using our assumption that \( q \) is a cartesian fibration, we can choose a \( q \)-cartesian edge \( \bar{e} : y' \to y \) of the simplicial set \( Y \) satisfying \( q(\bar{e}) = \bar{e} \). Using our assumption that \( p \) is a cartesian fibration, we can choose a \( p \)-cartesian edge \( e : x' \to x \) of \( X \) satisfying \( p(e) = \bar{e} \). Then \( e \) is a special edge of \( X \) satisfying \( (q \circ p)(e) = q(\bar{e}) = \bar{e} \).
To complete the proof, it will suffice to show that every \((q \circ p)\)-cartesian edge \(f : x'' \rightarrow x\) of \(X\) is special. Let \(\overline{f} : z'' \rightarrow z\) be the image of \(f\) under \((q \circ p) : X \rightarrow Z\). Using \((\ast)\), we can choose a special edge \(e : x' \rightarrow x\) satisfying \((q \circ p)(e) = \overline{f}\). Since \(e\) is \((q \circ p)\)-cartesian, we can choose a 2-simplex \(\sigma\) of \(X\) satisfying
\[
\begin{align*}
d_0(\sigma) &= e & d_1(\sigma) &= f & (q \circ p)(\sigma) &= s_0(\overline{e}).
\end{align*}
\]
Set \(g = d_2(\sigma)\), so that we can view \(\sigma\) informally as a diagram

\[
\begin{array}{ccc}
x' & \xrightarrow{g} & x'' \\
\downarrow{f} & & \downarrow{e} \\
x & \xrightarrow{y'} & y.
\end{array}
\]

Set \(y' = p(x') \in Y\) and \(z' = q(y') \in Z\). Since \(f\) is \((q \circ p)\)-cartesian, the edge \(g\) is an isomorphism in the \(\infty\)-category \(X_{z'}\) (Remark 5.1.3.8). Then \(g\) is \(p'\)-cartesian, where \(p' : X_{z'} \rightarrow Y_{z'}\) is the projection map (Proposition 5.1.1.8). Applying Remark 5.1.3.5, we conclude that \(g\) is locally \(p\)-cartesian. Since \(p\) is a cartesian fibration, it follows that \(g\) is \(p\)-cartesian (Remark 5.1.4.5). Invoking Proposition 5.1.4.12 we deduce that \(f\) is also \(p\)-cartesian. Since \(p(g)\) is an isomorphism in the \(\infty\)-category \(Y_{z'}\), it is \(q\)-cartesian (Proposition 5.1.4.11). Applying Proposition 5.1.4.12, we conclude that \(p(f)\) is also \(q\)-cartesian.

Recall that an \(\infty\)-category \(\mathcal{C}\) is a Kan complex if and only if every morphism in \(\mathcal{C}\) is an isomorphism (Proposition 4.4.2.1). We now establish a relative version of this assertion:

**Proposition 5.1.4.14.** Let \(q : X \rightarrow S\) be a morphism of simplicial sets. The following conditions are equivalent:

1. The morphism \(q\) is a right fibration.
2. The morphism \(q\) is a cartesian fibration and every edge of \(X\) is \(q\)-cartesian.
3. The morphism \(q\) is a cartesian fibration and, for every vertex \(s \in S\), the fiber \(X_s = \{s\} \times_S X\) is a Kan complex.

**Proof.** The equivalence (1) \(\Leftrightarrow\) (2) is immediate from the definitions. The implication (2) \(\Rightarrow\) (3) follows from Propositions 5.1.4.11 and 4.4.2.1. We will complete the proof by showing that (3) implies (2). Assume that \(q\) is a cartesian fibration and that each fiber of \(q\) is a Kan complex. Let \(h : x \rightarrow z\) be an edge of \(X\); we wish to show that \(h\) is \(q\)-cartesian. Since \(q\) is a cartesian fibration, we can choose a \(q\)-cartesian edge \(g : y \rightarrow z\) of \(X\) satisfying
q(g) = q(h). The assumption that g is q-cartesian then guarantees the existence of a 2-simplex σ of X satisfying
\[ d_0(\sigma) = g \quad d_1(\sigma) = h \quad q(\sigma) = s_0(q(h)), \]
as depicted in the diagram

\[ \begin{array}{c}
  y \\
  \downarrow f \\
  \hdots x \hspace{1cm} h \\
  \downarrow \downarrow g \\
  \hdots z.
\end{array} \]

Set \( s = q(x) \), so that \( f \) is a morphism in the ∞-category \( X_s = \{s\} \times_S X \). Since \( X_s \) is a Kan complex, \( f \) is an isomorphism (Proposition 1.3.6.10). Applying Remark 5.1.3.8 and Corollary 5.1.3.9, we deduce that \( h \) is q-cartesian.

Recall that every ∞-category \( C \) has an underlying Kan complex \( C^\simeq \), obtained by discarding the noninvertible morphisms of \( C \) (Construction 4.4.3.1). Using Proposition 5.1.4.14, we can establish a relative version of this result.

**Corollary 5.1.4.15.** Let \( q : X \to S \) be a cartesian fibration of simplicial sets, and let \( X' \subseteq X \) be the simplicial subset spanned by those simplices \( \sigma : \Delta^n \to X \) which carry each edge of \( \Delta^n \) to a q-cartesian edge of \( X \). Then the morphism \( q\mid_{X'} : X' \to S \) is a right fibration of simplicial sets.

**Proof.** Choose integers \( 0 < i \leq n \); we wish to show that every lifting problem

\[ \begin{array}{c}
  \Lambda^n_i \xrightarrow{\sigma_0} X' \\
  \downarrow \downarrow \sigma \\
  \Delta^n \xrightarrow{\sigma} S
\end{array} \]

admits a solution. In the special case \( i = n = 1 \), this follows immediately from our assumption that \( q \) is a cartesian fibration. Assume therefore that \( n \geq 2 \). We first show that \( \sigma_0 \) can be extended to an \( n \)-simplex \( \sigma : \Delta^n \to X \) satisfying \( q \circ \sigma = \sigma \). For \( i < n \), this follows from the assumption that \( q \) is an inner fibration. For \( i = n \), it follows from the assumption that the edge

\[ \Delta^1 \simeq N_\bullet(\{n - 1 < n\}) \hookrightarrow \Lambda^n_i \xrightarrow{\sigma_0} X' \hookrightarrow X \]

is q-cartesian. We now complete the proof by showing that \( \sigma \) factors through the simplicial subset \( X' \); that is, it carries each edge of \( \Delta^n \) to a q-cartesian edge of \( X \). For \( n \geq 3 \), this
is immediate (since every edge of $\Delta^n$ is contained in $\Lambda^n_\ast$). The case $n = 2$ follows from Proposition 5.1.4.12.

**Proposition 5.1.4.16.** Let $q : X \to S$ be a cartesian fibration of simplicial sets, and let $X' \subseteq X$ be a full simplicial subset with the following property:

$(\ast)$ For every vertex $y \in X'$ and every edge $\overline{e} : \overline{x} \to q(\overline{y})$ in $S$, there exists a vertex $x \in X'$ and a $q$-cartesian edge $e : x \to y$ of $X$ satisfying $q(e) = \overline{e}$.

Then $q' = q|_{X'}$ is a cartesian fibration from $X'$ to $S$. Moreover, an edge $e$ of $X'$ is $q'$-cartesian if and only if it is $q$-cartesian.

**Proof.** Since the inclusion map $X' \hookrightarrow X$ is an inner fibration (see Definition 4.1.2.15), the restriction $q|_{X'}$ is also an inner fibration. Remark 5.1.1.7 guarantees that every edge of $X'$ which is $q$-cartesian is also $q'$-cartesian, so that $(\ast)$ immediately guarantees that $q'$ is a cartesian fibration. To complete the proof, we must show that if $e : x \to z$ is a $q'$-cartesian edge of $X'$, then $e$ is $q$-cartesian when viewed as an edge of $X$. Applying $(\ast)$, we can choose a $q$-cartesian edge $e' : y \to z$ satisfying $q(e') = q(e)$, where $y$ belongs to $X'$. Then $e'$ is also $q'$-cartesian, so Remark 5.1.3.8 guarantees that there exists a 2-simplex

$$
\begin{array}{ccc}
  & y & \\
 u & \nearrow & \searrow e' \\
 x & \downarrow & \downarrow z \\
 & x & \leftarrow \rightarrow z
\end{array}
$$

of $X'$, where $u$ is an isomorphism in the $\infty$-category $\{q(x)\} \times_S X'$. It follows that $u$ is also an isomorphism in the $\infty$-category $\{q(x)\} \times_S X$, and is therefore $q$-cartesian (Proposition 5.1.4.11). Applying Proposition 5.1.4.12, we see that the edge $e$ is also $q$-cartesian. \(\square\)

We now study the behavior of cartesian fibrations with respect to the slice and coslice constructions of \S 4.3.

**Proposition 5.1.4.17.** Let $q : X \to S$ be a cartesian fibration of simplicial sets and let $f : K \to X$ be any morphism of simplicial sets. Then:

1. The induced map $q' : X_f \to S_{/(q \circ f)}$ is a cartesian fibration of simplicial sets.

2. An edge $e$ of $X_f$ is $q'$-cartesian if and only if its image in $X$ is $q$-cartesian.

**Proof.** The morphism $q'$ factors as a composition

$$
X_f \xrightarrow{u} X \times_S S_{/(q \circ f)} \xrightarrow{v} S_{/(q \circ f)}.
$$
Since $q$ is an inner fibration, the morphism $u$ is a right fibration (Proposition 4.3.6.8). In particular, $u$ is a cartesian fibration and every edge of $X_f$ is $u$-cartesian (Proposition 5.1.4.14). The morphism $v$ is a pullback of $q$, and is therefore a cartesian fibration (Proposition 5.1.4.6). Moreover, an edge of $X \times_S S_{(qof)}$ is $v$-cartesian if and only if its image in $X$ is $q$-cartesian. Assertions (1) and (2) now follow from Proposition 5.1.4.13.

\textbf{Lemma 5.1.4.18.} Let $q : X \to S$ be an inner fibration of simplicial sets, let $f : B \to X$ be a morphism of simplicial sets, let $A$ be a simplicial subset of $B$, and let

$$q' : X_f/ \to X_{[A]/} \times_S S_{(qof|_{A})}/ S_{(qof)}/$$

be the induced map. Let $\bar{v}$ be an edge of the simplicial set $X_f/$, and let $e$ be its image in $X$. If $e$ is $q$-cartesian, then $\bar{v}$ is $q'$-cartesian.

\textbf{Proof.} Let $q'' : X_{[A]/} \times_S S_{(qof|_{A})}/ S_{(qof)}/ \to S_{(qof)}/$ be the projection map onto the second factor. Then $q''$ is a pullback of the map $u : X_{[A]/} \to S_{(qof|_{A})}/$, and is therefore an inner fibration (Corollary 4.3.6.10). By virtue of Corollary 5.1.1.14, the edge $\bar{v}$ is $(q'' \circ q')$-cartesian and the image of $\bar{v}$ in $X_{[A]/}$ is $u$-cartesian. It follows from Remark 5.1.1.11 that $q'(\bar{v})$ is $q''$-cartesian, so that $\bar{v}$ is $q'$-cartesian by virtue of Corollary 5.1.2.6.

\textbf{Proposition 5.1.4.19.} Let $q : X \to S$ be a cartesian fibration of simplicial sets and let $f : K \to X$ be any morphism of simplicial sets. Then:

(1) The induced map $q' : X_f/ \to S_{(qof)}/$ is a cartesian fibration of simplicial sets.

(2) An edge $e$ of $X_f/ \to q'$-cartesian if and only if its image in $X$ is $q$-cartesian.

\textbf{Proof.} The morphism $q'$ factors as a composition

$$X_f/ \xrightarrow{\mu} X \times_S S_{(qof)}/ \xrightarrow{v} S_{(qof)}/,$$

where $v$ is a pullback of $q$ and is therefore a cartesian fibration by virtue of Remark 5.1.4.6. The morphism $u$ is a left fibration (Proposition 4.3.6.8), and therefore an inner fibration. It follows that $q'$ is an inner fibration (Remark 4.1.1.8).

Let us say that an edge $e$ of $X_f/ \to q'$-cartesian if its image in $X$ is $q$-cartesian. If this condition is satisfied, then $u(e)$ is $v$-cartesian (Remark 5.1.4.6) and $e$ is $u$-cartesian (Lemma 5.1.4.18), so that $e$ is $q'$-cartesian by virtue of Remark 5.1.1.6. This proves the “if” direction of assertion (2).

To prove (1), it will suffice to show that for every vertex $y$ of the simplicial set $X_f/ \to S_{(qof)}/$ and every edge $\bar{v} : \bar{v} \to q'(y)$ of the simplicial set $S_{(qof)}/$, there exists a special edge $e : x \to y$ of $X_f/ \to q'(e) = \bar{v}$. Since $v$ is a cartesian fibration, we can choose a $v$-cartesian edge $\bar{e} : \bar{x} \to u(y)$ of the simplicial set $X \times_S S_{(qof)}/$. In this case, the image $\bar{e}$ in $X$ is
5.1. CARTESIAN FIBRATIONS

$q$-cartesian (Remark 5.1.4.6). Corollary 5.1.1.15 then guarantees that there exists an edge $e : x \to y$ of $X_f$ satisfying $u(e) = \bar{e}$. The edge $e$ is automatically special and satisfies $q'(e) = (v \circ u)(e) = v(\bar{e}) = \bar{e}$, as desired.

To complete the proof of (2), it will suffice to show that every $q'$-cartesian edge $e : x \to z$ of $X_f$ is special. It follows from the preceding argument that there exists a special edge $e' : y \to z$ satisfying $q'(e') = q'(e)$, which is also $q'$-cartesian. Applying Remark 5.1.3.8 we can choose a 2-simplex $\sigma$ of $X_f$ as indicated in the diagram

$$
\begin{array}{c}
\triangle \leftarrow e'' \rightarrow \triangle \\
\uparrow \quad \quad \downarrow \\
\leftarrow e' \rightarrow \rightarrow e \\
\downarrow \quad \quad \uparrow \\
x \quad \quad \quad \quad z,
\end{array}
$$

where $e''$ is an isomorphism in the $\infty$-category $\{q'(x)\} \times S_{(q \circ f_1)} / X_f$. Using Proposition 5.1.4.11 we deduce that the image of $e''$ in $X$ is $q$-cartesian. Applying Proposition 5.1.4.12 we conclude the image of $e$ in $X$ is also $q$-cartesian, as desired. \hfill \square

Proposition 5.1.4.20. Suppose we are given a commutative diagram of simplicial sets

$$
\begin{array}{ccc}
X_0 & \xrightarrow{F_0} & X \\
\downarrow U_0 & & \downarrow U \\
S & \xleftarrow{F_1} & X_1
\end{array}
$$

satisfying the following conditions:

- The morphisms $U_0$ and $U_1$ are cartesian fibrations.
- The morphism $F_0$ carries $U_0$-cartesian edges of $X_0$ to $U$-cartesian edges of $X$.
- The morphism $F_1$ carries $U_1$-cartesian edges of $X_1$ to $U$-cartesian edges of $X$.
- The morphism $F_1$ is an isofibration.

Then the induced map $U_{01} : X_0 \times_X X_1 \to S$ is also a cartesian fibration. Moreover, an edge $e = (e_0, e_1)$ of $X_0 \times_X X_1$ is $U_{01}$-cartesian if and only if $e_0$ is $U_0$-cartesian and $e_1$ is $U_1$-cartesian.

Proof. Let $\pi : X_0 \times_X X_1 \to X_0$ and $\pi' : X_0 \times_X X_1 \to X_1$ be the projection maps. Since $F_1$ is an isofibration, $\pi$ is also an isofibration. In particular, $\pi$ is an inner fibration, so the
composition \( U_{01} = U_0 \circ \pi \) is also an inner fibration. Let us say that an edge \( e = (e_0, e_1) \) of \( X_0 \times_X X_1 \) is **special** if \( e_0 \) is \( U_0 \)-cartesian and \( e_1 \) is \( U_1 \)-cartesian. The second assumption guarantees that \( e \) is \( \pi \)-cartesian (Remark 5.1.1.11) and the first guarantees that \( \pi(e) \) is \( U_0 \)-cartesian. Applying Corollary 5.1.2.4, we deduce that every special edge of \( X_0 \times_X X_1 \) is \( U_{01} \)-cartesian.

To prove that \( U_{01} \) is a cartesian fibration, it will suffice to show that for every vertex \( x = (x_0, x_1) \) of \( X_0 \times_X X_1 \) and every edge \( e : s \to U_{01}(x) \) in \( S \), there exists a special edge \( e : y \to x \) of \( X_0 \times_X X_1 \) satisfying \( U_{01}(e) = \pi(e) \). Since \( U_0 \) is a cartesian fibration, we can choose a \( U_0 \)-cartesian edge \( e_0 : y_0 \to x_0 \) of \( X_0 \) satisfying \( U_0(e_0) = \pi(e) \). Similarly, we can choose a \( U_1 \)-cartesian edge \( e_1 : y_1 \to x_1 \) of \( X_1 \) satisfying \( U_1(e_1) = \pi(e) \). We now observe that \( F_0(e_0) \) and \( F_1(e_1) \) are \( U \)-cartesian edges of \( X \) having the same target and the same image in the simplicial set \( S \). Applying Remark 5.1.3.8, we can choose a 2-simplex \( \sigma \) of \( X \) as indicated in the diagram.

\[
\begin{array}{ccc}
F_1(y_1) & \quad & \ F_1(e_1) \\
\downarrow v & & \downarrow \quad \ \\
F_0(y_0) & \quad & \ F_1(x_1),
\end{array}
\]

where \( v \) is an isomorphism in the \( \infty \)-category \( X_s = \{s\} \times S X \). Our assumption that \( F_1 \) is an isofibration guarantees that we can lift \( v \) to an isomorphism \( \tilde{v} : y'_1 \to y_1 \) in the \( \infty \)-category \( \{s\} \times S X_1 \). Since \( F_1 \) is an inner fibration, we can lift \( \sigma \) to a 2-simplex \( \tilde{\sigma} \) of \( X_1 \) with boundary indicated in the diagram.

\[
\begin{array}{ccc}
y_1 & \quad & \ y_1 \\
\downarrow \quad v & & \downarrow \quad e_1 \\
y'_1 & \quad & \ x_1,
\end{array}
\]

It follows from Propositions 5.1.4.11 and 5.1.4.12 that \( e'_1 \) is a \( U_1 \)-cartesian edge of \( X_1 \), so that \( e = (e_0, e'_1) \) is a special edge of \( X_0 \times_X X_1 \) with target \( x = (x_0, x_1) \) which satisfies \( U_{01}(e) = \pi(e) \).

To complete the proof of Proposition 5.1.4.20, it will suffice to show that if \( f : z \to x \) is a \( U_{01} \)-cartesian edge of the fiber product \( X_0 \times_X X_1 \), then \( f \) is special. Set \( s = U_{01}(z) \). Applying the above argument, we can choose a special edge \( e : y \to x \) satisfying \( U_{01}(e) = U_{01}(f) \). Using Remark 5.1.3.8, we can choose a 2-simplex \( \tau \) of \( X_0 \times_X X_1 \) with boundary indicated...
in the diagram

\[ \begin{array}{ccc}
  y & \xrightarrow{v} & e \\
  \downarrow \searrow & & \swarrow \\
  z & & x
\end{array} \]

where \( v \) is an isomorphism in the \( \infty \)-category \( \{ s \} \times_S (X_0 \times_X X_1) \). Applying Propositions \[5.1.4.11\] and \[5.1.4.12\] to the 2-simplices \( \pi(\tau) \) and \( \pi'(\tau) \), we conclude that the edges \( \pi(f) \) and \( \pi'(f) \) are \( U_0 \)-cartesian and \( U_1 \)-cartesian, as desired.

As an application of Proposition \[5.1.4.20\], we record a generalization of Proposition \[5.1.4.19\] which will be useful later.

**Corollary 5.1.4.21.** Suppose we are given a commutative diagram of simplicial sets

\[ \begin{array}{ccc}
  X' & \xrightarrow{u} & X \\
  \downarrow q' & & \downarrow q \\
  S & \xrightarrow{q} & \ast
\end{array} \]

where \( q \) and \( q' \) are cartesian fibrations and the morphism \( u \) carries \( q' \)-cartesian edges of \( X' \) to \( q \)-cartesian edges of \( X \). Let \( f : K \to X \) be a morphism of simplicial sets. Then \( q' \) induces a cartesian fibration \( \tilde{q}' : X' \times_X X_f/ \to S_{(q_0f)/} \). Moreover, an edge of \( X' \times_X X_f/ \) is \( \tilde{q}' \)-cartesian if and only if its image in \( X' \) is \( q' \)-cartesian.

**Proof.** Let \( \bar{u} : X' \times_S S_{(q_0f)/} \to X \times_S S_{(q_0f)/} \) denote the pullback of \( u \), let \( \tilde{q} : X \times_S S_{(q_0f)/} \to S_{(q_0f)/} \) be given by projection onto the second factor, and let \( v : X_f/ \to X \times_S S_{(q_0f)/} \) be the left fibration of Proposition \[4.3.6.8\]. Note that \( \tilde{q} \) is a pullback of \( q \), and therefore a cartesian fibration (Remark \[5.1.4.6\]). Moreover, an edge of \( X \times_S S_{(q_0f)/} \) is \( \tilde{q} \)-cartesian if and only if its image in \( X \) is \( q \)-cartesian. Similarly, the composite map \( \tilde{q} \circ \bar{u} \) is a pullback of \( q' \). It follows that \( \tilde{q} \circ \bar{u} \) is a cartesian fibration, and that an edge of \( X' \times_S S_{(q_0f)/} \) is \( (\tilde{q} \circ \bar{u}) \)-cartesian if and only if its image in \( X' \) is \( q' \)-cartesian. Applying Proposition \[5.1.4.19\], we deduce that the composition \( \tilde{q} \circ v \) is a cartesian fibration, and that an edge of \( X_f/ \) is \( (\tilde{q} \circ v) \)-cartesian if and only if its image in \( X \) is \( q \)-cartesian. The desired result now follows by applying Proposition
5.1.4.20 to the diagram

\[
\begin{array}{ccc}
X' \times_S S_{(q \circ f)}/ & \xrightarrow{\bar{u}} & \bar{X} \times_S S_{(q \circ f)}/ \xleftarrow{\bar{v}} \bar{X}/ \\
\downarrow \pi & & \downarrow \\
S_{(q \circ f)}/ & & 
\end{array}
\]

5.1.5 Fiberwise Equivalence

Let \( \mathcal{D} \) be an \( \infty \)-category. Our primary goal in this section is to show that, when studying \( \infty \)-categories \( \mathcal{C} \) equipped with a cartesian fibration \( \mathcal{C} \to \mathcal{D} \), equivalence can be detected fiberwise. More precisely, we have the following result:

**Theorem 5.1.5.1.** Suppose we are given a commutative diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{C}' \\
\downarrow U & & \downarrow U' \\
\mathcal{D} & \xrightarrow{\bar{F}} & \mathcal{D}'
\end{array}
\]

where \( U \) is a cartesian fibration of \( \infty \)-categories, \( U' \) is an isofibration of \( \infty \)-categories, and \( \bar{F} \) is an equivalence of \( \infty \)-categories. Then the functor \( F \) is an equivalence of \( \infty \)-categories if and only if it satisfies the following conditions:

1. For every object \( D \in \mathcal{D} \) having image \( D' = \bar{F}(D) \) in \( \mathcal{D}' \), the induced functor
   \[
   F_D : \mathcal{C}_D = \{ D \} \times_D \mathcal{C} \to \{ D' \} \times_{\mathcal{D}'} \mathcal{C}' = \mathcal{C}'_{D'}
   \]
   is an equivalence of \( \infty \)-categories.

2. The functor \( F \) carries \( U \)-cartesian morphisms of \( \mathcal{C} \) to \( U' \)-cartesian morphisms of \( \mathcal{C}' \).

Moreover, if these conditions are satisfied, then \( U' \) is also a cartesian fibration of \( \infty \)-categories.

We will give the proof of Theorem 5.1.5.1 at the end of this section. First, let us collect some of its consequences.
Corollary 5.1.5.2. Suppose we are given a commutative diagram of ∞-categories

Assume that $U$ and $U'$ are isofibrations of ∞-categories and that $F$ and $F'$ are equivalences of ∞-categories. Then:

- The functor $U$ is a cartesian fibration if and only if $U'$ is a cartesian fibration.
- The functor $U$ is a cocartesian fibration if and only if $U'$ is a cocartesian fibration.

Proof. We will prove the first assertion; the second follows by a similar argument. It follows from Theorem 5.1.5.1 that if $U$ is a cartesian fibration, then $U'$ is also a cartesian fibration.

To prove the converse, choose functors $G' : C' \to C$ and $G : D' \to D$ which are homotopy inverse to the equivalences $F$ and $F'$, respectively. We then have isomorphisms

$$U \circ G' \circ F \simeq U \simeq G \circ F \circ U = G \circ U' \circ F$$

in the functor ∞-category $\text{Fun}(C, D)$. Since $F$ is an equivalence of ∞-categories, it follows that there exists an isomorphism $\overline{\alpha} : U \circ G' \to G \circ U'$ in the functor ∞-category $\text{Fun}(C', D')$. Using our assumption that $U$ is an isofibration, we can lift $\overline{\alpha}$ to an isomorphism of functors $\alpha : G' \to G$ (Proposition 4.4.5.8). Applying Theorem 5.1.5.1 to the commutative diagram

we conclude that if $U'$ is a cartesian fibration, then $U$ is also a cartesian fibration.

Corollary 5.1.5.3. Suppose we are given a commutative diagram of ∞-categories
Assume that \( U \) and \( U' \) are isofibrations of \( \infty \)-categories and that \( F \) and \( \overline{F} \) are equivalences of \( \infty \)-categories. Then:

- The functor \( U \) is a right fibration if and only if \( U' \) is a right fibration.
- The functor \( U \) is a left fibration if and only if \( U' \) is a left fibration.

**Proof.** We will prove the first assertion; the second follows by a similar argument. Assume first that \( U' \) is a right fibration of \( \infty \)-categories. Then \( U' \) is a cartesian fibration (Proposition 5.1.4.14), so Corollary 5.1.5.2 implies that \( U \) is a cartesian fibration. To prove that \( U \) is a right fibration, it will suffice to show that for every object \( D \in \mathcal{D} \), the fiber \( C_D = \{ D \} \times_{\mathcal{D}} \mathcal{C} \) is a Kan complex (Proposition 5.1.4.14). This follows from Remark 4.5.1.21, since the functor \( F \) induces an equivalence of \( \infty \)-categories \( F_D : C_D \rightarrow C'_D \) (Corollary 4.5.2.26).

We now prove the reverse implication. Arguing as in the proof of Corollary 5.1.5.2, we can construct a commutative diagram:

\[
\begin{array}{ccc}
\mathcal{C}' & \xrightarrow{G} & \mathcal{C} \\
\downarrow{U'} & & \downarrow{U} \\
\mathcal{D}' & \xrightarrow{\overline{G}} & \mathcal{D},
\end{array}
\]

where \( G \) and \( \overline{G} \) are homotopy inverses of the equivalences \( F \) and \( \overline{F} \), respectively. It then follows from the preceding argument that if \( U \) is a right fibration of \( \infty \)-categories, then \( U' \) is also a right fibration of \( \infty \)-categories. \( \square \)

**Corollary 5.1.5.4.** Suppose we are given a commutative diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{C}' \\
\downarrow{U} & & \downarrow{U'} \\
\mathcal{D} & \xrightarrow{\overline{F}} & \mathcal{D}'.
\end{array}
\]

where \( U \) and \( U' \) are right fibrations and the functor \( \overline{F} \) is an equivalence of \( \infty \)-categories. Then \( F \) is an equivalence of \( \infty \)-categories if and only if, for every object \( D \in \mathcal{D} \) having image \( D' = \overline{F}(D) \in \mathcal{D}' \), the induced map of fibers \( F_D : C_D \rightarrow C'_D \) is a homotopy equivalence of Kan complexes.

The proof of Theorem 5.1.5.1 will require some preliminaries. Our first step is to show that if \( U : \mathcal{C} \rightarrow \mathcal{D} \) is an isofibration of \( \infty \)-categories, then the collection of \( U \)-cartesian morphisms of \( \mathcal{C} \) is invariant under categorical equivalence.
Lemma 5.1.5.5. Suppose we are given a commutative diagram of $\infty$-categories

$$
\begin{array}{ccc}
C & \xrightarrow{F} & C' \\
\downarrow U & & \downarrow U' \\
D & \xrightarrow{F} & D',
\end{array}
$$

where the functors $U$ and $U'$ are inner fibrations and the functors $F$ and $F'$ are fully faithful. Let $g : Y \to Z$ be a morphism in $C$. If $F(g)$ is a $U'$-cartesian morphism of $C'$, then $g$ is a $U$-cartesian morphism of $C$.

Proof. By virtue of Proposition 5.1.2.1, it will suffice to show that for every object $X \in C$, the diagram of Kan complexes

$$
\begin{array}{ccc}
\text{Hom}_C(X,Y,Z) \times_{\text{Hom}_C(Y,Z)} \{g\} & \xrightarrow{\text{Hom}_C(X,Y,Z)} & \text{Hom}_C(X,Z) \\
\downarrow \text{Hom}_D(U(X),U(Y),U(Z)) \times_{\text{Hom}_D(U(Y),U(Z))} \{U(g)\} & & \downarrow \text{Hom}_D(U(X),U(Z))
\end{array}
$$

is a homotopy pullback square. Set $X' = F(X)$, $Y' = F(Y)$, $Z' = F(Z)$, and $g' = F(g)$. Since the functors $F$ and $F'$ are fully faithful, (5.6) is homotopy equivalent to the diagram

$$
\begin{array}{ccc}
\text{Hom}_{C'}(X',Y',Z') \times_{\text{Hom}_{C'}(Y',Z')} \{g'\} & \xrightarrow{\text{Hom}_{C'}(X',Z')} & \text{Hom}_{C'}(X',Z') \\
\downarrow \text{Hom}_{D'}(U'(X'),U'(Y'),U'(Z')) \times_{\text{Hom}_{D'}(U'(Y'),U'(Z'))} \{U'(g')\} & & \downarrow \text{Hom}_{D'}(U'(X'),U'(Z')).
\end{array}
$$

(5.7)

Our assumption that $g'$ is $U'$-cartesian guarantees that (5.7) is a homotopy pullback square of Kan complexes (Proposition 5.1.2.1), so that (5.6) is also a homotopy pullback square (Corollary 3.4.1.12).
**Proposition 5.1.5.6.** Suppose we are given a commutative diagram of \(\infty\)-categories

\[
\begin{array}{ccc}
C & \xrightarrow{F} & C' \\
\downarrow U & & \downarrow U' \\
D & \xrightarrow{\mathcal{F}} & D',
\end{array}
\]

where the functors \(U\) and \(U'\) are isofibrations and the functors \(F\) and \(\mathcal{F}\) are equivalences of \(\infty\)-categories. Let \(g : Y \to Z\) be a morphism in \(C\). Then \(g\) is \(U\)-cartesian if and only if \(F(g)\) is \(U'\)-cartesian.

**Proof.** It follows from Lemma 5.1.5.5 that if \(F(g)\) is \(U'\)-cartesian, then \(g\) is \(U\)-cartesian. For the converse, suppose that \(g\) is \(U\)-cartesian. Arguing as in the proof of Corollary 5.1.5.2, we can construct a commutative diagram

\[
\begin{array}{ccc}
C' & \xrightarrow{G} & C \\
\downarrow U' & & \downarrow U \\
D' & \xrightarrow{\mathcal{G}} & D,
\end{array}
\]

where \(G\) and \(\mathcal{G}\) are homotopy inverses of the equivalences \(F\) and \(\mathcal{F}\), respectively. Then \(G(F(g))\) is isomorphic to \(g\) as an object of the arrow \(\infty\)-category \(\text{Fun} (\Delta^1, C)\). Invoking Corollary 5.1.2.5, we conclude that \(G(F(g))\) is \(U\)-cartesian, so that \(F(g)\) is \(U'\)-cartesian by virtue of Lemma 5.1.5.5. \(\square\)

**Proposition 5.1.5.7.** Suppose we are given a commutative diagram of \(\infty\)-categories

\[
\begin{array}{ccc}
C & \xrightarrow{F} & C' \\
\downarrow q & & \downarrow q' \\
D & \xrightarrow{\mathcal{F}} & D'.
\end{array}
\]

Assume that:

1. The functors \(q\) and \(q'\) are inner fibrations.
2. The inner fibration \(q\) is cartesian and the functor \(F\) carries \(q\)-cartesian morphisms of \(C\) to locally \(q'\)-cartesian morphisms of \(C'\).
5.1. CARTESIAN FIBRATIONS

(3) The functor $F : D \to D'$ is fully faithful.

Then $F$ is fully faithful if and only if, for every object $D \in D$ having image $D' = F(D) \in D'$, the induced map of fibers $F_D : C_D \to C'_{D'}$ is fully faithful.

Proof. The “only if” direction follows from Proposition 4.6.2.6. For the converse, assume that each of the functors $F_D$ is fully faithful; we will show that $F$ is fully faithful. Let $X$ and $Z$ be objects of $C$ having images $\bar{X}, \bar{Z} \in D$; we wish to show that the upper horizontal map in the diagram of Kan complexes

$$
\begin{array}{ccc}
\text{Hom}_C(X, Z) & \longrightarrow & \text{Hom}_C(F(X), F(Z)) \\
\downarrow & & \downarrow \\
\text{Hom}_D(\bar{X}, \bar{Z}) & \longrightarrow & \text{Hom}_{D'}(F(\bar{X}), F(\bar{Z}))
\end{array}
$$

is a homotopy equivalence. Since $q$ and $q'$ are inner fibrations, the vertical maps are Kan fibrations (Proposition 4.6.1.19). Assumption (3) guarantees that the lower horizontal map is a homotopy equivalence. By virtue of Proposition 3.2.8.1 it will suffice to show that for every morphism $\bar{e} : \bar{X} \to \bar{Z}$ in $D$, the induced map of fibers

$$
\theta : \text{Hom}_C(X, Z)_{\bar{e}} \to \text{Hom}_C(F(X), F(Z))_{F(\bar{e})}
$$

is a homotopy equivalence.

Let $[\theta]$ denote the homotopy class of $\theta$, regarded as a morphism in the homotopy category hKan. Since $q$ is a cartesian fibration, there exists a $q'$-cartesian morphism $g : Y \to Z$ of $C$ satisfying $q(g) = \bar{e}$. We then have a commutative diagram

$$
\begin{array}{ccc}
\text{Hom}_{C_\bar{X}}(X, Y) & \longrightarrow & \text{Hom}_{C'_{F(\bar{X})}}(F(X), F(Y)) \\
\downarrow & & \downarrow \\
\text{Hom}_C(X, Z)_{\bar{e}} & \longrightarrow & \text{Hom}_C(F(X), F(Z))_{F(\bar{e})}
\end{array}
$$

in hKan, where the vertical maps are given by the composition law of Notation 5.1.3.10. Assumption (2) guarantees that $F(g)$ is locally $q'$-cartesian, so that the vertical maps in this diagram are isomorphisms in hKan (Proposition 5.1.3.11). It will therefore suffice to show that the functor $F_{\bar{X}}$ induces a homotopy equivalence of mapping spaces $\text{Hom}_{C_\bar{X}}(X, Y) \to \text{Hom}_{C'_{F(\bar{X})}}(F(X), F(Y))$, which follows from our assumption that $F_{\bar{X}}$ is fully faithful. □
Remark 5.1.5.8. In the situation of Proposition 5.1.5.7 we can replace (2) with the following \textit{a priori} weaker assumption:

\[(2')\] For every object \(Z \in C\) and every morphism \(\overline{u} : Y \rightarrow q(Z)\) in \(D\), there exists a \(q\)-cartesian \(u : Y \rightarrow Z\) of \(C\) satisfying \(q(u) = \overline{u}\) and for which \(F(u)\) is locally \(q'\)-cartesian.

Assume that (2) is satisfied and let \(v : X \rightarrow Z\) be any \(q\)-cartesian morphism in \(C\); we wish to show that \(F(v)\) is locally \(q'\)-cartesian. To prove this, we can assume without loss of generality that \(D = \Delta^1 = D'\) and that \(F\) is the identity map. Using (2'), we can choose another \(q\)-cartesian morphism \(u : Y \rightarrow Z\) satisfying \(q(u) = q(v)\) for which \(F(u)\) is \(q'\)-cartesian. Applying Remark 5.1.3.8 we see that \(v\) can be obtained as a composition of \(u\) with an isomorphism in the ∞-category \(C\). Then \(F(v)\) can be obtained as the composition of \(F(u)\) with an isomorphism in the ∞-category \(C'\), and is therefore \(q\)-cartesian by virtue of Corollary 5.1.2.4 (and Proposition 5.1.1.8).

Proof of Theorem 5.1.5.1. Suppose we are given a commutative diagram of ∞-categories

\[
\begin{array}{ccc}
C & \xrightarrow{F} & C' \\
\downarrow{U} & & \downarrow{U'} \\
D & \xrightarrow{\overline{F}} & D'
\end{array}
\]

where \(U\) is a cartesian fibration of ∞-categories, \(U'\) is an isofibration of ∞-categories, and \(\overline{F}\) is an equivalence of ∞-categories. If \(F\) satisfies conditions (1) and (2) of Theorem 5.1.5.1 then it is fully faithful (Proposition 5.1.5.7) and essentially surjective (Remark 4.6.2.16), hence an equivalence of ∞-categories by virtue of Theorem 4.6.2.17. Conversely, if \(\overline{F}\) is an equivalence of ∞-categories, then it satisfies conditions (1) and (2) by virtue of Corollary 4.5.2.26 and Proposition 5.1.5.7 respectively. To complete the proof, we must show that if these conditions are satisfied, then \(U'\) is also a cartesian fibration of ∞-categories.

Let \(Z'\) be an object of \(C'\) and let \(\overline{g} : Y' \rightarrow U'(Z')\) be a morphism in \(D'\); we wish to show that \(\overline{g}\) can be lifted to a \(U'\)-cartesian morphism \(Y' \rightarrow Z'\) in \(C'\). Since \(\overline{F}\) is essentially surjective, we can choose an object \(Z \in C\) and an isomorphism \(v : F(Z) \rightarrow Z'\) in the ∞-category \(C'\). Since \(\overline{F}\) is essentially surjective, we can choose an object \(\overline{Y} \in D\) and an isomorphism \(\overline{u} : \overline{F}(\overline{Y}) \rightarrow \overline{Y}'\) in the ∞-category \(D'\). Since \(\overline{F}\) is fully faithful at the level of
homotopy categories, we can choose a morphism $\overline{g} : \overline{Y} \to U(Z)$ in $\mathcal{D}$ for which the diagram

\[
\begin{array}{ccc}
F(\overline{Y}) & \xrightarrow{F(\overline{g})} & F(U(Z)) \\
\downarrow \cong & & \downarrow U'(v) \\
\overline{Y'} & \xrightarrow{\overline{g}'} & \overline{Z'},
\end{array}
\]

commutes in the homotopy category $h\mathcal{D}'$, and can therefore be lifted to a commutative diagram $\overline{\sigma}$ in $\infty$-category $\mathcal{D}'$ (see Exercise 1.4.2.10). Using our assumption that $U$ is a cartesian fibration, we can lift $\overline{g}$ to a $U$-cartesian morphism $\overline{g} : \overline{Y} \to \overline{Z}$ of $\mathcal{C}$. Since $U'$ is an isofibration, Corollary 4.4.5.9 guarantees that we can lift $\overline{\sigma}$ to a commutative diagram $\overline{\sigma} :$

\[
\begin{array}{ccc}
F(Y) & \xrightarrow{F(g)} & F(Z) \\
\downarrow \cong & & \downarrow \cong \\
Y' & \xrightarrow{g'} & Z'
\end{array}
\]

in the $\infty$-category $\mathcal{C}'$, where the vertical maps are isomorphisms. To complete the proof, it will suffice to show that the morphism $g'$ is $U'$-cartesian. This follows from Corollary 5.1.2.5 since the morphism $F(g)$ is $U'$-cartesian (Proposition 5.1.5.6).

5.1.6 Equivalence of Inner Fibrations

Let $\mathcal{C}$ and $\mathcal{D}$ be $\infty$-categories. Recall that a functor $F : \mathcal{C} \to \mathcal{D}$ is an equivalence of $\infty$-categories if there exists a functor $G : \mathcal{D} \to \mathcal{C}$ such that $G \circ F$ and $F \circ G$ are isomorphic to $\text{id}_\mathcal{C}$ and $\text{id}_\mathcal{D}$ as objects of the $\infty$-categories $\text{Fun}(\mathcal{C}, \mathcal{C})$ and $\text{Fun}(\mathcal{D}, \mathcal{D})$, respectively (Definition 4.5.1.10). In this section, we study a relative version of this notion, where $\mathcal{C}$ and $\mathcal{D}$ are simplicial sets equipped with inner fibrations $U : \mathcal{C} \to E$ and $V : \mathcal{D} \to E$ over the same base simplicial set $E$ (which need not be an $\infty$-category). Recall that, in this case, the simplicial set

\[
\text{Fun}_{/E}(\mathcal{C}, \mathcal{D}) = \{U\} \times_{\text{Fun}(\mathcal{C}, E)} \text{Fun}(\mathcal{C}, \mathcal{D})
\]

is also an $\infty$-category (Corollary 4.1.4.8).
Definition 5.1.6.1. Suppose we are given a commutative diagram of simplicial sets

![Diagram](https://via.placeholder.com/150)

where $U$ and $V$ are inner fibrations. Let $G : D \to C$ be a morphism of simplicial sets. We say that $G$ is a *homotopy inverse of $F$ relative to $E$* if the following conditions are satisfied:

- The composition $U \circ G$ is equal to $V$: that is, the diagram

![Diagram](https://via.placeholder.com/150)

is commutative.

- The composite morphisms $G \circ F$ and $F \circ G$ are isomorphic to $\text{id}_C$ and $\text{id}_D$ as objects of the ∞-categories $\text{Fun}_E(C, C)$ and $\text{Fun}_E(D, D)$, respectively.

We say that $F$ is an *equivalence of inner fibrations over $E$* if there exists a morphism of simplicial sets $G : D \to C$ which is a homotopy inverse of $F$ relative to $E$. We say that inner fibrations $U : C \to E$ and $V : D \to E$ are *equivalent* if there exists a morphism of simplicial sets $F : C \to D$ which is an equivalence of inner fibrations over $E$ (so that, in particular, we have $U = V \circ F$).

Example 5.1.6.2. Let $C$ and $D$ be ∞-categories, so that the projection maps $U : C \to \Delta^0$ and $V : D \to \Delta^0$ are inner fibrations. Then a functor $F : C \to D$ is an equivalence of ∞-categories if and only if it is an equivalence of inner fibrations over $\Delta^0$. In particular, the inner fibrations $U$ and $V$ are equivalent (in the sense of Definition 5.1.6.1) if and only if the ∞-categories $C$ and $D$ are equivalent (in the sense of Definition 4.5.1.10).

Remark 5.1.6.3 (Two-out-of-Three). Suppose we are given a commutative diagram of simplicial sets

![Diagram](https://via.placeholder.com/150)
where the vertical maps are inner fibrations. If any two of the morphisms $F$, $F'$, and $F' \circ F$ are equivalences of inner fibrations over $\mathcal{E}$, then so is the third. In particular, the collection of equivalences of inner fibrations over $\mathcal{E}$ is closed under composition.

**Remark 5.1.6.4** (Functoriality). Let $U : \mathcal{C} \to \mathcal{E}$ and $V : \mathcal{D} \to \mathcal{E}$ be inner fibrations of simplicial sets, and let $F : \mathcal{C} \to \mathcal{D}$ be an equivalence of inner fibrations over $\mathcal{E}$. For every morphism of simplicial sets $\mathcal{E}' \to \mathcal{E}$, the induced map $F' : \mathcal{E}' \times_{\mathcal{E}} \mathcal{C} \to \mathcal{E}' \times_{\mathcal{E}} \mathcal{D}$ is an equivalence of inner fibrations over $\mathcal{E}'$. In particular, for every object $E \in \mathcal{E}$, the induced map $F_E : \{E\} \times_{\mathcal{E}} \mathcal{C} \to \{E\} \times_{\mathcal{E}} \mathcal{D}$ is an equivalence of $\infty$-categories.

**Proposition 5.1.6.5.** Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{D} \\
\downarrow{U} & & \downarrow{V} \\
\mathcal{E} & & \\
\end{array}
\]

Then:

(1) If $U$ and $V$ are inner fibrations and $F$ is an equivalence of inner fibrations over $\mathcal{E}$, then $F$ is a categorical equivalence of simplicial sets.

(2) If $U$ and $V$ are isofibrations and $F$ is a categorical equivalence of simplicial sets, then it is an equivalence of inner fibrations over $\mathcal{E}$.

**Proof.** We first prove (1). Assume that $U$ and $V$ are inner fibration and that $F$ is an equivalence of inner fibrations over $\mathcal{E}$. We wish to show that $F$ is a categorical equivalence of simplicial sets. Fix an $\infty$-category $\mathcal{K}$, and let $\theta_F : \pi_0(\text{Fun}(\mathcal{D}, \mathcal{K})^\simeq) \to \pi_0(\text{Fun}(\mathcal{C}, \mathcal{K})^\simeq)$ be the map given by precomposition with $F$. We wish to show that $\theta_F$ is a bijection. Let $G : \mathcal{D} \to \mathcal{C}$ be a homotopy inverse of $F$ relative to $\mathcal{E}$, so that precomposition with $G$ determines a map $\theta_G : \pi_0(\text{Fun}(\mathcal{D}, \mathcal{K})^\simeq) \to \pi_0(\text{Fun}(\mathcal{C}, \mathcal{K})^\simeq)$. We claim that $\theta_G$ is an inverse of $\theta_F$. We will show that $\theta_G$ is a left inverse of $\theta_F$; a similar argument will show that $\theta_G$ is a right inverse of $\theta_F$. Fix a morphism $H : \mathcal{C} \to \mathcal{K}$; we wish to show that $H$ is isomorphic to $H \circ G \circ F$ as an object of the $\infty$-category $\text{Fun}(\mathcal{C}, \mathcal{K})$. This is clear, since postcomposition with $H$ determines a functor of $\infty$-categories $\text{Fun}/_{\mathcal{E}}(\mathcal{C}, \mathcal{C}) \to \text{Fun}(\mathcal{C}, \mathcal{K})$.

We now prove (2). Let $Q$ be a contractible Kan complex containing a pair of distinct
vertices $x$ and $y$, and form a pushout diagram of simplicial sets

$$
\begin{array}{ccc}
\{x\} \times C & \xrightarrow{F} & D \\
\downarrow & & \downarrow \\
Q \times C & \rightarrow & M.
\end{array}
$$

Since the vertical maps are monomorphisms, this diagram is also a categorical pushout square (Proposition [4.5.4.11]). In particular, if $F$ is a categorical equivalence, then the map $Q \times C \to M$ is also a categorical equivalence (Proposition [4.5.4.10]). Since $Q$ is contractible, the inclusion $\{y\} \times C \hookrightarrow Q \times C$ is a categorical equivalence (Remark [4.5.3.7]), so the inclusion $\{y\} \times C \hookrightarrow M$ is also a categorical equivalence. If $U$ is an isofibration, then the lifting problem

$$
\begin{array}{ccc}
\{y\} \times C & \xrightarrow{\text{id}} & C \\
\downarrow & & \downarrow U \\
M & \rightarrow & \mathcal{E}
\end{array}
$$

admits a solution, which we can identify with a pair of morphisms $G : D \to C$ and $u : Q \to \text{Fun}_{/\mathcal{E}}(C, C)$ satisfying $u(x) = G \circ F$ and $u(y) = \text{id}_C$. It follows that $G \circ F$ is isomorphic to $\text{id}_C$ as an object of the $\infty$-category $\text{Fun}_{/\mathcal{E}}(C, C)$.

Repeating the above argument with $F$ replaced by $G$, we conclude that there exists a morphism $H : C \to D$ in $(\text{Set}_\Delta)/S$ such that $H \circ G$ is isomorphic to $\text{id}_D$ as an object of the $\infty$-category $\text{Fun}_{/\mathcal{E}}(D, D)$. Then $F$ and $H$ are both isomorphic to $H \circ G \circ F$ as objects of the $\infty$-category $\text{Fun}_{/\mathcal{E}}(C, D)$, and are therefore isomorphic to each other. We may therefore assume without loss of generality that $H = F$, so that $G$ is a homotopy inverse of $F$ relative to $\mathcal{E}$. In particular, $F$ is an equivalence of inner fibrations over $\mathcal{E}$. □

**Warning 5.1.6.6.** Assertion (2) of Proposition [5.1.6.5] need not be true if $U$ and $V$ are only assumed to be inner fibrations. For example, let $\mathcal{E}$ be an $\infty$-category and let $\mathcal{E}' \subseteq \mathcal{E}$ be a full subcategory for which the inclusion map $\iota : \mathcal{E}' \hookrightarrow \mathcal{E}$ is an equivalence. Then we have a commutative diagram of $\infty$-categories

$$
\begin{array}{ccc}
\mathcal{E}' & \xrightarrow{\iota} & \mathcal{E} \\
\downarrow & & \downarrow \text{id} \\
\mathcal{E} & \xrightarrow{\iota} & \mathcal{E}
\end{array}
$$
where the vertical maps are inner fibrations. However, $\iota$ is not an equivalence of inner fibrations over $E$ unless $E' = E$.

**Example 5.1.6.7.** Let $C$ be an $\infty$-category and let $F : K \rightarrow C$ be a diagram. It follows from Theorem 4.6.4.17 and Proposition 5.1.6.5 that the slice and coslice diagonal morphisms

$$\delta_{/F} : C_{/F} \hookrightarrow C \times_{\text{Fun}(K,C)} \{F\} \quad \delta_{C_{/F}} : C_{C_{/F}} \hookrightarrow \{F\} \times_{\text{Fun}(K,C)} C$$

are equivalences of right and left fibrations over $C$, respectively. In particular, for every morphism of simplicial sets $D \rightarrow C$, the induced maps

$$D \times_C C_{/F} \hookrightarrow D \times_{\text{Fun}(K,C)} \{F\} \quad D \times_C C_{C_{/F}} \hookrightarrow \{F\} \times_{\text{Fun}(K,C)} D$$

are equivalences of inner fibrations over $D$ (Remark 5.1.6.4); in particular, they are categorical equivalences of simplicial sets (Proposition 5.1.6.5).

**Corollary 5.1.6.8.** Suppose we are given a commutative diagram of simplicial sets

$$\begin{array}{ccc}
C & \xrightarrow{F} & D \\
U \downarrow & & \downarrow V \\
\mathcal{E} & \downarrow & \\
\mathcal{E},
\end{array}$$

where $U$ and $V$ are inner fibrations and $\mathcal{E} = \Delta^n$ is a standard simplex. Then $F$ is an equivalence of inner fibrations over $\mathcal{E}$ if and only if it an equivalence of $\infty$-categories.

**Proof.** Our assumption that $\mathcal{E} = \Delta^n$ is a standard simplex guarantees that the inner fibrations $U$ and $V$ are isofibrations (Example 4.4.1.6), so the desired result follows from Proposition 5.1.6.5.

**Proposition 5.1.6.9.** Suppose we are given a commutative diagram of simplicial sets

$$\begin{array}{ccc}
C & \xrightarrow{F} & D \\
U \downarrow & & \downarrow V \\
\mathcal{E} & \downarrow & \\
\mathcal{E},
\end{array}$$

where $U$ and $V$ are inner fibrations. The following conditions are equivalent:

1. For every morphism of simplicial sets $B \rightarrow \mathcal{E}$, postcomposition with $F$ induces a homotopy equivalence of Kan complexes $\text{Fun}_{/\mathcal{E}}(B,C) \simeq \rightarrow \text{Fun}_{/\mathcal{E}}(B,D) \simeq$. 

For every morphism of simplicial sets \( B \to \mathcal{E} \), postcomposition with \( F \) induces an equivalence of \( \infty \)-categories \( \text{Fun}_{/\mathcal{E}}(B, \mathcal{C}) \to \text{Fun}_{/\mathcal{E}}(B, \mathcal{D}) \).

The morphism \( F \) is an equivalence of inner fibrations over \( \mathcal{E} \).

For every simplex \( \sigma : \Delta^n \to \mathcal{E} \), the induced map \( F_\sigma : \Delta^n \times_\mathcal{E} \mathcal{C} \to \Delta^n \times_\mathcal{E} \mathcal{D} \) is an equivalence of \( \infty \)-categories.

**Proof.** We first show that (1) implies (2). Assume that (1) is satisfied and let \( B \to \mathcal{E} \) be a morphism of simplicial sets; we wish to show that the induced map \( \text{Fun}_{/\mathcal{E}}(B, \mathcal{C}) \to \text{Fun}_{/\mathcal{E}}(B, \mathcal{D}) \) is an equivalence of \( \infty \)-categories. By virtue of Theorem 4.5.7.1, it will suffice to show that for every simplicial set \( \mathcal{A} \), the induced map

\[
\text{Fun}(\mathcal{B}', \text{Fun}_{/\mathcal{E}}(B, \mathcal{C})) \to \text{Fun}(\mathcal{B}', \text{Fun}_{/\mathcal{E}}(B, \mathcal{D}))
\]

is a homotopy equivalence of Kan complexes. This follows by applying (1) to the composite map \( \mathcal{B}' \times B \to B \to \mathcal{E} \).

We now prove that (2) implies (3). Assume that condition (2) is satisfied. Setting \( \mathcal{B} = \mathcal{D} \), we deduce that composition with \( F \) induces an equivalence of \( \infty \)-categories \( \text{Fun}_{/\mathcal{E}}(\mathcal{D}, \mathcal{C}) \to \text{Fun}_{/\mathcal{E}}(\mathcal{D}, \mathcal{D}) \). In particular, there exists a morphism \( \mathcal{G} : \mathcal{D} \to \mathcal{C} \) in \( (\text{Set}_\Delta)_{/\mathcal{E}} \) such that \( F \circ \mathcal{G} \) is isomorphic to \( \text{id}_\mathcal{D} \) as an object of the \( \infty \)-category \( \text{Fun}_{/\mathcal{E}}(\mathcal{D}, \mathcal{D}) \). It follows that \( F \circ G \circ F \) is isomorphic to \( F \) as an object of the \( \infty \)-category \( \text{Fun}_{/\mathcal{E}}(\mathcal{C}, \mathcal{D}) \). Applying condition (2) in the case \( \mathcal{B} = \mathcal{C} \), we see that postcomposition with \( F \) induces an equivalence of \( \infty \)-categories \( \text{Fun}_{/\mathcal{E}}(\mathcal{C}, \mathcal{C}) \to \text{Fun}_{/\mathcal{E}}(\mathcal{C}, \mathcal{D}) \), so that \( G \circ F \) is isomorphic to \( \text{id}_\mathcal{C} \) as an object of \( \text{Fun}_{/\mathcal{E}}(\mathcal{C}, \mathcal{C}) \). It follows that \( G \) is a homotopy inverse of \( F \) relative to \( \mathcal{E} \). In particular, \( F \) is an equivalence of inner fibrations over \( \mathcal{E} \).

The implication (3) \( \Rightarrow \) (4) follows by combining Remark 5.1.6.4 with Corollary 5.1.6.8.

We will complete the proof by showing that (4) implies (1). Assume that condition (4) is satisfied, and let \( B \) be a simplicial set equipped with a morphism \( B \to \mathcal{E} \). We wish to show that composition with \( F \) induces a homotopy equivalence of Kan complexes \( \theta_B : \text{Fun}_{/\mathcal{E}}(B, \mathcal{C}) \to \text{Fun}_{/\mathcal{E}}(B, \mathcal{D}) \). Assume first that the simplicial set \( B \) has dimension \( \leq n \), for some integer \( n \geq -1 \). Our proof proceeds by induction on \( n \). If \( n = -1 \), then \( B \) is empty and there is nothing to prove. We may therefore assume without loss of generality that \( n \geq 0 \). Let \( A \) be the \( (n-1) \)-skeleton of \( B \). Our inductive hypothesis guarantees that \( \theta_A \) is a homotopy equivalence. By virtue of Proposition 3.2.8.1, it will suffice to verify the following:

\begin{itemize}
  \item[(*)] The restriction maps
  \[
  \text{Fun}_{/\mathcal{E}}(B, \mathcal{C}) \to \text{Fun}_{/\mathcal{E}}(A, \mathcal{C}) \quad \text{Fun}_{/\mathcal{E}}(B, \mathcal{D}) \to \text{Fun}_{/\mathcal{E}}(A, \mathcal{D})
  \]
  
  are isofibrations of \( \infty \)-categories, and therefore induce Kan fibrations
  \[
  \text{Fun}_{/\mathcal{E}}(B, \mathcal{C}) \Rightarrow \text{Fun}_{/\mathcal{E}}(A, \mathcal{C}) \quad \text{Fun}_{/\mathcal{E}}(B, \mathcal{D}) \Rightarrow \text{Fun}_{/\mathcal{E}}(A, \mathcal{D})
  \]
\end{itemize}
see Proposition 4.4.3.7.

\(\ast\) For every object \(T \in \text{Fun}_{/\mathcal{E}}(A, C)\), the induced map of fibers

\[
\{T\} \times_{\text{Fun}_{/\mathcal{E}}(A, C)} \text{Fun}_{/\mathcal{E}}(B, C) \to \{F \circ T\} \times_{\text{Fun}_{/\mathcal{E}}(A, D)} \text{Fun}_{/\mathcal{E}}(B, D)
\]

is an equivalence of \(\infty\)-categories, and therefore induces a homotopy equivalence of Kan complexes

\[
\{T\} \times_{\text{Fun}_{/\mathcal{E}}(A, C)} \simeq \text{Fun}_{/\mathcal{E}}(B, C) \simeq \{F \circ T\} \times_{\text{Fun}_{/\mathcal{E}}(A, D)} \simeq \text{Fun}_{/\mathcal{E}}(B, D)
\]

(see Remark 4.5.1.19).

Let \(J\) denote the set of all nondegenerate \(n\)-simplices of \(B\). Proposition 1.1.3.13 supplies a pushout diagram of simplicial sets

\[
\begin{array}{c}
\prod_{\sigma \in J} \partial \Delta^n \\
\downarrow \\
A \\
\downarrow \\
B.
\end{array}
\]

Consequently, to verify \((\ast)\) and \((\ast')\), we can assume without loss of generality that \(B = \Delta^n\) is a standard simplex and that \(A = \partial \Delta^n\) is its boundary. Replacing \(C\) and \(D\) by the fiber products \(\Delta^n \times_{\mathcal{E}} C\) and \(\Delta^n \times_{\mathcal{E}} D\), we can reduce further to the case where \(\mathcal{E} = \Delta^n\) is a standard simplex. Applying Example 4.4.1.6, we deduce that \(U\) and \(V\) are isofibrations, so that assertion \((\ast)\) follows from Proposition 4.4.5.1. Invoking assumption (4), we deduce that \(F\) is an equivalence of \(\infty\)-categories, and therefore induces equivalences

\[
\text{Fun}(A, C) \to \text{Fun}(A, D) \quad \text{Fun}(B, C) \to \text{Fun}(B, D).
\]

Assertion \((\ast')\) now follows from Corollary 4.5.2.26.

We now treat the case where \(B\) is a general simplicial set. For each \(n \geq 0\), let \(\text{sk}_n(B)\) denote the \(n\)-skeleton of \(B\) (Construction 1.1.3.5). Using \((\ast)\) and Corollary 4.5.6.20 we see that \(\theta_B\) can be realized as the inverse limit of a tower

\[
\cdots \to \text{Fun}_{/S}(\text{sk}_2(B), X) \to \text{Fun}_{/S}(\text{sk}_1(B), X) \to \text{Fun}_{/S}(\text{sk}_0(B), X) \\
\downarrow_{\theta_{\text{sk}_2(B)}} \downarrow_{\theta_{\text{sk}_1(B)}} \downarrow_{\theta_{\text{sk}_0(B)}} \\
\cdots \to \text{Fun}_{/S}(\text{sk}_2(B), X') \to \text{Fun}_{/S}(\text{sk}_1(B), X') \to \text{Fun}_{/S}(\text{sk}_0(B), X')
\]

where each of the transition maps is a Kan fibration. The preceding arguments show that each of the vertical maps \(\theta_{\text{sk}_n(B)}\) is a homotopy equivalence of Kan complexes. Invoking Example 4.5.6.16 we deduce that \(\theta_B\) is a homotopy equivalence of Kan complexes. \(\square\)
Let $F : C \to D$ be a morphism of simplicial sets. Then $F$ determines a pullback functor $F^* : (\text{Set}_{\Delta})/_D \to (\text{Set}_{\Delta})/_C$, given on objects by the formula $F^*(\tilde{D}) = C \times_D \tilde{D}$.

**Proposition 5.1.6.10.** Let $V : \tilde{D} \to D$ be an isofibration of $\infty$-categories, let $C$ be a simplicial set, and let $F, G : C \to D$ be morphisms of simplicial sets which are isomorphic when viewed as objects of the $\infty$-category $\text{Fun}(C, D)$. Then the isofibrations $F^*(\tilde{D}) \to C$ and $G^*(\tilde{D}) \to C$ are equivalent (in the sense of Definition 5.1.6.1).

**Warning 5.1.6.11.** The conclusion of Proposition 5.1.6.10 does not necessarily hold if $V : \tilde{D} \to D$ is assumed only to be an inner fibration of simplicial sets. See Warning 5.1.6.6.

**Proof of Proposition 5.1.6.10.** Since $F$ and $G$ are isomorphic as objects of $\text{Fun}(C, D)$, there exists a contractible Kan complex $X$ containing vertices $f$ and $g$ and a functor $H : X \to \text{Fun}(C, D)$ satisfying $H(f) = F$ and $H(g) = G$. Let us identify $H$ with a morphism of simplicial sets $X \times C \to D$, and let $\tilde{C}$ denote the fiber product $(X \times C) \times_D \tilde{D}$. We will show that the inclusion maps

$$F^*(\tilde{D}) = \{f\} \times_X \tilde{C} \hookrightarrow \tilde{C} \leftrightarrow \{g\} \times_X \tilde{C} = G^*(\tilde{D})$$

are equivalences of inner fibrations over $C$. To prove this, we may assume without loss of generality that $C = \Delta^n$ is a standard simplex (Proposition 5.1.6.9); in this case, we wish to show that both inclusion maps are equivalences of $\infty$-categories (Corollary 5.1.6.8). This follows by applying Corollary 4.5.2.23 to the diagram of pullback squares

$$
\begin{array}{ccc}
F^*(\tilde{D}) & \rightarrow & \tilde{C} \\
\downarrow & & \downarrow \\
\{f\} \times C & \rightarrow & X \times C & \leftarrow & \{g\} \times C,
\end{array}
$$

here the vertical maps are isofibrations (since they are pullbacks of $V$) and the lower horizontal maps are equivalences of $\infty$-categories (since $X$ is a contractible Kan complex).

We now study properties of inner fibrations that are invariant under equivalence.

**Lemma 5.1.6.12.** Let $U : D \to E$ be an isofibration of simplicial sets and $F : C \hookrightarrow D$ be a monomorphism of simplicial sets. The following conditions are equivalent:

1. The restriction $(U \circ F) : C \to E$ is an inner fibration and $F$ is an equivalence of inner fibrations over $E$.
2. There exists a morphism $G : D \to C$ in $(\text{Set}_{\Delta})/_E$ satisfying $G \circ F = \text{id}_C$ and an isomorphism $u : \text{id}_D \to F \circ G$ in the $\infty$-category $\text{Fun}_{/E}(D, D)$ whose image in $\text{Fun}_{/E}(C, D)$ is the identity morphism $\text{id}_F : F \to F \circ G \circ F = F$. 

\[\square\]
Proof. We first show that (2) implies (1). Suppose that there exists a morphism \(G : D \to C\) satisfying \(G \circ F = \text{id}_C\). Then \(F\) and \(G\) exhibit \(C\) as a retract of \(D\) in the category \((\text{Set}_\Delta)_{/\mathcal{E}}\). Since \(U : D \to \mathcal{E}\) is an isofibration, it follows that \((U \circ F) : C \to \mathcal{E}\) is an isofibration (Remark 4.5.5.10). In particular, \(U \circ F\) is an inner fibration (Remark 4.5.5.7). If there exists an isomorphism \(u : \text{id}_D \to F \circ G\) in the \(\infty\)-category \(\text{Fun}_{/\mathcal{E}}(D, D)\), then \(G\) is a homotopy inverse of \(F\) relative to \(\mathcal{E}\), so that \(F\) is an equivalence of inner fibrations over \(\mathcal{E}\).

We now show that (1) implies (2). Assume that \(U \circ F\) is an inner fibration and that \(F\) is an equivalence of inner fibrations over \(\mathcal{E}\). Let \(G' : D \to C\) be a homotopy inverse of \(F\) relative to \(\mathcal{E}\), so that there exists an isomorphism \(e : \text{id}_C \to G' \circ F\) in the \(\infty\)-category \(\text{Fun}_{/\mathcal{E}}(C, C)\). Applying Proposition 4.4.5.8, we can lift \(e\) to an isomorphism \(\tilde{e} : G \to G'\) in the \(\infty\)-category \(\text{Fun}_{/\mathcal{E}}(D, C)\), where \(G : D \to C\) satisfies \(G \circ F = \text{id}_C\). Note that \(F\) is a categorical equivalence of simplicial sets (Proposition 5.1.6.5), and therefore induces a categorical equivalence

\[
(\Delta^1 \times C) \coprod_{(\partial \Delta^1 \times C)} (\partial \Delta^1 \times D) \hookrightarrow \Delta^1 \times D.
\]

Since \(U\) is an isofibration, every lifting problem

\[
(\Delta^1 \times C) \coprod_{(\partial \Delta^1 \times C)} (\partial \Delta^1 \times D) \to D \\
\Delta^1 \times D \to \mathcal{E}
\]

admits a solution. In particular, there exists a morphism \(u : \text{id}_D \to F \circ G\) in the \(\infty\)-category \(\text{Fun}_{/\mathcal{E}}(D, D)\) whose image in \(\text{Fun}_{/\mathcal{E}}(C, D)\) is the identity map \(\text{id}_F\). We will complete the proof by showing that \(u\) is an isomorphism in the \(\infty\)-category \(\text{Fun}_{/\mathcal{E}}(D, D)\). Using the criterion of Proposition 4.4.4.9 we are reduced to checking that, for each vertex \(D \in D\) having image \(E = U(D) \in \mathcal{E}\), the induced map \(u_D : D \to (F \circ G)(D)\) is an isomorphism in the \(\infty\)-category \(\mathcal{D}_E = \{E\} \times_\mathcal{E} D\). This is clear, since \(D\) is isomorphic (in the \(\infty\)-category \(\mathcal{D}_E\)) to an object of the form \(F(C)\) for \(C \in \mathcal{C}_E\), and the morphism \(u_{F(C)}\) is equal to the identity \(\text{id}_{F(C)}\). \(\square\)

Proposition 5.1.6.13. Let \(U : \mathcal{C} \to \mathcal{E}\) and \(V : \mathcal{D} \to \mathcal{E}\) be inner fibrations of simplicial sets which are equivalent to one another. Then:

1. The morphism \(U\) is an isofibration if and only if \(V\) is an isofibration.
2. The morphism \(U\) is a cartesian fibration if and only if \(V\) is a cartesian fibration.
3. The morphism \(U\) is a right fibration if and only if \(V\) is a right fibration.
(4) The morphism $U$ is a cocartesian fibration if and only if $V$ is a cocartesian fibration.

(5) The morphism $U$ is a left fibration if and only if $V$ is a left fibration.

(6) The morphism $U$ is a Kan fibration if and only if $V$ is a Kan fibration.

Proof. Let $F : C \rightarrow D$ be an equivalence of inner fibrations over $\mathcal{E}$. We first prove (1). Assume that $V$ is an isofibration; we will show that $U$ is also an isofibration. Choose a monomorphism of simplicial sets $C \hookrightarrow Q$, where $Q$ is a contractible Kan complex (Exercise 3.1.7.10). Replacing $D$ by the product $D \times Q$, we can assume that $F$ is a monomorphism of simplicial sets. In this case, Lemma 5.1.6.12 guarantees that $F$ exhibits $C$ as a retract of $D$ in the category $(\text{Set}_\Delta)/\mathcal{E}$, so that $U$ is an isofibration by virtue of Remark 4.5.5.10.

To prove (2), we may assume without loss of generality that $\mathcal{E} = \Delta^n$ is a standard simplex (Proposition 5.1.4.7). In this case, $U$ and $V$ are isofibrations (Example 4.4.1.6) and $F$ is an equivalence of $\infty$-categories (Corollary 5.1.6.8). It follows from Corollary 5.1.5.2 that $U$ is a cartesian fibration if and only if $V$ is a cartesian fibration.

To prove (3), suppose that $U$ is a right fibration; we will show that $V$ is a right fibration. It follows from (2) that $V$ is a cartesian fibration. It will therefore suffice to show that, for each vertex $E \in \mathcal{E}$, the $\infty$-category $\{E\} \times_\mathcal{E} D$ is a Kan complex (Proposition 5.1.4.14). By virtue of Remark 5.1.6.4, the morphism $F$ induces an equivalence of $\infty$-categories $F_E : \{E\} \times_\mathcal{E} C \rightarrow \{E\} \times_\mathcal{E} D$. It will therefore suffice to show that $\{E\} \times_\mathcal{E} C$ is a Kan complex (Remark 4.5.1.21), which follows from our assumption that $U$ is a right fibration.

Assertions (4) and (5) follow by similar arguments. Assertion (6) follows by combining (3) and (5) (see Example 4.2.1.5). □

**Proposition 5.1.6.14.** Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
C & \xrightarrow{F} & D \\
\downarrow{U} & & \downarrow{V} \\
\mathcal{E}, & & \\
\end{array}
\]

where $U$ and $V$ are cartesian fibrations. Then $F$ is an equivalence of inner fibrations over $\mathcal{E}$ if and only if the following conditions are satisfied:

(1) For every vertex $E \in \mathcal{E}$, the induced map $F_E : \{E\} \times_\mathcal{E} C \rightarrow \{E\} \times_\mathcal{E} D$ is an equivalence of $\infty$-categories.

(2) The morphism $F$ carries $U$-cartesian edges of $C$ to $V$-cartesian edges of $D$.  

028B
5.2. COVARIANT TRANSPORT

Proof. By virtue of Proposition 5.1.6.9, we may assume without loss of generality that \( E = \Delta^n \) is a standard simplex, so that \( F \) is an equivalence of inner fibrations over \( E \) if and only if it is an equivalence of \( \infty \)-categories (Corollary 5.1.6.8). Since \( U \) and \( V \) are isofibrations (Example 4.4.1.6), the desired result follows from Theorem 5.1.5.1.

Corollary 5.1.6.15. Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{D} \\
U \downarrow & & \downarrow V \\
\mathcal{E} & & \\
\end{array}
\]

where \( U \) and \( V \) are right fibrations. Then \( F \) is an equivalence of inner fibrations if and only if, for every vertex \( E \in \mathcal{E} \), the induced map \( F_E : \{E\} \times_\mathcal{E} \mathcal{C} \to \{E\} \times_\mathcal{E} \mathcal{D} \) is a homotopy equivalence of Kan complexes.

5.2 Covariant Transport

Let \( X \to S \) be a covering map of topological spaces. For every point \( s \in S \), the fiber \( X_s = \{s\} \times_S X \) is equipped with an action of the fundamental group \( \pi_1(S, s) \). More generally, the construction \( s \mapsto X_s \) determines a functor from the fundamental groupoid \( \pi_{\leq 1}(S) \) to the category of sets, which will refer to as the monodromy representation of the covering map \( X \to S \) (see Example 5.2.0.5 below).

It will be convenient to place monodromy in a more general context. Recall that if \( X \to S \) is a covering map of topological spaces, then the induced map \( \text{Sing}_\bullet(X) \to \text{Sing}_\bullet(S) \) is a covering map of simplicial sets (Proposition 3.1.4.9). In particular, it is a left covering map of simplicial sets (Definition 4.2.3.8).

Construction 5.2.0.1 (Covariant Transport for Left Covering Maps). Let \( U : \mathcal{E} \to \mathcal{C} \) be a left covering map of simplicial sets. For each vertex \( C \in \mathcal{C} \), the fiber \( \mathcal{E}_C = \{C\} \times_\mathcal{C} \mathcal{E} \) is a discrete simplicial set, which we will identify with its underlying set of vertices (Remark 4.2.3.17). If \( \bar{C} \) is a vertex of \( \mathcal{E}_C \) and \( f : C \to D \) is an edge of \( \mathcal{C} \), then our assumption that \( U \) is a left covering map guarantees that there is a unique edge \( \bar{f} : \bar{C} \to f_!(\bar{C}) \) of \( \mathcal{E} \) satisfying \( U(\bar{f}) = f \). The construction \( \bar{C} \mapsto f_!(\bar{C}) \) then determines a function \( f_! : \mathcal{E}_C \to \mathcal{E}_D \), which we will refer to as covariant transport along \( f \).

Example 5.2.0.2. In the situation of Construction 5.2.0.1, suppose that \( e = \text{id}_C \) is a degenerate edge of \( \mathcal{C} \). Then the covariant transport function \( e_! : \mathcal{E}_C \to \mathcal{E}_C \) is the identity function.
Proposition 5.2.0.3. Let $U : \mathcal{E} \to \mathcal{C}$ be a left covering map of simplicial sets. Then there is a unique functor

$$h\text{Tr}_{\mathcal{E}/\mathcal{C}} : h\mathcal{C} \to \text{Set}$$

with the following properties:

- For each vertex $C \in \mathcal{C}$, we have $h\text{Tr}_{\mathcal{E}/\mathcal{C}}(C) = \mathcal{E}_C$.

- Let $f : C \to D$ be an edge of $\mathcal{C}$, and let $[f]$ denote the corresponding morphism in the homotopy category $h\mathcal{C}$. Then $h\text{Tr}_{\mathcal{E}/\mathcal{C}}([f])$ is the covariant transport function $f_! : \mathcal{E}_C \to \mathcal{E}_D$ of Construction 5.2.0.1.

Proof. By virtue of Example 5.2.0.2 (and the proof of Proposition 1.2.5.4), it will suffice to show that if $\sigma$ is a 2-simplex $\sigma$ of $\mathcal{C}$ as indicated in the diagram

then the covariant transport function $h_! : \mathcal{E}_C \to \mathcal{E}_E$ is equal to the composition $g_! \circ f_!$. Fix a vertex $X \in \mathcal{E}_C$. By construction, there is an edge $\tilde{f} : X \to f_!(X)$ satisfying $U(\tilde{f}) = f$ and an edge $\tilde{h} : X \to h_!(X)$ satisfying $U(\tilde{h}) = h$. Since $U$ is a left covering map, we can lift $\sigma$ (uniquely) to a 2-simplex of $\mathcal{E}$ with boundary indicated in the diagram

The edge $\tilde{g}$ then satisfies $U(\tilde{g}) = g$, and therefore witnesses the identity $g_!(f_!(X)) = h_!(X)$. □

Definition 5.2.0.4. Let $U : \mathcal{E} \to \mathcal{C}$ be a left covering morphism of simplicial sets and let $h\text{Tr}_{\mathcal{E}/\mathcal{C}} : h\mathcal{C} \to \text{Set}$ be the functor of Proposition 5.2.0.3. We will refer to $h\text{Tr}_{\mathcal{E}/\mathcal{C}}$ as the homotopy transport representation of $U$.

Example 5.2.0.5 (The Monodromy Representation). Let $X \to S$ be a covering map of topological spaces. Applying Proposition 5.2.0.3 to the induced map $\text{Sing}_\bullet(X) \to \text{Sing}_\bullet(S)$, we obtain a functor from the fundamental groupoid $\pi_{\leq 1}(S)$ to the category of sets, which we will denote by $h\text{Tr}_{X/S} : \pi_{\leq 1}(S) \to \text{Set}$ and refer to as the monodromy representation of $f$. Concretely, it is given on objects by the formula $h\text{Tr}_{X/S}(s) = \{s\} \times_S X$. 027T
5.2. COVARIANT TRANSPORT

Example 5.2.0.6. Let $\text{Set}_*$ denote the category of pointed sets, so that the forgetful functor $\text{Set}_* \to \text{Set}$ induces a left covering morphism of simplicial sets $N_*\text{(Set}_*) \to N_*\text{(Set)}$ (Example 4.2.3.3). Then the homotopy transport functor $h\text{Tr}_{N_*\text{(Set}_*)/N_*\text{(Set)}}$ is isomorphic to the identity functor $\text{id}_{\text{Set}} : \text{Set} \to \text{Set}$.

Our first goal in this section is to generalize the definition of the homotopy transport representation $h\text{Tr}_\mathcal{E}/\mathcal{C}$ to the case where $U : \mathcal{E} \to \mathcal{C}$ is a cocartesian fibration of simplicial sets. In §5.2.2, we associate to each edge $f : C \to D$ of the simplicial set $\mathcal{C}$ a functor of $\infty$-categories $f_! : \mathcal{E}_C \to \mathcal{E}_D$, which we refer to as the covariant transport functor associated to $f$ (Definition 5.2.2.4). Unlike the covariant transport function of Construction 5.2.0.1, the functor $f_!$ is not uniquely determined: it is well-defined only up to isomorphism (Proposition 5.2.2.8). To construct it (and to establish its uniqueness up to isomorphism), we will exploit the fact that postcomposition with $U$ induces a cocartesian fibration $\text{Fun}(\mathcal{E}_C, \mathcal{E}) \to \text{Fun}(\mathcal{E}_C, \mathcal{C})$, which we prove in §5.2.1 (see Theorem 5.2.1.1).

In §5.2.5, we study the behavior of covariant transport with respect to composition. Suppose we are given a 2-simplex $\sigma$ of the simplicial set $\mathcal{C}$, which we view as a commutative diagram

\[
\begin{array}{ccc}
D & \to & E \\
\downarrow f & & \downarrow g \\
C & \to & C
\end{array}
\]

In this case, we will show that there is an isomorphism of covariant transport functors $h_! \simeq g_! \circ f_!$ (Proposition 5.2.5.1). As a consequence, we can regard the construction $C \mapsto \mathcal{E}_C$ as a functor from the homotopy category $h\mathcal{C}$ to the homotopy category $h\text{QCat}$ of Construction 4.5.1.1, which we denote by $h\text{Tr}_\mathcal{E}/\mathcal{C} : h\mathcal{C} \to h\text{QCat}$ and refer to as the homotopy transport representation of the cocartesian fibration $U$ (Construction 5.2.5.2).

The remainder of this section is devoted to the following:

Question 5.2.0.7. Let $\mathcal{C}$ be a simplicial set and let $\mathcal{F} : h\mathcal{C} \to h\text{QCat}$ be a functor. Can $\mathcal{F}$ be obtained as the homotopy transport representation of a cocartesian fibration $U : \mathcal{E} \to \mathcal{C}$?

The answer to Question 5.2.0.7 is "no" in general. However, there are two important special cases where the answer is "yes":

- In §5.2.7, we show that any set-valued functor $h\mathcal{C} \to \text{Set}$ can be realized as the homotopy transport representation of a cocartesian fibration $U : \mathcal{E} \to \mathcal{C}$. Moreover, we can arrange that $U$ is a left covering map. In this case, the simplicial set $\mathcal{E}$ is uniquely determined up to isomorphism (Corollary 5.2.7.3) and can be described explicitly using the classical category of elements construction, which we review in §5.2.6.
Every functor of ∞-categories $E_0 \to E_1$ can be realized as the covariant transport functor associated to a cocartesian fibration $U : E \to \Delta^1$: that is, Question 5.2.0.7 has an affirmative answer in the case $\mathcal{C} = \Delta^1$ (see Proposition 5.2.3.15). We prove this in §5.2.3 using an explicit construction which generalizes the join operation on simplicial sets (Construction 5.2.3.1). In §5.2.4, we show that the ∞-category $E$ is determined uniquely up to equivalence (see Remark 5.2.4.3).

We will eventually give a complete answer to Question 5.2.0.7: a functor between ordinary categories $\mathcal{F} : \text{hC} \to \text{hQCat}$ is (isomorphic to) the homotopy transport representation of a cocartesian fibration $U : E \to \mathcal{C}$ if and only if it can be promoted to a diagram $\mathcal{F} : \mathcal{C} \to \mathcal{QCat}$ (Remark 5.7.5.15), where $\mathcal{QCat}$ denotes the ∞-category of small ∞-categories (Construction 5.6.4.1). In §5.2.8, we prove a preliminary result in this direction by showing that if $\mathcal{C}$ is an ∞-category, then the homotopy transport representation of any cocartesian fibration $U : E \to \mathcal{C}$ can always be promoted to an enriched functor, where we regard $\text{hC}$ and $\mathcal{QCat}$ as enriched over the homotopy category of Kan complexes $\text{hKan}$ (Construction 5.2.8.9).

Remark 5.2.0.8. In the preceding discussion, we have confined our attention to the case of cocartesian fibrations $U : E \to \mathcal{C}$. Of course, all of our results have counterparts for cartesian fibrations, which can be obtained from passing to opposite ∞-categories.

5.2.1 Exponentiation for Cartesian Fibrations

In this section, we study the behavior of (co)cartesian fibrations with respect to the formation of functor ∞-categories. Our main result can be stated as follows:

Theorem 5.2.1.1. Let $q : X \to S$ be a morphism of simplicial sets, let $B$ be a simplicial set, and let $q' : \text{Fun}(B, X) \to \text{Fun}(B, S)$ be the morphism given by postcomposition with $q$. Then:

(1) If $q$ is a cartesian fibration of simplicial sets, then $q'$ is also a cartesian fibration of simplicial sets.

(2) Assume that $q$ is a cartesian fibration, and let $e$ be an edge of the simplicial set $\text{Fun}(B, X)$. Then $e$ is $q'$-cartesian if and only if, for every vertex $b \in B$, the evaluation map $\text{ev}_b : \text{Fun}(B, X) \to \text{Fun}(\{b\}, X) \simeq X$ carries $e$ to a $q$-cartesian edge of $X$.

(1') If $q$ is a cocartesian fibration of simplicial sets, then $q'$ is also a cocartesian fibration of simplicial sets.

(2') Assume that $q$ is a cocartesian fibration, and let $e$ be an edge of the simplicial set $\text{Fun}(B, X)$. Then $e$ is $q'$-cocartesian if and only if, for every vertex $b \in B$, the evaluation map $\text{ev}_b : \text{Fun}(B, X) \to \text{Fun}(\{b\}, X) \simeq X$ carries $e$ to a $q$-cartesian edge of $X$. 
Remark 5.2.1.2. Let $\mathcal{C}$ be an $\infty$-category, so that the projection map $q : \mathcal{C} \to \Delta^0$ is a cartesian fibration (Example 5.1.4.3). In this case, part (1) of Theorem 5.2.1.1 is equivalent to the assertion that for every simplicial set $B$, the simplicial set $\text{Fun}(B, \mathcal{C})$ is also an $\infty$-category (Theorem 1.4.3.7). By virtue of Proposition 5.1.4.11, part (2) is equivalent to the assertion that a morphism of $\text{Fun}(B, \mathcal{C})$ is an isomorphism if and only if, for every vertex $b \in B$, its image under the evaluation functor $\text{ev}_b : \text{Fun}(B, \mathcal{C}) \to \mathcal{C}$ is an isomorphism in $\mathcal{C}$ (Theorem 4.4.4.4).

The proof of Theorem 5.2.1.1 will require some preliminaries. Let $q : X \to S$ be an inner fibration of simplicial sets. By definition, $q$ is a cartesian fibration if and only if for every vertex $z \in X$ and every edge $\tau : s \to q(z)$ of $S$, there exists a $q$-cartesian edge $e : y \to z$ in $X$ satisfying $q(e) = \tau$. To prove Theorem 5.2.1.1 we need to show that the edge $e$ can be chosen to depend functorially on $z$.

Proposition 5.2.1.3. Let $q : X \to S$ be a cartesian fibration of simplicial sets, and let $Y \subseteq \text{Fun}(\Delta^1, X)$ be the full simplicial subset of $\text{Fun}(\Delta^1, X)$ spanned by those edges $e : \Delta^1 \to X$ which are $q$-cartesian (see Definition 4.1.2.17). Then the restriction map

$$\theta : Y \to \text{Fun}(\Delta^1, S) \times_{\text{Fun}(\{1\}, S)} \text{Fun}(\{1\}, X)$$

is a trivial Kan fibration of simplicial sets.

Proof. Let $n \geq 0$ be an integer; we wish to show that every lifting problem of the form

![Diagram](5.8)

admits a solution. In the case $n = 0$, this follows immediately from our assumption that $q$ is a cartesian fibration. Let us therefore assume that $n > 0$. Unwinding the definitions, we can rephrase (5.8) as a lifting problem

$$(\Delta^1 \times \partial \Delta^n) \amalg_{\{1\} \times \partial \Delta^n} \{1\} \times \Delta^n \xrightarrow{h_0} X \xrightarrow{q} S,$$
where the morphism $h_0$ has the property that $h_0|_{\Delta^1 \times \{i\}}$ is a $q$-cartesian edge of $X$ for $0 \leq i \leq n$. Let

$$(\Delta^1 \times \partial\Delta^n) \cup (\{1\} \times \Delta^n) = Y(0) \subset Y(1) \subset Y(2) \subset \cdots \subset Y(n+1) = \Delta^1 \times \Delta^n$$

be the sequence of simplicial subsets appearing in the proof of Lemma 3.1.2.10 so that $h_0$ can be identified with a morphism of simplicial sets from $Y(0)$ to $X$. We will show that, for $0 \leq j \leq n + 1$, there exists a morphism of simplicial sets $h_j : Y(j) \to X$ satisfying $h_j|_{Y(0)} = h_0$ and $q \circ h_j = \overline{h}|_{Y(j)}$ (taking $j = n + 1$, this will complete the proof of Proposition 5.2.1.3). We proceed by induction on $j$, the case $j = 0$ being vacuous. Assume that $j > 0$ and that we have already constructed a morphism $h_{j-1} : Y(j-1) \to X$ satisfying $h_{j-1}|_{Y(0)} = h_0$ and $q \circ h_{j-1} = \overline{h}|_{Y(j-1)}$. By virtue of Lemma 3.1.2.10, we have a pushout diagram of simplicial sets

$$\begin{array}{cccc}
\Lambda^{n+1}_j & \xrightarrow{\sigma_0} & Y(j-1) \\
\downarrow & & \downarrow \\
\Delta^{n+1} & \xrightarrow{\sigma} & Y(j)
\end{array}$$

Consequently, to prove the existence of $h_j$, it suffices to solve the lifting problem

$$\begin{array}{cccc}
\Lambda^{n+1}_j & \xrightarrow{h_{j-1} \circ \sigma_0} & X \\
\downarrow & & \downarrow q \\
\Delta^{n+1} & \xrightarrow{\overline{h}_0 \circ \sigma} & S.
\end{array}$$

For $0 < j < n + 1$, the existence of the desired solution follows from our assumption that $q$ is an inner fibration. In the case $j = n + 1$, the existence follows from the fact that the composite map

$$\Delta^1 \simeq N_{\bullet}(\{n < n + 1\}) \hookrightarrow \Lambda^{n+1}_j \xrightarrow{\sigma_0} Y(n) \xrightarrow{h_n} X$$

is the edge of $X$ given by the restriction $h_0|_{\Delta^1 \times \{n\}}$, and is therefore $q$-cartesian. \hfill \Box

**Lemma 5.2.1.4.** Let $q : X \to S$ be an inner fibration of simplicial sets, let $B$ be a simplicial set, and let $q' : \text{Fun}(B, X) \to \text{Fun}(B, S)$ be the map given by postcomposition with $q$ (so that $q'$ is also an inner fibration; see Corollary 4.1.4.3). Let $e$ be an edge of the simplicial set $\text{Fun}(B, X)$.

(1) Suppose that, for every vertex $b \in B$, the evaluation map

$$\text{ev}_b : \text{Fun}(B, X) \to \text{Fun}(\{b\}, X) \simeq X$$
carries e to a q-cartesian edge of X. Then e is q'-cartesian.

(2) Suppose that, for every vertex \( b \in B \), the evaluation map
\[
ev_b : \text{Fun}(B, X) \to \text{Fun}(\{b\}, X) \simeq X
\]
carries e to a q'-cocartesian edge of X. Then e is q'-cocartesian.

**Proof.** We will give a proof of (2); assertion (1) follows by a similar argument. We proceed as in the proof of Lemma 4.4.4.8. Suppose we are given an integer \( n \geq 2 \); we wish to show that every lifting problem
\[
\begin{array}{ccc}
\Lambda^n_0 & \xrightarrow{\sigma_0} & \text{Fun}(B, X) \\
\downarrow & & \downarrow q' \\
\Delta^n & \xrightarrow{\sigma} & \text{Fun}(B, S)
\end{array}
\]
admits a solution, provided that the composite map
\[
\Delta^1 \simeq N_{\bullet}([0 < 1]) \hookrightarrow \Lambda^n_0 \xrightarrow{\sigma_0} \text{Fun}(B, X)
\]
is the edge e. Unwinding the definitions, we can rewrite this as a lifting problem
\[
\begin{array}{ccc}
B \times \Lambda^n_0 & \xrightarrow{F_0} & X \\
\downarrow & & \downarrow q \\
B \times \Delta^n & \xrightarrow{F} & \text{S}
\end{array}
\]
Let \( P \) denote the collection of all pairs \((A, F_A)\), where \( A \subseteq B \) is a simplicial subset and \( F_A : A \times \Delta^n \to X \) is a morphism of simplicial sets satisfying
\[
F_{A}|_{A \times \Lambda^n_0} = F_0|_{A \times \Lambda^n_0} \quad q \circ F_A = F|_{A \times \Delta^n}
\]
We regard \( P \) as partially ordered set, where \((A, F_A) \leq (A', F_{A'})\) if \( A \subseteq A' \) and \( F_A = F_{A'}|_{A \times \Delta^n} \). The partially ordered set \( P \) satisfies the hypotheses of Zorn’s lemma, and therefore has a maximal element \((A_{\text{max}}, F_{A_{\text{max}}})\). We will complete the proof by showing that \( A_{\text{max}} = B \). Assume otherwise. Then there exists some nondegenerate \( m \)-simplex \( \tau : \Delta^m \to B \) whose image is not contained in \( A_{\text{max}} \). Choosing \( m \) as small as possible, we can assume that \( \tau \) carries the boundary \( \partial \Delta^m \) into \( A_{\text{max}} \). Let \( A' \subseteq B \) be the union of \( A_{\text{max}} \) with the image of
\( \tau \), so that we have a pushout diagram of simplicial sets

\[
\begin{array}{ccc}
\partial \Delta^m & \longrightarrow & A_{\text{max}} \\
\downarrow & & \downarrow \\
\Delta^m & \longrightarrow & A'.
\end{array}
\]

We will complete the proof by showing that the lifting problem

\[
\begin{array}{ccc}
(A_{\text{max}} \times \Delta^n) \coprod (A' \times \Delta^n) & \longrightarrow & X \\
\downarrow & & \downarrow q \\
A' \times \Delta^n & \longrightarrow & S
\end{array}
\]

admits a solution (contradicting the maximality of the pair \((A_{\text{max}}, F_{A_{\text{max}}})\)).

Choose a sequence of simplicial subsets

\[ Y(0) \subset Y(1) \subset Y(2) \subset \cdots \subset Y(t) = \Delta^m \times \Delta^n \]

satisfying the requirements of Lemma 4.4.4.7 so that \( F_{A_{\text{max}}} \) determines a map of simplicial sets \( G_0 : Y(0) \rightarrow X \). We will show that, for \( 0 \leq s \leq t \), there exists a morphism of simplicial sets \( G_s : Y(s) \rightarrow X \) satisfying \( G_s|_{Y(0)} = G_0 \) and \( q \circ G_s = F|_{Y(s)} \) (in the case \( s = t \), this will complete the proof of Lemma 5.2.1.4). We proceed by induction on \( s \), the case \( s = 0 \) being vacuous. Assume that \( s > 0 \) and that we have already constructed a morphism \( G_{s-1} : Y(s-1) \rightarrow X \) satisfying \( G_{s-1}|_{Y(0)} = F_0 \) and \( q \circ G_{s-1} = F|_{Y(s-1)} \). By construction, there exist integers \( \ell \geq 2, 0 \leq k < \ell \) and a pushout diagram of simplicial sets

\[
\begin{array}{ccc}
\Lambda_{k}^{\ell} & \longrightarrow & Y(s-1) \\
\downarrow & & \downarrow \\
\Delta^\ell & \longrightarrow & Y(s).
\end{array}
\]

Moreover, in the special case \( k = 0 \), we can assume that \( \tau(0) = (0,0) \) and \( \tau(1) = (0,1) \), so that the composite map

\[
\Delta^1 \cong N_\bullet(\{0 < 1\}) \hookrightarrow \Lambda_k^{\ell} \xrightarrow{\tau_0} Y(s-1) \xrightarrow{G_{s-1}} X
\]
5.2. COVARIANT TRANSPORT

Corresponds to a $q$-cocartesian edge $e'$ of $X$. To construct the desired extension $F_s$, it suffices to solve the lifting problem

```
\Lambda^\ell_k \xrightarrow{G_{s-1} \circ \tau_0} X
\downarrow
\Delta^\ell \xrightarrow{F_{sr}} S.
```

For $0 < k < \ell$, the existence of the desired solution follows from our assumption that $q$ is an inner fibration; when $k = 0$, it follows from the fact that $e'$ is $q$-cocartesian.

**Proof of Theorem 5.2.1.1.** Assume that $q : X \to S$ is a cartesian fibration of simplicial sets (the case where $q$ is a cocartesian fibration can be handled by a similar argument). Let $B$ be any simplicial set and let $q' : \text{Fun}(B, X) \to \text{Fun}(B, S)$ be the map given by postcomposition with $q$. Then $q'$ is an inner fibration (Corollary 4.1.4.3). Let us say that an edge $e$ of the simplicial set $\text{Fun}(B, X)$ is *special* if, for every vertex $b \in B$, the evaluation map $\text{ev}_b : \text{Fun}(B, X) \to \text{Fun}(\{b\}, X) \simeq X$ carries $e$ to a $q$-cartesian edge of $X$. By virtue of Lemma 5.2.1.4, every special edge of $\text{Fun}(B, X)$ is $q'$-cartesian. Moreover, Proposition 5.2.1.3 guarantees that for every vertex $z \in \text{Fun}(B, X)$ and every edge $\bar{\tau} : \bar{y} \to q'(z)$ of $\text{Fun}(B, S)$, there exists a special edge $e : y \to z$ of $\text{Fun}(B, X)$ satisfying $q'(e) = \bar{\tau}$. It follows that $q'$ is a cartesian fibration.

To complete the proof, it will suffice to show that every $q'$-cartesian edge $e : x \to z$ of the simplicial set $\text{Fun}(B, X)$ is special. By virtue of the preceding argument, there exists a special edge $e' : y \to z$ of $\text{Fun}(B, X)$ satisfying $q'(e') = q'(e)$, which is also $q'$-cartesian. Applying Remark 5.1.3.8, we can choose a 2-simplex $\sigma$ of $\text{Fun}(B, X)$ as indicated in the diagram

```
\begin{align*}
\text{ev}_b(y) & \quad \text{ev}_b(x') \quad \text{ev}_b(z) \\
\text{ev}_b(x) & \quad \text{ev}_b(e) \quad \text{ev}_b(z) \\
\text{ev}_b(x) & \quad \text{ev}_b(e) \quad \text{ev}_b(z)
\end{align*}
```

where $e''$ is an isomorphism in the $\infty$-category $\{q'(x)\} \times_{\text{Fun}(B,S)} \text{Fun}(B, X)$. For each vertex $b \in B$, the evaluation functor $\text{ev}_b$ carries $\sigma$ to a 2-simplex.
in the simplicial set $X$. Since $e'$ is special, the edge $ev_b(e')$ is $q$-cartesian. The edge $ev_{b''}(e'')$ is an isomorphism in a fiber of $q$, and is therefore also $q$-cartesian (Proposition 5.1.4.11). Applying Proposition 5.1.4.12, we deduce that $ev_b(e)$ is $q$-cartesian. Allowing the vertex $b$ to vary, we conclude that $e$ is a special edge of $\text{Fun}(B, X)$, as desired. \hfill \Box

### 5.2.2 Covariant Transport Functors

Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration between categories (Definition 5.0.0.3) and let $f : C \to D$ be a morphism in the category $\mathcal{C}$. If $X$ is an object of the fiber $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$, then our assumption that $U$ is a cocartesian fibration guarantees that we can choose an object $f!(X)$ of the fiber $\mathcal{E}_D = \{D\} \times_{\mathcal{C}} \mathcal{E}$ together with a $U$-cocartesian morphism $\tilde{f}_X : X \to f!(X)$ satisfying $U(\tilde{f}_X) = f$. In this case, we can view the construction $X \mapsto f!(X)$ as a functor from the category $\mathcal{E}_C$ to the category $\mathcal{E}_D$.

**Proposition 5.2.2.1.** Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of categories and let $f : C \to D$ be a morphism of $\mathcal{C}$. For each object $X \in \mathcal{E}_C$, let $\tilde{f}_X$ be a $U$-cocartesian morphism of $\mathcal{E}$ having source $X$ and satisfying $U(\tilde{f}_X) = f$. Then there is a unique functor $f! : \mathcal{E}_C \to \mathcal{E}_D$ with the following properties:

- For each object $X \in \mathcal{E}_C$, the object $f!(X) \in \mathcal{E}_D$ is the target of the morphism $\tilde{f}_X$.
- The construction $X \mapsto \tilde{f}_X$ determines a natural transformation from the inclusion functor $\mathcal{E}_C \to \mathcal{E}$ to the functor $f! : \mathcal{E}_C \to \mathcal{E}_D \subseteq \mathcal{E}$.

**Proof.** For each object $X \in \mathcal{E}_C$, let $f!(X)$ denote the target of the morphism $\tilde{f}_X$. Let $u : X \to Y$ be a morphism in the category $\mathcal{E}_C$. Invoking our assumption that $\tilde{f}_X$ is $U$-cocartesian, we see that there is a unique morphism $f!(u) : f!(X) \to f!(Y)$ for which the diagram

$$
\begin{array}{ccc}
X & \xrightarrow{\tilde{f}_X} & f!(X) \\
\downarrow{u} & & \downarrow{f!(u)} \\
Y & \xrightarrow{\tilde{f}_Y} & f!(Y)
\end{array}
$$

is commutative (in the category $\mathcal{E}$). Note that if $v : Y \to Z$ is another morphism in the category $\mathcal{E}_C$, then the calculation

$$f!(v) \circ f!(u) \circ \tilde{f}_X = f!(v) \circ \tilde{f}_Y \circ u = \tilde{f}_Z \circ v \circ u$$

shows that $f!(v \circ u) = f!(v) \circ f!(u)$. Similarly, for each object $X \in \mathcal{E}_C$, the calculation

$$\tilde{f}_X \circ \text{id}_{f!(X)} = \tilde{f}_X = \text{id}_X \circ f_X$$

shows that $f!(\text{id}_X) = \text{id}_{f!(X)}$. We can therefore regard $f!$ as a
functor from the category $\mathcal{E}_C$ to $\mathcal{E}_D$, and the commutativity of (5.9) guarantees that the construction $X \mapsto \tilde{f}_X$ determines a natural transformation from the inclusion $\mathcal{E}_C \hookrightarrow \mathcal{E}$ to the functor $f_!$.

Construction 5.2.2.2. Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of categories, let $f : C \to D$ be a morphism of the category $\mathcal{C}$, and let $f_! : \mathcal{E}_C \to \mathcal{E}_D$ be the functor of Proposition 5.2.2.1. We will refer to $f_!$ as the functor of covariant transport along $f$.

Warning 5.2.2.3. In the situation of Construction 5.2.2.2, the covariant transport functor $f_! : \mathcal{E}_C \to \mathcal{E}_D$ depends not only on the cocartesian fibration $U : \mathcal{E} \to \mathcal{C}$ and the morphism $f : C \to D$, but also on the system of $U$-cocartesian lifts $\{\tilde{f}_X : X \to f_!(X)\}_{X \in \mathcal{E}_C}$. A different system of cocartesian lifts $\{\tilde{f}'_X : X \to f'_!(X)\}_{X \in \mathcal{E}_C}$ will give rise to a different covariant transport functor $f'_! : \mathcal{E}_C \to \mathcal{E}_D$. However, there is a canonical isomorphism of functors $\alpha : f_! \simeq f'_!$, which is uniquely determined by the requirement that for every object $X \in \mathcal{E}_C$, the diagram

$$
\begin{array}{ccc}
\Delta^1 \times \mathcal{E}_C & \xrightarrow{\tilde{F}} & \mathcal{E} \\
\downarrow & & \downarrow U \\
\Delta^1 \xrightarrow{f} \mathcal{C}
\end{array}
$$

is commutative.

We now apply the results of §5.2.1 to extend Construction 5.2.2.2 to the $\infty$-categorical setting.

Definition 5.2.2.4. Let $U : \mathcal{E} \to \mathcal{C}$ be an inner fibration of simplicial sets, let $f : C \to D$ be an edge of $\mathcal{C}$, and let $\mathcal{E}_C = \{C\} \times _\mathcal{C} \mathcal{E}$ and $\mathcal{E}_D = \{D\} \times _\mathcal{C} \mathcal{E}$ denote the corresponding fibers of $U$. We will say that a functor $\tilde{F} : \mathcal{E}_C \to \mathcal{E}_D$ is given by covariant transport along $f$ if there exists a morphism of simplicial sets $\tilde{F} : \Delta^1 \times \mathcal{E}_C \to \mathcal{E}$ satisfying the following conditions:

1. The diagram of simplicial sets

$$
\begin{array}{ccc}
\Delta^1 \times \mathcal{E}_C & \xrightarrow{\tilde{F}} & \mathcal{E} \\
\downarrow & & \downarrow U \\
\Delta^1 \xrightarrow{f} \mathcal{C}
\end{array}
$$

commutes.
(2) The restriction \( \tilde{F}\rvert_{\{0\} \times \mathcal{E}_C} \) is the identity map \( \text{id}_{\mathcal{E}_C} \), and the restriction \( \tilde{F}\rvert_{\{1\} \times \mathcal{E}_C} \) is equal to \( F \).

(3) For every object \( X \) of the \( \infty \)-category \( \mathcal{E}_C \), the composite map

\[
\Delta^1 \times \{X\} \hookrightarrow \Delta^1 \times \mathcal{E}_C \xrightarrow{\tilde{F}} \mathcal{E}
\]

is a locally \( U \)-cocartesian edge of the simplicial set \( \mathcal{E} \).

If these conditions are satisfied, we say that the morphism \( \tilde{F} \) witnesses \( F \) as given by covariant transport along \( f \).

**Example 5.2.2.5.** Let \( U : \mathcal{E} \to \mathcal{C} \) be an inner fibration of simplicial sets and let \( C \) be a vertex of \( \mathcal{C} \). Then the projection map

\[
\Delta^1 \times \mathcal{E}_C \to \mathcal{E}_C \hookrightarrow \mathcal{E}
\]

exhibits the identity functor \( \text{id}_{\mathcal{E}_C} \) as given by covariant transport along the degenerate edge \( \text{id}_C \). See Example 5.1.3.6.

**Example 5.2.2.6.** Let \( U : \mathcal{E} \to \mathcal{C} \) be a left covering map of simplicial sets. Then, for every edge \( f : C \to D \) in \( \mathcal{C} \), there is a unique functor \( \mathcal{E}_C \to \mathcal{E}_D \) given by covariant transport along \( f \), which can be identified with the covariant transport function given by Construction 5.2.0.1.

**Example 5.2.2.7.** Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration between ordinary categories, let \( f : C \to D \) be a morphism in \( \mathcal{C} \), and choose a collection of \( U \)-cocartesian morphisms \( \{\tilde{f}_X : X \to f_!(X)\}_{X \in \mathcal{E}_C} \) satisfying \( U(\tilde{f}_X) = f \). According to Proposition 5.2.2.1 there is a unique functor \( f_! : \mathcal{E}_C \to \mathcal{E}_D \) for which the construction \( X \mapsto \tilde{f}_X \) determines a natural transformation of functors \( \tilde{f} : \text{id}_{\mathcal{E}_C} \to f_! \). Passing to nerves, we obtain a natural transformation \( \text{id}_{N_\bullet(\mathcal{E}_C)} \to N_\bullet(f_!) \), which exhibits the functor

\[
N_\bullet(f_!) : N_\bullet(\mathcal{E}_C) \to N_\bullet(\mathcal{E}_D)
\]

as given by covariant transport along \( f \) (regarded as an edge of the simplicial set \( N_\bullet(\mathcal{C}) \)).

Stated more informally, the covariant transport construction for cocartesian fibrations of ordinary categories (see Construction 5.2.2.2) can be regarded as a special case Definition 5.2.2.4.

**Proposition 5.2.2.8.** Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets and let \( f : C \to D \) be an edge of \( \mathcal{C} \). Then:

- There exists a functor \( F : \mathcal{E}_C \to \mathcal{E}_D \) which is given by covariant transport along \( f \).
5.2. COVARIANT TRANSPORT

- An arbitrary functor \( F' : \mathcal{E}_C \to \mathcal{E}_D \) is given by covariant transport along \( f \) if and only if it is isomorphic to \( F \) (as an object of the \( \infty \)-category \( \text{Fun}(\mathcal{E}_C, \mathcal{E}_D) \)).

**Notation 5.2.2.9.** Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets and let \( f : \mathcal{C} \to \mathcal{D} \) be an edge of the simplicial set \( \mathcal{C} \). Applying Proposition 5.2.2.8, we conclude that the collection of functors \( \mathcal{E}_C \to \mathcal{E}_D \) which are given by covariant transport along \( f \) comprise a single isomorphism class in the \( \infty \)-category \( \text{Fun}(\mathcal{E}_C, \mathcal{E}_D) \). We will denote this isomorphism class by \( [f!] \), which we regard as an element of the set \( \pi_0(\text{Fun}(\mathcal{E}_C, \mathcal{E}_D) \cong) \). We will often use the notation \( f! \) to denote a particular choice of representative of this isomorphism class: that is, a particular choice of functor \( \mathcal{E}_C \to \mathcal{E}_D \) which is given by covariant transport along \( f \).

We now explain how to deduce Proposition 5.2.2.8 from Theorem 5.2.1.1. For this purpose, it will be convenient to introduce a bit more terminology.

**Definition 5.2.2.10.** Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets. Let \( K \) be another simplicial set, let \( H : \Delta^1 \times K \to \mathcal{E} \) be a morphism. We will say that \( H \) is a \( U \)-cocartesian lift of \( H = U \circ H \) if, for every vertex \( x \in K \), the restriction \( H|_{\Delta^1 \times \{x\}} \) is a \( U \)-cocartesian edge of \( \mathcal{E} \).

**Remark 5.2.2.11.** In the situation of Definition 5.2.2.10, we can identify \( H \) and \( \overline{H} \) with edges of the simplicial sets \( \text{Fun}(K, \mathcal{E}) \) and \( \text{Fun}(K, \mathcal{C}) \), respectively. Then \( H \) is a \( U \)-cocartesian lift of \( \overline{H} \) if and only if it is \( U' \)-cocartesian, where \( U' : \text{Fun}(K, \mathcal{E}) \to \text{Fun}(K, \mathcal{C}) \) is given by postcomposition with \( U \). (see Theorem 5.2.1.1).

**Example 5.2.2.12.** Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets, let \( f : \mathcal{C} \to \mathcal{D} \) be an edge of \( \mathcal{C} \), let \( \mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E} \) and \( \mathcal{E}_D = \{D\} \times_{\mathcal{C}} \mathcal{E} \) denote the corresponding fibers of \( U \). Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\Delta^1 \times \mathcal{E}_C & \xrightarrow{\tilde{F}} & \mathcal{E} \\
\downarrow & & \downarrow U \\
\Delta^1 & \xrightarrow{f} & \mathcal{C},
\end{array}
\]

where the restriction \( \tilde{F}|_{\{0\} \times \mathcal{E}_C} \) is the identity map from \( \mathcal{E}_C \) to itself, and set \( F = \tilde{F}|_{\{1\} \times \mathcal{E}_C} \in \text{Fun}(\mathcal{E}_C, \mathcal{E}_D) \). Then \( \tilde{F} \) witnesses \( F \) as given by covariant transport along \( f \) (in the sense of Definition 5.2.2.4) if and only if it is a \( U \)-cocartesian lift of \( U \circ \tilde{F} \) (in the sense of Definition 5.2.2.10).
Lemma 5.2.2.13. Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets, let \( K \) be a simplicial set, and suppose we are given a lifting problem

\[
\begin{array}{cccl}
\{0\} \times K & \xrightarrow{H_0} & \mathcal{E} & \xleftarrow{U} \\
\downarrow & & \downarrow & \\
\Delta^1 \times K & \xrightarrow{\overline{H}} & \mathcal{C}.
\end{array}
\] (5.10)

Then:

1. The lifting problem (5.10) admits a solution \( H : \Delta^1 \times K \to \mathcal{E} \) which is a \( U \)-cocartesian lift of \( \overline{H} \).

2. Let \( F \) be any object of the \( \infty \)-category \( \text{Fun}_{/\mathcal{C}}(\{1\} \times K, \mathcal{E}) \). Then \( F \) is isomorphic to \( H|_{\{1\} \times K} \) (as an object of \( \text{Fun}_{/\mathcal{C}}(\{1\} \times K, \mathcal{E}) \)) if and only if \( F = H'|_{\{1\} \times K} \), where \( H' \) is another \( U \)-cocartesian lift of \( \overline{H} \) which solves the lifting problem (5.10).

Proof. By virtue of Remark 5.2.2.11 (and Theorem 5.2.1.1), we can replace \( U \) by the induced map \( \text{Fun}(K, \mathcal{E}) \to \text{Fun}(K, \mathcal{C}) \) and thereby reduce to the case where \( K = \Delta^0 \). In this case, assertion (1) follows immediately from our assumption that \( U \) is a cocartesian fibration, and assertion (2) follows from Remark 5.1.3.8.

Proof of Proposition 5.2.2.8. Apply Lemma 5.2.2.13 in the special case where \( K \) is the \( \infty \)-category \( \mathcal{E}_C \), \( H_0 : K \to \mathcal{E} \) is the inclusion map, and \( \overline{H} \) is the composite map \( \Delta^1 \xrightarrow{f} \mathcal{C} \) (see Example 5.2.2.12).

We also have a dual version of Definition 5.2.2.4:

Definition 5.2.2.14. Let \( U : \mathcal{E} \to \mathcal{C} \) be an inner fibration of simplicial sets, let \( C \) and \( D \) be vertices of \( \mathcal{C} \), and let \( f : C \to D \) be an edge of \( \mathcal{C} \). We say that a functor \( F : \mathcal{E}_D \to \mathcal{E}_C \) is given by contravariant transport along \( f \) if there exists a morphism of simplicial sets \( \tilde{F} : \Delta^1 \times \mathcal{E}_D \to \mathcal{E} \) satisfying the following conditions:

1. The diagram of simplicial sets

\[
\begin{array}{cccl}
\Delta^1 \times \mathcal{E}_D & \xrightarrow{\tilde{F}} & \mathcal{E} & \xleftarrow{U} \\
\downarrow & & \downarrow & \\
\Delta^1 & \xrightarrow{f} & \mathcal{C}
\end{array}
\]

commutes.
5.2. COVARIANT TRANSPORT

(2) The restriction \( \partial \mid_{\{1\} \times \mathcal{E}_D} \) is equal to the identity map \( \text{id}_{\mathcal{E}_D} \), and the restriction \( \partial \mid_{\{0\} \times \mathcal{E}_D} \) is equal to \( F \).

(3) For every object \( Y \) of the \( \infty \)-category \( \mathcal{E}_D \), the composite map

\[
\Delta^1 \times \{Y\} \hookrightarrow \Delta^1 \times \mathcal{E}_D \xrightarrow{\partial} \mathcal{E}
\]

is a locally \( U \)-cartesian edge of the simplicial set \( \mathcal{E} \).

If these conditions are satisfied, we say that the morphism \( \partial \) witnesses \( F \) as given by contravariant transport along \( f \).

Remark 5.2.2.15. Let \( U : \mathcal{E} \rightarrow \mathcal{C} \) be an inner fibration of simplicial sets, let \( C \) and \( D \) be vertices of \( \mathcal{C} \), and let \( f : C \rightarrow D \) be a morphism of simplicial sets. Then a functor \( F : \mathcal{C} \rightarrow \mathcal{E}_D \) is given by covariant transport along \( f \) if and only if the opposite functor \( \underline{F} : \mathcal{E}_D \rightarrow \mathcal{C} \) is given by contravariant transport along \( f \) with respect to the cartesian fibration \( U : \mathcal{E} \rightarrow \mathcal{C} \).

Proposition 5.2.2.16 has a counterpart for cartesian fibrations:

Proposition 5.2.2.16. Let \( U : \mathcal{E} \rightarrow \mathcal{C} \) be a cartesian fibration of simplicial sets and let \( f : C \rightarrow D \) be an edge of \( \mathcal{C} \). Then:

- There exists a functor \( F : \mathcal{E}_D \rightarrow \mathcal{E}_C \) which is given by contravariant transport along \( f \).
- An arbitrary functor \( F' : \mathcal{E}_D \rightarrow \mathcal{E}_C \) is given by contravariant transport along \( f \) if and only if it is isomorphic to \( F \) (as an object of the \( \infty \)-category \( \text{Fun}(\mathcal{E}_D, \mathcal{E}_C) \)).

Notation 5.2.2.17. Let \( U : \mathcal{E} \rightarrow \mathcal{C} \) be a cartesian fibration of simplicial sets and let \( f : C \rightarrow D \) be an edge of the simplicial set \( \mathcal{C} \). It follows from Proposition 5.2.2.16 that the collection of functors \( \mathcal{E}_D \rightarrow \mathcal{E}_C \) which are given by contravariant transport along \( f \) comprise a single isomorphism class in the \( \infty \)-category \( \text{Fun}(\mathcal{E}_D, \mathcal{E}_C) \). We will denote this isomorphism class by \([f] \), which we regard as an element of the set \( \pi_0(\text{Fun}(\mathcal{E}_D, \mathcal{E}_C)) \). We will often use the notation \( f^* \) to denote a particular choice of representative of this isomorphism class: that is, a particular choice of functor \( \mathcal{E}_D \rightarrow \mathcal{E}_C \) which is given by contravariant transport along \( f \).

For Kan fibrations, there is a close relationship between covariant and contravariant transport:

Proposition 5.2.2.18. Let \( U : \mathcal{E} \rightarrow \mathcal{C} \) be a Kan fibration of simplicial sets and let \( f : C \rightarrow D \) be an edge of \( \mathcal{C} \). Then the covariant and contravariant transport morphisms \([f] \in \text{Hom}_{\text{hKan}}(\mathcal{E}_C, \mathcal{E}_D)\) and \([f^*] \in \text{Hom}_{\text{hKan}}(\mathcal{E}_D, \mathcal{E}_C)\) are inverse to one another (as morphisms in the homotopy category \( \text{hKan} \)).
Proof. Choose morphisms of Kan complexes \( f_1 : \mathcal{E}_C \to \mathcal{E}_D \) and \( f^* : \mathcal{E}_D \to \mathcal{E}_C \) representing the homotopy classes \([f_1]\) and \([f^*]\), respectively. We will show that \( f^* \circ f_1 \) is homotopic to the identity morphism \( \text{id}_{\mathcal{E}_C} \); a similar argument will show that \( f_1 \circ f^* \) is homotopic to \( \text{id}_{\mathcal{E}_D} \). Let \( D \) denote the fiber product \( \text{Fun}(\mathcal{E}_C, \mathcal{E}) \times_{\text{Fun}(\mathcal{E}_C, \mathcal{C})} \mathcal{C} \), and let \( \pi : D \to \mathcal{C} \) be the projection map onto the second factor. Since \( U \) is a Kan fibration, it follows from Corollary 3.1.3.2 that \( \pi \) is also a Kan fibration. Let \( \tilde{f} : \Delta^1 \times \mathcal{E}_C \to \mathcal{E} \) be a morphism witnessing \( f_1 \) as given by covariant transport along \( f \). Then \( \tilde{f} \) determines an edge \( h \) of the simplicial set \( D \) satisfying \( \pi(h) = f \). Let \( \tilde{f}' : \Delta^1 \times \mathcal{E}_D \to \mathcal{E} \) be a morphism which witnesses \( f^* \) as given by contravariant transport along \( f \), so that the composite morphism

\[
\Delta^1 \times \mathcal{E}_C \xrightarrow{\text{id} \times f_1} \Delta^1 \times \mathcal{E}_D \xrightarrow{\tilde{f}'} \mathcal{E}
\]

determines an edge \( h' \) of the simplicial set \( D \) satisfying \( \pi(h') = f \). The edges \( h \) and \( h' \) have the same target (the vertex of \( D \) corresponding to the morphism \( f_1 \)). Invoking our assumption that \( \pi \) is a Kan fibration, we deduce that there exists a 2-simplex \( \sigma \) of \( D \) satisfying \( d_0(\sigma) = h', d_1(\sigma) = h \), and \( \pi(\sigma) = s_0(f) \); we can represent \( \sigma \) as a diagram

We now observe that the edge \( v = d_2(\sigma) \) of \( D \) can be identified with a map of simplicial sets \( V : \Delta^1 \times \mathcal{E}_C \to \mathcal{E}_C \) which is a homotopy from \( \text{id}_{\mathcal{E}_C} = V\mid_{\{0\} \times \mathcal{E}_C} \) to \( f^* \circ f_1 = V\mid_{\{1\} \times \mathcal{E}_C} \). \qed

We close this section by establishing a converse to Proposition 5.2.2.18:

**Theorem 5.2.2.19.** Let \( U : \mathcal{E} \to \mathcal{C} \) be a morphism of simplicial sets. The following conditions are equivalent:

1. The morphism \( U \) is a Kan fibration.
2. The morphism \( U \) is a left fibration and, for every edge \( f : C \to D \) of the simplicial set \( \mathcal{C} \), the covariant transport morphism \([f_1] : \mathcal{E}_C \to \mathcal{E}_D\) is an isomorphism in the homotopy category \( \text{hKan} \).
3. The morphism \( U \) is a right fibration and, for every edge \( f : C \to D \) of the simplicial set \( \mathcal{C} \), the contravariant transport morphism \([f^*] : \mathcal{E}_D \to \mathcal{E}_C\) is an isomorphism in the homotopy category \( \text{hKan} \).
5.2. COVARIANT TRANSPORT

Proof. We will show that (1) ⇔ (2); the proof of the equivalence (1) ⇔ (3) is similar. The implication (1) ⇒ (2) is immediate from Proposition 5.2.2.18. For the converse, assume that $U : \mathcal{E} \to \mathcal{C}$ is a left fibration of simplicial sets and that, for every edge $f : C \to D$ of $\mathcal{C}$, the covariant transport morphism $[f]$ is an isomorphism in the homotopy category $h\text{Kan}$. We wish to show that $U$ is a Kan fibration. By virtue of Example 4.2.1.5, it will suffice to show that $U$ is a right fibration. By Proposition 4.2.6.1, this is equivalent to the assertion that the induced map

$$\theta : \text{Fun}(\Delta^1, \mathcal{E}) \to \text{Fun}(\{1\}, \mathcal{E}) \times_{\text{Fun}(\{1\}, \mathcal{C})} \text{Fun}(\Delta^1, \mathcal{C})$$

is a trivial Kan fibration. Note that our assumption that $U$ is a left fibration guarantees that $\theta$ is also a left fibration (Proposition 4.2.5.1).

Fix an edge $f : C \to D$ of the simplicial set $\mathcal{C}$ and let $\text{Fun}(\Delta^1, \mathcal{E})_f$ denote the fiber $\text{Fun}(\Delta^1, \mathcal{E}) \times_{\text{Fun}(\Delta^1, \mathcal{C})} \{f\}$. Then evaluation at the vertex $1 \in \Delta^1$ induces a morphism $\theta_f : \text{Fun}(\Delta^1, \mathcal{E})_f \to \mathcal{E}_D$. Note that $\theta_f$ is a pullback of $\theta$, and is therefore also a left fibration. Since $\mathcal{E}_D$ is a Kan complex (Corollary 4.4.2.3, Corollary 4.4.3.8 guarantees that $\theta_f$ is a Kan fibration (so $\text{Fun}(\Delta^1, \mathcal{C})_f$ is also a Kan complex). Evaluation at the vertex $0 \in \Delta^1$ induces another morphism of simplicial sets $u : \text{Fun}(\Delta^1, \mathcal{E})_f \to \mathcal{E}_C$. Since $U$ is a left fibration, the morphism $u$ is a trivial Kan fibration. By construction, the homotopy class $[f]$ can be represented by the morphism of Kan complexes given by the composition

$$\mathcal{E}_C \xrightarrow{v} \text{Fun}(\Delta^1, \mathcal{E})_f \xrightarrow{\theta_f} \mathcal{E}_D,$$

where $v$ is a section of $u$ (and therefore a homotopy equivalence). Consequently, our assumption that $[f]$ is an isomorphism in $h\text{Kan}$ guarantees that $\theta_f$ is a homotopy equivalence of Kan complexes (Remark 3.1.6.16). Applying Corollary 3.2.7.4, we deduce that the fibers of $\theta_f$ are contractible Kan complexes. Since every fiber of $\theta$ can also be viewed as a fiber of $\theta_f$ for some edge $f$ of the simplicial set $\mathcal{C}$, it follows that the fibers of $\theta$ are also contractible Kan complexes. Invoking Proposition 4.4.2.14, we conclude that $\theta$ is a trivial Kan fibration, as desired.

\hspace{1cm} \Box

Corollary 5.2.2.20. Let $U : \mathcal{E} \to \mathcal{C}$ be a morphism of simplicial sets. The following conditions are equivalent:

1. The morphism $U$ is a covering map (Definition 3.1.4.1).
2. The morphism $U$ is a left covering map (Definition 4.2.3.8) and, for every edge $f : C \to D$ of the simplicial set $\mathcal{C}$, the covariant transport functor $f : \mathcal{E}_C \to \mathcal{E}_D$ is a bijection.
3. The morphism $U$ is a right covering map (Definition 4.2.3.8) and, for every edge $f : C \to D$ of the simplicial set $\mathcal{C}$, the contravariant transport morphism $f^* : \mathcal{E}_D \to \mathcal{E}_C$ is a bijection.

Proof. Combine Theorem 5.2.2.19 with Corollary 4.2.3.20. \hspace{1cm} \Box
5.2.3 Example: The Relative Join

Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories. Our goal in this section is to show that \( F \) is given by covariant transport, in the sense of Definition 5.2.2.4. More precisely, we will show that there exists a cocartesian fibration of \( \infty \)-categories \( \mathcal{M} \to \Delta^1 \) equipped with isomorphisms \( \mathcal{C} \simeq \{0\} \times_{\Delta^1} \mathcal{M} \) and \( \mathcal{D} = \{1\} \times_{\Delta^1} \mathcal{M} \) carrying \( F \) to a functor

\[
\{0\} \times_{\Delta^1} \mathcal{M} \to \{1\} \times_{\Delta^1} \mathcal{M}
\]

which is given by covariant transport along the nondegenerate edge of \( \Delta^1 \) (Proposition 5.2.3.15). We will prove this by an explicit construction, using a generalization of the join operation studied in §4.3. (in §5.2.4, we will show that the \( \infty \)-category \( \mathcal{M} \) is determined up to equivalence by the functor \( F : \mathcal{C} \to \mathcal{D} \) (see Corollary 5.2.4.2 and Remark 5.2.4.3).

Construction 5.2.3.1 (The Relative Join). Let \( \mathcal{E} \) be a simplicial set. By virtue of Remark 4.3.3.20, there is a unique morphism of simplicial sets \( \rho : \Delta^1 \times \mathcal{E} \to \mathcal{E} \star \mathcal{E} \) for which the diagram

\[
\begin{array}{ccc}
{0} \times \mathcal{E} & \to & \Delta^1 \times \mathcal{E} & \leftarrow & {1} \times \mathcal{E} \\
\downarrow \text{id}_\mathcal{E} & & \rho & \downarrow \text{id}_\mathcal{E} \\
\mathcal{E} \star \emptyset & \to & \mathcal{E} \star \mathcal{E} & \leftarrow & \emptyset \star \mathcal{E}
\end{array}
\]

is commutative.

Let \( F : \mathcal{C} \to \mathcal{E} \) and \( G : \mathcal{D} \to \mathcal{E} \) be morphisms of simplicial sets. We let \( \mathcal{C} \star \mathcal{D} \) denote the fiber product \((\mathcal{C} \star \mathcal{D}) \times_{(\mathcal{E} \star \mathcal{E})} (\Delta^1 \times \mathcal{E})\), so that we have a pullback diagram

\[
\begin{array}{ccc}
\mathcal{C} \star \mathcal{D} & \to & \mathcal{C} \star \mathcal{D} \\
\downarrow \Delta^1 \times \mathcal{E} & & \rho \downarrow \Delta^1 \times \mathcal{E} \\
\mathcal{C} \star \mathcal{E} & \to & \mathcal{E} \star \mathcal{E}
\end{array}
\]

We will refer to \( \mathcal{C} \star \mathcal{D} \) as the join of \( \mathcal{C} \) and \( \mathcal{D} \) relative to \( \mathcal{E} \).

Remark 5.2.3.2. Let \( F : \mathcal{C} \to \mathcal{E} \) and \( G : \mathcal{D} \to \mathcal{E} \) be morphisms of simplicial sets, and let \( K \) be a simplicial set. By virtue of Remark 4.3.3.20, morphisms from \( K \) to the relative join \( \mathcal{C} \star \mathcal{D} \) are given by maps \( \pi : K \to \Delta^1 \) together with commutative diagrams

\[
\begin{array}{ccc}
{0} \times_{\Delta^1} K & \to & K & \leftarrow & {1} \times_{\Delta^1} K \\
\downarrow & & \downarrow & & \downarrow \\
\mathcal{C} & \to & \mathcal{E} & \leftarrow & \mathcal{D}
\end{array}
\]

\[
\begin{array}{ccc}
{0} \times_{\Delta^1} K & \to & K & \leftarrow & {1} \times_{\Delta^1} K \\
\downarrow & & \downarrow & & \downarrow \\
\mathcal{C} & \to & \mathcal{E} & \leftarrow & \mathcal{D}
\end{array}
\]
5.2. COVARIANT TRANSPORT

Remark 5.2.3.3. Let $F : \mathcal{C} \to \mathcal{E}$ and $G : \mathcal{D} \to \mathcal{E}$ be morphisms of simplicial sets. Then the inclusion maps $\mathcal{C} \hookrightarrow \mathcal{C} \star \mathcal{D} \hookleftarrow \mathcal{D}$ lift uniquely to monomorphisms

$$\iota_\mathcal{C} : \mathcal{C} \hookrightarrow \mathcal{C} \star \mathcal{E} \quad \iota_\mathcal{D} : \mathcal{D} \hookrightarrow \mathcal{C} \star \mathcal{E},$$

which fit into a commutative diagram

$$\begin{array}{ccc}
\mathcal{C} & \xrightarrow{\iota_\mathcal{C}} & \mathcal{C} \star \mathcal{E} \mathcal{D} & \xleftarrow{\iota_\mathcal{D}} & \mathcal{D} \\
\{0\} & \downarrow & & \downarrow & \{1\} \\
\end{array}$$

in which both squares are pullbacks. In the future, we will often abuse notation by identifying $\mathcal{C}$ and $\mathcal{D}$ with their images under the monomorphisms $\iota_\mathcal{C}$ and $\iota_\mathcal{D}$, respectively (which are full simplicial subsets of the relative join $\mathcal{C} \star \mathcal{E} \mathcal{D}$).

Example 5.2.3.4. Let $F : \mathcal{C} \to \mathcal{E}$ and $G : \mathcal{D} \to \mathcal{E}$ be morphisms of simplicial sets. If $\mathcal{D}$ is empty, then the inclusion map $\iota_\mathcal{C} : \mathcal{C} \hookrightarrow \mathcal{C} \star \mathcal{E} \mathcal{D}$ is an isomorphism of simplicial sets. If $\mathcal{C}$ is empty, then the inclusion map $\iota_\mathcal{D} : \mathcal{D} \hookrightarrow \mathcal{C} \star \mathcal{E} \mathcal{D}$ is an isomorphism of simplicial sets.

Example 5.2.3.5. Let $\mathcal{C}$ and $\mathcal{D}$ be simplicial sets, so that we have unique morphisms $F : \mathcal{C} \to \Delta^0$ and $G : \mathcal{D} \to \Delta^0$. Then the relative join $\mathcal{C} \star_{\Delta^0} \mathcal{D}$ agrees with the join $\mathcal{C} \star \mathcal{D}$ introduced in Construction 4.3.3.13.

Example 5.2.3.6. Let $\mathcal{E}$ be a simplicial set. Then the relative join $\mathcal{E} \star_{\mathcal{E}} \mathcal{E}$ is isomorphic to $\Delta^1 \times \mathcal{E}$.

Example 5.2.3.7. Let $\mathcal{E}$ be a simplicial set equipped with a morphism $\pi : \mathcal{E} \to \Delta^1$, and set $\mathcal{C} = \{0\} \times_{\Delta^1} \mathcal{E}$ and $\mathcal{D} = \{1\} \times_{\Delta^1} \mathcal{E}$. Then the relative join $\mathcal{C} \star_{\mathcal{E}} \mathcal{D}$ is isomorphic to $\mathcal{E}$.

Example 5.2.3.8. Let $F : \mathcal{C} \to \mathcal{E}$ and $G : \mathcal{D} \to \mathcal{E}$ be functors between categories. Then the relative join $N_{\bullet}(\mathcal{C}) \star_{N_{\bullet}(\mathcal{E})} N_{\bullet}(\mathcal{D})$ can be identified with the nerve of the category

$$\mathcal{C} \star_{\mathcal{E}} \mathcal{D} = (\mathcal{C} \star \mathcal{D}) \times_{(\mathcal{E} \star \mathcal{E})} ([1] \times \mathcal{E}),$$

which can be described more concretely as follows:

- The set of objects $\text{Ob}(\mathcal{C} \star_{\mathcal{E}} \mathcal{D})$ is the disjoint union of $\text{Ob}(\mathcal{C})$ with $\text{Ob}(\mathcal{D})$.
- For every pair of objects $X, Y \in \text{Ob}(\mathcal{C} \star_{\mathcal{E}} \mathcal{D})$, we have

$$\text{Hom}_{\mathcal{C} \star_{\mathcal{E}} \mathcal{D}}(X, Y) = \begin{cases}
\text{Hom}_\mathcal{C}(X, Y) & \text{if } X, Y \in \text{Ob}(\mathcal{C}) \\
\text{Hom}_\mathcal{D}(X, Y) & \text{if } X, Y \in \text{Ob}(\mathcal{D}) \\
\text{Hom}_\mathcal{E}(F(X), G(Y)) & \text{if } X \in \text{Ob}(\mathcal{C}), Y \in \text{Ob}(\mathcal{D}) \\
\emptyset & \text{if } X \in \text{Ob}(\mathcal{D}), Y \in \text{Ob}(\mathcal{C}).
\end{cases}$$
Remark 5.2.3.9 (Base Change). Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
C' & \rightarrow & E' \\
\downarrow & & \downarrow \\
C & \rightarrow & E
\end{array}
\quad \begin{array}{ccc}
D' & \leftarrow & D \\
\downarrow & & \downarrow \\
D & \leftarrow & D
\end{array}
\]

where both squares are pullbacks. Then the induced diagram

\[
\begin{array}{ccc}
C' \star_{E'} D' & \rightarrow & E' \\
\downarrow & & \downarrow \\
C \star_{E} D & \rightarrow & E
\end{array}
\]

is also a pullback square.

Remark 5.2.3.10. Let \( G : D \rightarrow E \) be a fixed morphism of simplicial sets. Then the construction

\[
(F : C \rightarrow E) \mapsto C \star_{E} D
\]

carries colimits in the category \((\text{Set}_{\Delta})_{/E}\) to colimits in the category \((\text{Set}_{\Delta})_{/D}\). In particular, the construction \( C \mapsto (C \star_{E} D) \) commutes with filtered colimits and carries pushout diagrams to pushout diagrams.

The relative join \( C \star_{E} D \) of Construction 5.2.3.1 is defined for arbitrary diagrams of simplicial sets \( C \xrightarrow{F} E \leftarrow G \xleftarrow{D} \). However, as our notation suggests, we will be primarily interested in the special case where \( C, D, \) and \( E \) are \( \infty \)-categories. In this case, we have the following generalization of Corollary 4.3.3.24:

Proposition 5.2.3.11. Let \( F : C \rightarrow E \) and \( G : D \rightarrow E \) be functors of \( \infty \)-categories. Then the relative join \( C \star_{E} D \) is an \( \infty \)-category.

Lemma 5.2.3.12. Let \( U : E \rightarrow E' \) be an inner fibration of simplicial sets. Then the induced map

\[
\Delta^1 \times E = E \star_{E} E \rightarrow E \star_{E'} E
\]

is also an inner fibration of simplicial sets.
Proof. Suppose we are given integers $0 < i < n$; we wish to show that every lifting problem

\[
\begin{array}{ccc}
\Lambda^n_i & \xrightarrow{\sigma_0} & \Delta^1 \times \mathcal{E} \\
\downarrow & & \downarrow \\
\Delta^n & \xrightarrow{\sigma} & \mathcal{E} \ast_{\mathcal{E}'} \mathcal{E}
\end{array}
\] (5.11)

admits a solution. Let $\alpha$ denote the composite map

\[
\Delta^n \xrightarrow{\bar{\sigma}} \mathcal{E} \ast_{\mathcal{E}'} \mathcal{E} \to \Delta^0 \ast_{\Delta^0} \Delta^0 \simeq \Delta^1.
\]

If $\alpha$ is a constant morphism, then the existence of $\sigma$ is immediate. We may therefore assume without loss of generality that $\alpha$ is not constant. Write $\sigma_0 = (\alpha_0, \tau_0)$, where $\alpha_0 = \alpha|_{\Lambda^n_i}$ and $\tau_0 : \Lambda^n_i \to \mathcal{E}$ is a morphism of simplicial sets, and let $\bar{\tau}$ denote the composite map

\[
\Delta^n \xrightarrow{\bar{\tau}} \mathcal{E} \ast_{\mathcal{E}'} \mathcal{E} \to \mathcal{E}'.
\]

Since $U$ is an inner fibration, the lifting problem

\[
\begin{array}{ccc}
\Lambda^n_i & \xrightarrow{\tau_0} & \mathcal{E} \\
\downarrow & & \downarrow & & \downarrow \\
\Delta^n & \xrightarrow{\tau} & \mathcal{E}'
\end{array}
\]

admits a solution. We now observe that the pair $\sigma = (\alpha, \tau)$ can be regarded as an $n$-simplex of $\Delta^1 \times \mathcal{E}$ which solves the lifting problem $\mathcal{E} \ast_{\mathcal{E}'} \mathcal{E} \to \mathcal{E}'$. \hfill \qed

**Lemma 5.2.3.13.** Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{U} & \mathcal{E} & \xleftarrow{V} & \mathcal{D} \\
\downarrow W & & & & \downarrow V \\
\mathcal{C}' & \xrightarrow{W} & \mathcal{E}' & \xleftarrow{V} & \mathcal{D}'
\end{array}
\]

in which the vertical morphisms are inner fibrations. Then the induced map

\[
F : \mathcal{C} \ast_{\mathcal{E}} \mathcal{D} \to \mathcal{C}' \ast_{\mathcal{E}'} \mathcal{D}'
\]

is also an inner fibration.
Proof. Unwinding the definitions, we see that $F$ factors as a composition

$$\mathcal{C} \star \mathcal{E} \xrightarrow{G} \mathcal{C} \star \mathcal{E}' \xrightarrow{H} \mathcal{C}' \star \mathcal{E}',$$

where $G$ is a pullback of the inner fibration $\mathcal{E} \star \mathcal{E} \to \mathcal{E} \star \mathcal{E}'$ of Lemma 5.2.3.12 and $H$ is a pullback of the inner fibration $\mathcal{C} \star \mathcal{D} \to \mathcal{C}' \star \mathcal{D}'$ of Proposition 4.3.3.23. \qed

Proof of Proposition 5.2.3.11. Let $F : \mathcal{C} \to \mathcal{E}$ and $G : \mathcal{D} \to \mathcal{E}$ be functors of $\infty$-categories. Applying Lemma 5.2.3.13, we see that the natural map

$$\mathcal{C} \star \mathcal{E} \xrightarrow{\Delta^2} \Delta^1 \simeq \Delta^0$$

is an inner fibration of simplicial sets. Since $\Delta^1$ is an $\infty$-category, it follows that $\mathcal{C} \star \mathcal{E}$ is also an $\infty$-category (Remark 4.1.1.9). \qed

Remark 5.2.3.14 (Morphism Spaces in the Relative Join). Let $F : \mathcal{C} \to \mathcal{E}$ and $G : \mathcal{D} \to \mathcal{E}$ be morphisms of simplicial sets. If $X$ and $Y$ are vertices of the relative join $\mathcal{C} \star \mathcal{E}$, then we have canonical isomorphisms of simplicial sets

$$\text{Hom}_{\mathcal{C} \star \mathcal{E}}(X, Y) \simeq \begin{cases} 
\text{Hom}_\mathcal{C}(X, Y) & \text{if } X, Y \in \mathcal{C} \\
\text{Hom}_\mathcal{D}(X, Y) & \text{if } X, Y \in \mathcal{D} \\
\text{Hom}_\mathcal{E}(F(X), G(Y)) & \text{if } X \in \mathcal{C}, Y \in \mathcal{D} \\
\emptyset & \text{if } X \in \mathcal{D}, Y \in \mathcal{C}.
\end{cases}$$

The pinched morphism spaces $\text{Hom}^P_{\mathcal{C} \star \mathcal{E}}(X, Y)$ and $\text{Hom}^R_{\mathcal{C} \star \mathcal{E}}(X, Y)$ admit similar descriptions.

We now specialize Construction 5.2.3.1 to the case where $\mathcal{D} = \mathcal{E}$ and the morphism $G : \mathcal{D} \to \mathcal{E}$ is the identity. Our goal is to prove the following:

Proposition 5.2.3.15. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories. Then:

1. The projection map $\pi : \mathcal{C} \star \mathcal{D} \to \Delta^1$ is a cocartesian fibration of $\infty$-categories.

2. The map

$$\bar{F} : \Delta^1 \times \mathcal{C} \simeq (\mathcal{C} \star \mathcal{C}) \to \mathcal{C} \star \mathcal{D}$$

witnesses the functor $F$ as given by covariant transport along the nondegenerate edge of $\Delta^1$.

The proof of Proposition 5.2.3.15 will require some preliminaries.
Lemma 5.2.3.16. Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{D} \\
U & \downarrow & \downarrow V \\
\mathcal{C}' & \xrightarrow{F'} & \mathcal{D}',
\end{array}
\]

so that \(U\) and \(V\) induce a morphism \(W : \mathcal{C} \star_D \mathcal{D} \to \mathcal{C}' \star_{D'} \mathcal{D}'\). Let \(e\) be an edge of the simplicial set \(\mathcal{C} \star_D \mathcal{D}\) satisfying the following conditions:

1. If \(e\) is contained in \(\mathcal{C}\), then it is \(U\)-cocartesian when viewed as an edge of \(\mathcal{C}\).
2. The image of \(e\) under the map

\[\rho : \mathcal{C} \star_D \mathcal{D} \to \mathcal{D} \star_D \mathcal{D} \simeq \Delta^1 \times \mathcal{D} \to \mathcal{D}\]

is \(V\)-cocartesian.

Then \(e\) is \(W\)-cocartesian.

Proof. Let \(n \geq 2\) be an integer and suppose we are given a lifting problem

\[
\begin{array}{ccc}
\Lambda^n_0 & \xrightarrow{\sigma_0} & \mathcal{C} \star_D \mathcal{D} \\
\downarrow & & \downarrow W \\
\Delta^n & \xrightarrow{\sigma'} & \mathcal{C}' \star_{D'} \mathcal{D}',
\end{array}
\]

(5.12)

where \(\sigma_0\) carries \(N_\bullet(\{0 < 1\}) \subseteq \Lambda^n_0\) to the edge \(e\). If \(\sigma'\) is contained in the simplicial subset \(\mathcal{C}' \subseteq \mathcal{C}' \star_{D'} \mathcal{D}'\), then the lifting problem (5.12) admits a solution by virtue of assumption (1). Let us therefore assume that \(\sigma'\) is not contained in \(\mathcal{C}'\). Let \(\rho : \mathcal{C} \star_D \mathcal{D} \to \mathcal{D}\) be as in (2), and define \(\rho' : \mathcal{C}' \star_{D'} \mathcal{D}' \to \mathcal{D}'\) similarly. Unwinding the definitions, we can rewrite (5.12) as a lifting problem

\[
\begin{array}{ccc}
\Lambda^n_0 & \xrightarrow{\rho \circ \sigma_0} & \mathcal{D} \\
\downarrow & & \downarrow V \\
\Delta^n & \xrightarrow{\rho' \circ \sigma'} & \mathcal{D}',
\end{array}
\]

which admits a solution by virtue of assumption (2). \(\square\)
Lemma 5.2.3.17. Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{D} \\
\downarrow{U} & & \downarrow{V} \\
\mathcal{C}' & \xrightarrow{F'} & \mathcal{D}'
\end{array}
\]

Suppose that \( U \) and \( V \) are cocartesian fibrations, and that the morphism \( F \) carries \( U \)-cocartesian edges of \( \mathcal{C} \) to \( V \)-cocartesian edges of \( \mathcal{D} \). Then the induced map \( W : \mathcal{C} \star_D \mathcal{D} \to \mathcal{C}' \star_{D'} \mathcal{D}' \) is also a cocartesian fibration. Moreover, an edge \( e \) of \( \mathcal{C} \star_D \mathcal{D} \) is \( W \)-cocartesian if and only if it satisfies conditions (1) and (2) of Lemma 5.2.3.16.

Proof. It follows from Lemma 5.2.3.12 that \( W \) is an inner fibration of simplicial sets. Let us say that an edge of \( \mathcal{C} \star_D \mathcal{D} \) is special if it satisfies conditions (1) and (2) of Lemma 5.2.3.16, so that every special edge of \( \mathcal{C} \star_D \mathcal{D} \) is \( W \)-cocartesian. We consider three cases:

- Suppose that \( X \) belongs to \( \mathcal{C} \) and \( Y \) belongs to \( \mathcal{C}' \). In this case, our assumption that \( U \) is a cocartesian fibration guarantees that we can lift \( \overline{e} \) to a \( U \)-cocartesian edge \( e : X \to Y \) of \( \mathcal{C} \subseteq \mathcal{C} \star_D \mathcal{D} \). Since \( F(e) \) is a \( V \)-cocartesian edge of \( \mathcal{D} \), the edge \( e \) is special.

- Suppose that \( X \) belongs to \( \mathcal{C} \) and \( Y \) belongs to \( \mathcal{D}' \). In this case, we can identify \( \overline{e} \) with an edge \( e_0 : V(F(X)) \to \overline{Y} \) of the simplicial set \( \mathcal{D}' \). Since \( V \) is a cocartesian fibration, we can lift \( \overline{e}_0 \) to a \( V \)-cocartesian morphism \( e_0 : F(X) \to Y \) of \( \mathcal{D} \), which we can identify with a special edge \( e : X \to Y \) of the simplicial set \( \mathcal{C} \star_D \mathcal{D} \) satisfying \( W(e) = \overline{e} \).

- Suppose that \( X \) belongs to \( \mathcal{D} \) and \( Y \) belongs to \( \mathcal{D}' \). In this case, our assumption that \( V \) is a cocartesian fibration guarantees that we can lift \( \overline{e} \) to a \( V \)-cocartesian edge \( e : X \to Y \) of \( \mathcal{D} \subseteq \mathcal{C} \star_D \mathcal{D} \), which is then special when regarded as an edge of \( \mathcal{C} \star_D \mathcal{D} \).

To complete the proof, it will suffice to show that every \( W \)-cocartesian edge \( e : X \to Y \) of \( \mathcal{C} \star_D \mathcal{D} \) is special. Applying the preceding argument, we can choose a special edge \( e' : X \to Y' \) satisfying \( W(e') = W(e) \). Set \( \overline{Y} = W(Y) = W(Y') \). Since \( e \) and \( e' \) are both \( W \)-cocartesian, Remark 5.1.3.8 supplies a 2-simplex \( \sigma \) of the simplicial set \( \mathcal{C} \star_D \mathcal{D} \) with boundary given by

\[
\begin{array}{ccc}
Y & \xrightarrow{u} & Y' \\
\downarrow{e} & & \downarrow{e'} \\
X & & 
\end{array}
\]

where \( u \) is an isomorphism in the \( \infty \)-category \( \{\overline{Y}\} \times_{(\mathcal{C}' \star_{D'} \mathcal{D}')} (\mathcal{C} \star_D \mathcal{D}) \). Applying Remark 5.1.3.8 to the cocartesian fibrations \( U \) and \( V \), we deduce that the edge \( e \) is also special. \( \square \)
Example 5.2.3.18. Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories. Applying Lemma 5.2.3.17 to the diagram

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{D} \\
\downarrow & & \downarrow \\
\Delta^0 & \xrightarrow{\Delta^0} & \Delta^0
\end{array}
\]

we deduce that the projection map

\[
\pi : \mathcal{C} \star \mathcal{D} \to \Delta^0 \star \Delta^0 \simeq \Delta^1
\]

is a cocartesian fibration. Moreover, a morphism \( e : X \to Y \) of the \( \infty \)-category \( \mathcal{C} \star \mathcal{D} \) is \( \pi \)-cocartesian if and only if it satisfies one of the following three conditions:

- The objects \( X \) and \( Y \) belong to \( \mathcal{C} \) and \( e \) is an isomorphism in the \( \infty \)-category \( \mathcal{C} \).
- The objects \( X \) and \( Y \) belong to \( \mathcal{D} \) and \( e \) is an isomorphism in the \( \infty \)-category \( \mathcal{D} \).
- The object \( X \) belongs to \( \mathcal{C} \), the object \( Y \) belongs to \( \mathcal{D} \), and \( e \) corresponds to an isomorphism \( e_0 : F(X) \to Y \) in the \( \infty \)-category \( \mathcal{D} \) (under the identification of Remark 5.2.3.14).

Proof of Proposition 5.2.3.15. Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories, so that the projection map \( \pi : \mathcal{C} \star \mathcal{D} \to \Delta^1 \) of Example 5.2.3.18 is a cocartesian fibration. Note that the morphism

\[
H : \Delta^1 \times \mathcal{C} \simeq \mathcal{C} \ast \mathcal{C} \to \mathcal{C} \star \mathcal{D}
\]

satisfies \( H|_{\{0\} \times \mathcal{C}} = \text{id}_\mathcal{C} \) and \( H|_{\{1\} \times \mathcal{C}} = F \). To complete the proof, it will suffice to show that for every object \( C \in \mathcal{C} \), the restriction \( H|_{\Delta^1 \times \{C\}} \) is a \( \pi \)-cocartesian morphism \( e : X \to F(X) \) in the \( \infty \)-category \( \mathcal{C} \star \mathcal{D} \). This follows from the criterion of Example 5.2.3.18 since \( e \) corresponds to the identity morphism \( \text{id}_{F(X)} : F(X) \to F(X) \) under the identification of Remark 5.2.3.14.

Passing to opposite \( \infty \)-categories, we obtain a dual version of Proposition 5.2.3.15:

Variant 5.2.3.19. Let \( G : \mathcal{D} \to \mathcal{C} \) be a functor of \( \infty \)-categories. Then:

1. The projection map \( \pi : \mathcal{C} \star \mathcal{D} \to \Delta^1 \) is a cartesian fibration of \( \infty \)-categories.
2. The map

\[
h : \Delta^1 \times \mathcal{D} \simeq (\mathcal{D} \ast \mathcal{D}) \to \mathcal{C} \ast \mathcal{D}
\]

witnesses the functor \( G \) as given by contravariant transport along the nondegenerate edge of \( \Delta^1 \).
5.2.4 Fibrations over the 1-Simplex

Let $\mathcal{M}$ be an $\infty$-category equipped with a cocartesian fibration $\pi : \mathcal{M} \to \Delta^1$. Our goal in this section is to show that $\mathcal{M}$ is determined (up to equivalence) by the $\infty$-categories $\mathcal{C} = \{0\} \times \Delta^1 \mathcal{M}$, $\mathcal{D} = \{1\} \times \Delta^1 \mathcal{M}$, and the functor $F : \mathcal{C} \to \mathcal{D}$ given by covariant transport along the nondegenerate edge of $\Delta^1$. This is a consequence of the following:

**Theorem 5.2.4.1.** Let $U : \mathcal{M} \to \Delta^1$ be a functor of $\infty$-categories, and suppose we are given a commutative diagram

$$
\begin{array}{ccc}
\{1\} \times \mathcal{C} & \longrightarrow & \{1\} \times \mathcal{D} \\
\downarrow & & \downarrow g \\
\Delta^1 \times \mathcal{C} & \longrightarrow & \mathcal{M}
\end{array}
$$

in the category $(\text{Set}_\Delta)/_{\Delta^1}$. Then $\sigma$ is a categorical pushout diagram of simplicial sets (Definition 4.5.4.1) if and only if the following conditions are satisfied:

1. The restriction $h|_{\{0\} \times \mathcal{C}} : \mathcal{C} \to \{0\} \times \Delta^1 \mathcal{M}$ is a categorical equivalence of simplicial sets.
2. The morphism $g : \mathcal{D} \to \{1\} \times \Delta^1 \mathcal{M}$ is a categorical equivalence of simplicial sets.
3. For every vertex $C \in \mathcal{C}$, the restriction $h|_{\Delta^1 \times \{C\}}$ is a $U$-cocartesian morphism of $\mathcal{M}$.

Moreover, if these conditions are satisfied, then $U$ is a cocartesian fibration.

**Corollary 5.2.4.2.** Let $U : \mathcal{M} \to \Delta^1$ be a cocartesian fibration of $\infty$-categories with fibers $\mathcal{C} = \{0\} \times \Delta^1 \mathcal{M}$ and $\mathcal{D} = \{1\} \times \Delta^1 \mathcal{M}$. Let $h : \Delta^1 \times \mathcal{C} \to \mathcal{M}$ be a functor which witnesses the functor $F = h|_{\{1\} \times \mathcal{C}}$ as given by covariant transport along the nondegenerate edge of $\Delta^1$ (Definition 5.2.2.4). Then $h$ induces a categorical equivalence of simplicial sets

$$(\Delta^1 \times \mathcal{C}) \coprod_{\{1\} \times \mathcal{C}} \mathcal{D} \to \mathcal{M}.$$ 

**Proof.** Combine Theorem 5.2.4.1 with Proposition 4.5.4.11. \qed

**Remark 5.2.4.3.** Let $U : \mathcal{M} \to \Delta^1$ be a cocartesian fibration of $\infty$-categories. It follows from Corollary 5.2.4.2 that the $\infty$-category $\mathcal{M}$ can be recovered (up to equivalence) from the $\infty$-categories $\mathcal{C} = \{0\} \times \Delta^1 \mathcal{M}$, $\mathcal{D} = \{1\} \times \Delta^1 \mathcal{M}$, and the covariant transport functor $F : \mathcal{C} \to \mathcal{D}$. Similarly, if $U : \mathcal{M} \to \Delta^1$ is a cartesian fibration, then the $\infty$-category $\mathcal{M}$ can be recovered from $\mathcal{C}$, $\mathcal{D}$, and the contravariant transport functor $G : \mathcal{D} \to \mathcal{C}$. 

For any functor of ∞-categories $F : C \to D$, the projection map

$$C \star_D D \to \Delta^0 \star \Delta^0 \simeq \Delta^1$$

is a cocartesian fibration (Proposition 5.2.3.15). The commutative diagram of simplicial sets

$$\begin{array}{ccc}
\emptyset \star C & \longrightarrow & \emptyset \star_D D \\
\downarrow & & \downarrow \\
C \star_C C & \longrightarrow & C \star_D D
\end{array}$$

satisfies the hypotheses of Theorem 5.2.4.1, and is therefore a categorical pushout square. This is a special case of the following more general assertion, which does not require $C$ and $D$ to be ∞-categories:

**Proposition 5.2.4.4.** Let $f : X \to Y$ be a morphism of simplicial sets. Then the diagram

$$\begin{array}{ccc}
\{1\} \times X & \longrightarrow & Y \\
\downarrow & & \downarrow \\
\Delta^1 \times X & \longrightarrow & X \star_Y Y
\end{array} \quad (5.13)$$

is a categorical pushout square of simplicial sets. Here the lower horizontal map is given by the composition

$$\Delta^1 \times X \simeq X \star X \xrightarrow{\text{id} \star f} X \star_Y Y.$$ 

**Example 5.2.4.5.** In the special case $Y = \Delta^0$, Proposition 5.2.4.4 asserts that the diagram

$$\begin{array}{ccc}
\{1\} \times X & \longrightarrow & \Delta^0 \\
\downarrow & & \downarrow \\
\Delta^1 \times X & \longrightarrow & X^0
\end{array}$$

is a categorical pushout square: that is, that the comparison map $X \diamond \Delta^0 \to X \star \Delta^0$ of Notation 4.5.8.3 is a categorical equivalence. This is the content of Proposition 4.5.8.12 (which is a special case of Theorem 4.5.8.8).
Corollary 5.2.4.6. Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
X & \to & Y \\
\downarrow & & \downarrow \\
X' & \to & Y',
\end{array}
\]

where the vertical maps are categorical equivalences. Then the induced map \( X \star_Y Y \to X' \star_{Y'} Y' \) is also a categorical equivalence of simplicial sets.

**Proof.** Combine Propositions 5.2.4.4 and 4.5.4.9. □

**Proof of Proposition 5.2.4.4.** The diagram (5.13) determines a morphism of simplicial sets

\[
\lambda_X : (\Delta^1 \times X) \coprod_{(\{1\} \times X)} Y \to X \star_Y Y,
\]

and we wish to show that \( \lambda_X \) is a categorical equivalence of simplicial sets (obtained by applying Construction 5.3.4.7 to the diagram \([1] \to \text{Set}_\Delta \) determined by the morphism \( f \)). We wish to show that \( \lambda_X \) is a categorical equivalence of simplicial sets (Proposition 4.5.4.11). By virtue of Corollary 4.5.7.3, it will suffice to prove that for every map \( \Delta^n \to Y \), the induced map

\[
\Delta^n \times_Y ((\Delta^1 \times X) \coprod_{(\{1\} \times X)} Y) \to \Delta^n \times_Y (X \star_Y Y)
\]

is a categorical equivalence. Using Remark 5.2.3.9, we can replace \( Y \) by \( \Delta^n \) and \( X \) by the fiber product \( \Delta^n \times_Y X \), and thereby reduce the proof of Proposition 5.2.4.4 to the special case where \( Y = \Delta^n \) is a standard simplex.

Since the collection of categorical equivalences is closed under the formation of filtered colimits (Corollary 4.5.7.2), we may assume without loss of generality that the simplicial set \( X \) is finite (see Remark 3.5.1.8). In particular, \( X \) has dimension \( \leq m \) for some integer \( m \geq -1 \). We proceed by induction on \( m \). If \( m = -1 \), then \( X \) is empty and the morphism \( \lambda_X \) is an isomorphism (see Example 5.2.3.4). Assume that \( m \geq 0 \); we now proceed by induction on the number of nondegenerate \( m \)-simplices of \( X \). If \( X \) does not have dimension \( \leq m - 1 \), then a choice of nondegenerate \( m \)-simplex of \( X \) determines a pushout diagram

\[
\begin{array}{ccc}
\partial \Delta^m & \to & \Delta^m \\
\downarrow & & \downarrow \\
X' & \to & X,
\end{array}
\]
where the horizontal maps are monomorphisms (Proposition 1.1.3.13). We then obtain a cubical diagram

where the front and back faces are categorical pushout squares (Proposition 4.5.4.11).

Our inductive hypothesis guarantees that the morphisms \( \lambda_{X'} \) and \( \lambda_{\partial \Delta^m} \) are categorical equivalences. Consequently, to show that \( \lambda_X \) is a categorical equivalence, it will suffice to show that \( \lambda_{\Delta^m} \) is a categorical equivalence. We can therefore replace \( X \) by \( \Delta^m \), and thereby reduce the proof of Proposition 5.2.4.4 to the special case where \( f : \Delta^m \to \Delta^n \) is a morphism between standard simplices.

Suppose that \( f(m) < n \). In this case, we can identify \( f \) with a morphism from \( X = \Delta^m \) to the simplex \( \Delta^{n-1} \) (regarded as a simplicial subset of \( \Delta^n \)), and we can identify \( X \star_Y Y \) with the right cone \( (X \star_{\Delta^{n-1}} \Delta^{n-1})^\circ \). Under this identification, \( \lambda_X \) corresponds to the composition

\[
(\Delta^1 \times X) \coprod_{\{1\} \times X} (\Delta^{n-1})^\circ \xrightarrow{\lambda'} (\Delta^1 \times X)^\circ \coprod_{\{1\} \times X} (\Delta^{n-1})^\circ \\
\cong (\Delta^1 \times X) \coprod_{\{1\} \times X} (\Delta^{n-1})^\circ \\
\xrightarrow{\lambda''} (X \star_{\Delta^{n-1}} \Delta^{n-1})^\circ,
\]

where \( \lambda' \) is a pushout of the map

\[
(\Delta^1 \times X) \coprod_{\{1\} \times X} (\{1\} \times X)^\circ \to (\Delta^1 \times X)^\circ
\]
and is therefore inner anodyne by virtue of Example [4.3.6.5] (since the inclusion \( \{1\} \times X \hookrightarrow \Delta^1 \times X \) is right anodyne; see Proposition [4.2.5.3]). Consequently, to show that \( \lambda_X \) is a categorical equivalence, it will suffice to show that \( \lambda'' \) is a categorical equivalence. By virtue of Corollary [4.5.8.9], we are reduced to proving Proposition [5.2.4.4] for the map \( f : X \to \Delta^{n-1} \).

Applying this argument repeatedly, we can reduce to the case where \( f(m) = n \).

Let \( Z(0) \) denote the simplicial subset of \( \Delta^1 \times \Delta^m \) given by the union of \( \Delta^1 \times \partial \Delta^m \) with \( \{1\} \times \Delta^m \), and let

\[
Z(0) \subset Z(1) \subset Z(2) \subset \cdots \subset Z(m) \subset Z(m + 1) = \Delta^1 \times \Delta^m
\]

be the sequence of simplicial subsets appearing in Lemma [3.1.2.10]. Note that \( \lambda_X \) carries \( Z(m) \) into the simplicial subset \( \partial \Delta^m \star Y \subseteq X \star Y \). We therefore obtain a cubical diagram of simplicial sets

\[
\begin{array}{ccc}
Z(0) & \rightarrow & (\Delta^1 \times \partial \Delta^m) \coprod_{(\{1\} \times \partial \Delta^m)} Y \\
\downarrow & & \downarrow \\
Z(m) & \rightarrow & \partial \Delta^m \star Y \\
\downarrow & & \downarrow \\
\Delta^1 \times \Delta^m & \rightarrow & (\Delta^1 \times \Delta^m) \coprod_{(\{1\} \times \Delta^m)} Y \\
\downarrow \text{id} & & \downarrow \lambda_{\Delta^m} \\
\Delta^1 \times \Delta^m & \rightarrow & \Delta^m \star Y
\end{array}
\]

where the front and back faces are pushout squares and the vertical maps are monomorphisms. It follows that the front and back faces are categorical pushout squares (Example [4.5.4.12]). Our inductive hypothesis guarantees that \( \lambda_{\partial \Delta^m} \) is a categorical equivalence, and the inclusion \( Z(0) \hookrightarrow Z(m) \) is inner anodyne by construction (see Lemma [3.1.2.10]). Applying Proposition [4.5.4.9] we conclude that \( \lambda_{\Delta^m} \) is also a categorical equivalence.

\[\square\]

Proof of Theorem [5.2.4.1]. Let \( U : \mathcal{M} \to \Delta^1 \) be a functor of \( \infty \)-categories and suppose we
are given a commutative diagram \( \sigma \):

\[
\begin{array}{ccc}
\{1\} \times C & \xrightarrow{F} & \{1\} \times D \\
\downarrow & & \downarrow \ g \\
\Delta^1 \times C & \xrightarrow{h} & M
\end{array}
\]

in the category \( (\text{Set}_\Delta)_{/\Delta^1} \). We wish to show that \( \sigma \) is a categorical pushout square if and only if conditions (1) through (3) of Theorem 5.2.4.1 are satisfied.

We first reduce to the case where \( C \) and \( D \) are \( \infty \)-categories. Choose inner anodyne morphisms \( C \hookrightarrow C' \) and \( D \hookrightarrow D' \), where \( C' \) and \( D' \) are \( \infty \)-categories (Corollary 4.1.3.3). Since the fiber \( \{1\} \times \Delta \times M \) is an \( \infty \)-category, we can extend \( g \) to a functor \( g' : D' \to \{1\} \times \Delta \times M \).

Similarly, the composition \( C \xrightarrow{F} D \hookrightarrow D' \) extends to a functor of \( \infty \)-categories \( F' : C' \to D' \). Using Exercise 3.1.7.10, we can factor \( F' \) as a composition \( C' \xrightarrow{F''} D'' \xrightarrow{v} D' \), where \( F'' \) is a monomorphism and \( v \) is a trivial Kan fibration. It follows from Lemma 1.4.7.5 that the inclusion map

\[
(\Delta^1 \times C) \coprod_{\{(1) \times C\}} (\{1\} \times C') \hookrightarrow \Delta^1 \times C'
\]

is inner anodyne, so that we can extend \( h \) to a functor \( h' : \Delta^1 \times C' \to M \) satisfying \( h'|_{\{1\} \times C'} = g' \circ F' \). By virtue of Proposition 4.5.4.9 \( \sigma \) is a categorical pushout square if and only if the diagram \( \sigma \):

\[
\begin{array}{ccc}
\{1\} \times C' & \xrightarrow{F''} & \{1\} \times D'' \\
\downarrow & & \downarrow \ g' \circ v \\
\Delta^1 \times C' & \xrightarrow{h'} & M
\end{array}
\]

is a categorical pushout square. We may therefore replace \( C \) and \( D \) by \( C' \) and \( D'' \), and thereby reduce to the case where \( C \) and \( D \) are \( \infty \)-categories and \( F \) is a monomorphism.

The assumption that \( F \) is a monomorphism guarantees that the natural map

\[
\iota : (\Delta^1 \times C) \coprod_{\{(1) \times C\}} D \to C \star_D D
\]

is also a monomorphism, and Proposition 5.2.4.4 guarantees that \( \iota \) is a categorical equivalence of simplicial sets. Since \( M \) is an \( \infty \)-category, Lemma 4.5.5.2 guarantees the existence of a functor \( G : C \star_D D \to M \) satisfying \( G|_{\Delta^1 \times C} = h \) and \( G|_D = g \). By virtue of Proposition 4.5.4.9 the diagram \( \sigma \) is a categorical pushout square if and only if the functor \( G \) is an equivalence of \( \infty \)-categories.
Note that the functor $G$ fits into a commutative diagram

$$
\begin{array}{ccc}
\mathcal{C} \times_D \mathcal{D} & \xrightarrow{G} & \mathcal{M} \\
\downarrow U' & & \downarrow U \\
\mathcal{C}^{\Delta^1} & \xrightarrow{\Delta^1} &
\end{array}
$$

where $U'$ is the cocartesian fibration of Proposition 5.2.3.15 and the functor $U$ is an isofibration (Example 4.4.1.6). The desired result now follows by applying the criterion of Theorem 5.1.5.1 (and invoking Remark 5.1.5.8). \hfill \Box

### 5.2.5 The Homotopy Transport Representation

We now study the behavior of the transport functors of §5.2.2 with respect to composition.

**Proposition 5.2.5.1** (Transitivity). Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets and let $\sigma$ be a 2-simplex of $\mathcal{C}$, which we display as a diagram

$$
\begin{array}{ccc}
D & \xrightarrow{f} & E \\
\downarrow g & & \downarrow h \\
C & \xrightarrow{h} & E.
\end{array}
$$

Let $f_! : \mathcal{E}_C \to \mathcal{E}_D$ and $g_! : \mathcal{E}_D \to \mathcal{E}_E$ be functors which are given by covariant transport along $f$ and $g$, respectively. Then the composite functor $(g_! \circ f_!) : \mathcal{E}_C \to \mathcal{E}_E$ is given by covariant transport along $h$.

**Proof.** Without loss of generality, we may replace $U$ by the projection map $\Delta^2 \times_\mathcal{C} \mathcal{E} \to \Delta^2$, and thereby reduce to the case where $\mathcal{C} = \Delta^2$ and $\sigma$ is the unique nondegenerate 2-simplex of $\mathcal{C}$. In this case, $\mathcal{E}$ is an $\infty$-category. Let $u : \text{id}_{\mathcal{E}_C} \to f_!$ be a morphism in the $\infty$-category $\text{Fun}(\mathcal{E}_C, \mathcal{E})$ which witnesses $f_!$ as given by covariant transport along $f$, and let $v : \text{id}_{\mathcal{E}_D} \to g_!$ be a morphism in the $\infty$-category $\text{Fun}(\mathcal{E}_D, \mathcal{E})$ which witnesses $g_!$ as given by covariant transport along $g$. Let $v' : f_! \to g_! \circ f_!$ denote the image of $v$ under the functor $\text{Fun}(\mathcal{E}_D, \mathcal{E}) \to \text{Fun}(\mathcal{E}_C, \mathcal{E})$ given by precomposition with $f_!$. Let $w : \text{id}_{\mathcal{E}_C} \to g_! \circ f_!$ be a composition of $u$ with $v'$ in the $\infty$-category $\text{Fun}(\mathcal{E}_C, \mathcal{E})$. We will complete the proof by showing that $w$ witnesses $g_! \circ f_!$ as given by covariant transport along $h$. To prove this, we must show that for every object $X \in \mathcal{E}_C$, the morphism $w_X : X \to (g_! \circ f_!)(X)$ is $U$-cocartesian. This follows from Corollary 5.1.2.4 since $w_X$ is a composition of the $U$-cocartesian morphisms $u_X : X \to f_!(X)$ and $v_{f!(X)} : f!(X) \to (g_! \circ f_!)(X)$. \hfill \Box
5.2. COVARIANT TRANSPORT

**Construction 5.2.5.2** (The Homotopy Transport Representation: Covariant Case). Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets and let $h\text{QCat}$ denote the homotopy category of $\infty$-categories. It follows from Proposition 5.2.5.1 and Example 5.2.2.5 that there is a unique functor $h\text{Tr}_{\mathcal{E}/\mathcal{C}} : h\mathcal{C} \to h\text{QCat}$ with the following properties:

- For each vertex $C$ of the simplicial set $\mathcal{C}$, $h\text{Tr}_{\mathcal{E}/\mathcal{C}}(C)$ is the $\infty$-category $\mathcal{E}_C = \{C\} \times_\mathcal{C} \mathcal{E}$ (regarded as an object of $h\text{QCat}$).

- For each edge $f : C \to D$ of the simplicial set $\mathcal{C}$ representing a morphism $[f] \in \text{Hom}_{h\mathcal{C}}(C, D)$, we have $h\text{Tr}_{\mathcal{E}/\mathcal{C}}([f]) = [f!]$. Here $[f!]$ denotes the isomorphism class of the covariant transport functor of Notation 5.2.2.9, which we regarded as an element of the set
  $$\text{Hom}_{h\text{QCat}}(\mathcal{E}_C, \mathcal{E}_D) = \pi_0(\text{Fun}(\mathcal{E}_C, \mathcal{E}_D)^\sim).$$

We will refer to $h\text{Tr}_{\mathcal{E}/\mathcal{C}}$ as the *homotopy transport representation* of the cocartesian fibration $U$.

**Example 5.2.5.3.** Let $U : \mathcal{E} \to \mathcal{C}$ be a left covering map of simplicial sets. Then the homotopy transport representation $h\text{Tr}_{\mathcal{E}/\mathcal{C}}$ of Construction 5.2.5.2 coincides with the functor $h\text{Tr}_{\mathcal{E}/\mathcal{C}} : h\mathcal{C} \to \text{Set}$ of Proposition 5.2.0.3 (here we abuse notation by identifying the category of sets with the full subcategory of $h\text{Kan}$ spanned by the discrete simplicial sets).

**Remark 5.2.5.4.** Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets, and let $h\text{Tr}_{\mathcal{E}/\mathcal{C}} : h\mathcal{C} \to h\text{QCat}$ be the homotopy transport representation of Construction 5.2.5.2. It follows from Proposition 5.1.4.14 that $U$ is a left fibration if and only if the functor $h\text{Tr}_{\mathcal{E}/\mathcal{C}}$ factors through the full subcategory $h\mathcal{Kan} \subseteq h\text{QCat}$. In particular, if $U$ is a left fibration, then Construction 5.2.5.2 determines a functor $h\mathcal{C} \to h\mathcal{Kan}$ which we will also refer to as the *homotopy transport representation* of the left fibration $U$.

**Remark 5.2.5.5.** Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of $\infty$-categories, let $f : \mathcal{C} \to \mathcal{D}$ be a morphism of $\mathcal{C}$, and let $f_! : \mathcal{E}_C \to \mathcal{E}_D$ be given by covariant transport along $f$. If $f$ is an isomorphism in the $\infty$-category $\mathcal{C}$, then $f_!$ is an equivalence of $\infty$-categories. This follows from the observation that the homotopy transport functor $h\text{Tr}_{\mathcal{E}/\mathcal{C}} : h\mathcal{C} \to h\text{QCat}$ carries isomorphisms to isomorphisms.

**Remark 5.2.5.6** (Base Change). Suppose we are given a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{E}' & \longrightarrow & \mathcal{E} \\
\downarrow U' & & \downarrow U \\
\mathcal{C}' & \longrightarrow & \mathcal{C},
\end{array}
\]

then $h\text{Tr}_{\mathcal{E}/\mathcal{C}}$ descends to a functor $h\text{Tr}_{\mathcal{E}'/\mathcal{C}'}$ that we will also refer to as the *homotopy transport representation* of the cocartesian fibration $U'$.
where $U$ and $U'$ are cocartesian fibrations. Then the homotopy transport representation $h\operatorname{Tr}_{\mathcal{E}'/\mathcal{C}'}$ is isomorphic to the composite functor

$$h\mathcal{C}' \to h\mathcal{C} \xrightarrow{h\operatorname{Tr}_{\mathcal{E}/\mathcal{C}}} h\mathcal{Q}\mathcal{C}.$$

Construction 5.2.5.2 has an analogue for cartesian fibrations:

**Construction 5.2.5.7 (The Homotopy Transport Representation: Contravariant Case).**
Let $U : \mathcal{E} \to \mathcal{C}$ be a cartesian fibration of simplicial sets and let $h\mathcal{Q}\mathcal{C}$ denote the homotopy category of $\infty$-categories (Construction 4.5.1.1). It follows from Proposition 5.2.5.1 and Example 5.2.2.5 that there is a unique functor $h\operatorname{Tr}_{\mathcal{E}/\mathcal{C}} : h\mathcal{C}^{\text{op}} \to h\mathcal{Q}\mathcal{C}$ satisfying the following conditions:

- For each vertex $C$ of the simplicial set $\mathcal{C}$, $h\operatorname{Tr}_{\mathcal{E}/\mathcal{C}}(C)$ is the $\infty$-category $\mathcal{E}_C = \{C\} \times_C \mathcal{E}$ (regarded as an object of $h\mathcal{Q}\mathcal{C}$).

- For each edge $f : C \to D$ of the simplicial set $\mathcal{C}$ representing a morphism $[f] \in \operatorname{Hom}_{h\mathcal{C}}(C, D)$, we have $h\operatorname{Tr}_{\mathcal{E}/\mathcal{C}}([f]) = [f^*]$, where $[f^*]$ denotes the isomorphism class of the contravariant transport functor of Notation 5.2.2.17.

We will refer to $h\operatorname{Tr}_{\mathcal{E}/\mathcal{C}}$ as the homotopy transport representation of the cartesian fibration $U$.

**Warning 5.2.5.8.**
Let $U : \mathcal{E} \to \mathcal{C}$ be a morphism of simplicial sets which is both a cartesian fibration and a cocartesian fibration. Then Constructions 5.2.5.2 and 5.2.5.7 supply functors $h\mathcal{C} \to h\mathcal{Q}\mathcal{C}$ and $h\mathcal{C}^{\text{op}} \to h\mathcal{Q}\mathcal{C}$ respectively, which are both referred to as the homotopy transport representation of $U$ and both denoted by $h\operatorname{Tr}_{\mathcal{E}/\mathcal{C}}$. We will see later that these two functors are interchangeable data: either can be recovered from the other (see Proposition 6.2.3.5).

**Example 5.2.5.9.**
Let $U : \mathcal{E} \to \mathcal{C}$ be a morphism of simplicial sets. Combining Remark 5.2.5.4 with Theorem 5.2.2.19, we deduce that the following conditions are equivalent:

- The morphism $U$ is a Kan fibration.

- The morphism $U$ is a cocartesian fibration and the homotopy transport representation $h\operatorname{Tr}_{\mathcal{E}/\mathcal{C}} : h\mathcal{C} \to h\mathcal{Q}\mathcal{C}$ of Construction 5.2.5.2 factors through the subcategory $h\operatorname{Kan}^\sim \subseteq h\mathcal{Q}\mathcal{C}$.

- The morphism $U$ is a cartesian fibration and the homotopy transport representation $h\operatorname{Tr}_{\mathcal{E}/\mathcal{C}} : h\mathcal{C}^{\text{op}} \to h\mathcal{Q}\mathcal{C}$ of Construction 5.2.5.7 factors through the subcategory $h\operatorname{Kan}^\sim \subseteq h\mathcal{Q}\mathcal{C}$. 
If these conditions are satisfied, then $h\Tr_{E/C}'$ is given by the composition

$$hC^{op} \xrightarrow{h\Tr_{E/C}^{op}} (h\text{Kan}^{\simeq})^{op} \xrightarrow{\iota} h\text{Kan}^{\simeq},$$

where $\iota$ is the isomorphism which carries each morphism in $h\text{Kan}^{\simeq}$ to its inverse.

### 5.2.6 Elements of Set-Valued Functors

Throughout this section, we let Set denote the category of sets.

**Construction 5.2.6.1 (The Category of Elements).** Let $\mathcal{C}$ be a category and let $\mathcal{F} : C \to \text{Set}$ be a functor. We define a category $\int_{\mathcal{C}} \mathcal{F}$ as follows:

- The objects of $\int_{\mathcal{C}} \mathcal{F}$ are pairs $(C, x)$, where $C$ is an object of $\mathcal{C}$ and $x$ is an element of the set $\mathcal{F}(C)$.
- If $(C, x)$ and $(C', x')$ are objects of $\int_{\mathcal{C}} \mathcal{F}$, then a morphism from $(C, x)$ to $(C', x')$ in the category $\int_{\mathcal{C}} \mathcal{F}$ is a morphism $f : C \to C'$ in the category $\mathcal{C}$ for which the induced map $\mathcal{F}(f) : \mathcal{F}(C) \to \mathcal{F}(C')$ carries $x$ to $x'$.
- Composition of morphisms in $\int_{\mathcal{C}} \mathcal{F}$ is given by composition of morphisms in $\mathcal{C}$.

We will refer to $\int_{\mathcal{C}} \mathcal{F}$ as the category of elements of the functor $\mathcal{F}$. Note that the construction $(C, x) \mapsto C$ determines a functor $\int_{\mathcal{C}} \mathcal{F} \to \mathcal{C}$, which we will refer to as the forgetful functor.

**Variant 5.2.6.2.** Let $\mathcal{C}$ be a category and let $\mathcal{F} : \mathcal{C}^{op} \to \text{Set}$ be a functor. We define a category $\int^\mathcal{C} \mathcal{F}$ as follows:

- The objects of $\int^\mathcal{C} \mathcal{F}$ are pairs $(C, x)$, where $C$ is an object of $\mathcal{C}$ and $x$ is an element of the set $\mathcal{F}(C)$.
- If $(C, x)$ and $(C', x')$ are objects of $\int^\mathcal{C} \mathcal{F}$, then a morphism from $(C, x)$ to $(C', x')$ in the category $\int^\mathcal{C} \mathcal{F}$ is a morphism $f : C \to C'$ in the category $\mathcal{C}$ for which the induced map $\mathcal{F}(f) : \mathcal{F}(C') \to \mathcal{F}(C)$ carries $x'$ to $x$.
- Composition of morphisms in $\int^\mathcal{C} \mathcal{F}$ is given by composition of morphisms in $\mathcal{C}$.

We will refer to $\int^\mathcal{C} \mathcal{F}$ as the category of elements of the functor $\mathcal{F}$. Note that the construction $(C, x) \mapsto C$ determines a functor $\int^\mathcal{C} \mathcal{F} \to \mathcal{C}$, which we will refer to as the forgetful functor.

**Remark 5.2.6.3.** Let $\mathcal{C}$ be a category and let $\mathcal{F} : \mathcal{C} \to \text{Set}$ be a functor. Then we have a canonical isomorphism of categories

$$(\int C \mathcal{F})^{op} \simeq (\int^\mathcal{C} \mathcal{F}),$$
where $\int_{\mathcal{C}} \mathcal{F}$ is the category of elements introduced in Construction 5.2.6.1 and $\int^{\mathcal{C}^\text{op}} \mathcal{F}$ is the category of elements introduced in Variant 5.2.6.2.

**Example 5.2.6.4.** Let $X : \Delta^\text{op} \to \text{Set}$ be a simplicial set. Then $\int^\Delta X$ is the *category of simplices* $\Delta_X$ introduced in Construction 1.1.8.19.

**Example 5.2.6.5.** Let $\mathcal{C}$ be a category, let $X$ be an object of $\mathcal{C}$, and let $h_X : \mathcal{C} \to \text{Set}$ denote the functor corepresented by $X$ (given on objects by the formula $h_X(Y) = \text{Hom}_\mathcal{C}(X,Y)$). Then the category of elements $\int_{\mathcal{C}} h_X$ can be identified with the coslice category $\mathcal{C}_{X/}$ of Variant 4.3.1.4. Similarly, if $h_X : \mathcal{C}^\text{op} \to \text{Set}$ is the functor represented by $X$ (given on objects by $h_X(Y) = \text{Hom}_\mathcal{C}(Y,X)$), then the category of elements $\int_{\mathcal{C}} h_X$ can be identified with the slice category $\mathcal{C}/_X$.

**Remark 5.2.6.6.** Let $\mathcal{C}$ be a category and let $\mathcal{F} : \mathcal{C} \to \text{Set}$ be a functor. Then the category of elements $\int_{\mathcal{C}} \mathcal{F}$ fits into a pullback diagram

$$
\begin{array}{ccc}
\int_{\mathcal{C}} \mathcal{F} & \to & \text{Set}_* \\
\downarrow & & \downarrow \\
\mathcal{C} & \to & \text{Set}.
\end{array}
$$

Here $\text{Set}_*$ denotes the category of pointed sets (see Example 4.2.3.3).

**Remark 5.2.6.7.** Let $\mathcal{C}$ be a small category, let $\text{Fun}(\mathcal{C}^\text{op}, \text{Set})$ be the category of set-valued functors on $\mathcal{C}^\text{op}$, and let $h : \mathcal{C} \to \text{Fun}(\mathcal{C}^\text{op}, \text{Set})$ be the Yoneda embedding (so that $h$ carries each object $C \in \mathcal{C}$ to the representable functor $h_C = \text{Hom}_\mathcal{C}(\bullet, C)$). For any object $\mathcal{F} \in \text{Fun}(\mathcal{C}^\text{op}, \text{Set})$, the category of elements $\int^\mathcal{C} \mathcal{F}$ fits into a pullback diagram

$$
\begin{array}{ccc}
\int^\mathcal{C} \mathcal{F} & \to & \text{Fun}(\mathcal{C}^\text{op}, \text{Set})/_{\mathcal{F}} \\
\downarrow & & \downarrow \\
\mathcal{C} & \to & \text{Fun}(\mathcal{C}^\text{op}, \text{Set}).
\end{array}
$$

This is essentially a reformulation of Yoneda’s lemma (we will return to this point in §[?]).

We now show that, up to isomorphism, every functor $\mathcal{F} : \mathcal{C} \to \text{Set}$ can be recovered from the category of elements $\int_{\mathcal{C}} \mathcal{F}$ (together with the forgetful functor $\int_{\mathcal{C}} \mathcal{F} \to \mathcal{C}$). Let $\text{Cat}$ denote the category of (small) categories.

**Proposition 5.2.6.8.** Let $\mathcal{C}$ be a small category. Then:
5.2. COVARIANT TRANSPORT

- **Construction 5.2.6.1** determines a fully faithful functor
  \[ \text{Fun}(\mathcal{C}, \text{Set}) \to \text{Cat}_{/\mathcal{C}} \quad \mathcal{F} \mapsto \int_{\mathcal{C}} \mathcal{F}. \]

- **Variant 5.2.6.2** determines a fully faithful functor
  \[ \text{Fun}(\mathcal{C}^{\text{op}}, \text{Set}) \to \text{Cat}_{/\mathcal{C}} \quad \mathcal{F} \mapsto \int_{\mathcal{C}} \mathcal{F}. \]

**Proof.** We will prove the first assertion; the second follows by a similar argument. Let \( \mathcal{F} \) and \( \mathcal{G} \) be functors from \( \mathcal{C} \) to the category of sets, and let \( T : (\int_{\mathcal{C}} \mathcal{F}) \to (\int_{\mathcal{C}} \mathcal{G}) \) be a functor for which the diagram

\[
\begin{array}{ccc}
\int_{\mathcal{C}} \mathcal{F} & \xrightarrow{T} & \int_{\mathcal{C}} \mathcal{G} \\
\downarrow & & \downarrow \\
\mathcal{C} & \xrightarrow{f} & \mathcal{C}
\end{array}
\]

is strictly commutative, where the vertical maps are the forgetful functors. We wish to show that there is a unique natural transformation of functors

\[ f : \mathcal{F} \to \mathcal{G} \quad \{f_C : \mathcal{F}(C) \to \mathcal{G}(C)\}_{C \in \mathcal{C}} \]

for which the functor \( T \) is given on objects by the construction \( T(C, x) = (C, f_C(x)) \). Note that this requirement uniquely determines the function \( f_C : \mathcal{F}(C) \to \mathcal{G}(C) \) for each object \( C \in \mathcal{C} \). We must show that the resulting collection \( \{f_C\}_{C \in \mathcal{C}} \) is a natural transformation: that is, for every morphism \( u : C \to D \) in the category \( \mathcal{C} \), the diagram of sets

\[
\begin{array}{ccc}
\mathcal{F}(C) & \xrightarrow{f_C} & \mathcal{G}(C) \\
\downarrow & & \downarrow \\
\mathcal{F}(u) & \xrightarrow{f(u)} & \mathcal{G}(u) \\
\mathcal{F}(D) & \xrightarrow{f_D} & \mathcal{G}(D)
\end{array}
\]

is commutative. Fix an element \( x \in \mathcal{F}(C) \), so that \( u \) can be regarded as a morphism from \( (C, x) \) to \( (D, \mathcal{F}(u)(x)) \) in the category \( \int_{\mathcal{C}} \mathcal{F} \). Applying the functor \( T \), we deduce that \( u \) can also be regarded as a morphism from \( (C, f_C(x)) \) to \( (D, f_D(\mathcal{F}(u)(x))) \) in the category \( \int_{\mathcal{C}} \mathcal{G} \). It follows that \( \mathcal{G}(u)(f_C(x)) = f_D(\mathcal{F}(u)(x)) \), as desired. \( \square \)

**Remark 5.2.6.9.** Let \( \mathcal{C} \) be a category, let \( \mathcal{F} : \mathcal{C} \to \text{Set} \) be a functor, and let \( \int_{\mathcal{C}} \mathcal{F} \) denote the category of elements of \( \mathcal{F} \) (Construction 5.2.6.1). Then the forgetful functor \( \int_{\mathcal{C}} \mathcal{F} \to \mathcal{C} \)
is a left covering functor, in the sense of Definition 4.2.3.1. This follows from the pullback diagram

\[
\begin{array}{ccc}
E & \xrightarrow{F} & \text{Set} \\
\downarrow & & \downarrow \\
\mathcal{C} & \xrightarrow{F} & \text{Set}
\end{array}
\]

of Remark 5.2.6.6, together with Remark 4.2.3.6 and Example 4.2.3.3. We will see in §5.2.7 that the converse is also true: for every left covering functor \( U : \mathcal{E} \to \mathcal{C} \), there exists a functor \( \mathcal{F} : \mathcal{C} \to \text{Set} \) and isomorphism \( \mathcal{E} \simeq \int_{\mathcal{C}} \mathcal{F} \) which is compatible with the functor \( U \) (Corollary 5.2.7.5). By virtue of Proposition 5.2.6.8 the functor \( \mathcal{F} \) is unique up to canonical isomorphism.

5.2.7 Covering Space Theory

Let \( S \) be a topological space. Every covering map \( f : X \to S \) determines a functor from the fundamental groupoid \( \pi_{\leq 1}(S) \) to the category of sets, given by the monodromy representation of Example 5.2.0.5. Under some mild assumptions on the topological space \( S \), the converse is also true: every functor \( \pi_{\leq 1}(S) \to \text{Set} \) can be obtained as the monodromy representation of an essentially unique covering map \( f : X \to S \). More precisely, we have the following:

**Theorem 5.2.7.1** (The Fundamental Theorem of Covering Space Theory). Let \( S \) be a topological space which is semilocally simply connected. Then the construction \( X \mapsto \hTr X/S \) determines an equivalence of categories

\[
\{ \text{Covering maps } f : X \to S \} \to \text{Fun}(\pi_{\leq 1}(S), \text{Set}).
\]

The proof of Theorem 5.2.7.1 can be broken into two parts:

(a) If \( S \) is a topological space which is semilocally simply connected, then the construction \( X \mapsto \Sing_\bullet(X) \) induces an equivalence of categories

\[
\{ \text{Covering maps of topological spaces } f : X \to S \}
\]

\[
\{ \text{Covering maps of simplicial sets } \mathcal{E} \to \Sing_\bullet(S) \}.\]
(b) For every Kan complex $C$, the formation of monodromy representations determines an equivalence of categories

$$\{\text{Covering maps } \mathcal{E} \to C\} \to \text{Fun}(\pi_{\leq 1}(C), \text{Set}) \quad \mathcal{E} \mapsto h\text{Tr}_{\mathcal{E}/C}.$$

The proof of $(a)$ requires some point-set topology; we defer a discussion to §[?]. Our goal in this section is to give a proof of $(b)$ (see Corollary 5.2.6.9). We will deduce $(b)$ from a more general statement, which classifies left coverings of an arbitrary simplicial set $C$ (Corollary 5.2.7.3).

**Proposition 5.2.7.2.** Let $U : \mathcal{E} \to C$ be a left covering map of simplicial sets, and let $h\text{Tr}_{\mathcal{E}/C} : hC \to \text{Set}$ be the homotopy transport representation of Proposition 5.2.0.3. Then there is a canonical isomorphism of simplicial sets

$$\mathcal{E} \simeq C \times_{N^*_{\text{h}(C)}} N^* \left( \int_{hC} h\text{Tr}_{\mathcal{E}/C} \right).$$

**Proof.** Every vertex $X \in \mathcal{E}$ can be regarded as an element of the set $h\text{Tr}_{\mathcal{E}/C}(U(X))$, and the construction $(X \in \mathcal{E}) \mapsto (\mathcal{E}_U(X), X)$ determines a functor $h\text{Tr}_{\mathcal{E}/C} : h\mathcal{E} \to \text{Set}_*$. Let us identify $h\text{Tr}_{\mathcal{E}/C}$ with a morphism of simplicial sets from $C$ to $N^*(\text{Set})$ and $h\text{Tr}_{\mathcal{E}/C}$ with a morphism of simplicial sets from $\mathcal{E}$ to $N^*(\text{Set}_*)$, so that we have a commutative diagram of simplicial sets

$$
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{h\text{Tr}_{\mathcal{E}/C}} & N^*(\text{Set}_*) \\
\downarrow U & & \downarrow \\
C & \xrightarrow{h\text{Tr}_{\mathcal{E}/C}} & N^*(\text{Set})
\end{array}
$$

which we can identify with a morphism of simplicial sets $V : \mathcal{E} \to C \times_{N^*_{\text{h}(C)}} N^* \left( \int_{hC} h\text{Tr}_{\mathcal{E}/C} \right)$. Since $U$ and the projection map $\int_C h\text{Tr}_{\mathcal{E}/C} \to hC$ are both left covering maps (Remark 5.2.6.9), it follows that $V$ is a left covering map (Remark 4.2.3.14). By construction, $V$ is bijective at the level of vertices, and is therefore an isomorphism of simplicial sets (Proposition 4.2.3.19). $\square$

**Corollary 5.2.7.3.** Let $C$ be a simplicial set, and let $\text{LCov}(C)$ denote the full subcategory of $(\text{Set}_\Delta)_/C$ spanned by the left covering maps $U : \mathcal{E} \to C$. Then the formation of homotopy transport representations supplies an equivalence of categories

$$\text{LCov}(C) \to \text{Fun}(hC, \text{Set}) \quad (U : \mathcal{E} \to C) \mapsto h\text{Tr}_{\mathcal{E}/C}.$$
Proof. Proposition 5.2.7.2 shows that the functor
\[
(\mathcal{F} \in \text{Fun}(h\mathcal{C}, \text{Set})) \mapsto \mathcal{C} \times_{N_{\bullet}(h\mathcal{C})} N_{\bullet}(\int_{h\mathcal{C}} \mathcal{F}) \in \text{LCov}(C)
\]
is a left homotopy inverse to the functor $\mathcal{E} \mapsto h\text{Tr}_{\mathcal{E}/C}$. By virtue of Example 5.2.0.6 and Remark 5.2.5.6, it is also a right homotopy inverse. 

Corollary 5.2.7.4. Let $U : \mathcal{E} \to \mathcal{C}$ be a morphism of simplicial sets. The following conditions are equivalent:

1. There exists a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{E} & \rightarrow & N_{\bullet}(D) \\
\downarrow & & \downarrow \uparrow \\
\mathcal{C} & \rightarrow & N_{\bullet}(h\mathcal{C}),
\end{array}
\]

where $V : D \to h\mathcal{C}$ is a left covering functor (in the sense of Definition 4.2.3.1).

2. For every category $\mathcal{C}'$ and every morphism of simplicial sets $N_{\bullet}(\mathcal{C}') \to C$, the fiber product $N_{\bullet}(\mathcal{C}') \times_{\mathcal{C}} \mathcal{E}$ is isomorphic to the nerve of a category $\mathcal{E}'$ and the projection $\mathcal{E}' \to \mathcal{C}'$ is left covering functor (in the sense of Definition 4.2.3.1).

3. For every $n$-simplex $\sigma : \Delta^n \to \mathcal{C}$, the fiber product $\Delta^n \times_{\mathcal{C}} \mathcal{E}$ is isomorphic to the nerve of a category $\mathcal{E}'$ and the projection $\mathcal{E}' \to [n]$ is a left covering functor (in the sense of Definition 4.2.3.1).

4. The morphism $U$ is a left covering map of simplicial sets (in the sense of Definition 4.2.3.8).

Proof. The implication (1) $\Rightarrow$ (2) follows from Remark 4.2.3.6, the implication (2) $\Rightarrow$ (3) is trivial, and the implication (3) $\Rightarrow$ (4) follows by combining Remark 4.2.3.15 with Proposition 4.2.3.16. The implication (4) $\Rightarrow$ (1) follows from Proposition 5.2.7.2.

Corollary 5.2.7.5. Let $\mathcal{C}$ be a category. Then:

- Construction 5.2.6.1 determines a fully faithful functor

\[
\text{Fun}(\mathcal{C}, \text{Set}) \to \text{Cat}_{/\mathcal{C}} \quad \mathcal{F} \mapsto \int_{\mathcal{C}} \mathcal{F},
\]

whose essential image consists of the left covering functors $U : \mathcal{E} \to \mathcal{C}$. 

5.2. COVARIANT TRANSPORT

- Variant 5.2.6.2 determines a fully faithful functor
  \[ \text{Fun}(C^{\text{op}}, \text{Set}) \to \text{Cat}_{/C} \quad \mathcal{F} \mapsto \int^C \mathcal{F}, \]
  whose essential image consists of the right covering functors \( U : \mathcal{E} \to \mathcal{C} \).

**Corollary 5.2.7.6.** Let \( \mathcal{C} \) be a Kan complex. Then the construction \(( U : \mathcal{E} \to \mathcal{C} ) \mapsto \text{hTr}_{\mathcal{E}_{/\mathcal{C}}} \) induces an equivalence of categories
  \[ \{ \text{Covering maps } \mathcal{E} \to \mathcal{C} \} \to \text{Fun}(\pi_{\leq 1}(\mathcal{C}), \text{Set}). \]

**Proof.** Combine Corollaries 5.2.7.3 and 4.4.3.9. \( \square \)

### 5.2.8 Parametrized Covariant Transport

Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of \( \infty \)-categories. To every morphism \( f : C \to D \) in the \( \infty \)-category \( \mathcal{C} \), Definition 5.2.2.4 associates a covariant transport functor \( f^! : \mathcal{E}_C \to \mathcal{E}_D \), which is uniquely determined up to isomorphism (see Proposition 5.2.2.8). Our goal in this section is to show that the functor \( f^! \) can be chosen to depend functorially on the morphism \( f \): that is, the construction \( f \mapsto f^! \) can be promoted to a functor from the Kan complex \( \text{Hom}_\mathcal{C}(C,D) \) to the \( \infty \)-category \( \text{Fun}(\mathcal{E}_C, \mathcal{E}_D) \). We begin by introducing a more elaborate version of Definition 5.2.2.4.

**Definition 5.2.8.1** (Parametrized Covariant Transport). Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets and let \( C \) and \( D \) be vertices of \( \mathcal{C} \). We will say that a morphism \( F : \text{Hom}_\mathcal{C}(C,D) \times \mathcal{E}_C \to \mathcal{E}_D \) is given by parametrized covariant transport if there exists a morphism of simplicial sets \( \bar{F} : \Delta^1 \times \text{Hom}_\mathcal{C}(C,D) \times \mathcal{E}_C \to \mathcal{E} \) satisfying the following conditions:

1. The diagram of simplicial sets

   \[
   \begin{array}{ccc}
   \Delta^1 \times \text{Hom}_\mathcal{C}(C,D) \times \mathcal{E}_C & \xrightarrow{\bar{F}} & \mathcal{E} \\
   & \downarrow{U} & \\
   \Delta^1 \times \text{Hom}_\mathcal{C}(C,D) & \xrightarrow{\bar{F}|_{\{0\} \times \text{Hom}_\mathcal{C}(C,D) \times \mathcal{E}_C}} & \mathcal{C}
   \end{array}
   \]

   commutes (where the lower horizontal map is induced by the inclusion \( \text{Hom}_\mathcal{C}(C,D) \hookrightarrow \text{Fun}(\Delta^1, \mathcal{C}) \)).

2. The restriction \( \bar{F}|_{\{0\} \times \text{Hom}_\mathcal{C}(C,D) \times \mathcal{E}_C} \) is given by projection onto \( \mathcal{E}_C \), and the restriction \( \bar{F}|_{\{1\} \times \text{Hom}_\mathcal{C}(C,D) \times \mathcal{E}_C} \) is equal to \( F \).
(3) For every edge $f : C \to D$ of $\mathcal{C}$ and every object $X \in \mathcal{E}_C$, the composite map

$$\Delta^1 \times \{f\} \times \{X\} \hookrightarrow \Delta^1 \times \text{Hom}_C(C, D) \times \mathcal{E}_C \xrightarrow{F} \mathcal{E}$$

is a $U$-cocartesian edge of $\mathcal{E}$.

If these conditions are satisfied, we say that the morphism $\tilde{F}$ witnesses $F$ as given by parametrized covariant transport.

**Remark 5.2.8.2.** Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets, let $C$ and $D$ be vertices of $\mathcal{C}$, and let $F : \text{Hom}_C(C, D) \times \mathcal{E}_C \to \mathcal{E}_D$ be given by parametrized covariant transport. Then, for every edge $f : C \to D$, the composite map

$$\{f\} \times \mathcal{E}_C \hookrightarrow \text{Hom}_C(C, D) \times \mathcal{E}_C \xrightarrow{F} \mathcal{E}_D$$

is given by covariant transport along $f$, in the sense of Definition 5.2.2.4. In other words, we can identify $F$ with a diagram $\text{Hom}_C(C, D) \to \text{Fun}(\mathcal{E}_C, \mathcal{E}_D)$, which carries each edge $f \in \text{Hom}_C(C, D)$ to the covariant transport functor $f_!$ of Notation 5.2.2.9.

**Example 5.2.8.3.** Let $\text{Set}^*$ denote the category of pointed sets (Example 4.2.3.3), and let $V : \text{Set}^* \to \text{Set}$ denote the forgetful functor $(X,x) \mapsto X$. Then the induced map $N^\bullet(V) : N^\bullet(\text{Set}^*) \to N^\bullet(\text{Set})$ is a cocartesian fibration (in fact, it is a left covering map), whose fiber over an object $X \in N^\bullet(\text{Set})$ can be identified with the set $X$. For every pair of sets $X$ and $Y$, the evaluation map

$$\text{ev} : \text{Hom}_{\text{Set}}(X,Y) \times X \to Y \quad (f,x) \mapsto f(x)$$

is given by parametrized covariant transport (in the sense of Definition 5.2.8.1).

**Proposition 5.2.8.4.** Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets, and let $C$ and $D$ be vertices of $\mathcal{C}$. Then:

- There exists a morphism $F : \text{Hom}_C(C, D) \times \mathcal{E}_C \to \mathcal{E}_D$ which is given by parametrized covariant transport.

- An arbitrary diagram $F' : \text{Hom}_C(C, D) \times \mathcal{E}_C \to \mathcal{E}_D$ is given by parametrized covariant transport if and only if it is isomorphic to $F$ (as an object of the $\infty$-category $\text{Fun}(\text{Hom}_C(C, D) \times \mathcal{E}_C, \mathcal{E}_D)$).

**Proof.** Apply Lemma 5.2.2.13 to the simplicial set $K = \text{Hom}_C(C, D) \times \mathcal{E}_C$. □
Remark 5.2.8.5 (Functoriality). Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{c}
\mathcal{E} \\
\downarrow U \\
\mathcal{C}
\end{array} \xrightarrow{G} \begin{array}{c}
\mathcal{E}' \\
\downarrow U' \\
\mathcal{C'}
\end{array}
\]

where \( U \) and \( U' \) are cocartesian fibrations. Let \( C \) and \( D \) be vertices of \( \mathcal{C} \) having images \( C' = \overline{U}(C) \) and \( D' = \overline{U}(D) \), respectively, so that \( G \) induces functors \( G_C : \mathcal{E}_C \to \mathcal{E}'_{C'} \) and \( G_D : \mathcal{E}_D \to \mathcal{E}'_{D'} \). Let \( \varphi : \text{Hom}_C(C, D) \to \text{Hom}_{C'}(C', D') \) be the morphism induced by \( \overline{G} \), and let

\[
F : \text{Hom}_C(C, D) \times \mathcal{E}_C \to \mathcal{E}_D \quad F' : \text{Hom}_{C'}(C', D') \times \mathcal{E}'_{C'} \to \mathcal{E}'_{D'}
\]

be given by parametrized covariant transport with respect to \( U \) and \( U' \). Suppose that the morphism \( G \) carries \( U \)-cocartesian edges of \( \mathcal{E} \) to \( U' \)-cocartesian edges of \( \mathcal{E}' \). Then the diagram

\[
\begin{array}{ccc}
\text{Hom}_C(C, D) \times \mathcal{E}_C & \xrightarrow{F} & \mathcal{E}_D \\
\downarrow \varphi \times G_C & & \downarrow G_D \\
\text{Hom}_{C'}(C', D') \times \mathcal{E}'_{C'} & \xrightarrow{F'} & \mathcal{E}'_{D'}
\end{array}
\]

commutes up to isomorphism: that is, \( G_D \circ F \) and \( F' \circ (\varphi \times G_C) \) are isomorphic as objects of the \( \infty \)-category \( \text{Fun}(\text{Hom}_C(C, D) \times \mathcal{E}_C, \mathcal{E}'_{D'}) \). This follows by applying the uniqueness assertion of Lemma 5.2.2.13 to the lifting problem

\[
\begin{array}{c}
\{0\} \times \text{Hom}_C(C, D) \times \mathcal{E}_C \\
\downarrow \Delta^1 \\
\Delta^1 \times \text{Hom}_C(C, D) \times \mathcal{E}_C
\end{array} \xrightarrow{U'} \begin{array}{c}
\mathcal{E}' \\
\downarrow \mathcal{C}'
\end{array}
\]

Variant 5.2.8.6 (Parametrized Contravariant Transport). Let \( U : \mathcal{E} \to \mathcal{C} \) be a cartesian fibration of simplicial sets and let \( C \) and \( D \) be vertices of \( \mathcal{C} \). Applying Proposition 5.2.8.4 to the opposite cocartesian fibration \( U^{\text{op}} : \mathcal{C}^{\text{op}} \to \mathcal{E}^{\text{op}} \), we obtain a diagram \( \text{Hom}_C(C, D) \to \text{Fun}(\mathcal{E}_D, \mathcal{E}_C) \), carrying each edge \( f : C \to D \) to a functor \( f^* : \mathcal{E}_D \to \mathcal{E}_C \) given by contravariant transport along \( f \).
Let $\mathcal{C}$ be an \infty-category. Recall that, for every pair of objects $X, Y \in \mathcal{C}$, the morphism space $\text{Hom}_\mathcal{C}(X, Y)$ can be identified with the fiber over $Y$ of the left fibration $\{X\} \tilde{\times}_\mathcal{C} \mathcal{C} \to \mathcal{C}$ of Proposition 4.6.4.11, or with the fiber over $X$ of the right fibration $\mathcal{C} \tilde{\times}_\mathcal{C} \{Y\}$. In either case, parametrized transport recovers the composition law of $\mathcal{C}$:

**Proposition 5.2.8.7.** Let $\mathcal{C}$ be an \infty-category containing objects $C$, $D$, and $E$. Then the composition law

$$\circ : \text{Hom}_\mathcal{C}(D, E) \times \text{Hom}_\mathcal{C}(C, D) \to \text{Hom}_\mathcal{C}(C, E)$$

of Construction 4.6.8.9 is given by parametrized covariant transport for the left fibration $U : \{C\} \tilde{\times}_\mathcal{C} \mathcal{C} \to \mathcal{C}$ (in the sense of Definition 5.2.8.1), and also by parametrized contravariant transport for the right fibration $V : \mathcal{C} \tilde{\times}_\mathcal{C} \{E\} \to \mathcal{C}$.

**Proof.** We will prove the first assertion; the second follows by a similar argument. Let $S : \Delta^1 \times \Delta^1 \to \Delta^2$ be the morphism given on vertices by the formula $T(i, j) = i(j + 1)$, and let $T$ be a section of the trivial Kan fibration $\text{Hom}_\mathcal{C}(C, D, E) \to \text{Hom}_\mathcal{C}(D, E) \times \text{Hom}_\mathcal{C}(C, D)$ (see Corollary 4.6.8.5). Then the composite map

$$\Delta^1 \times \Delta^1 \times \text{Hom}_\mathcal{C}(D, E) \times \text{Hom}_\mathcal{C}(C, D) \xrightarrow{S \times T} \Delta^2 \times \text{Hom}_\mathcal{C}(C, D, E) \to \mathcal{C}$$

carries $\{0\} \times \Delta^1 \times \text{Hom}_\mathcal{C}(D, E) \times \text{Hom}_\mathcal{C}(C, D)$ to the vertex $C$, and can therefore be identified with a functor

$$\tilde{F} : \Delta^1 \times \text{Hom}_\mathcal{C}(D, E) \times \text{Hom}_\mathcal{C}(C, D) \to \{C\} \tilde{\times}_\mathcal{C} \mathcal{C}.$$

which exhibits the composition law as given by parametrized covariant transport for the left fibration $U$. \hfill $\square$

Proposition 5.2.5.1 has a counterpart for parametrized covariant transport:

**Proposition 5.2.8.8.** Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of \infty-categories. Let $C, D,$ and $E$ be objects of $\mathcal{C}$, and let

$$F : \text{Hom}_\mathcal{C}(C, D) \times \mathcal{E}_C \to \mathcal{E}_D \quad G : \text{Hom}_\mathcal{C}(D, E) \times \mathcal{E}_D \to \mathcal{E}_E$$

$$H : \text{Hom}_\mathcal{C}(C, E) \times \mathcal{E}_C \to \mathcal{E}_E$$

be given by parametrized covariant transport. Then the diagram

$$\begin{array}{ccc}
\text{Hom}_\mathcal{C}(D, E) \times \text{Hom}_\mathcal{C}(C, D) \times \mathcal{E}_C & \xrightarrow{id \times F} & \text{Hom}_\mathcal{C}(D, E) \times \mathcal{E}_D \\
\downarrow & & \downarrow G \\
\text{Hom}_\mathcal{C}(C, E) \times \mathcal{E}_C & \xrightarrow{H} & \mathcal{E}_E
\end{array}$$

(5.14)

commutes in the homotopy category $\text{hQCat}$; here the left vertical map is given by the composition law of Construction 4.6.8.9.
Proof. Let $\text{Hom}_C(C, D, E)$ be the Kan complex defined in Notation 4.6.8.1, let $H'$ denote the composite map

$$\text{Hom}_C(C, D, E) \times \mathcal{E}_C \to \text{Hom}_C(C, E) \times \mathcal{E}_E,$$

and let $H''$ denote the composition

$$\text{Hom}_C(C, D, E) \times \mathcal{E}_C \to \text{Hom}_C(D, E) \times \text{Hom}_C(C, D) \times \mathcal{E}_C \to \text{Hom}_C(D, E) \times \mathcal{E}_E.$$

We will show that $H'$ and $H''$ are isomorphic when regarded as objects of the $\infty$-category $\text{Fun}(\text{Hom}_C(C, D, E) \times \mathcal{E}_C, \mathcal{E}_E)$. The homotopy commutativity of the diagram (5.14) will then follow by precomposing with any section of the trivial Kan fibration $\text{Hom}_C(C, D, E) \to \text{Hom}_C(D, E) \times \text{Hom}_C(C, D)$.

Choose morphisms

$$\tilde{F} : N_\bullet(\{0 < 1\}) \times \text{Hom}_C(C, D) \times \mathcal{E}_C \to \mathcal{E},$$

$$\tilde{G} : N_\bullet(\{1 < 2\}) \times \text{Hom}_C(D, E) \times \mathcal{E}_D \to \mathcal{E},$$

$$\tilde{H} : N_\bullet(\{0 < 2\}) \times \text{Hom}_C(C, E) \times \mathcal{E}_C \to \mathcal{E},$$

which witness $F$, $G$, and $H$ as given by parametrized covariant transport, respectively. Composing with the projection maps

$$\text{Hom}_C(C, D) \leftarrow \text{Hom}_C(C, D, E) \to \text{Hom}_C(C, E),$$

we obtain morphisms

$$\tilde{F}' : N_\bullet(\{0 < 1\}) \times \text{Hom}_C(C, D, E) \times \mathcal{E}_C \to \mathcal{E},$$

$$\tilde{H}' : N_\bullet(\{0 < 2\}) \times \text{Hom}_C(C, D, E) \times \mathcal{E}_C \to \mathcal{E}.$$

Let $\tilde{G}'$ denote the composite map

$$N_\bullet(\{1 < 2\}) \times \text{Hom}_C(C, D, E) \times \mathcal{E}_C \to N_\bullet(\{1 < 2\}) \times \text{Hom}_C(D, E) \times \text{Hom}_C(C, D) \times \mathcal{E}_C \to N_\bullet(\{1 < 2\}) \times \text{Hom}_C(D, E) \times \mathcal{E}_D \times \mathcal{E}_C \to \mathcal{E}.$$
Since $U$ is an inner fibration, the lifting problem

\[
\begin{array}{c}
\Delta_1^2 \times \text{Hom}_C(C, D, E) \times E^C \rightarrow E \\
\Delta^2 \times \text{Hom}_C(C, D, E) \times E^C \rightarrow C
\end{array}
\]

admits a solution $\Phi : \Delta^2 \times \text{Hom}_C(C, D, E) \times E^C \rightarrow E$. Let $\tilde{H}''$ denote the restriction of $\Phi$ to the product $N_\bullet\{(0, 2)\} \times \text{Hom}_C(C, D, E) \times E^C$. Using Proposition 5.1.4.12, we see that $\tilde{H}''$ is a $U$-cocartesian lift of $U \circ \tilde{H}'' = U \circ \tilde{H}'$, in the sense of Definition 5.2.2.10. Applying the uniqueness assertion of Lemma 5.2.2.13, we conclude that the restrictions $\tilde{H}' = \tilde{H}'|\{2\} \times \text{Hom}_C(C, D, E) \times E^C$ and $\tilde{H}'' = \tilde{H}''|\{2\} \times \text{Hom}_C(C, D, E) \times E^C$ are isomorphic when regarded as objects of the $\infty$-category $\text{Fun}(\text{Hom}_C(C, D, E) \times E^C, E^D)$, as desired.

Using Proposition 5.2.8.8, we obtain the following refinement of Construction 5.2.5.2:

**Construction 5.2.8.9 (Enriched Homotopy Transport: Covariant Case).** Let $U : E \rightarrow C$ be a cocartesian fibration of $\infty$-categories and let us regard the homotopy category $hC$ as enriched over the homotopy category $h\text{Kan}$ of Kan complexes (Construction 4.6.8.13). It follows from Proposition 5.2.8.8 (and Example 5.2.2.5) that there is a unique $h\text{Kan}$-enriched functor $h\text{Tr}_{E/C} : hC \rightarrow hQ\text{Cat}$ with the following properties:

- For each object $C$ of the $\infty$-category $C$, $h\text{Tr}_{E/C}(C)$ is the $\infty$-category $E^C = \{C\} \times_C E$ (regarded as an object of $hQ\text{Cat}$).

- For every pair of objects $C, D \in C$, the induced map

  \[ h\text{Tr}_{E/C} : \text{Hom}_C(C, D) \rightarrow \text{Fun}(E^C, E^D)^\simeq \]

  in $h\text{Kan}$ corresponds to the parametrized covariant transport functor $\text{Hom}_C(C, D) \times E^C \rightarrow E^D$ of supplied by Proposition 5.2.8.4 (which is well-defined up to isomorphism).

We will refer to $h\text{Tr}_{E/C}$ as the *enriched homotopy transport representation* of the cocartesian fibration $U$. Note that the underlying functor of ordinary categories $hC \rightarrow hQ\text{Cat}$ coincides with homotopy transport representation of Construction 5.2.5.2.
5.2. COVARIANT TRANSPORT

Remark 5.2.8.10 (Functoriality). Suppose we are given a commutative diagram of ∞-categories

![Diagram](image)

where $U$ and $U'$ are cocartesian fibrations and the functor $G$ carries $U$-cocartesian morphisms of $\mathcal{E}$ to $U'$-cocartesian morphisms of $\mathcal{E}'$. For each object $C \in \mathcal{C}$ having image $C' = G(C)$, $G$ restricts to a functor $G_C : \mathcal{E}_C \to \mathcal{E}'_{C'}$. It follows from Remark 5.2.8.5 that the construction $C \mapsto G_C$ determines a natural transformation of h Kan-enriched functors $\alpha : \text{hTr}_{\mathcal{E}/\mathcal{C}} \to \text{hTr}_{\mathcal{E}'/\mathcal{C}'} \circ \text{h}G$ from $\text{hC}$ to $\text{hQCat}$. Moreover, if (5.15) is a pullback square, then $\alpha$ is an isomorphism of h Kan-enriched functors.

Variant 5.2.8.11 (Enriched Homotopy Transport: Left Fibrations). Let $U : \mathcal{E} \to \mathcal{C}$ be a left fibration of ∞-categories. Applying Construction 5.2.8.9, we obtain an h Kan-enriched functor

$$\text{hTr}_{\mathcal{E}/\mathcal{C}} : \text{hC} \to \text{hKan},$$

given on objects by the formula $\text{hTr}_{\mathcal{E}/\mathcal{C}}(C) = \{C\} \times_{\mathcal{C}} \mathcal{E}$.

Variant 5.2.8.12 (Enriched Homotopy Transport: Contravariant Case). Let $U : \mathcal{E} \to \mathcal{C}$ be a cartesian fibration of ∞-categories. Applying Construction 5.2.8.9 to the opposite functor $U^{\text{op}}$, we deduce that there is a unique h Kan-enriched functor $\text{hTr}_{\mathcal{E}/\mathcal{C}} : \text{hC}^{\text{op}} \to \text{hQCat}$ with the following properties:

- For each object $C$ of the ∞-category $\mathcal{C}$, $\text{hTr}_{\mathcal{E}/\mathcal{C}}(C)$ is the ∞-category $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ (regarded as an object of $\text{hQCat}$).
- For every pair of objects $C, D \in \mathcal{C}$, the induced map

$$\text{hTr}_{\mathcal{E}/\mathcal{C}} : \text{Hom}_\mathcal{C}(C, D) \to \text{Fun}(\mathcal{E}_D, \mathcal{E}_C)$$

is given by the parametrized contravariant transport functor $\mathcal{E}_D \times \text{Hom}_\mathcal{C}(C, D) \to \mathcal{E}_C$ of Variant 5.2.8.6.

We will refer to $\text{hTr}_{\mathcal{E}/\mathcal{C}}$ as the \textit{enriched homotopy transport representation} of the cartesian fibration $U$. If $U$ is a right fibration, then $\text{hTr}_{\mathcal{E}/\mathcal{C}}$ takes values in the full subcategory $\text{hKan} \subseteq \text{hQCat}$.

Example 5.2.8.13. Let $\mathcal{C}$ be an ∞-category and let $\text{hC}$ denote its homotopy category, which we regard as enriched over the homotopy category $\text{hKan}$ of Kan complexes. Applying Proposition 5.2.8.7, we obtain the following:
CHAPTER 5. FIBRATIONS OF $\infty$-CATEGORIES

For every object $C \in \mathcal{C}$, the corepresentable hKan-enriched functor

$$hC \to h\text{Kan} \quad D \mapsto \text{Hom}_C(C, D)$$

is the enriched homotopy transport representation for the left fibration $\{C\} \times_C \mathcal{C} \to \mathcal{C}$.

For every object $D \in \mathcal{C}$, the representable hKan-enriched functor

$$hC^{\text{op}} \to h\text{Kan} \quad C \mapsto \text{Hom}_C(C, D)$$

is the enriched homotopy transport representation for the right fibration $\mathcal{C} \times_C \{D\} \to \mathcal{C}$.

5.3 Fibrations over Ordinary Categories

Let $\text{Set}_\Delta$ denote the category of simplicial sets, let $\text{QCat} \subset \text{Set}_\Delta$ denote the full subcategory spanned by the $\infty$-categories, and let $h\text{QCat}$ denote its homotopy category (Construction 4.5.1.1). In §5.2.5 we associated to every cocartesian fibration of simplicial sets $U : \mathcal{E} \to S$ a functor $h\text{Tr}_{\mathcal{E}/S} : hS \to h\text{QCat}$ called the homotopy transport representation of $U$, given on objects by the formula $h\text{Tr}_{\mathcal{E}/S}(s) = \{s\} \times_S \mathcal{E}$ (Construction 5.2.5.2). In §5.3.1 we specialize to the situation where $S = N_\bullet(\mathcal{C})$ is the nerve of an ordinary category $\mathcal{C}$. In this case, we show that $h\text{Tr}_{\mathcal{E}/N_\bullet(\mathcal{C})}$ can be lifted to a functor taking values in the category $\text{QCat}$. More precisely, we introduce a functor $s\text{Tr}_{\mathcal{E}/\mathcal{C}} : \mathcal{C} \to \text{QCat}$ which we refer to as the strict transport representation of $U$ (Construction 5.3.1.5), and show that the diagram

$$\begin{array}{ccc}
\text{QCat} & \xrightarrow{s\text{Tr}_{\mathcal{E}/\mathcal{C}}} & \text{QCat} \\
\downarrow & & \downarrow \\
\mathcal{C} & \xrightarrow{h\text{Tr}_{\mathcal{E}/N_\bullet(\mathcal{C})}} & h\text{QCat}
\end{array}$$

commutes up to canonical isomorphism (Corollary 5.3.1.8).

Our primary goal in this section is to show that a cocartesian fibration $U : \mathcal{E} \to N_\bullet(\mathcal{C})$ can be recovered, up to equivalence, from its strict transport representation $s\text{Tr}_{\mathcal{E}/\mathcal{C}}$. To formulate this precisely, we need another construction. In §5.3.3 we associate to every diagram $\mathcal{F} : \mathcal{C} \to \text{Set}_\Delta$ a simplicial set $N_{\mathcal{F}}(\mathcal{C})$, which we will refer to as the $\mathcal{F}$-weighted nerve of $\mathcal{C}$ (Definition 5.3.3.1). The weighted nerve is equipped with a projection map $V : N_{\mathcal{F}}(\mathcal{C}) \to N_\bullet(\mathcal{C})$, whose fiber over an object $C \in \mathcal{C}$ can be identified with the simplicial set $\mathcal{F}(C)$ (Example 5.3.3.8). If each of these simplicial sets is an $\infty$-category, then $V$ is a cocartesian fibration of $\infty$-categories (Proposition 5.3.3.15). Our main results can be summarized as follows:
5.3. FIBRATIONS OVER ORDINARY CATEGORIES

(1) Let \( \mathcal{F} : \mathcal{C} \to \text{QCat} \) be a diagram of \( \infty \)-categories having weighted nerve \( \mathcal{E} = N_{\mathcal{F}}(\mathcal{C}) \). Then there is a natural transformation from \( \mathcal{F} \) to the strict transport representation \( \text{sTr}_{\mathcal{E}/\mathcal{C}} \), which carries each object \( C \in \mathcal{C} \) to an equivalence of \( \infty \)-categories \( \mathcal{F}(C) \to \text{sTr}_{\mathcal{E}/\mathcal{C}}(C) \) (Corollary 5.3.4.19).

(2) Let \( U : \mathcal{E} \to N_{\bullet}(\mathcal{C}) \) be a cocartesian fibration of \( \infty \)-categories having strict transport representation \( \mathcal{F} = \text{sTr}_{\mathcal{E}/\mathcal{C}} \). Then \( U \) is equivalent (in the sense of Definition 5.1.6.1) to the cocartesian fibration \( N_{\mathcal{F}}(\mathcal{C}) \to N_{\bullet}(\mathcal{C}) \) (Theorem 5.3.5.6).

The proof of (1) is relatively straightforward. However, the proof of (2) is somewhat more difficult: given a cocartesian fibration \( U : \mathcal{E} \to N_{\bullet}(\mathcal{C}) \) there is no obvious comparison map between the simplicial sets \( \mathcal{E} \) and \( N_{\mathcal{F}}(\mathcal{C}) \). To relate them, we need an auxiliary construction. In §5.3.2, we associate to every diagram \( \mathcal{F} : \mathcal{C} \to \text{Set}_{\Delta} \) a simplicial set \( \text{holim}(\mathcal{F}) \), which we refer to as the homotopy colimit of \( \mathcal{F} \) (Construction 5.3.2.1). The formation of homotopy colimits plays an important role in the classical homotopy theory of simplicial sets: it can be regarded as a replacement for the usual notion of colimit (see Remark 5.3.2.9) which is compatible with weak homotopy equivalence (Proposition 5.3.2.18). Beware that the homotopy colimit \( \text{holim}(\mathcal{F}) \) is generally not an \( \infty \)-category (even in the special case where \( \mathcal{F} \) is a diagram of \( \infty \)-categories). Nevertheless, it is equipped with a projection map \( \text{holim}(\mathcal{F}) \to N_{\bullet}(\mathcal{C}) \), whose fiber over each object \( C \in \mathcal{C} \) can be identified with the simplicial set \( \mathcal{F}(C) \), and which behaves in certain respects like a cocartesian fibration. In §5.3.4, we make this heuristic precise by introducing the notion of a scaffold. If \( U : \mathcal{E} \to N_{\bullet}(\mathcal{C}) \) is a cocartesian fibration of \( \infty \)-categories, we define a scaffold of \( U \) to be a commutative diagram

\[
\begin{array}{ccc}
\text{holim}(\mathcal{F}) & \xrightarrow{\lambda} & \mathcal{E} \\
\text{U} \downarrow & \text{\textbullet} & \text{\textbullet} \\
N_{\bullet}(\mathcal{C}) & \xrightarrow{\text{\textbullet}} & \text{\textbullet}
\end{array}
\]

where \( \lambda \) restricts to a categorical equivalence \( \mathcal{F}(C) \to \mathcal{E}_C \) for each \( C \in \mathcal{C} \) and behaves well with respect to the collection of \( U \)-cocartesian morphisms of \( \mathcal{E} \) (Definition 5.3.4.2). We are primarily interested in two examples:

- To any cocartesian fibration \( U : \mathcal{E} \to N_{\bullet}(\mathcal{C}) \), we associate a universal scaffold \( \lambda_u : \text{holim}(\mathcal{F}) \to \mathcal{E} \), where \( \mathcal{F} = \text{sTr}_{\mathcal{E}/\mathcal{C}} \) is the strict transport representation of \( U \) (see Construction 5.3.4.7 and Proposition 5.3.4.8).
CHAPTER 5. FIBRATIONS OF ∞-CATEGORIES

- To any diagram of ∞-categories \( \mathcal{F} : \mathcal{C} \to \mathbf{QCat} \), we associate a taut scaffold \( \lambda : \text{holim}(\mathcal{F}) \to \mathcal{E} \), where \( \mathcal{E} = \mathcal{N}_\bullet(\mathcal{C}) \) is the \( \mathcal{F} \)-weighted nerve of \( \mathcal{C} \) (see Construction 5.3.4.11 and Proposition 5.3.4.17).

In §5.3.5, we show that every scaffold \( \text{holim}(\mathcal{F}) \to \mathcal{E} \) is a categorical equivalence of simplicial sets (Theorem 5.3.5.7). In particular, if \( U : \mathcal{E} \to \mathcal{N}_\bullet(\mathcal{C}) \) is a cocartesian fibration with strict transport representation \( \mathcal{F} = s\text{Tr}_{\mathcal{E}/\mathcal{C}} \), then we can exploit the taut and universal scaffolds

\[
\mathcal{N}_\bullet(\mathcal{C}) \xleftarrow{\lambda} \text{holim}(\mathcal{F}) \xrightarrow{\lambda_u} \mathcal{E},
\]

to deduce the existence of an equivalence of ∞-categories \( \mathcal{E} \simeq \mathcal{N}_\bullet(\mathcal{C}) \) (compatible with the projection \( \mathcal{N}_\bullet(\mathcal{C}) \)), thereby obtaining a proof of (2) (see Theorem 5.3.5.6).

We close this section by describing some other applications of our theory of scaffolds. Let \( U : \mathcal{D} \to \mathcal{C} \) and \( V : \mathcal{E} \to \mathcal{D} \) be morphisms of simplicial sets, and let \( \text{Res}_{\mathcal{D}/\mathcal{C}}(\mathcal{E}) \) denote the direct image of \( \mathcal{E} \) along \( U \) (see Construction 4.5.9.1). In §5.3.6, we show that if \( U \) is a cocartesian fibration and \( V \) is a cartesian fibration, then the projection map \( \text{Res}_{\mathcal{D}/\mathcal{C}}(\mathcal{E}) \to \mathcal{C} \) is also a cartesian fibration (Proposition 5.3.6.6). In §5.3.7, we apply this result to study the oriented fiber product of Definition 4.6.4.1. For any functor of ∞-categories \( F : \mathcal{A} \to \mathcal{B} \), projection onto the second factor determines a cocartesian fibration \( \mathcal{A} \times \mathcal{B} \to \mathcal{B} \) (Proposition 5.3.7.1) which is, in some sense, freely generated by the ∞-category \( \mathcal{A} \) (Theorem 5.3.7.7).

Remark 5.3.0.1. There is a close analogy between the homotopy colimit construction (studied in §5.3.2) and the weighted nerve construction (studied in §5.3.3).

- The formation of homotopy colimits determines a functor

\[
\text{Fun}(\mathcal{C}, \text{Set}_\Delta) \to (\text{Set}_\Delta)/\mathcal{N}_\bullet(\mathcal{C}) \quad \mathcal{F} \mapsto \text{holim}(\mathcal{F}).
\]

This functor has a right adjoint, which carries an object \( \mathcal{E} \in (\text{Set}_\Delta)/\mathcal{N}_\bullet(\mathcal{C}) \) to the diagram

\[
\mathcal{C} \to \text{Set}_\Delta \quad C \mapsto \text{Fun}/\mathcal{N}_\bullet(\mathcal{C})(\mathcal{N}_\bullet(\mathcal{C}/C), \mathcal{E}).
\]

See Corollary 5.3.2.24.

- The formation of weighted nerves determines a functor

\[
\text{Fun}(\mathcal{C}, \text{Set}_\Delta) \to (\text{Set}_\Delta)/\mathcal{N}_\bullet(\mathcal{C}) \quad \mathcal{F} \mapsto \mathcal{N}_\bullet(\mathcal{C}).
\]

This functor has a left adjoint, which carries an object \( \mathcal{E} \in (\text{Set}_\Delta)/\mathcal{N}_\bullet(\mathcal{C}) \) to the diagram

\[
\mathcal{C} \to \text{Set}_\Delta \quad C \mapsto \mathcal{N}_\bullet(\mathcal{C}/C) \times_{\mathcal{N}_\bullet(\mathcal{C})} \mathcal{E}.
\]

See Corollary 5.3.3.22.
5.3. FIBRATIONS OVER ORDINARY CATEGORIES

Remark 5.3.0.2. After restricting to diagrams of Kan complexes, the results of this section supply a dictionary

\[
\begin{array}{ccc}
\{\text{Left fibrations } \mathcal{E} \to \mathbf{N}_\ast(C)\} & \xrightarrow{\mathbf{N}_\ast(-)(C)} & \{\text{Functors } C \to \mathbf{Kan}\} \\
\xrightarrow{\mathbf{sTr}_{(-)/C}} & & \\
\{\text{sTr}_{-}/C\}
\end{array}
\]

This dictionary was formulated in work of Heuts and Moerdijk (using the language of model categories) which is closely related to the contents of this section. For more details, we refer the reader to [27].

5.3.1 The Strict Transport Representation

Let \( \mathcal{C} \) be a category and let \( U : \mathcal{E} \to \mathbf{N}_\ast(C) \) be a cocartesian fibration of \( \infty \)-categories. To each morphism \( f : C \to D \) of \( \mathcal{C} \), the homotopy transport representation \( \mathbf{hTr}_{\mathcal{E}/\mathbf{N}_\ast(C)} \) associates the homotopy class \([f_!]\), where \( f_! : \mathcal{E}_C \to \mathcal{E}_D \) is given by covariant transport along \( f \). Beware that the functor \( f_! \) is only well-defined up to isomorphism. For example, the value of \( f_! \) on an object \( X \in \mathcal{E}_C \) depends on an auxiliary choice: namely, the choice of a \( U \)-cocartesian morphism \( \tilde{f} : X \to Y \) satisfying \( U(\tilde{f}) = f \) (once we have made this choice, we can take \( f_!(X) \) to be the object \( Y \in \mathcal{E}_D \)). Our goal in this section is to show that, by replacing each fiber \( \mathcal{E}_C \) by an equivalent \( \infty \)-category, the ambiguity in the definition of the transport functors can be eliminated. More precisely, we will associate to each object \( C \in \mathcal{C} \) a simplicial set \( \mathbf{sTr}_{\mathcal{E}/\mathcal{C}}(C) \) with the following properties:

- There is a trivial Kan fibration of simplicial sets \( \mathbf{ev}_C : \mathbf{sTr}_{\mathcal{E}/\mathcal{C}}(C) \to \mathcal{E}_C \) (Proposition 5.3.1.7). In particular, \( \mathbf{sTr}_{\mathcal{E}/\mathcal{C}}(C) \) is an \( \infty \)-category which is equivalent to \( \mathcal{E}_C \).

- Every morphism \( f : C \to D \) in the category \( \mathcal{C} \) determines a functor of \( \infty \)-categories \( \mathbf{sTr}_{\mathcal{E}/\mathcal{C}}(f) : \mathbf{sTr}_{\mathcal{E}/\mathcal{C}}(C) \to \mathbf{sTr}_{\mathcal{E}/\mathcal{C}}(D) \), which does not depend on any auxiliary choices. Moreover, the assignment \( f \mapsto \mathbf{sTr}_{\mathcal{E}/\mathcal{C}}(f) \) is compatible with composition, and therefore determines a functor \( \mathbf{sTr}_{\mathcal{E}/\mathcal{C}} : \mathcal{C} \to \mathbf{QCat} \) which we will refer to as the strict transport representation of \( U \) (Construction 5.3.1.5).

- For every morphism \( f : C \to D \) in \( \mathcal{C} \), the diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\mathbf{sTr}_{\mathcal{E}/\mathcal{C}}(C) & \xrightarrow{\mathbf{sTr}_{\mathcal{E}/\mathcal{C}}(f)} & \mathbf{sTr}_{\mathcal{E}/\mathcal{C}}(D) \\
\downarrow{\mathbf{ev}_C} & & \downarrow{\mathbf{ev}_D} \\
\mathcal{E}_C & \xrightarrow{f_!} & \mathcal{E}_D
\end{array}
\]
commutes up to isomorphism. Consequently, the strict transport representation $sTr_{\mathcal{E}/\mathcal{C}}$ can be regarded as a refinement of the homotopy transport representation $hTr_{\mathcal{E}/N_\bullet(C)}$ of Construction 5.2.5.2.

We begin by considering a closely related construction.

**Construction 5.3.1.1.** Let $\text{Cat}$ denote the ordinary category whose objects are (small) categories and whose morphisms are functors. If $\mathcal{C}$ is a category, then the construction $\mathcal{C} \mapsto \mathcal{C}_{/\mathcal{C}}$ determines a functor $\mathcal{C} \to (\text{Cat}_{/\mathcal{C}})^{op}$, carrying each morphism $f : \mathcal{C} \to \mathcal{D}$ in $\mathcal{C}$ to the functor

$$\mathcal{C}_{\mathcal{D}/} \to \mathcal{C}_{/\mathcal{C}} \quad (g : \mathcal{D} \to E) \mapsto ((g \circ f) : \mathcal{C} \to E).$$

For any morphism of simplicial sets $U : \mathcal{E} \to N_\bullet(C)$, we let $wTr_{\mathcal{E}/\mathcal{C}} : \mathcal{C} \to \text{Set}_\Delta$ denote the functor given on objects by the formula

$$wTr_{\mathcal{E}/\mathcal{C}}(C) = \text{Fun}_{/N_\bullet(C)}(N_\bullet(\mathcal{C}_{/\mathcal{C}}), \mathcal{E}).$$

We will refer to $wTr_{\mathcal{E}/\mathcal{C}}$ as the **weak transport representation** of $U$.

**Remark 5.3.1.2.** Let $\mathcal{C}$ be a category and let $U : \mathcal{E} \to N_\bullet(C)$ be an inner fibration of $\infty$-categories. Then, for every object $C \in \mathcal{C}$, the simplicial set

$$wTr_{\mathcal{E}/\mathcal{C}}(C) = \text{Fun}_{/N_\bullet(C)}(N_\bullet(\mathcal{C}_{/\mathcal{C}}), \mathcal{E})$$

is an $\infty$-category (Corollary 4.1.4.8).

**Remark 5.3.1.3.** Let $\mathcal{C}$ be a category and let $U : \mathcal{E} \to N_\bullet(C)$ be a morphism of simplicial sets. For each object $C \in \mathcal{C}$, we can regard the identity morphism $\text{id}_C$ as an object of the coslice $\infty$-category $\mathcal{C}_{/\mathcal{C}}$. Evaluation on $\text{id}_C$ determines a morphism of simplicial sets

$$\text{ev}_C : wTr_{\mathcal{E}/\mathcal{C}}(C) \to \mathcal{E}_C.$$

Note that $\text{id}_C$ is an initial object of the category $\mathcal{C}_{/\mathcal{C}}$, so the inclusion map $\{\text{id}_C\} \to N_\bullet(C_{/\mathcal{C}})$ is left anodyne (Corollary 4.6.6.25). If $U$ is a left fibration of $\infty$-categories, then $\text{ev}_C$ is a trivial Kan fibration of simplicial sets. It follows that the simplicial set $wTr_{\mathcal{E}/\mathcal{C}}(C)$ is a Kan complex, and that $\text{ev}_C$ is a homotopy equivalence of Kan complexes.

**Example 5.3.1.4.** Let $\mathcal{C}$ be a category and let $U : \mathcal{E} \to N_\bullet(C)$ be a left covering map of simplicial sets. Then, for every object $C \in \mathcal{C}$, the evaluation map $\text{ev}_C : wTr_{\mathcal{E}/\mathcal{C}}(C) \to \mathcal{E}_C$ is an isomorphism of simplicial sets (Exercise 4.2.5.5). It follows that the simplicial set $wTr_{\mathcal{E}/\mathcal{C}}(C)$ is discrete (see Remark 4.2.3.17). We can therefore identify $wTr_{\mathcal{E}/\mathcal{C}}$ with a functor from $\mathcal{C}$ to the category of sets, which is isomorphic to the homotopy transport representation $hTr_{\mathcal{E}/N_\bullet(C)} : \mathcal{C} \to \text{Set}$ of Definition 5.2.0.4.
Let $C$ be a category and let $U : \mathcal{E} \to N_{\bullet}(C)$ be a cocartesian fibration of $\infty$-categories. For an object $C \in C$, the evaluation map $ev_C : w\text{Tr}_{\mathcal{E}/C}(C) \to \mathcal{E}_C$ of Remark 5.3.1.3 is generally not an equivalence of $\infty$-categories. By definition, an object of $w\text{Tr}_{\mathcal{E}/C}(C)$ can be identified with a functor of $\infty$-categories $F : N_{\bullet}(C_{C/}) \to \mathcal{E}$ for which the diagram

$$
\begin{array}{ccc}
N_{\bullet}(C_{C/}) & \xrightarrow{F} & \mathcal{E} \\
\downarrow & & \downarrow \\
N_{\bullet}(C) & \xrightarrow{U} & \mathcal{E} \\
\end{array}
$$

is commutative. This functor carries $\text{id}_C$ to an object $X = ev_C(F) \in \mathcal{E}_C$, and carries each morphism $f : C \to D$ of $C$ to an object $Y \in \mathcal{E}_D$ equipped with a morphism $\tilde{f} : X \to Y$ satisfying $U(\tilde{f}) = f$. To guarantee that this data can be recovered from $X$ (at least up to isomorphism), we need to impose an additional condition which guarantees that $\tilde{f}$ is $U$-cocartesian.

Construction 5.3.1.5 (The Strict Transport Representation). Let $C$ be a category and let $U : \mathcal{E} \to N_{\bullet}(C)$ be a cocartesian fibration of $\infty$-categories. For every object $C \in C$, we let $s\text{Tr}_{\mathcal{E}/C}(C)$ denote the full subcategory of $w\text{Tr}_{\mathcal{E}/C}(C) = \text{Fun}_{N_{\bullet}(C)}(N_{\bullet}(C_{C/}), \mathcal{E})$ spanned by those commutative diagrams

$$
\begin{array}{ccc}
N_{\bullet}(C_{C/}) & \xrightarrow{F} & \mathcal{E} \\
\downarrow & & \downarrow \\
N_{\bullet}(C) & \xrightarrow{U} & \mathcal{E} \\
\end{array}
$$

where $F$ carries each morphism of $N_{\bullet}(C_{C/})$ to a $U$-cocartesian morphism of $\mathcal{E}$. The construction $C \mapsto s\text{Tr}_{\mathcal{E}/C}(C)$ determines a functor $s\text{Tr} : C \to Q\text{Cat}$, which we will refer to as the strict transport representation of the cocartesian fibration $U$.

Remark 5.3.1.6. In the situation of Construction 5.3.1.5, suppose that $U : \mathcal{E} \to N_{\bullet}(C)$ is a left fibration of $\infty$-categories. It follows that every morphism of $\mathcal{E}$ is $U$-cocartesian (Proposition 5.1.4.14), so the strict transport representation $s\text{Tr}_{\mathcal{E}/C} : C \to Q\text{Cat}$ coincides with the weak transport representation $w\text{Tr}_{\mathcal{E}/C}$.

We now wish to show that Construction 5.3.1.5 is a refinement of the homotopy transport representation introduced in §5.2.5. This is a consequence of the following generalization of Remark 5.3.1.3.
Proposition 5.3.1.7. Let $\mathcal{C}$ be a category and let $U : \mathcal{E} \to \mathcal{N}_*(\mathcal{C})$ be a cocartesian fibration of $\infty$-categories. Then, for every object $C \in \mathcal{C}$, the evaluation map of Remark 5.3.1.3 induces a trivial Kan fibration of $\infty$-categories $\text{ev}_C : s\text{Tr}_{\mathcal{E}/C}(C) \to \mathcal{E}_C$.

Corollary 5.3.1.8. Let $\mathcal{C}$ be a category and let $U : \mathcal{E} \to \mathcal{N}_*(\mathcal{C})$ be a cocartesian fibration of $\infty$-categories. Then the diagram of functors

\begin{equation*}
\begin{array}{ccc}
\text{QCat} & \xrightarrow{s\text{Tr}_{\mathcal{E}/C}} & \text{QCat} \\
\downarrow & & \downarrow \\
\text{hTr}_{\mathcal{E}/\mathcal{N}_*(\mathcal{C})} & \xrightarrow{\text{ev}} & \text{hQCat} \\
\end{array}
\end{equation*}

commutes up to natural isomorphism, given by the construction

$(C \in \mathcal{C}) \mapsto (\text{ev}_C : s\text{Tr}_{\mathcal{E}/C}(C) \to \text{hTr}_{\mathcal{E}/\mathcal{N}_*(\mathcal{C})}(C) = \mathcal{E}_C)$.

Proof. It follows from Proposition 5.3.1.7 that for each object $C \in \mathcal{C}$, the evaluation functor $\text{ev}_C$ is a trivial Kan fibration, and therefore an isomorphism in the homotopy category $\text{hQCat}$. To complete the proof, it will suffice to show that the construction $C \mapsto \text{ev}_C$ is a natural transformation: that is, for every morphism $f : C \to D$ of $\mathcal{C}$, the diagram of $\infty$-categories

\begin{equation*}
\begin{array}{ccc}
s\text{Tr}_{\mathcal{E}/C}(C) & \xrightarrow{s\text{Tr}_{\mathcal{E}/C}(f)} & s\text{Tr}_{\mathcal{E}/C}(D) \\
\downarrow^{\text{ev}_C} & & \downarrow^{\text{ev}_D} \\
\mathcal{E}_C & \xrightarrow{f} & \mathcal{E}_D \\
\end{array}
\end{equation*}

commutes up to natural isomorphism. Let $s : \mathcal{E}_C \to s\text{Tr}_{\mathcal{E}/C}(C)$ be a section of the trivial Kan fibration $\text{ev}_C$. Then the homotopy class $[s]$ is an inverse of $[\text{ev}_C]$ in the homotopy category $\text{hQCat}$. It will therefore suffice to show that the diagram

\begin{equation*}
\begin{array}{ccc}
s\text{Tr}_{\mathcal{E}/C}(C) & \xrightarrow{s\text{Tr}_{\mathcal{E}/C}(f)} & s\text{Tr}_{\mathcal{E}/C}(D) \\
\downarrow^{s} & & \downarrow^{\text{ev}_D} \\
\mathcal{E}_C & \xrightarrow{f} & \mathcal{E}_D \\
\end{array}
\end{equation*}

commutes up to isomorphism: that is, that the composite functor

$\mathcal{E}_C \xrightarrow{s} s\text{Tr}_{\mathcal{E}/C}(C) \xrightarrow{s\text{Tr}_{\mathcal{E}/C}(f)} s\text{Tr}_{\mathcal{E}/C}(D) \xrightarrow{\text{ev}_D} \mathcal{E}_D$
is given by covariant transport along $f$.

Unwinding the definitions, we can identify the composition

$$\mathcal{E}_C \rightarrow s\text{Tr}_{\mathcal{E}/C}(C) \subseteq w\text{Tr}_{\mathcal{E}/C}(C) = \text{Fun}_{N_\bullet(C)}(N_\bullet(C)/C), \mathcal{E})$$

with a functor $H : N_\bullet(C/C) \times \mathcal{E}_C \rightarrow \mathcal{E}$. Let us regard $\text{id}_C$ and $f$ as objects of the category $C_C$, so that $f$ lifts to a morphism $\tilde{f} : \text{id}_C \rightarrow f$ corresponding to an edge $e : \Delta^1 \rightarrow N_\bullet(C/C)$. Let $H_e$ denote the composition

$$\Delta^1 \times \mathcal{E}_C \xrightarrow{e \times \text{id}} N_\bullet(C/C) \times \mathcal{E}_C \xrightarrow{H} \mathcal{E}.$$ 

Unwinding the definitions, we see that the commutative diagram

$$\begin{array}{ccc}
\Delta^1 \times \mathcal{E}_C & \xrightarrow{H_e} & \mathcal{E} \\
\downarrow \downarrow & & \downarrow U \\
\Delta^1 & \xrightarrow{f} & N_\bullet(C)
\end{array}$$

witnesses the composite functor $\text{ev}_D \circ s\text{Tr}_{\mathcal{E}/C}(f) \circ s$ as given by covariant transport along $f$, in the sense of Definition 5.2.2.4.

**Corollary 5.3.1.9** (Functoriality). Suppose we are given a commutative diagram of $\infty$-categories

$$\begin{array}{ccc}
\mathcal{E} & \xrightarrow{F} & \mathcal{E}' \\
\downarrow U & & \downarrow U' \\
N_\bullet(C)
\end{array}$$

where $U$ and $U'$ are cocartesian fibrations. The following conditions are equivalent:

1. The functor $F$ carries $U$-cocartesian morphisms of $\mathcal{E}$ to $U'$-cocartesian morphisms of $\mathcal{E}'$.

2. The induced map of weak transport representations $w\text{Tr}_{\mathcal{E}/C} \rightarrow w\text{Tr}_{\mathcal{E}'/C}$ carries $s\text{Tr}_{\mathcal{E}/C}$ into $s\text{Tr}_{\mathcal{E}'/C}$.

**Proof.** The implication (1) $\Rightarrow$ (2) is immediate from the definitions. Conversely, suppose that condition (2) is satisfied, and let $f : X \rightarrow Y$ be a $U$-cocartesian morphism of $\mathcal{E}$; we wish to show that $F(f)$ is $U'$-cocartesian. Set $C = U(X)$. Using Proposition 5.3.1.7, we can choose an object $\tilde{X} \in s\text{Tr}_{\mathcal{E}/C}(C)$ satisfying $\text{ev}_C(\tilde{X}) = X$. Let us identify $X$ with a
functor of ∞-categories $G : N_{\bullet}(C_{J}) \to \mathcal{E}$. Write $\overline{f}$ for the image $U(f)$, which we regard as a morphism in the coslice category $C_{J}$. Assumption (2) guarantees that $F$ carries $\overline{X}$ to an object of $sTr_{\mathcal{E}'}_{/C}(\overline{C})$, so that $(F \circ G)(\overline{f})$ is a $U'$-cocartesian morphism of $\mathcal{E}'$. Since $f$ is isomorphic to $G(\overline{f})$ (as an object of the ∞-category $\text{Fun}(\Delta^{1}, \mathcal{E})$), it follows that $F(\overline{f})$ is also $U'$-cocartesian.

The remainder of this section is devoted to the proof of Proposition 5.3.1.7. With an eye toward future applications, we will formulate a more general result, which can be applied to cocartesian fibrations $U : \mathcal{E} \to \mathcal{C}$ where $\mathcal{C}$ is not given by (the nerve of) an ordinary category.

**Notation 5.3.1.10 (Cocartesian Sections).** Let $U : \mathcal{E} \to \mathcal{C}$ and $U' : \mathcal{E}' \to \mathcal{C}$ be cocartesian fibrations of simplicial sets. Then the simplicial set

$$\text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E}) = \{U'\} \times_{\text{Fun}(\mathcal{E}', \mathcal{C})} \text{Fun}(\mathcal{E}', \mathcal{E})$$

is an ∞-category (see Corollary 4.1.4.8). We let $\text{Fun}^{\text{CCart}}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E})$ denote the full subcategory of $\text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E})$ whose objects are morphisms $F : \mathcal{E}' \to \mathcal{E}$ which satisfy the identity $U \circ F = U'$ and carry $U'$-cocartesian edges of $\mathcal{E}'$ to $U$-cocartesian edges of $\mathcal{E}$.

**Variant 5.3.1.11 (Cartesian Sections).** Let $U : \mathcal{E} \to \mathcal{C}$ and $U' : \mathcal{E}' \to \mathcal{C}$ be cartesian fibrations of simplicial sets. We let $\text{Fun}^{\text{Cart}}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E})$ denote the full subcategory of $\text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E})$ whose objects are morphisms $F : \mathcal{E}' \to \mathcal{E}$ which satisfy the identity $U \circ F = U'$ and carry $U'$-cartesian edges of $\mathcal{E}'$ to $U$-cartesian edges of $\mathcal{E}$. Note that we have a canonical isomorphism of simplicial sets

$$\text{Fun}^{\text{Cart}}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E})^{\text{op}} = \text{Fun}^{\text{Cart}}_{/\mathcal{C}_{\text{op}}}(\mathcal{E}'_{\text{op}}, \mathcal{E}_{\text{op}}).$$

In the special case $\mathcal{E}' = \mathcal{C}$, we will refer to $\text{Fun}^{\text{Cart}}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ as the ∞-category of cartesian sections of $U$.

**Remark 5.3.1.12.** Suppose we are given a commutative diagram of simplicial sets

$$\begin{array}{ccc}
\mathcal{E}' & \xrightarrow{F} & \mathcal{E} \\
U' \downarrow & & \downarrow U \\
\mathcal{C} & \xrightarrow{U} & 
\end{array}$$

where $U$ and $U'$ are cocartesian fibrations. Let $e : X \to Y$ be an edge of $\mathcal{C}$. The following conditions are equivalent:

1. For every $U'$-cocartesian edge $\overline{e} : \overline{X} \to \overline{Y}$ of $\mathcal{E}'$ satisfying $U'(\overline{e}) = e$, the image $F(\overline{e})$ is a $U$-cocartesian edge of $\mathcal{E}$.

2. For every vertex $\overline{X}$ of $\mathcal{E}'$ satisfying $U'(\overline{X}) = X$, there exists a $U'$-cocartesian edge $\overline{e} : \overline{X} \to \overline{Y}$ of $\mathcal{E}'$ such that $F(\overline{e})$ is $U$-cocartesian and $U'(\overline{e}) = e$.
The implication (1) ⇒ (2) is immediate from the definitions, and the implication (2) ⇒ (1) follows from Remark 5.1.3.8.

Let \( W \) be the collection of edges of \( \mathcal{C} \) which satisfy these conditions. Then \( W \) contains all degenerate edges of \( \mathcal{C} \) and is closed under composition: that is, for every 2-simplex

\[
\begin{tikzcd}
Y \\
\arrow[swap]{r}{e'} & Z \\
X \\
\arrow[swap]{r}{e''} & 
\end{tikzcd}
\]

of \( \mathcal{C} \), if \( e \) and \( e' \) belong to \( W \), then \( e'' \) also belongs to \( W \) (see Proposition 5.1.4.12).

\begin{remark}
We will be primarily interested in the special case of Notation 5.3.1.10 where \( U' : \mathcal{E}' \to \mathcal{C} \) is a left fibration of simplicial sets. In this case, an object \( F \in \text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E}) \) belongs to the full subcategory \( \text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{E}', \mathcal{E}) \) if and only if it carries every edge of \( \mathcal{E}' \) to a \( U \)-cocartesian edge of \( \mathcal{E} \) (Proposition 5.1.4.14).
\end{remark}

\begin{example}
Let \( \mathcal{C} \) be a category and let \( U : \mathcal{E} \to N_{\bullet}(\mathcal{C}) \) be a cocartesian fibration of \( \infty \)-categories. Then the strict transport representation \( s\text{Tr}_{\mathcal{E}/\mathcal{C}} \) of Construction 5.3.1.5 is given on objects by the formula

\[
s\text{Tr}_{\mathcal{E}/\mathcal{C}}(\mathcal{C}) = \text{Fun}_{/N_{\bullet}(\mathcal{C})}^{\text{Cart}}(N_{\bullet}(\mathcal{C}/\mathcal{C}), \mathcal{E}).
\]

\begin{remark}
Let \( U : \mathcal{E} \to \mathcal{C} \) and \( U' : \mathcal{E}' \to \mathcal{C} \) be cocartesian fibrations of simplicial sets. Then the full subcategory \( \text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{E}', \mathcal{E}) \subseteq \text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E}) \) is replete (Example 4.4.1.11). That is, if \( F \) and \( G \) are isomorphic objects of \( \text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E}) \), then \( F \) carries \( U' \)-cocartesian edges of \( \mathcal{E}' \) to \( U \)-cocartesian edges of \( \mathcal{E} \) if and only if \( G \) has the same property. In fact, we can be more precise: for every particular edge \( e \) of \( \mathcal{E}' \), the image \( F(e) \) is \( U \)-cocartesian if and only if \( G(e) \) is \( U \)-cocartesian. To prove this, we can assume without loss of generality that \( \mathcal{C} = \Delta^1 \), in which case it follows from Corollary 5.1.2.5.
\end{remark}

\begin{remark}[Detecting Isomorphisms]
Let \( U : \mathcal{E} \to \mathcal{C} \) and \( U' : \mathcal{E}' \to \mathcal{C} \) be cocartesian fibrations of \( \infty \)-categories, and let \( \alpha : F \to G \) be a morphism in the \( \infty \)-category \( \text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{E}', \mathcal{E}) \). The following conditions are equivalent:

\begin{enumerate}
  \item The morphism \( \alpha \) is an isomorphism in the \( \infty \)-category \( \text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{E}', \mathcal{E}) \).
  \item The image of \( \alpha \) is an isomorphism in the \( \infty \)-category \( \text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E}) \).
  \item The image of \( \alpha \) is an isomorphism in the \( \infty \)-category \( \text{Fun}(\mathcal{E}', \mathcal{E}) \).
\end{enumerate}
\end{remark}
(4) For each object $X \in \mathcal{C}$, the induced map $\alpha_X : F(X) \to G(X)$ is an isomorphism in the $\infty$-category $\mathcal{E}_X$.

(5) For each object $X \in \mathcal{C}$, the induced map $\alpha_X : F(X) \to G(X)$ is an isomorphism in the $\infty$-category $\mathcal{E}$.

The implications (1) ⇔ (2) is immediate, the equivalences (2) ⇔ (3) and (4) ⇔ (5) follow from Corollary 4.4.3.18, and the equivalence (3) ⇔ (5) follows from Theorem 4.4.4.4.

**Remark 5.3.1.17** (Functoriality). Let $U : \mathcal{E} \to \mathcal{C}$ and $U' : \mathcal{E}' \to \mathcal{C}$ be cocartesian fibrations of simplicial sets. Suppose that we are given a morphism of simplicial sets $F : \mathcal{C}_0 \to \mathcal{C}$, and set $\mathcal{E}_0 = \mathcal{C}_0 \times_\mathcal{C} \mathcal{E}$ and $\mathcal{E}'_0 = \mathcal{C}_0 \times_\mathcal{C} \mathcal{E}'$. Then pullback along $F$ determines a morphism of simplicial sets

$$F^* : \text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E}) \to \text{Fun}_{/\mathcal{C}_0}(\mathcal{E}'_0, \mathcal{E}_0),$$

which we will refer to as the **restriction map**.

**Remark 5.3.1.18.** In the situation of Remark 5.3.1.17, suppose that $F : \mathcal{C}_0 \to \mathcal{C}$ is a monomorphism of simplicial sets. Then the restriction map $F^* : \text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E}) \to \text{Fun}_{/\mathcal{C}_0}(\mathcal{E}'_0, \mathcal{E}_0)$ is an isofibration. To see this, we first observe that $\text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E})$ can be regarded as a replete subcategory of the fiber product

$$\text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E}) \times_{\text{Fun}_{/\mathcal{C}_0}(\mathcal{E}'_0, \mathcal{E}_0)} \text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E})$$

(Remark 5.3.1.15). It will therefore suffice to show that the restriction map

$$\text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E}) \to \text{Fun}_{/\mathcal{C}_0}(\mathcal{E}'_0, \mathcal{E}_0) \simeq \text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E})$$

is an isofibration, which follows from Proposition 4.5.5.14.

**Remark 5.3.1.19.** Let $U : \mathcal{E} \to \mathcal{C}$ and $U' : \mathcal{E}' \to \mathcal{C}$ be cocartesian fibrations of simplicial sets, and let $K$ be an arbitrary simplicial set. Then:

- The projection map $\mathcal{C} \times_{\text{Fun}(K, \mathcal{C})} \text{Fun}(K, \mathcal{E}) \to \mathcal{C}$ is also a cocartesian fibration.

- The canonical isomorphism

$$\text{Fun}(K, \text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E})) \simeq \text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{C} \times_{\text{Fun}(K, \mathcal{C})} \text{Fun}(K, \mathcal{E}))$$

restricts to an isomorphism of full subcategories

$$\text{Fun}(K, \text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{E})) \simeq \text{Fun}_{/\mathcal{C}}(\mathcal{E}', \mathcal{C} \times_{\text{Fun}(K, \mathcal{C})} \text{Fun}(K, \mathcal{E})).$$

Both assertions follow immediately from Theorem 5.2.1.1.
Remark 5.3.1.20. Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets. Let $\mathcal{E}^\circ \subseteq \mathcal{E}$ be the simplicial subset whose $n$-simplices are maps $\Delta^n \to \mathcal{E}$ which carry each edge of $\Delta^n$ to a $U$-cocartesian edge of $\mathcal{E}$, so that $U$ restricts to a left fibration $U^\circ : \mathcal{E}^\circ \to \mathcal{C}$ (see Corollary 5.1.4.15). Then $\text{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E}^\circ)$ can be identified with the core of the $\infty$-category $\text{Fun}_{/\mathcal{C}^\text{Cart}}(\mathcal{C}, \mathcal{E})$.

Proposition 5.3.1.21. Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets, let $F : C_0 \to \mathcal{C}$ be a left anodyne morphism of simplicial sets, and set $E_0 = C_0 \times_\mathcal{C} E$. Then the restriction map $F^* : \text{Fun}_{/\mathcal{C}}(\mathcal{C}, E) \to \text{Fun}_{/\mathcal{C}_0}(\mathcal{C}_0, E_0)$ of Remark 5.3.1.17 is a trivial Kan fibration.

Proof. Since $F$ is a monomorphism of simplicial sets, the functor $F^*$ is an isofibration of $\infty$-categories (Remark 5.3.1.18). It will therefore suffice to show that $F^*$ is an equivalence of $\infty$-categories (see Proposition 4.5.5.20). By virtue of Proposition 4.5.1.22, this is equivalent to the assertion that for simplicial set $X$, the induced map $\text{Fun}(X, \text{Fun}_{/\mathcal{C}}(\mathcal{C}, E)) \to \text{Fun}(X, \text{Fun}_{/\mathcal{C}_0}(\mathcal{C}_0, E_0))$ is a homotopy equivalence of Kan complexes (in fact, it suffices to verify this for $X = \Delta^1$; see Theorem 4.5.7.1). Replacing $E$ by the fiber product $C_0 \times_{\text{Fun}(X, \mathcal{C})} \text{Fun}(X, \mathcal{E})$ and using Remark 5.3.1.19, we are reduced to proving that $F^*$ restricts to a homotopy equivalence $F^* : \text{Fun}_{/\mathcal{C}^\text{Cart}}(\mathcal{C}, E) \to \text{Fun}_{/\mathcal{C}_0}(\mathcal{C}_0, E_0)$. Let $U^\circ : \mathcal{E}^\circ \to \mathcal{E}$ denote the underlying left fibration of $U$. Using Remark 5.3.1.20, we can identify $\theta$ with the map $\text{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E}^\circ) \to \text{Fun}_{/\mathcal{C}}(\mathcal{C}_0, \mathcal{E}^\circ \times_\mathcal{C} E \simeq \text{Fun}_{/\mathcal{C}_0}(\mathcal{C}_0, \mathcal{E}^\circ)$, given by precomposition with $F$. Since $F$ is left anodyne, this map is a trivial Kan fibration (Proposition 4.2.5.4).

Corollary 5.3.1.22. Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of $\infty$-categories, let $U' : \mathcal{E}' \to \mathcal{C}$ be a left fibration of $\infty$-categories, and let $X$ be an initial object of $\mathcal{E}'$. Then evaluation at $X$ induces a trivial Kan fibration of $\infty$-categories

$$\text{ev}_X : \text{Fun}_{/\mathcal{C}^\text{Cart}}(\mathcal{E}', \mathcal{E}) \to \{X\} \times_\mathcal{C} \mathcal{E}.$$ 

Proof. By virtue of Remark 5.3.1.13, we can replace $U$ by the projection map $\mathcal{E}' \times_\mathcal{C} \mathcal{E} \to \mathcal{E}'$ and thereby reduce to the case where $U'$ is the identity map. In this case, the desired result follows from Proposition 5.3.1.21 since the inclusion map $\{X\} \to \mathcal{E}'$ is left anodyne (Corollary 4.6.6.25).
Proof of Proposition 5.3.1.7. Let \( \mathcal{C} \) be a category and let \( U : \mathcal{E} \to N_\bullet(\mathcal{C}) \) be a cocartesian fibration of \( \infty \)-categories. By virtue of Example 5.3.1.14, it will suffice to show that the evaluation functor

\[
ev_C : \text{Fun}_{\mathcal{C}/}^{\mathcal{E}}(N_\bullet(\mathcal{C}), \mathcal{E}) \to \mathcal{E}_C
\]

is a trivial Kan fibration. This is a special case of Corollary 5.3.1.22, since the identity morphism \( \text{id}_C \) is initial when viewed as an object of the coslice category \( \mathcal{C}/_C \).

We conclude by recording another special case of Corollary 5.3.1.22 which will be useful later:

**Corollary 5.3.1.23.** Let \( U : \mathcal{E} \to \mathcal{C}^\circ \) be a cocartesian fibration of simplicial sets. Then evaluation at 0 induces a trivial Kan fibration of simplicial sets

\[
\text{Fun}_{\mathcal{C}^\circ, \mathcal{E}}^{\mathcal{C}^\circ, \mathcal{E}}(0) \times_{\mathcal{C}^\circ} \mathcal{E}.
\]

**Proof.** Combine Corollary 5.3.1.22 with Example 4.3.7.11.

### 5.3.2 Homotopy Colimits of Simplicial Sets

Let \( f_0 : A \to A_0 \) and \( f_1 : A \to A_1 \) be morphisms of simplicial sets. Recall that the homotopy pushout of \( A_0 \) with \( A_1 \) along \( A \) is defined to be the simplicial set

\[
A_0 \coprod_A^h A_1 = A_0 \coprod_{(0) \times A} (\Delta^1 \times A) \coprod_{(1) \times A} A_1
\]

(see Construction 3.4.2.2). This construction has two essential properties:

1. The formation of homotopy pushouts is compatible with weak homotopy equivalence. That is, if we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
A_0 & \xleftarrow{f_0} & A \\
\downarrow & & \downarrow \\
B_0 & \xleftarrow{g_0} & B
\end{array}
\quad \begin{array}{ccc}
& f_1 & \\
A & \rightarrow & A_1 \\
\downarrow & \downarrow & \downarrow \\
& B & \rightarrow & B_1
\end{array}
\]

in which the vertical maps are weak homotopy equivalences, then the induced map \( A_0 \coprod_A^h A_1 \to B_0 \coprod_B^h B_1 \) is also a weak homotopy equivalence (Corollary 3.4.2.15).

2. The homotopy pushout is equipped with a comparison map \( A_0 \coprod_A^h A_1 \to A_0 \coprod_A A_1 \), which is a weak homotopy equivalence if either \( f_0 : A_0 \to A \) or \( f_1 : A_1 \to A \) is a monomorphism (Corollary 3.4.2.13).
Our goal in this section is to introduce a variant of the homotopy pushout construction which can be applied to more general diagrams of simplicial sets. To every category \( \mathcal{C} \) and every functor \( F : \mathcal{C} \rightarrow \text{Set} \), we introduce a simplicial set \( \text{holim} \mapsto (F) \) which we refer to as the homotopy colimit of \( F \) (Construction 5.3.2.1). The homotopy colimit satisfies an analogue of property (1): it is compatible both with weak homotopy equivalence (Proposition 5.3.2.18) and with categorical equivalence (Variant 5.3.2.19). Moreover, there is a natural epimorphism from the homotopy colimit \( \text{holim} \mapsto (F) \) to the usual colimit \( \lim \mapsto (F) \) (Remark 5.3.2.9). We will see later that this map is often a weak homotopy equivalence (Corollary 7.5.6.14).

Construction 5.3.2.1. Let \( \mathcal{C} \) be a category and let \( F : \mathcal{C} \rightarrow \text{Set} \) be a functor. For every integer \( n \geq 0 \), we let \( \text{holim} \mapsto (F)_n \) denote the set of all ordered pairs \((\sigma, \tau)\), where \( \sigma : [n] \rightarrow \mathcal{C} \) is an \( n \)-simplex of the nerve \( N_\bullet(\mathcal{C}) \) and \( \tau \) is an \( n \)-simplex of the simplicial set \( F(\sigma(0)) \).

If \((\sigma, \tau)\) is an element of \( \text{holim} \mapsto (F)_n \) and \( \alpha : [m] \rightarrow [n] \) is a nondecreasing function of linearly ordered sets, we set \( \alpha^*(\sigma, \tau) = (\sigma \circ \alpha, \tau') \in \text{holim} \mapsto (F)_m \), where \( \tau' \) is given by the composite map
\[
\Delta^m \xrightarrow{\alpha} \Delta^n \xrightarrow{\tau} F(\sigma(0)) \rightarrow F((\sigma \circ \alpha)(0)).
\]
By means of this construction, the assignment \([n] \mapsto \text{holim} \mapsto (F)_n\) determines a simplicial set \( \text{holim} \mapsto (F) = \text{holim} \mapsto (F)_\bullet \) which we will refer to as the homotopy colimit of the diagram \( F \). Note that the construction \((\sigma, \tau) \mapsto \sigma\) determines a morphism of simplicial sets \( U : \text{holim} \mapsto (F) \rightarrow N_\bullet(\mathcal{C}) \), which we will refer to as the projection map.

Example 5.3.2.2 (Discrete Diagrams). Let \( \mathcal{C} \) be a category having only identity morphisms, and let \( F : \mathcal{C} \rightarrow \text{Set} \) be a diagram of simplicial sets. Then the homotopy colimit \( \text{holim} \mapsto (F) \) can be identified with the disjoint union \( \coprod_{C \in \mathcal{C}} F(C) \).

Remark 5.3.2.3. Let \( T : \mathcal{C}' \rightarrow \mathcal{C} \) be a functor between categories, let \( F : \mathcal{C} \rightarrow \text{Set} \) be a diagram of simplicial sets indexed by \( \mathcal{C} \), and let \( F' \) denote the composition \( F \circ T \). Then we have a pullback diagram of simplicial sets
\[
\begin{array}{ccc}
\text{holim}(F') & \rightarrow & \text{holim}(F) \\
\downarrow U' & & \downarrow U \\
N_\bullet(\mathcal{C}') & \xrightarrow{N_\bullet(T)} & N_\bullet(\mathcal{C}),
\end{array}
\]
where \( U \) and \( U' \) denote the projection maps of Construction 5.3.2.1. In particular, for every object \( C \in \mathcal{C} \), we have a canonical isomorphism of simplicial sets
\[
F(C) \simeq \{C\} \times_{N_\bullet(\mathcal{C})} \text{holim}(F).
\]
Example 5.3.2.4 (Constant Diagrams). Let $\mathcal{C}$ be a category, let $X$ be a simplicial set, and let $\mathcal{F} : \mathcal{C} \to \text{Set}_\Delta$ be the constant diagram taking the value $X$. Combining Remark 5.3.2.3 with Example 5.3.2.2, we obtain a canonical isomorphism of simplicial sets $\operatorname{holim}(\mathcal{F}) \simeq N_\bullet(\mathcal{C}) \times X$. In particular, if $X = \Delta^0$, then the projection map $\operatorname{holim}(\mathcal{F}) \to N_\bullet(\mathcal{C})$ is an isomorphism.

Example 5.3.2.5 (Set-Valued Functors). Let $\mathcal{C}$ be a category and let $\mathcal{F} : \mathcal{C} \to \text{Set}$ be a diagram of sets indexed by $\mathcal{C}$. Let us abuse notation by identifying $\mathcal{F}$ with a diagram of simplicial sets (by identifying each of the sets $\mathcal{F}(C)$ as a discrete simplicial set). Then there is a canonical isomorphism of simplicial sets $\operatorname{holim}(\mathcal{F}) \simeq N_\bullet(\int_{\mathcal{C}} \mathcal{F})$.

Here $\int_{\mathcal{C}} \mathcal{F}$ denotes the category of elements of the functor $\int_{\mathcal{C}} \mathcal{F}$ (Construction 5.2.6.1).

Example 5.3.2.6 (Corepresentable Functors). Let $\mathcal{C}$ be a category and let $h^C : \mathcal{C} \to \text{Set}$ be the functor corepresented by an object $C \in \mathcal{C}$, given by $h^C(D) = \text{Hom}_{\mathcal{C}}(C, D)$. Let us abuse notation by regarding $h^C$ as a functor from $\mathcal{C}$ to the category of simplicial sets (by identifying each morphism set $\text{Hom}_{\mathcal{C}}(C, D)$ with the corresponding discrete simplicial set). Combining Examples 5.3.2.5 and 5.2.6.5, we obtain a canonical isomorphism of simplicial sets $\operatorname{holim}(h^C) \simeq N_\bullet(C_{/C})$.

Remark 5.3.2.7. Let $\mathcal{C}$ be a category, let $\mathcal{F} : \mathcal{C} \to \text{Set}_\Delta$ be a diagram of simplicial sets indexed by $\mathcal{C}$, and let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a full subcategory. Suppose that, for every object $C \in \mathcal{C}$ which does not belong to $\mathcal{C}_0$, the simplicial set $\mathcal{F}(C)$ is empty. Then the image of the projection map $\operatorname{holim}(\mathcal{F}) \to N_\bullet(\mathcal{C})$ is contained in $N_\bullet(\mathcal{C}_0)$. Setting $\mathcal{F}_0 = \mathcal{F}|_{\mathcal{C}_0}$, we deduce that the canonical map $\operatorname{holim}(\mathcal{F}_0) \simeq N_\bullet(\mathcal{C}_0) \times N_\bullet(\mathcal{C}) \xrightarrow{\operatorname{holim}} \operatorname{holim}(\mathcal{F}) \xleftarrow{\operatorname{holim}} \operatorname{holim}(\mathcal{F})$ is an isomorphism.

Remark 5.3.2.8 (Functoriality). Let $\mathcal{C}$ be a category. Then the formation of homotopy colimits determines a functor $\operatorname{holim} : \text{Fun}(\mathcal{C}, \text{Set}_\Delta) \to (\text{Set}_\Delta)_{N_\bullet(\mathcal{C})/} F \mapsto \operatorname{holim}(F)$. Moreover, this functor preserves small limits and colimits.

Remark 5.3.2.9 (Comparison with the Colimit). Let $\mathcal{F} : \mathcal{C} \to \text{Set}_\Delta$ be a diagram of simplicial sets and let $\{t_C : \mathcal{F}(C) \to X\}_{C \in \mathcal{C}}$ be a collection of morphisms which exhibit $X$ as a colimit of the diagram $\mathcal{F}$. The morphisms $t_C$ then determine a natural transformation...
5.3. FIBRATIONS OVER ORDINARY CATEGORIES

$t_\bullet : F \to X$, where $X : C \to \text{Set}_\Delta$ denotes the constant functor taking the value $X$. Using Example 5.3.2.4 we obtain a morphism of simplicial sets

$$\theta : \text{holim}(F) \to \text{holim}(X) \simeq N_\bullet(C) \times X \to X,$$

which we will refer to as the comparison map. Note that, for every vertex $C \in C$, the restriction of $\theta$ to the fiber $\{C\} \times N_\bullet(C) \text{holim}(F)$ can be identified with the morphism $t_C$. Since $X$ is the union of the images of the morphisms $t_C$, it follows that the comparison map $\theta : \text{holim}(F) \to \text{lim}(F)$ is an epimorphism of simplicial sets.

**Example 5.3.2.10** (Disjoint Unions). Let $I$ be a set, which we regard as a category having only identity morphisms. Let $F : I \to \text{Set}_\Delta$ be a functor, which we identify with a collection of simplicial sets $\{X_i\}_{i \in I}$. Then the comparison map $\text{holim}(F) \to \text{lim}(F) = \coprod_{i \in I} X_i$ is an isomorphism of simplicial sets.

**Notation 5.3.2.11** (The Mapping Simplex). Suppose we are given a diagram of simplicial sets

$$X(0) \xrightarrow{f(1)} X(1) \xrightarrow{f(2)} X(2) \xrightarrow{f(n)} X(n),$$

which we will identify with a functor $F : [n] \to \text{Set}_\Delta$. We denote the homotopy colimit $\text{holim}(F)$ by $\text{holim}(X(0) \to \cdots \to X(n))$, and refer to it as the mapping simplex of the diagram $F$.

Let $F : C \to \text{Set}_\Delta$ be any diagram of simplicial sets and suppose we are given an $n$-simplex of $N_\bullet(C)$, corresponding to a diagram $C_0 \to \cdots \to C_n$ in the category $C$. By virtue of Remark 5.3.2.3 the fiber product $\Delta^n \times N_\bullet(C) \text{holim}(F)$ can be identified with the mapping simplex of the diagram $F(C_0) \to \cdots \to F(C_n)$. When $n = 0$, this mapping simplex can be identified with the simplicial set $F(C_0)$ (Example 5.3.2.4). For larger values of $n$, the mapping simplex can be computed recursively:

**Remark 5.3.2.12.** Let $n \geq 1$ and let $F : [n] \to \text{Set}_\Delta$ be a diagram of simplicial sets which we denote by

$$X(0) \to X(1) \to X(2) \to \cdots \to X(n).$$

Let $F' : [n] \to \text{Set}_\Delta$ denote the constant diagram taking the value $X(0)$. Let $F_0 \subseteq F$ be the subfunctor given by the diagram

$$\emptyset \to X(1) \to X(2) \to \cdots \to X(n),$$
and define \( F'_0 \subseteq F' \) similarly, so that we have a pushout diagram

\[
\begin{array}{ccc}
F'_0 & \rightarrow & F_0 \\
\downarrow & & \downarrow \\
F' & \rightarrow & F
\end{array}
\]

in the category \( \text{Fun}(\Delta^n, \text{Set}) \). Applying Remark 5.3.2.8, we deduce that the induced diagram of simplicial sets

\[
\begin{array}{ccc}
\text{holim}(F'_0) & \rightarrow & \text{holim}(F_0) \\
\downarrow & & \downarrow \\
\text{holim}(F') & \rightarrow & \text{holim}(F)
\end{array}
\]

is also a pushout square. Using Example 5.3.2.4 and Remark 5.3.2.7, we can rewrite this diagram as

\[
\begin{array}{ccc}
\text{holim}(F'_0) & \rightarrow & \text{holim}(F_0) \\
\downarrow & & \downarrow \\
\text{holim}(F') & \rightarrow & \text{holim}(F)
\end{array}
\]

\[\Rightarrow\]

\[
\begin{array}{ccc}
\text{holim}(f) & \rightarrow & \text{holim}(X(0) \rightarrow \cdots \rightarrow X(n)) \\
\downarrow & & \downarrow \\
\Delta^n \times X(0) & \rightarrow & \text{holim}(X(0) \rightarrow \cdots \rightarrow X(n)).
\end{array}
\]

**Example 5.3.2.13 (The Mapping Cylinder).** Let \( f : X \rightarrow Y \) be a morphism of simplicial sets, which we identify with a diagram \( F : [1] \rightarrow \text{Set}_\Delta \). We will denote the homotopy colimit \( \text{holim}(F) \) by \( \text{holim}(f : X \rightarrow Y) \) and refer to it as the *mapping cylinder* of the morphism \( f \). Applying Remark 5.3.2.12, we obtain an isomorphism of simplicial sets

\[\text{holim}(f) \simeq (\Delta^1 \times X) \coprod_{(1) \times X} Y;\]

that is, the mapping cylinder \( \text{holim}(f) \) can be identified with the homotopy pushout \( X \coprod^h_X Y \) of Construction 3.4.2.2.

**Remark 5.3.2.14.** Let \( n \) be a nonnegative integer, and suppose we are given a diagram of simplicial sets

\[X(0) \rightarrow X(1) \rightarrow X(2) \rightarrow \cdots \rightarrow X(n).\]
For each integer $0 \leq i \leq n$, let $\Delta_{\geq i}^n$ denote the nerve of the linearly ordered set $\{i < i + 1 < \cdots < n\}$, which we regard as a simplicial subset of $\Delta^n$. Applying Remark 5.3.2.12 repeatedly, we can identify the mapping simplex $\operatorname{holim}(X(0) \to \cdots \to X(n))$ with the iterated pushout
\[
(\Delta^n \times X(0)) \coprod \left( \prod_{(\Delta_{\geq 1}^n \times X(0))} \prod_{(\Delta_{\geq 2}^n \times X(1))} \cdots \prod_{(\{n\} \times X(n-1))} \{n\} \times X(n). \right).
\]

**Example 5.3.2.15 (Homotopy Quotients).** Let $G$ be a group and let $BG$ denote the associated groupoid (consisting of a single object with automorphism group $G$). Let $X$ be a simplicial set equipped with an action of $G$, which we identify with a functor $\mathcal{F} : BG \to \operatorname{Set}_\Delta$. We will denote the homotopy colimit $\operatorname{holim}(\mathcal{F})$ by $X_{hG}$, and refer to it as the **homotopy quotient** of $X$ by the action of $G$.

**Example 5.3.2.16.** Let $\mathcal{C}$ be the partially ordered set depicted in the diagram
\[
\bullet \leftarrow \bullet \rightarrow \bullet
\]
and suppose we are given a functor $\mathcal{F} : \mathcal{C} \to \operatorname{Set}_\Delta$, which we identify with a diagram of simplicial sets
\[
A_0 \xleftarrow{f_0} A \xrightarrow{f_1} A_1.
\]
The the homotopy colimit $\operatorname{holim}(\mathcal{F})$ can be identified with the iterated homotopy pushout
\[
(\bigcoprod_A A_0) \coprod_A (\bigcoprod_A A_1).
\]
In particular, the comparison map $q_0 : A \bigcoprod_A A_0 \to A \bigcoprod_A A_0 \simeq A_0$ induces an epimorphism of simplicial sets
\[
q : \operatorname{holim}(\mathcal{F}) \to A_0 \bigcoprod_A A_1.
\]
Note that $q_0$ is always a weak homotopy equivalence of simplicial sets (Corollary 3.4.2.13), so that $q$ is also a weak homotopy equivalence (Corollary 3.4.2.14). Beware that $q$ is never an isomorphism, except in the trivial case where the simplicial set $A$ is empty (in which case the homotopy colimit $\operatorname{holim}(\mathcal{F})$ and the homotopy pushout $A_0 \bigcoprod_A A_1$ can both be identified with the disjoint union $A_0 \bigcoprod A_1$).

**Exercise 5.3.2.17.** Let $\mathcal{C}$ be a category and let $\mathcal{F} : \mathcal{C} \to \operatorname{Set}_\Delta$ be a diagram of simplicial sets with the following properties:

- For every object $C \in \mathcal{C}$, the simplicial set $\mathcal{F}(C)$ is a Kan complex.
• For every morphism \( u: C \to C' \) in \( C \), the induced map \( \mathcal{F}(u): \mathcal{F}(C) \to \mathcal{F}(C') \) is a Kan fibration.

Show that the projection map \( \text{holim}(\mathcal{F}) \to N_\bullet(C) \) is a left fibration of simplicial sets.

We now apply the preceding analysis to study the homotopy invariance properties of Construction 5.3.2.1.

**Proposition 5.3.2.18.** Let \( C \) be a category and let \( \alpha: \mathcal{F} \to \mathcal{G} \) be a levelwise weak homotopy equivalence between diagrams \( \mathcal{F}, \mathcal{G}: C \to \text{Set}_\Delta \). Then the induced map \( \text{holim}(\alpha): \text{holim}(\mathcal{F}) \to \text{holim}(\mathcal{G}) \) is a weak homotopy equivalence of simplicial sets.

**Proof.** By virtue of Proposition 3.4.2.16, it will suffice to show that for every \( n \)-simplex \( \Delta^n \to N_\bullet(C) \), the induced map \( \Delta^n \times_{N_\bullet(C)} \text{holim}(\mathcal{F}) \to \Delta^n \times_{N_\bullet(C)} \text{holim}(\mathcal{G}) \) is a weak homotopy equivalence. Using Remark 5.3.2.3, we are reduced to proving Proposition 5.3.2.18 in the special case where \( C \) is the linearly ordered set \( [n] = \{0 < 1 < \cdots < n\} \). We now proceed by induction on \( n \). If \( n = 0 \), the desired result follows immediately from Example 5.3.2.2. Let us therefore assume that \( n > 0 \). Let \( \mathcal{F}' \) denote the restriction of \( \mathcal{F} \) to the full subcategory \( \{1 < 2 < \cdots < n\} \) and define \( \mathcal{G}' \) similarly. The natural transformation \( \alpha \) determines a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\Delta^n \times \mathcal{F}(0) & \xleftarrow{\alpha_0} & N_\bullet(\{1 < \cdots < n\}) \times \mathcal{F}(0) \to \text{holim}(\mathcal{F}') \\
| & & | \\
\Delta^n \times \mathcal{G}(0) & \xleftarrow{\alpha_0} & N_\bullet(\{1 < \cdots < n\}) \times \mathcal{G}(0) \to \text{holim}(\mathcal{G}')
\end{array}
\]

where the left horizontal maps are monomorphisms, the right vertical map is a weak homotopy equivalence by virtue of our inductive hypothesis, and the other vertical maps are weak homotopy equivalences by virtue of our assumption on \( \alpha \). The desired result now follows by combining Corollary 3.4.2.14 with Remark 5.3.2.12.

Using exactly the same argument, we see that the formation of homotopy colimits is compatible with categorical equivalence:

**Variant 5.3.2.19.** Let \( C \) be a category and let \( \alpha: \mathcal{F} \to \mathcal{G} \) be a levelwise categorical equivalence between diagrams \( \mathcal{F}, \mathcal{G}: C \to \text{Set}_\Delta \). Then the induced map \( \text{holim}(\alpha): \text{holim}(\mathcal{F}) \to \text{holim}(\mathcal{G}) \) is a categorical equivalence of simplicial sets.

**Proof.** By virtue of Corollary 4.5.7.3, it will suffice to show that for every \( n \)-simplex \( \Delta^n \to N_\bullet(C) \), the induced map \( \Delta^n \times_{N_\bullet(C)} \text{holim}(\mathcal{F}) \to \Delta^n \times_{N_\bullet(C)} \text{holim}(\mathcal{G}) \) is a categorical equivalence of simplicial sets. Using Remark 5.3.2.3, we are reduced to proving...
Variant 5.3.2.19 in the special case where $\mathcal{C}$ is the linearly ordered set $[n] = \{0 < 1 < \cdots < n\}$. We now proceed by induction on $n$. If $n = 0$, the desired result follows immediately from Example 5.3.2.2. Let us therefore assume that $n > 0$. Let $\mathcal{F}'$ denote the restriction of $\mathcal{F}$ to the full subcategory $\{1 < 2 < \cdots < n\}$ and define $\mathcal{G}'$ similarly. The natural transformation $\alpha$ determines a commutative diagram of simplicial sets

$$\Delta^n \times \mathcal{F}(0) \xleftarrow{\alpha} N_\bullet([1 < \cdots < n]) \times \mathcal{F}(0) \twoheadrightarrow \text{holim}(\mathcal{F}')$$

$$\Delta^n \times \mathcal{G}(0) \xleftarrow{\alpha} N_\bullet([1 < \cdots < n]) \times \mathcal{G}(0) \twoheadrightarrow \text{holim}(\mathcal{G}')$$

where the left horizontal maps are monomorphisms, the right vertical map is a categorical equivalence by virtue of our inductive hypothesis, and the other vertical maps are categorical equivalences by virtue of our assumption on $\alpha$. The desired result now follows by combining Corollary 4.5.4.14 with Remark 5.3.2.12.

The homotopy colimit of Construction 5.3.2.1 can be characterized by a universal mapping property.

**Construction 5.3.2.20.** Let $\mathcal{C}$ be a category and let $\mathcal{F} : \mathcal{C} \to \text{Set}_\Delta$ be a diagram of simplicial sets indexed by $\mathcal{C}$. For each object $C \in \mathcal{C}$, we let

$$f_C : N_\bullet(C) \times \mathcal{F}(C) \to \text{holim}(\mathcal{F})$$

denote the morphism of simplicial sets given on $n$-simplices by the formula $f_C(\sigma, \tau) = (\sigma, \tau)$, where $\sigma$ denotes the image of $\sigma$ in $N_\bullet(C)$ and $\tau$ denote the image of $\tau$ under the map $\mathcal{F}(C) \to \mathcal{F}(\sigma(0))$. Note that we can identify $f_C$ with a morphism of simplicial sets

$$u_{\mathcal{F},C} : \mathcal{F}(C) \to \text{Fun}_{/N_\bullet(C)}(N_\bullet(C), \text{holim}(\mathcal{F})) = \text{wTr}_{\text{holim}(\mathcal{F})/C}(\mathcal{F}).$$

This morphism depends functorially on $C$: that is, the collection $u_{\mathcal{F}} = \{u_{\mathcal{F},C}\}_{C \in \mathcal{C}}$ is a natural transformation from $\mathcal{F}$ to the weak transport representation $\text{wTr}_{\text{holim}(\mathcal{F})/C}$.

For every pair of functors $\mathcal{F}, \mathcal{G} : \mathcal{C} \to \text{Set}_\Delta$, let $\text{Hom}_{\text{Fun}(\mathcal{C}, \text{Set}_\Delta)}(\mathcal{F}, \mathcal{G})_\bullet$ denote the simplicial set parametrizing natural transformations from $\mathcal{F}$ to $\mathcal{G}$ (Example 2.4.2.2), described concretely by the formula

$$\text{Hom}_{\text{Fun}(\mathcal{C}, \text{Set}_\Delta)}(\mathcal{F}, \mathcal{G})_n = \text{Hom}_{\text{Fun}(\mathcal{C}, \text{Set}_\Delta)}(\mathcal{F}, \mathcal{G}^{\Delta^n}).$$

Here $\mathcal{G}^{\Delta^n} : \mathcal{C} \to \text{Set}_\Delta$ denotes the functor given by $\mathcal{G}^{\Delta^n}(C) = \text{Fun}(\Delta^n, \mathcal{G}(C))$. 
Proposition 5.3.2.21. Let \( \mathcal{F} : C \to \text{Set}_{\Delta} \) be a diagram of simplicial sets, let \( \mathcal{E} \) be a simplicial set, and define \( \mathcal{G} : C \to \text{Set}_{\Delta} \) by the formula \( \mathcal{G}(C) = \text{Fun}(N_{\bullet}(C_{C/}), \mathcal{E}) \). Then composition with the natural transformation \( u_{\mathcal{F}} \) of Construction 5.3.2.20 induces an isomorphism of simplicial sets

\[
\Phi_{\mathcal{F}} : \text{Fun}(\text{holim}(\mathcal{F}), \mathcal{E}) \to \text{Hom}_{\text{Fun}(C,\text{Set}_{\Delta})}(\mathcal{F}, \mathcal{G})_\bullet.
\]

Proof. For every object \( C \in C \), let \( h^C : C \to \text{Set}_{\Delta} \) denote the functor corepresented by \( C \) (given by \( h^C(D) = \text{Hom}_C(C, D) \), regarded as a discrete simplicial set). For every simplicial set \( K \), let \( K : C \to \text{Set}_{\Delta} \) denote the constant functor taking the value \( K \). Fix an integer \( n \geq 0 \); we wish to show that \( \Phi_{\mathcal{F}} \) induces a bijection from \( n \)-simplices of \( \text{Fun}(h^C_\Delta, \mathcal{E}) \) to \( n \)-simplices of \( \text{Hom}_{\text{Fun}(C,\text{Set}_{\Delta})}(\mathcal{F}, \mathcal{G})_\bullet \). Replacing \( \mathcal{E} \) by the simplicial set \( \text{Fun}(K \times \Delta^n, \mathcal{E}) \), we are reduced to proving that Construction 5.3.2.20 induces a bijection

\[
\Phi_0 : \text{Hom}_{\text{Set}_{\Delta}}(\text{holim}(h^C), \mathcal{E}) \to \text{Hom}_{\text{Fun}(C,\text{Set}_{\Delta})}(h^C, \mathcal{G})_\bullet.
\]

Let \( \mathcal{G}_0 : C \to \text{Set} \) denote the functor given on objects by the formula

\[
\mathcal{G}_0(C) = \text{Hom}_{\text{Set}_{\Delta}}(\Delta^0, \mathcal{G}(C)) = \text{Hom}_{\text{Set}_{\Delta}}(N_{\bullet}(C_{C/}), \mathcal{E}).
\]

Under the identification of \( \text{holim}(h^C) \simeq N_{\bullet}(C_{C/}) \) of Example 5.3.2.6, the function \( \Phi_0 \) corresponds to the bijection \( \mathcal{G}_0(C) \simeq \text{Hom}_{\text{Fun}(C,\text{Set})}(h^C, \mathcal{G}_0) \) supplied by Yoneda’s lemma.

Corollary 5.3.2.22. Let \( C \) be a small category. Then the homotopy colimit functor

\[
\text{Fun}(C,\text{Set}_{\Delta}) \to \text{Set}_{\Delta} \quad \mathcal{F} \mapsto \text{holim}(\mathcal{F})
\]

admits a right adjoint, given by the construction

\[
\text{Set}_{\Delta} \to \text{Fun}(C,\text{Set}_{\Delta}) \quad \mathcal{E} \mapsto (C \mapsto \text{Fun}(N_{\bullet}(C_{C/}), \mathcal{E})).
\]

Corollary 5.3.2.23. Let \( C \) be a category, let \( U : \mathcal{E} \to N_{\bullet}(C) \) be a morphism of simplicial sets, and let \( \mathcal{F} : C \to \text{Set}_{\Delta} \) be a functor. Then composition with the natural transformation \( u_{\mathcal{F}} \) of Construction 5.3.2.20 induces an isomorphism of simplicial sets

\[
\text{Fun}_{/N_{\bullet}(C)}(\text{holim}(\mathcal{F}), \mathcal{E}) \to \text{Hom}_{\text{Fun}(C,\text{Set}_{\Delta})}(\mathcal{F}, \text{wTr}_{\mathcal{E}/C})_\bullet,
\]

where \( \text{wTr}_{\mathcal{E}/C} \) is the weak transport representation of Construction 5.3.1.1.
5.3. FIBRATIONS OVER ORDINARY CATEGORIES

Proof. Define $G, H : C \to \text{Set}_\Delta$ by the formulae $G(C) = \text{Fun}(N \bullet(C), \mathcal{E})$ and $H(C) = \text{Fun}(N \bullet(C), N \bullet(C))$. We have a commutative diagram of simplicial sets

$$
\begin{array}{ccc}
\text{Fun}(\text{holim}(\mathcal{F}), \mathcal{E}) & \rightarrow & \text{Hom}_{\text{Fun}(C, \text{Set}_\Delta)}(\mathcal{F}, \mathcal{G})_\bullet \\
\downarrow U_\circ & & \downarrow U_\circ \\
\text{Fun}(\text{holim}(\mathcal{F}), N \bullet(C)) & \rightarrow & \text{Hom}_{\text{Fun}(C, \text{Set}_\Delta)}(\mathcal{F}, \mathcal{H})_\bullet,
\end{array}
$$

where the horizontal maps are isomorphisms by virtue of Proposition 5.3.2.21. Corollary 5.3.2.23 follows by restricting to fibers of the vertical maps. \qed

Corollary 5.3.2.24. Let $C$ be a small category. Then the homotopy colimit functor

$$\text{holim} : \text{Fun}(C, \text{Set}_\Delta) \to (\text{Set}_\Delta)/N \bullet(C)$$

admits a right adjoint, given by the functor

$$(\text{Set}_\Delta)/N \bullet(C) \to \text{Fun}(C, \text{Set}_\Delta) \quad (U : \mathcal{E} \to N \bullet(C)) \mapsto (w\text{Tr}_{\mathcal{E}/C} : C \to \text{Set}_\Delta)$$

of Construction 5.3.1.1.

5.3.3 The Weighted Nerve

Let $C$ be a category and let $\mathcal{F} : C \to \text{Kan}$ be a diagram of Kan complexes indexed by $C$. In §5.3.2 we introduced the homotopy colimit $\text{holim}(\mathcal{F})$, which is a simplicial set equipped with a projection map $U : \text{holim}(\mathcal{F}) \to N \bullet(C)$. If $\mathcal{F}$ carries each morphism of $C$ to a Kan fibration, then the projection map $U$ is a left fibration of simplicial sets (Exercise 5.3.2.17). Beware that $U$ is not a left fibration in general. In this section, we introduce a variant of the homotopy colimit $\text{holim}(\mathcal{F})$ which we will refer to as the $\mathcal{F}$-weighted nerve of $C$ and denote by $N \mathcal{F}(C)$ (Definition 5.3.3.1). The weighted nerve is equipped with a projection map

$N \mathcal{F}(C) \to N \bullet(C)$, which is a left fibration provided that $\mathcal{F}$ is a diagram of Kan complexes (Corollary 5.3.3.16). In §5.3.5, we will construct a comparison map $\lambda_t : \text{holim}(\mathcal{F}) \to N \mathcal{F}(C)$ (Construction 5.3.4.11) which is a categorical equivalence of simplicial sets (Corollary 5.3.5.9); in particular, it is a weak homotopy equivalence.

Definition 5.3.3.1 (The Weighted Nerve). Let $C$ be a category equipped with a functor $\mathcal{F} : C \to \text{Set}_\Delta$. For every integer $n \geq 0$, we let $N \mathcal{F}_n(C)$ denote the collection of all pairs $(\sigma, \tau)$, where $\sigma : [n] \to C$ is an $n$-simplex of $N \bullet(C)$ which we identify with a diagram

$$C_0 \to C_1 \to C_2 \to \cdots \to C_{n-1} \to C_n$$
and \( \tau \) is a collection of simplices \( \{ \tau_j : \Delta^j \to \mathcal{F}(C_j) \}_{0 \leq j \leq n} \) which fit into a commutative diagram of simplicial sets

\[
\begin{array}{ccccccccc}
\Delta^0 & \to & \Delta^1 & \to & \Delta^2 & \to & \cdots & \to & \Delta^n \\
\tau_0 \downarrow & & \tau_1 \downarrow & & \tau_2 \downarrow & & \cdots & & \tau_n \downarrow \\
\mathcal{F}(C_0) & \to & \mathcal{F}(C_1) & \to & \mathcal{F}(C_2) & \to & \cdots & \to & \mathcal{F}(C_n).
\end{array}
\]

For every nondecreasing function \( \alpha : [m] \to [n] \), we define a map \( \alpha^* : N_{n}^{\mathcal{F}} \to N_{m}^{\mathcal{F}} \) by the formula

\[
\alpha^*(\sigma, \tau) = (\sigma \circ \alpha, \tau'),
\]

where \( \tau' = \{ \tau'_i : \Delta^i \to \mathcal{F}(\alpha(i)) \}_{0 \leq i \leq m} \) is determined by the requirement that each \( \tau'_i \) is equal to the composition

\[
\Delta^i \xrightarrow{\alpha|[0<1<\cdots<i]} \Delta^{\alpha(i)} \xrightarrow{\tau_{\alpha(i)}} \mathcal{F}(\alpha(i)).
\]

By means of these restriction maps, we regard the construction \( [n] \mapsto N_{n}^{\mathcal{F}} \) as a simplicial set. We will denote this simplicial set by \( N_{-}^{\mathcal{F}}(\mathcal{C}) \) and refer to it as the \( \mathcal{F} \)-weighted nerve of \( \mathcal{C} \). Note that there is an evident projection map \( N_{-}^{\mathcal{F}}(\mathcal{C}) \to N_{-}(\mathcal{C}) \), given on simplices by the construction \((\sigma, \tau) \mapsto \sigma\).

**Example 5.3.3.2.** Let \( X \) be a simplicial set, which we identify with the constant functor \( \mathcal{F} : [0] \to \text{Set} \) taking the value \( X \). Then the weighted nerve \( N_{-}^{\mathcal{F}}([0]) \) can be identified with the simplicial set \( X \).

**Remark 5.3.3.3 (Vertices of the Weighted Nerve).** Let \( \mathcal{C} \) be a category equipped with a functor \( \mathcal{F} : \mathcal{C} \to \text{Set} \). Then vertices of the weighted nerve \( N_{-}^{\mathcal{F}}(\mathcal{C}) \) can be identified with pairs \((\mathcal{C}, x)\), where \( \mathcal{C} \) is an object of \( \mathcal{C} \) and \( x \) is a vertex of the simplicial set \( \mathcal{F}(\mathcal{C}) \).

**Remark 5.3.3.4 (Edges of the Weighted Nerve).** Let \( \mathcal{C} \) be a category equipped with a functor \( \mathcal{F} : \mathcal{C} \to \text{Set} \), and let \((\mathcal{C}, x)\) and \((\mathcal{D}, y)\) be vertices of the weighted nerve \( N_{-}^{\mathcal{F}}(\mathcal{C}) \) (see Remark 5.3.3.3). Edges of the weighted nerve \( N_{-}^{\mathcal{F}}(\mathcal{C}) \) with source \((\mathcal{C}, x)\) and target \((\mathcal{D}, y)\) can be identified with pairs \((f, e)\), where \( f : \mathcal{C} \to \mathcal{D} \) is a morphism of the category \( \mathcal{C} \) and \( e : \mathcal{F}(f)(x) \to y \) is an edge of the simplicial set \( \mathcal{F}(\mathcal{D}) \).

**Remark 5.3.3.5.** Let \( \mathcal{C} \) be a category and let \( \mathcal{F} : \mathcal{C} \to \text{Set} \) be a functor. Let \( K \) be an auxiliary simplicial set, and define \( \mathcal{F}^K : \mathcal{C} \to \text{Set} \) by the formula \( \mathcal{F}^K(\mathcal{C}) = \text{Fun}(K, \mathcal{F}(\mathcal{C})) \). Then the weighted nerves of \( \mathcal{F} \) and \( \mathcal{F}^K \) are related by a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
N_{-}^{\mathcal{F}^K}(\mathcal{C}) & \to & \text{Fun}(K, N_{-}^{\mathcal{F}}(\mathcal{C})) \\
\downarrow & & \downarrow \\
N_{-}(\mathcal{C}) & \to & \text{Fun}(K, N_{-}(\mathcal{C})).
\end{array}
\]
Example 5.3.3.6. Let \( \mathcal{C} \) be a category, and let \( \mathcal{F} : \mathcal{C} \to \text{Set}_\Delta \) be the functor given on objects by the formula \( \mathcal{F}(C) = N_\bullet(C/\mathcal{C}) \). Then there is a canonical isomorphism of simplicial sets
\[
N_\bullet \mathcal{F}(C) \cong N_\bullet(\text{Fun}(\{1\}, \mathcal{C})) = \text{Fun}(\Delta^1, N_\bullet(C)).
\]

Remark 5.3.3.7 (Functoriality in \( \mathcal{C} \)). Let \( \mathcal{C} \) be a category equipped with a functor \( \mathcal{F} : \mathcal{C} \to \text{Set}_\Delta \), let \( U : \mathcal{C}' \to \mathcal{C} \) be a functor between categories, and let \( \mathcal{F}' : \mathcal{C}' \to \text{Set}_\Delta \) denote the composition \( \mathcal{F} \circ U \). Then there is a pullback diagram of simplicial sets
\[
\begin{array}{ccc}
N_\bullet \mathcal{F}'(C') & \cong & N_\bullet \mathcal{F}(C) \\
\downarrow & & \downarrow \\
N_\bullet(C') & \xrightarrow{N_\bullet(U)} & N_\bullet(C).
\end{array}
\]

Example 5.3.3.8 (Fibers of the Weighted Nerve). Let \( \mathcal{F} : \mathcal{C} \to \text{Set}_\Delta \) be functor. For each object \( C \in \mathcal{C} \), Remark 5.3.3.7 and Example 5.3.3.2 supply an isomorphism of simplicial sets
\[
\mathcal{F}(C) \cong \{ C \} \times_{N_\bullet(C)} N_\bullet \mathcal{F}(C).
\]

Example 5.3.3.9 (The Weighted Nerve of a Constant Diagram). Let \( \mathcal{C} \) be a category, let \( X \) be a simplicial set, and let \( \mathcal{X} : \mathcal{C} \to \text{Set}_\Delta \) be the constant functor taking the value \( X \). Then Remark 5.3.3.7 and Example 5.3.3.2 supply an isomorphism of simplicial sets
\[
N_\bullet \mathcal{X}(C) \cong X \times N_\bullet(C).
\]

Remark 5.3.3.10 (Functoriality in \( \mathcal{F} \)). Let \( \mathcal{C} \) be a category. Then the construction \( \mathcal{F} \mapsto N_\bullet \mathcal{F}(C) \) determines a functor from the diagram category \( \text{Fun}(\mathcal{C}, \text{Set}_\Delta) \) to the category \( (\text{Set}_\Delta)/N_\bullet(C) \) of simplicial sets over the nerve \( N_\bullet(C) \). This functor commutes with all limits and with filtered colimits.

Exercise 5.3.3.11. Let \( \mathcal{C} \) be a category and let \( \alpha : \mathcal{F} \to \mathcal{G} \) be a natural transformation between functors \( \mathcal{F}, \mathcal{G} : \mathcal{C} \to \text{Set}_\Delta \). Show that, if \( \alpha \) is a levelwise trivial Kan fibration, then the induced map of weighted nerves \( N_\bullet \mathcal{F}(C) \to N_\bullet \mathcal{G}(C) \) is a trivial Kan fibration of simplicial sets.

Example 5.3.3.12 (The Weighted Nerve of a Cone). Let \( \mathcal{C} \) be a category and let \( \mathcal{C}^\circ \) denote the right cone on \( \mathcal{C} \) (Example 4.3.2.5), and let \( 1 \in \mathcal{C}^\circ \) denote the final object. Suppose we are given a diagram of simplicial sets \( \mathcal{F} : \mathcal{C}^\circ \to \text{Set}_\Delta \). Set \( \mathcal{F} = \mathcal{F}|_\mathcal{C} \) and \( Y = \mathcal{F}(1) \), so that \( \mathcal{F} \) determines a natural transformation \( \alpha : \mathcal{F} \to \mathcal{Y} \) (where \( \mathcal{Y} : \mathcal{C} \to \text{Set}_\Delta \) denotes the constant functor taking the value \( Y \)). Combining Remark 5.3.3.10 with Example 5.3.3.9 we obtain morphisms of simplicial sets
\[
N_\bullet \mathcal{F}(C) \xrightarrow{\alpha} N_\bullet \mathcal{Y}(C) \cong Y \times N_\bullet(C) \to Y.
\]
Unwinding the definitions, there is a canonical isomorphism of simplicial sets
\[ N^\circ \mathcal{F} \simeq N^\circ \mathcal{C} \ast_Y Y, \]
where the right hand side denotes the relative join of Construction 5.2.3.1.

**Example 5.3.3.13.** Let \( f : X \to Y \) be a morphism of simplicial sets, which we identify with a functor \( \mathcal{F} : [1] \to \text{Set}_\Delta \) (so that \( X = \mathcal{F}(0) \) and \( Y = \mathcal{F}(1) \)). Then Example 5.3.3.12 supplies an isomorphism of simplicial sets \( N^\circ \mathcal{F} \simeq X \ast_Y Y \).

**Example 5.3.3.14.** Let \( \mathcal{F} : C \to \text{Set}_\Delta \) be a functor. For every morphism \( f : C \to D \) in \( C \), Remark 5.3.3.7 and Example 5.3.3.13 supply an isomorphism of simplicial sets
\[ \Delta^1 \times_{N^\circ \mathcal{C}} N^\circ \mathcal{F} \simeq \mathcal{F}(C) \ast \mathcal{F}(D). \]

**Proposition 5.3.3.15.** Let \( C \) be a category and let \( \mathcal{F} : C \to \text{QCat} \) be a diagram of \( \infty \)-categories indexed by \( C \). Then:

1. The projection map \( U : N^\circ \mathcal{F} \to N^\circ \mathcal{C} \) is a cocartesian fibration of simplicial sets.
2. Let \( (f, e) : (C, x) \to (D, y) \) be an edge of the simplicial set \( N^\circ \mathcal{F} \) (see Remark 5.3.3.4). Then \( (f, e) \) is \( U \)-cocartesian if and only if \( e : \mathcal{F}(f)(x) \to y \) is an isomorphism in the \( \infty \)-category \( \mathcal{F}(D) \).

**Proof.** By virtue of Proposition 5.1.4.7 and Remark 5.3.3.7, we may assume without loss of generality that \( C \) is the linearly ordered set \([n] = \{0 < 1 < \cdots < n\}\) for some nonnegative integer \( n \). We proceed by induction on \( n \). If \( n = 0 \), then \( U \) can be identified with the projection map \( \mathcal{F}(0) \to \Delta^0 \) (Example 5.3.3.2), so that assertions (1) and (2) follow from Examples 5.1.4.3 and 5.1.1.4, respectively. Let us therefore assume that \( n > 0 \), so that \( C \) can be identified with the cone \( C_0 \) for \( C_0 = [n - 1] \). Set \( \mathcal{F}_0 = \mathcal{F}|_{C_0} \). It follows from our inductive hypothesis that the projection map \( U_0 : N^\circ \mathcal{F}_0 \to N^\circ (C_0) \) is a cocartesian fibration of \( \infty \)-categories, and that a morphism of \( N^\circ \mathcal{F}_0 \) is \( U_0 \)-cocartesian if and only if it satisfies the criterion described in (2). It follows that the functor \( N^\circ \mathcal{F}_0 \to \mathcal{F}(n) \) described in Example 5.3.3.12 carries \( U_0 \)-cocartesian morphisms to isomorphisms in the \( \infty \)-category \( \mathcal{F}(n) \). Unwinding the definitions, we can identify \( U \) with the map of relative joins
\[ N^\circ (C_0) \ast_{\mathcal{F}(n)} \mathcal{F}(n) \to \Delta^{n-1} \ast \Delta^0. \]

Assertion (1) now follows from Lemma 5.2.3.17. To prove (2), we can assume without loss of generality that \( n = 1 \), in which case the desired result follows from Example 5.2.3.18 (see Example 5.3.3.14). \( \square \)

**Corollary 5.3.3.16.** Let \( C \) be a category and let \( \mathcal{F} : C \to \text{Set}_\Delta \) be a functor. Suppose that, for every object \( C \in C \), the simplicial set \( \mathcal{F}(C) \) is a Kan complex. Then the projection map \( U : N^\circ \mathcal{F} \to N^\circ \mathcal{C} \) is a left fibration.
5.3. FIBRATIONS OVER ORDINARY CATEGORIES

Proof. Proposition 5.3.3.15 guarantees that $U$ is a cocartesian fibration. Moreover, for every object $C \in \mathcal{C}$, the fiber $U^{-1}\{C\} \simeq \mathcal{F}(C)$ is a Kan complex (Example 5.3.3.8). Applying Proposition 5.1.4.14, we conclude that $U$ is a left fibration.

Corollary 5.3.3.17. Let $\mathcal{C}$ be a category and let $\alpha : \mathcal{F} \to \mathcal{F}'$ be a natural transformation between functors $\mathcal{F}, \mathcal{F}' : \mathcal{C} \to \text{Set}_\Delta$. Then $\alpha$ is a levelwise categorical equivalence if and only if the induced map $T : N\mathcal{F}(C) \to N\mathcal{F}'(C)$ is a categorical equivalence of simplicial sets.

Proof. Assume first that $\alpha$ is a levelwise categorical equivalence. To prove that $T$ is a categorical equivalence of simplicial sets, it will suffice to show that for every simplex $\sigma : \Delta^n \to N\mathcal{F}(C)$, the induced map $T_\sigma : \Delta^n \times_{N\mathcal{F}(C)} N\mathcal{F}(C) \to \Delta^n \times_{N\mathcal{F}'(C)} N\mathcal{F}'(C)$ is a categorical equivalence of simplicial sets (Corollary 4.5.7.3). Using Remark 5.3.3.7, we can reduce to the special case where $\mathcal{C}$ is the linearly ordered $[n] = \{0 < 1 < \cdots < n\}$ for some $n \geq 0$. We now proceed by induction on $n$. If $n = 0$, the result is immediate from Example 5.3.3.2. The inductive step follows by combining Example 5.3.3.12 with Corollary 5.2.4.6.

We now prove the converse. Using Proposition 4.1.3.2, we can choose a commutative diagram

\[
\begin{array}{ccc}
\mathcal{F} & \xrightarrow{\alpha} & \mathcal{F}' \\
\downarrow & & \downarrow \\
\mathcal{G} & \xrightarrow{\beta} & \mathcal{G}'
\end{array}
\]

in the category $\text{Fun}(\mathcal{C}, \text{Set}_\Delta)$, where the vertical maps are levelwise categorical equivalences and the simplicial sets $\mathcal{G}(C)$ and $\mathcal{G}'(C)$ are $\infty$-categories for each $C \in \mathcal{C}$. Using the first part of the proof, we can replace $\alpha$ by $\beta$ and thereby reduce to the special case where $\mathcal{F}$ and $\mathcal{F}'$ are diagrams of $\infty$-categories. In this case, the projection maps $N\mathcal{F}(C) \to N\mathcal{G}(C) \to N\mathcal{G}'(C)$ are cocartesian fibrations of $\infty$-categories (Proposition 5.3.3.15). It then follows from Theorem 5.1.5.1 (together with Example 5.3.3.8) that if $T$ is an equivalence of $\infty$-categories, then $\alpha$ is a levelwise categorical equivalence.

Example 5.3.3.18. Let $\mathcal{C}$ be a category and let $\mathcal{F} : \mathcal{C} \to \text{Set}_\Delta$. Suppose that, for every object $C \in \mathcal{C}$, the simplicial set $\mathcal{F}(C)$ is an $\infty$-category, so that the projection map $U : N\mathcal{F}(C) \to N\mathcal{C}(C)$ is a cocartesian fibration (Proposition 5.3.3.15). Define $\mathcal{F}^\simeq : \mathcal{C} \to \text{Set}_\Delta$ by the formula $\mathcal{F}^\simeq(C) = \mathcal{F}(C)^\simeq$. Then $N\mathcal{F}^\simeq(C)$ can be identified with with simplicial subset of $N\mathcal{F}(C)$ spanned by those $n$-simplices which carry each edge of $\Delta^n$ to a $U$-cocartesian edge of $N\mathcal{F}(C)$. That is, the projection map $U^\simeq : N\mathcal{F}^\simeq(C) \to N\mathcal{C}(C)$ is the underlying left fibration of the cocartesian fibration $U$ (see Corollary 5.1.4.15).

Remark 5.3.3.19 (The Homotopy Transport Representation). Let $\mathcal{C}$ be a category equipped with a functor $\mathcal{F} : \mathcal{C} \to \text{QCat}$ and let $U : N\mathcal{F}(C) \to N\mathcal{C}(C)$ be the cocartesian fibration of
CHAPTER 5. FIBRATIONS OF ∞-CATEGORIES

Proposition 5.3.3.15. Then the homotopy transport representation

\[ h\text{Tr}_{N_{\xi}F/C}/N_{\bullet}(C) : C \to hQCat \]

of Construction 5.2.5.2 is canonically isomorphic to the composition \( C \xrightarrow{\mathcal{F}} QCat \to hQCat \).

To prove this, it suffices to observe that for every morphism \( f : C \to D \) in \( C \), the functor

\[ \mathcal{F}(f) : \mathcal{F}(C) \simeq \{C\} \times_{N_{\bullet}(C)} N_{\bullet}(C) \to \{D\} \times_{N_{\bullet}(C)} N_{\bullet}(C) \simeq \mathcal{F}(D) \]

is given by covariant transport along \( f \), which follows immediately from Proposition 5.2.3.15 and Example 5.3.3.14.

We conclude this section by showing that the weighted nerve can be characterized by a universal mapping property.

Notation 5.3.3.20. Let \( C \) be a category and suppose we are given a morphism of simplicial sets \( U : E \to N_{\bullet}(C) \). For every object \( C \in C \), let \( \mathcal{G}_E(C) \) denote the fiber product \( N_{\bullet}(C/C) \times_{N_{\bullet}(C)} E \). The construction \( C \mapsto \mathcal{G}_E(C) \) then determines a functor \( \mathcal{G}_E : C \to \text{Set}_\Delta \).

Suppose we are given an \( n \)-simplex \( \sigma \) of \( E \). Then \( U(\sigma) \) is an \( n \)-simplex of the simplicial set \( N_{\bullet}(C) \), which we can identify with a diagram

\[ C_0 \xrightarrow{f_1} C_1 \xrightarrow{f_2} C_2 \to \cdots \xrightarrow{f_n} C_n \]

in the category \( C \). For \( 0 \leq m \leq n \), we can view the diagram

\[ C_0 \xrightarrow{f_1} C_1 \xrightarrow{f_2} C_2 \to \cdots \xrightarrow{f_m} C_m \xrightarrow{\text{id}} C_m \]

as an \( m \)-simplex \( \tau_m \) of the simplicial set \( N_{\bullet}(C/C_m) \). The pair \( (\tau_m, U(\sigma)\vert_{\Delta^m}) \) can then be viewed as an \( m \)-simplex \( \tau_m \) of \( \mathcal{G}_E(C_m) \). Setting \( \tau = (\tau_0, \tau_1, \cdots, \tau_n) \), we observe that the pair \( (U(\sigma), \tau) \) can be regarded as an \( n \)-simplex \( u_E(\sigma) \) of the weighted nerve \( N_{\xi E}(C) \). Allowing \( n \) to vary, the construction \( \sigma \mapsto u_E(\sigma) \) determines a morphism of simplicial sets \( u_E : E \to N_{\xi E}(C) \) for which the diagram

\[ \begin{array}{ccc}
\mathcal{E} & \xrightarrow{u_E} & N_{\xi E}(C) \\
U \downarrow & & \downarrow \\
N_{\bullet}(C) & & \\
\end{array} \]

is commutative.
Proposition 5.3.3.21. Let \( \mathcal{C} \) be a category, let \( U : \mathcal{E} \to N_{\bullet}(\mathcal{C}) \) be a morphism of simplicial sets, and let \( u_{\mathcal{E}} : \mathcal{E} \to N_{\bullet}(\mathcal{E}) \) be the morphism of Notation 5.3.3.20. For every functor \( \mathcal{F} : \mathcal{C} \to \text{Set}_{\Delta} \), precomposition with \( u_{\mathcal{E}} \) induces a bijection
\[
T_{\mathcal{E}} : \text{Hom}_{\text{Fun}(\mathcal{C}, \text{Set}_{\Delta})}(\mathcal{G}_{\mathcal{E}}, \mathcal{F}) \to \text{Hom}_{(\text{Set}_{\Delta})/N_{\bullet}(\mathcal{C})}(\mathcal{E}, N_{\bullet}(\mathcal{C})).
\]

Corollary 5.3.3.22. Let \( \mathcal{C} \) be a category. Then the weighted nerve functor
\[
\text{Fun}(\mathcal{C}, \text{Set}_{\Delta}) \to (\text{Set}_{\Delta})/N_{\bullet}(\mathcal{C}) \quad \mathcal{F} \mapsto N_{\bullet}(\mathcal{C})
\]
has a left adjoint, given by the construction \( \mathcal{E} \mapsto \mathcal{G}_{\mathcal{E}} \) of Notation 5.3.3.20.

Proof of Proposition 5.3.3.21. The construction \( \mathcal{E} \mapsto T_{\mathcal{E}} \) carries colimits in the category \( (\text{Set}_{\Delta})/N_{\bullet}(\mathcal{C}) \) to limits in the arrow category \( \text{Fun}([1], \text{Set}) \). We can therefore assume without loss of generality that \( \mathcal{E} = \Delta^n \) is a standard simplex, so that the morphism \( U \) determines a diagram \( C_0 \to C_1 \to \cdots \to C_n \) in the category \( \mathcal{C} \). Unwinding the definitions, we see that the codomain of \( T_{\mathcal{E}} \) can be identified with the set of tuples \( \tau = (\tau_0, \tau_1, \cdots, \tau_n) \), where \( \tau_i : \Delta^i \to \mathcal{F}(C_i) \) are simplices for which the diagram
\[
\begin{array}{ccccccc}
\Delta^0 & \rightarrow & \Delta^1 & \rightarrow & \Delta^2 & \rightarrow & \cdots & \rightarrow & \Delta^n \\
\tau_0 & \downarrow & \tau_1 & \downarrow & \tau_2 & \downarrow & \cdots & \downarrow & \tau_n \\
\mathcal{F}(C_0) & \rightarrow & \mathcal{F}(C_1) & \rightarrow & \mathcal{F}(C_2) & \rightarrow & \cdots & \rightarrow & \mathcal{F}(C_n)
\end{array}
\]
is commutative. Let us regard \( \tau \) as fixed; we wish to prove that there is a unique natural transformation \( \alpha : \mathcal{G}_{\mathcal{E}} \to \mathcal{F} \) satisfying \( T_{\mathcal{E}}(\alpha) = \tau \).

Let \( D \) be an object of \( \mathcal{C} \) and let \( m \geq 0 \) be an integer. Then \( m \)-simplices of the simplicial set \( \mathcal{G}_{\mathcal{E}}(D) = N_{\bullet}(\mathcal{C}/D) \times N_{\bullet}(\mathcal{E}) \) can be identified with pairs \( (f, g) \), where \( g : [m] \to [n] \) is a nondecreasing function and \( f : C_{g(m)} \to D \) is a morphism in the category \( \mathcal{C} \). Let \( \alpha_D(f, g) \) denote the \( m \)-simplex of \( \mathcal{F}(D) \) given by the composition
\[
\Delta^m \xrightarrow{g} \Delta^{g(m)} \xrightarrow{\tau_{g(m)}} \mathcal{F}(C_{g(m)}) \xrightarrow{\mathcal{F}(f)} \mathcal{F}(D).
\]
The construction \( (f, g) \mapsto \alpha_D(f, g) \) determines a morphism of simplicial sets \( \alpha_D : \mathcal{G}_{\mathcal{E}}(D) \to \mathcal{F}(D) \). The assignment \( D \mapsto \alpha_D \) determines a natural transformation of functors \( \alpha : \mathcal{G}_{\mathcal{E}} \to \mathcal{F} \) satisfying \( T_{\mathcal{E}}(\alpha) = \tau \). This proves existence.

We now prove uniqueness. Suppose we are given another natural transformation \( \alpha' : \mathcal{G}_{\mathcal{E}} \to \mathcal{F} \) satisfying \( T_{\mathcal{E}}(\alpha') = \tau \); we wish to show that \( \alpha = \alpha' \). Fix an object \( D \in \mathcal{C} \) and an \( m \)-simplex of the simplicial set \( \mathcal{G}_{\mathcal{E}}(D) \), which we identify with a pair \( (f, g) \) as above. We wish to verify that \( \alpha_D(f, g) \) and \( \alpha'_D(f, g) \) coincide (as \( m \)-simplices of the simplicial set...
CHAPTER 5. FIBRATIONS OF ∞-CATEGORIES

Set \( n' = g(m) \), so that the function \( g \) factors as a composition \( [m] \xrightarrow{\delta} [n'] \xrightarrow{\iota} [n] \), where \( \iota : [n'] \hookrightarrow [n] \) is the inclusion map. Since \( \alpha_D \) and \( \alpha'_D \) are morphisms of simplicial sets, it will suffice to prove that \( \alpha_D(f, \iota) \) and \( \alpha'_D(f, \iota) \) coincide (as \( n' \)-simplices of the simplicial set \( \mathcal{F}(D) \)). Since both \( \alpha_D \) and \( \alpha'_D \) are natural in \( D \), we may assume without loss of generality that \( D = C_{r'} \) and that \( f \) is the identity morphism. In this case, the identities \( T_\mathcal{E}(\alpha) = \tau = T_\mathcal{E}(\alpha') \) give \( \alpha_D(f, \iota) = \tau_{n'} = \alpha'_D(f, \iota) \).

**Variant 5.3.23.** Let \( \mathcal{C} \) be a category, and let us regard \( \text{Fun}(\mathcal{C}, \text{Set}_\Delta) \) as equipped with the simplicial enrichment described in Example 2.4.2.2. For every morphism of simplicial sets \( \mathcal{E} \to N_\bullet(\mathcal{C}) \) and every functor \( \mathcal{F} : \mathcal{C} \to \text{Set}_\Delta \), precomposition with the morphism \( u_\mathcal{E} : \mathcal{E} \to N_{\mathcal{F}}(\mathcal{C}) \) of Notation 5.3.20 induces an isomorphism of simplicial sets

\[
\text{Hom}_{\text{Fun}(\mathcal{C}, \text{Set}_\Delta)}(\mathcal{F}_\mathcal{E}, \mathcal{F}) \times N_{\mathcal{F}}(\mathcal{C}) \to \text{Fun}_{/ N_\bullet(\mathcal{C})}(\mathcal{E}, N_{\mathcal{F}}(\mathcal{C})).
\]

To see that this map is bijective on \( m \)-simplices, we can replace \( \mathcal{E} \) by the product \( \Delta^m \times \mathcal{E} \) to reduce to the case \( m = 0 \), in which case it follows from Proposition 5.3.21.

### 5.3.4 Scaffolds of Cocartesian Fibrations

Let \( \mathcal{C} \) be a category and let \( \mathcal{F} : \mathcal{C} \to \text{QCat} \) be a (strictly commutative) diagram of \( \infty \)-categories indexed by \( \mathcal{C} \). Our goal in this section is to show that the diagram \( \mathcal{F} \) can be recovered, up to equivalence, from the weighted nerve \( N_{\mathcal{F}}(\mathcal{C}) \) of Definition 5.3.3.1. More precisely, we will show that there exists a levelwise categorical from \( \mathcal{F} \) to the strict transport representation \( sTr_{N_{\mathcal{F}}(\mathcal{C})/\mathcal{C}} \) of Construction 5.3.1.5 (Corollary 5.3.4.19).

We begin with some general remarks. Let \( \mathcal{U} : \mathcal{E} \to N_\bullet(\mathcal{C}) \) be any cocartesian fibration of simplicial sets and let \( wTr_{\mathcal{E}/\mathcal{C}} : \mathcal{C} \to \text{QCat} \) be the weak transport representation of \( U \) (Construction 5.3.1.1). Every levelwise categorical equivalence \( \alpha : \mathcal{F} \to sTr_{\mathcal{E}/\mathcal{C}} \) can be viewed as a natural transformation from \( \mathcal{F} \) to the weak transport representation \( wTr_{\mathcal{E}/\mathcal{C}} \), which we can identify (using Corollary 5.3.2.23) with a morphism from the homotopy colimit \( \operatorname{holim}(\mathcal{F}) \) into \( \mathcal{E} \). Our first goal is to give an explicit characterization of the collection of morphisms \( \lambda : \operatorname{holim}(\mathcal{F}) \to \mathcal{E} \) which arise in this way, which we will refer to as **scaffolds** of the cocartesian fibration \( U \) (Definition 5.3.4.2 and Remark 5.3.4.10).

**Definition 5.3.4.1.** Let \( \mathcal{C} \) be a category, let \( \mathcal{F} : \mathcal{C} \to \text{Set}_\Delta \) be a diagram of simplicial sets indexed by \( \mathcal{C} \), and let \( e \) be an edge of the homotopy colimit \( \operatorname{holim}(\mathcal{F}) \). Let us identify \( e \) with a pair \( (f, \bar{e}) \), where \( f : \mathcal{C} \to D \) is a morphism in the category \( \mathcal{C} \) and \( \bar{e} \) is an edge of the simplicial set \( \mathcal{F}(C) \). We will say that the edge \( e = (f, \bar{e}) \) is **horizontal** if \( \bar{e} \) is a degenerate edge of \( \mathcal{F}(C) \).

**Definition 5.3.4.2.** Let \( \mathcal{C} \) be a category, let \( U : \mathcal{E} \to N_\bullet(\mathcal{C}) \) be a cocartesian fibration of \( \infty \)-categories, and let \( \mathcal{F} : \mathcal{C} \to \text{Set}_\Delta \) be a diagram of simplicial sets. We will say that
a morphism of simplicial sets \( \lambda : \operatorname{holim}(\mathcal{F}) \to \mathcal{E} \) is a \textit{scaffold} if it satisfies the following conditions:

(0) The diagram of simplicial sets

\[
\begin{array}{ccc}
\text{holim}(\mathcal{F}) & \xrightarrow{\lambda} & \mathcal{E} \\
& \searrow U & \\
& \text{N}_\bullet(\mathcal{C}) & 
\end{array}
\]

is commutative (where the left vertical map is the projection map of Construction 5.3.2.1).

(1) The morphism \( \lambda \) carries horizontal edges of \( \operatorname{holim}(\mathcal{F}) \) to \( U \)-cocartesian morphisms of \( \mathcal{E} \).

(2) For every object \( C \in \mathcal{C} \), the induced map

\[
\mathcal{F}(C) \simeq \{C\} \times_{\text{N}_\bullet(\mathcal{C})} \operatorname{holim}(\mathcal{F}) \xrightarrow{\lambda} \{C\} \times_{\text{N}_\bullet(\mathcal{C})} \mathcal{E}
\]

is a categorical equivalence of simplicial sets.

\textbf{Example 5.3.4.3.} Let \( n \) be a nonnegative integer and let \( \mathcal{E} \) denote the nerve of the partially ordered set \( Q = \{(i,j) \in [n] \times [n] : j \leq i\} \). Then there is a cocartesian fibration of \( \infty \)-categories \( U : \mathcal{E} \to \Delta^n \), given on vertices by the formula \( U(i,j) = i \). Let \( \mathcal{F} : [n] \to \operatorname{Set}_\Delta \) denote the functor given by \( \mathcal{F}(i) = \Delta^i \), so that vertices of the homotopy colimit can be identified with elements of \( Q \). There is a unique morphism of simplicial sets \( \lambda : \operatorname{holim}(\mathcal{F}) \to \mathcal{E} \) which is the identity at the level of vertices, which is a scaffold of the cocartesian fibration \( U \). Moreover, \( \lambda \) is monomorphism, and an \( n \)-simplex \((i_0,j_0) \leq (i_1,j_1) \leq \cdots \leq (i_n,j_n)\) belongs to the image of \( \lambda \) if and only if \( j_n \leq i_0 \). The case \( n = 3 \) is depicted in the following diagram, where the image of \( \lambda \) is indicated with solid arrows:
Example 5.3.4.4. Let $\mathcal{E}$ be an $\infty$-category equipped with cocartesian fibration $U : \mathcal{E} \to \Delta^1$ having fibers $\mathcal{E}_0 = \{0\} \times_{\Delta^1} \mathcal{E}$ and $\mathcal{E}_1 = \{1\} \times_{\Delta^1} \mathcal{E}$. Choose a functor $F : \mathcal{E}_0 \to \mathcal{E}_1$ and a morphism $h : \Delta^1 \times \mathcal{E}_0 \to \mathcal{E}$ which witnesses $F$ as given by covariant transport along the nondegenerate edge of $\Delta^1$, in the sense of Definition 5.2.2.4. Then $F$ can be identified with a diagram $\mathcal{F} : [1] \to \text{QCat}$, and the map

$$\text{holim}(\mathcal{F}) = (\Delta^1 \times \mathcal{E}_0) \coprod_{\mathcal{E}_0} \mathcal{E}_1 \overset{(h, \text{id})}{\to} \mathcal{E}$$

is a scaffold.

Remark 5.3.4.5 (Isomorphism Invariance). In the situation of Definition 5.3.4.2, suppose that we are given a pair of morphisms $\lambda, \lambda' : \text{holim}(\mathcal{F}) \to \mathcal{E}$ which are isomorphic when viewed as objects of the $\infty$-category $\text{Fun}_{/N_{\bullet}(\mathcal{C})}(\text{holim}(\mathcal{F}), \mathcal{E})$. Then $\lambda$ is a scaffold if and only if $\lambda'$ is a scaffold (see Corollary 5.1.2.5 and Remark 4.5.1.15).

Remark 5.3.4.6 (Change of $\mathcal{E}$). Suppose we are given a commutative diagram

$$\begin{array}{ccc}
\mathcal{E} & \xrightarrow{T} & \mathcal{E}' \\
\downarrow{U} & & \downarrow{U'} \\
N_{\bullet}(\mathcal{C}), & \xrightarrow{} & N_{\bullet}(\mathcal{C})
\end{array}$$

where the vertical maps are cocartesian fibrations and $T$ is an equivalence of cocartesian fibrations over $N_{\bullet}(\mathcal{C})$. Then a morphism $\lambda : \text{holim}(\mathcal{F}) \to \mathcal{E}$ is a scaffold of the cocartesian fibration $U$ if and only if $T \circ \lambda$ is a scaffold of the cocartesian fibration $U'$.

We now describe two important examples of scaffolds, both of which can be regarded as generalizations of Example 5.3.4.3.

Construction 5.3.4.7 (The Universal Scaffold). Let $\mathcal{C}$ be a category, let $U : \mathcal{E} \to N_{\bullet}(\mathcal{C})$ be a cocartesian fibration of $\infty$-categories, and let $s\text{Tr}_{\mathcal{E}/\mathcal{C}}$ denote the strict transport representation of $U$ (Construction 5.3.1.5). For each $n \geq 0$, we can identify $n$-simplices of the homotopy colimit $\text{holim}(s\text{Tr}_{\mathcal{E}/\mathcal{C}})$ with pairs $(\sigma, \tau)$, where $\sigma$ is an $n$-simplex of $N_{\bullet}(\mathcal{C})$ (given by a diagram $C_0 \to C_1 \to \cdots \to C_n$ in the category $\mathcal{C}$) and $\tau$ is an $n$-simplex of the $\infty$-category $s\text{Tr}_{\mathcal{E}/\mathcal{C}}(C_0) = \text{Fun}_{/N_{\bullet}(\mathcal{C})}^\text{Cart}(N_{\bullet}(\mathcal{C}_{C_0/}), \mathcal{E})$, which we identify with a morphism of simplicial sets $\Delta^n \times N_{\bullet}(\mathcal{C}_{C_0/}) \to \mathcal{E}$. Let us identify the diagram $C_0 \to C_1 \to \cdots \to C_n$ with an $n$-simplex $\vec{\sigma}$ of the simplicial set $N_{\bullet}(\mathcal{C}_{C_0/})$, and let $\lambda_\sigma(\sigma, \tau)$ denote the $n$-simplex of $\mathcal{E}$ given by the composite map

$$\Delta^n \overset{(\text{id}, \vec{\sigma})}{\to} \Delta^n \times N_{\bullet}(\mathcal{C}_{C_0/}) \overset{\tau}{\to} \mathcal{E}.$$
The construction \( (\sigma, \tau) \mapsto \lambda_u(\sigma, \tau) \) determines a morphism of simplicial sets
\[
\lambda_u : \operatorname{holim}(\text{sTr}_E / C) \to \mathcal{E},
\]
which we will refer to as the universal scaffold of the cocartesian fibration \( U \).

**Proposition 5.3.4.8.** Let \( C \) be a category and let \( U : \mathcal{E} \to \mathcal{N}_\bullet(C) \) be a cocartesian fibration of \( \infty \)-categories. Then the morphism \( \lambda_u : \operatorname{holim}(\text{sTr}_E / C) \to \mathcal{E} \) of Construction 5.3.4.7 is a scaffold, in the sense of Definition 5.3.4.2.

**Proof.** It is clear that the composition \( U \circ \lambda_u \) coincides with the projection map \( \operatorname{holim}(\mathcal{F}) \to \mathcal{N}_\bullet(C) \). Let \( e \) be a horizontal edge of the homotopy colimit \( \operatorname{holim}(\text{sTr}_E / C) \), determined by a morphism \( \overline{e} : C \to D \) in the category \( C \) together with a degenerate edge \( \text{id}_T \) of the simplicial set \( \text{sTr}_E / C(C) \). Identifying \( T \) with an object of the \( \infty \)-category \( \text{Fun}^{\text{Cart}}_{/\mathcal{N}_\bullet(C)}(\mathcal{N}_\bullet(C_C)/, \mathcal{E}) \), we see that \( \lambda_u(e) \) coincides with the morphism \( T(\overline{e}) \) and is therefore a \( U \)-cocartesian morphism of \( \mathcal{E} \). To complete the proof, we observe that for every object \( C \in C \), the induced map
\[
\text{sTr}_E / C(C) \simeq \{ C \} \times_{\mathcal{N}_\bullet(C)} \operatorname{holim}(\text{sTr}_E / C) \xrightarrow{\lambda} \{ C \} \times_{\mathcal{N}_\bullet(C)} \mathcal{E}
\]
agrees with the map \( e_{\mathcal{C}} : \text{Fun}^{\text{Cart}}_{/\mathcal{N}_\bullet(C)}(\mathcal{N}_\bullet(C_C)/, \mathcal{E}) \to \mathcal{E}_C \) given by evaluation on the initial object \( \text{id}_C \in C_C \), and is therefore a trivial Kan fibration of simplicial sets (Proposition 5.3.1.7).

**Corollary 5.3.4.9.** Let \( C \) be a category and let \( U : \mathcal{E} \to \mathcal{N}_\bullet(C) \) be a cocartesian fibration of \( \infty \)-categories. Then there exists a diagram \( \mathcal{F} : C \to \text{QCat} \) and a scaffold \( \lambda : \operatorname{holim}(\mathcal{F}) \to \mathcal{E} \).

**Remark 5.3.4.10** (Universality). Let \( C \) be a category, let \( U : \mathcal{E} \to \mathcal{N}_\bullet(C) \) be a cocartesian fibration of \( \infty \)-categories, and let \( \mathcal{F} : C \to \text{Set}_\Delta \) be a diagram of simplicial sets. Applying Corollary 5.3.2.23, we obtain a bijection from the set of morphisms \( \lambda : \operatorname{holim}(\mathcal{F}) \to \mathcal{E} \) in the category \( (\text{Set}_\Delta)/\mathcal{N}_\bullet(C) \) to the set of natural transformations \( \alpha : \mathcal{F} \to \text{wTr}_E / C \). Unwinding the definitions, we see that \( \alpha \) factors through the subfunctor \( \text{sTr}_E / C \subseteq \text{wTr}_E / C \) if and only if \( \lambda \) satisfies condition (1) of Definition 5.3.4.2. If this condition is satisfied, then \( \alpha : \mathcal{F} \to \text{sTr}_E / C \) is a levelwise categorical equivalence if and only if \( \lambda \) satisfies condition (2) of Definition 5.3.4.2. We therefore obtain a bijection
\[
\{ \text{Levelwise categorical equivalences } \alpha : \mathcal{F} \to \text{sTr}_E / C \} \xrightarrow{\Phi} \{ \text{Scaffolds } \lambda : \operatorname{holim}(\mathcal{F}) \to \mathcal{E} \}.
\]
Concretely, this bijection carries a levelwise categorical equivalence $\alpha : \mathcal{F} \to s\text{Tr}_{E/C}$ to the composite map

$$\text{holim}(\mathcal{F}) \xrightarrow{\alpha} \text{holim}(s\text{Tr}_{E/C}) \xrightarrow{\lambda_u} \mathcal{E},$$

where $\lambda_u$ is the universal scaffold of Construction 5.3.4.7.

**Construction 5.3.4.11** (The Taut Scaffold). Let $\mathcal{F} : \mathcal{C} \to \text{Set}_\Delta$ be a diagram of simplicial sets. Suppose we are given an $n$-simplex of the homotopy colimit $\text{holim}(\mathcal{F})$ is a pair $(\sigma, \tau)$, where $\sigma$ is an $n$-simplex of $N_\bullet(\mathcal{C})$ (given by a diagram $C_0 \to \cdots \to C_n$ in the category $\mathcal{C}$) and $\tau$ is an $n$-simplex of the simplicial set $\mathcal{F}(C_0)$. For $0 \leq i \leq n$, let $\tau_i$ denote the composite map

$$\Delta^i \hookrightarrow \Delta^n \xrightarrow{\tau} \mathcal{F}(C_0) \to \mathcal{F}(C_i).$$

We then have a commutative diagram of simplicial sets

$$\begin{array}{ccccccc}
\Delta^0 & \to & \Delta^1 & \to & \Delta^2 & \to & \cdots & \to & \Delta^n \\
\tau_0 \downarrow & & \tau_1 \downarrow & & \tau_2 \downarrow & & \cdots \downarrow & & \tau_n \\
\mathcal{F}(C_0) & \to & \mathcal{F}(C_1) & \to & \mathcal{F}(C_2) & \to & \cdots & \to & \mathcal{F}(C_n).
\end{array}$$

Consequently, we can view the pair $(\sigma, \{\tau_i\}_{0 \leq i \leq n})$ as an $n$-simplex of the weighted nerve $N_\bullet(\mathcal{F}(\mathcal{C}))$. The construction $(\sigma, \tau) \mapsto (\sigma, \{\tau_i\}_{0 \leq i \leq n})$ determines a morphism of simplicial sets $\lambda_t : \text{holim}(\mathcal{F}) \to N_\bullet(\mathcal{F}(\mathcal{C}))$. In the special case where $\mathcal{F} : \mathcal{C} \to \text{QCat}$ is a diagram of $\infty$-categories, we will refer to $\lambda_t$ as the taut scaffold of the cocartesian fibration $N_\bullet(\mathcal{F}(\mathcal{C})) \to N_\bullet(\mathcal{C})$.

**Remark 5.3.4.12.** Let $\mathcal{C}$ be a category and let $\mathcal{F} : \mathcal{C} \to \text{Set}_\Delta$ be a functor. Then the diagram of simplicial sets

$$\begin{array}{ccc}
\text{holim}(\mathcal{F}) & \xrightarrow{\lambda_t} & N_\bullet(\mathcal{F}(\mathcal{C})) \\
\downarrow & & \downarrow \\
N_\bullet(\mathcal{C}) & & 
\end{array}$$

commutes, where $\lambda_t$ is the morphism of Construction 5.3.4.11 and the vertical morphism are the projection maps of Construction 5.3.2.1 and Definition 5.3.3.1.

**Example 5.3.4.13.** Let $X$ be a simplicial set, which we identify with a diagram $\mathcal{F} : [0] \to \text{Set}_\Delta$. Then the homotopy colimit $\text{holim}(\mathcal{F})$ and the weighted nerve $N_\bullet(\mathcal{F}([0]))$ can both be identified with $X$ (see Examples 5.3.2.2 and 5.3.3.2). Under these identifications, the taut scaffold $\lambda_t : \text{holim}(\mathcal{F}) \to N_\bullet(\mathcal{F}([0]))$ of Construction 5.3.4.11 corresponds to the identity map $\text{id}_X$. 
Remark 5.3.4.14 (Functoriality). Let $\mathcal{F} : C \to \text{Set}_\Delta$ be a diagram of simplicial sets and let $\lambda : \text{holim}(\mathcal{F}) \to N^\mathcal{F}_\bullet(C)$ be the morphism of Construction 5.3.4.11. If $T : C' \to C$ is any functor between categories, then $\lambda$ induces a morphism $\lambda' : \text{holim}(\mathcal{F}') \to N^\mathcal{F}_\bullet(C')$. Setting $\mathcal{F}' = \mathcal{F} \circ T$, we can use Remarks 5.3.2.3 and 5.3.3.7 to identify $\lambda'$ with a morphism from the homotopy colimit $\text{holim}(\mathcal{F}')$ to the weighted nerve $N^\mathcal{F}_\bullet(C')$. This morphism coincides with the map obtained by applying Construction 5.3.4.11 to the diagram $\mathcal{F}'$.

Example 5.3.4.15 (Comparison of Fibers). Let $\mathcal{F} : C \to \text{Set}_\Delta$ be a diagram of simplicial sets and let $\lambda : \text{holim}(\mathcal{F}) \to N^\mathcal{F}_\bullet(C)$ be the morphism of Construction 5.3.4.11. Combining Example 5.3.4.13 with Remark 5.3.4.14, we see that for every object $C \in C$, the induced map of fibers

$$\{C\} \times N^\mathcal{F}_\bullet(C) \text{holim}(\mathcal{F}) \to \{C\} \times N^\mathcal{F}_\bullet(C)$$

is an isomorphism of simplicial sets (under the identifications provided by Remark 5.3.2.3 and Example 5.3.3.8, it corresponds to the identity morphism $id : \mathcal{F}(C) \to \mathcal{F}(C)$).

Example 5.3.4.16. Let $f : X \to Y$ be a morphism of simplicial sets, which we identify with a diagram $\mathcal{F} : [1] \to \text{Set}_\Delta$. Then the homotopy colimit $\text{holim}(\mathcal{F})$ can be identified with the mapping cylinder $(\Delta^1 \times X) \coprod_{(1) \times X} Y$ (Example 5.3.2.13), and the weighted nerve $N^\mathcal{F}_\bullet([1])$ can be identified with the relative join $X \star_Y Y$ (Example 5.3.3.13). Under these identifications, Construction 5.3.4.11 corresponds to a morphism of simplicial sets

$$\lambda : (\Delta^1 \times X) \coprod_{(1) \times X} Y \to X \star_Y Y.$$

Unwinding the definitions, we see that this map classifies the commutative diagram

$$\begin{array}{ccc}
\emptyset \star_X X & \longrightarrow & \emptyset \star_Y Y \\
\downarrow & & \downarrow \\
X \star_X X & \longrightarrow & X \star_Y Y.
\end{array} \quad (5.16)
$$

In particular, the morphism $\lambda$ is an isomorphism if and only if (5.16) is a pushout square of simplicial sets.

Proposition 5.3.4.17. Let $\mathcal{F} : C \to \text{QCat}$ be a diagram of $\infty$-categories indexed by a category $C$. Then the morphism $\lambda : \text{holim}(\mathcal{F}) \to N^\mathcal{F}_\bullet(C)$ of Construction 5.3.4.11 is a scaffold of the cocartesian fibration $U : N^\mathcal{F}_\bullet(C) \to N_\bullet(C)$. 
Proof. Condition (0) of Definition 5.3.4.2 follows from Remark 5.3.4.12, condition (2) from Example 5.3.4.15, and condition (1) from the characterization of $U$-cocartesian morphisms supplied by Proposition 5.3.3.15.

Corollary 5.3.4.18. Let $\mathcal{F} : \mathcal{C} \to \text{Set}_\Delta$ be a diagram of simplicial sets. Then there exists a cocartesian fibration of $\infty$-categories $U : \mathcal{E} \to \text{N}_\bullet(\mathcal{C})$ and a scaffold $\lambda : \text{holim}(\mathcal{F}) \to \mathcal{E}$.

Proof. Using Proposition 4.1.3.2, we can choose a diagram of $\infty$-categories $\mathcal{F}' : \mathcal{C} \to \text{QCat}$ and a levelwise categorical equivalence $\alpha : \mathcal{F} \to \mathcal{F}'$. We can then take $\lambda$ to be the composition $\text{holim}(\mathcal{F}) \xrightarrow{\alpha} \text{holim}(\mathcal{F}') \xrightarrow{\lambda} \text{N}_{\mathcal{F}'}(\mathcal{C})$, where $\lambda_t$ is the taut scaffold of Proposition 5.3.4.17.

Corollary 5.3.4.19. Let $\mathcal{C}$ be a category, let $\mathcal{F} : \mathcal{C} \to \text{QCat}$ be a diagram of $\infty$-categories indexed by $\mathcal{C}$, and let $U : \text{N}_{\mathcal{F}}(\mathcal{C}) \to \text{N}_\bullet(\mathcal{C})$ be the cocartesian fibration of Proposition 5.3.3.15. Then there exists a levelwise categorical equivalence from $\mathcal{F}$ to the strict transport representation $s\text{Tr}_{\text{N}_{\mathcal{F}}(\mathcal{C})/\mathcal{C}}$.

Proof. Combine Proposition 5.3.4.17 with Remark 5.3.4.10 (for a more precise statement, see Construction 7.5.3.3).

In certain cases, one can improve on Example 5.3.4.15.

Proposition 5.3.4.20. Let $\mathcal{C}$ be a category and let $\mathcal{F} : \mathcal{C} \to \text{Set}_\Delta$ be a functor. Suppose that, for every morphism $u : C \to D$ in the category $\mathcal{C}$, the image $\mathcal{F}(u) : \mathcal{F}(C) \to \mathcal{F}(D)$ is a left covering map (Definition 4.2.3.8). Then the morphism $\lambda_t : \text{holim}(\mathcal{F}) \to \text{N}_{\mathcal{F}}(\mathcal{C})$ of Construction 5.3.4.11 is an isomorphism.

Proof. Let $(\sigma, \{\tau_i\}_{0 \leq i \leq n})$ be an $n$-simplex of the weighted nerve $\text{N}_{\mathcal{F}}(\mathcal{C})$. We identify $\sigma$ with a diagram $C_0 \to \cdots \to C_n$ in the category $\mathcal{C}$, and each $\tau_i$ with an $i$-simplex of the simplicial set $\mathcal{F}(C_i)$. We wish to show that there is a unique $n$-simplex $\tau$ of $\mathcal{F}(C_0)$ satisfying $\lambda_t(\sigma, \tau) = (\sigma, \{\tau_i\}_{0 \leq i \leq n})$. Note that, for this condition to be satisfied, the simplex $\tau$ must be a solution to the lifting problem

$$
\begin{array}{ccc}
0 & \xrightarrow{\mathcal{F}(C_0)} & \mathcal{F}(C_0) \\
\Delta^n & \xrightarrow{\tau} & \mathcal{F}(C_n).
\end{array}
$$

Since the inclusion $\{0\} \hookrightarrow \Delta^n$ is left anodyne (Example 4.3.7.11), our assumption that the right vertical map is a left covering guarantees that this lifting problem has a unique solution $\tau : \Delta^n \to \mathcal{F}(C_0)$ (Corollary 4.2.4.6). This proves uniqueness. To prove existence, write
\[ \lambda_t(\sigma, \tau) = (\sigma, \{\tau'_i\}_{0 \leq i \leq n}). \]

We wish to prove that \( \tau_i = \tau'_i \) for \( 0 \leq i \leq n \). For this, we observe that both \( \tau_i \) and \( \tau'_i \) can be viewed as solutions to a common lifting problem

\[
\begin{array}{ccc}
\{0\} & \xrightarrow{\tau(0)} & \mathcal{F}(C_i) \\
\downarrow & & \downarrow \mathcal{F}(C_n) \\
\Delta^i & \xrightarrow{\tau'_i} & \mathcal{F}(C_n).
\end{array}
\]

Since the inclusion \( \{0\} \hookrightarrow \Delta^i \) is left anodyne (Example 4.3.7.11) and the right vertical map is a left covering, the solution to this lifting problem is uniquely determined (Corollary 4.2.4.6).

\[ \square \]

**Example 5.3.4.21** (Set-Valued Functors). Let \( \mathcal{F} : \mathcal{C} \to \text{Set} \) be a diagram of sets, and let us abuse notation by identifying \( \mathcal{F} \) with a diagram of discrete simplicial sets. Then the taut scaffold \( \lambda_t : \text{holim}(\mathcal{F}) \to N_\bullet(\mathcal{C}) \) is an isomorphism. It follows that \( N_\bullet(\mathcal{C}) \) can be identified with the nerve of the category of elements \( \int_C \mathcal{F} \) (see Example 5.3.2.5).

**Corollary 5.3.4.22.** Let \( \mathcal{F} : \mathcal{C} \to \Delta \) be a functor which carries each morphism of \( \mathcal{C} \) to an isomorphism of simplicial sets. Then the morphism \( \lambda_t : \text{holim}(\mathcal{F}) \to N_\bullet(\mathcal{C}) \) of Remark 5.3.4.12 is an isomorphism.

**Corollary 5.3.4.23.** Let \( \mathcal{C} \) be a groupoid and let \( \mathcal{F} : \mathcal{C} \to \text{Kan} \) be a diagram of Kan complexes. Then the homotopy colimit \( \text{holim}(\mathcal{F}) \) is a Kan complex.

**Proof.** Using Corollaries 5.3.4.22 and 5.3.3.16 we see that the map \( U : \text{holim}(\mathcal{F}) \to N_\bullet(\mathcal{C}) \) is a left fibration. Since \( N_\bullet(\mathcal{C}) \) is a Kan complex (Proposition 1.2.4.2), it follows that \( U \) is a Kan fibration (Corollary 4.4.3.8), so that \( \text{holim}(\mathcal{F}) \) is also a Kan complex (Remark 3.1.1.11).

**Example 5.3.4.24** (Homotopy Quotients). Let \( G \) be a group and let \( BG \) denote the associated groupoid (consisting of a single object with automorphism group \( G \)). Let \( X \) be a simplicial set equipped with an action of \( G \), which we identify with a functor \( \mathcal{F} : BG \to \text{Set}_\Delta \). Applying Corollary 5.3.4.22, we obtain an isomorphism of simplicial sets \( X_{hG} \cong N_\bullet(\mathcal{F}(BG)) \), where \( X_{hG} \) is the homotopy quotient of \( X \) by the action of \( G \) (Example 5.3.2.15). If \( X \) is a Kan complex, then Corollary 5.3.4.23 guarantees that \( X_{hG} \) is also a Kan complex.

### 5.3.5 Application: Classification of Cocartesian Fibrations

**Let** \( \mathcal{C} \) be a category. In this section, we apply the results of §5.3.4 to classify cocartesian fibrations \( U : \mathcal{E} \to N_\bullet(\mathcal{C}) \) up to equivalence. First, we need to introduce a bit of terminology.
Definition 5.3.5.1. Let $\mathcal{C}$ be a category and let $\mathcal{F}_0, \mathcal{F}_1 : \mathcal{C} \to \mathbf{QCat}$ be diagrams of $\infty$-categories indexed by $\mathcal{C}$. We will say that $\mathcal{F}_0$ and $\mathcal{F}_1$ are **levelwise equivalent** if there exists another diagram $\mathcal{F} : \mathcal{C} \to \mathbf{QCat}$ equipped with levelwise categorical equivalences $\mathcal{F}_0 \to \mathcal{F} \leftarrow \mathcal{F}_1$ (see Definition 4.5.6.1).

Proposition 5.3.5.2. Let $\mathcal{C}$ be a category and suppose we are given a pair of functors $\mathcal{F}_0, \mathcal{F}_1 : \mathcal{C} \to \mathbf{QCat}$. Then $\mathcal{F}_0$ is levelwise equivalent to $\mathcal{F}_1$ (in the sense of Definition 5.3.5.1) if and only if the cocartesian fibrations $U_0 : N^{\mathcal{F}_0}_\bullet(\mathcal{C}) \to N_\bullet(\mathcal{C})$ and $U_1 : N^{\mathcal{F}_1}_\bullet(\mathcal{C}) \to N_\bullet(\mathcal{C})$ are equivalent (in the sense of Definition 5.1.6.1).

Corollary 5.3.5.3. For every category $\mathcal{C}$, levelwise equivalence determines an equivalence relation on the set of functors from $\mathcal{C}$ to $\mathbf{QCat}$.

Exercise 5.3.5.4. Give a direct proof of Corollary 5.3.5.3 (which does not use the characterization of Proposition 5.3.5.2).

Proof of Proposition 5.3.5.2. Assume first that the functors $\mathcal{F}_0, \mathcal{F}_1 : \mathcal{C} \to \mathbf{QCat}$ are levelwise equivalent. Then there exists a functor $\mathcal{F} : \mathcal{C} \to \mathbf{QCat}$ together with levelwise categorical equivalences $\mathcal{F}_0 \to \mathcal{F} \leftarrow \mathcal{F}_1$. Applying Corollary 5.3.3.17, we see that the induced maps $N^{\mathcal{F}_0}_\bullet(\mathcal{C}) \to N^{\mathcal{F}_1}_\bullet(\mathcal{C})$ are equivalences of cocartesian fibrations over $N_\bullet(\mathcal{C})$.

We now prove the converse. Suppose that there exists a functor $T : N^{\mathcal{F}_0}_\bullet(\mathcal{C}) \to N^{\mathcal{F}_1}_\bullet(\mathcal{C})$ which is an equivalence of cocartesian fibrations over $N_\bullet(\mathcal{C})$. Let $\lambda_0 : \text{holim}(\mathcal{F}_0) \to N^{\mathcal{F}_0}_\bullet(\mathcal{C})$ and $\lambda_1 : \text{holim}(\mathcal{F}_1) \to N^{\mathcal{F}_1}_\bullet(\mathcal{C})$ be the taut scaffolds of Construction 5.3.4.11. Then $T \circ \lambda_0$ is a scaffold of the cocartesian fibration $U_1$ (Remark 5.3.4.6). Applying Remark 5.3.4.10, we obtain levelwise categorical equivalences $\mathcal{F}_0 \to sTr_{N^{\mathcal{F}_1}_\bullet(\mathcal{C})/\mathcal{C}} \leftarrow \mathcal{F}_1$.

Warning 5.3.5.5. Let $\mathcal{C}$ be a category and let $\mathcal{F}_0, \mathcal{F}_1 : \mathcal{C} \to \mathbf{QCat}$ be diagrams. The assumption that $\mathcal{F}_0$ is levelwise equivalent to $\mathcal{F}_1$ (in the sense of Definition 5.3.5.1) does not guarantee the existence of a levelwise categorical equivalence directly from $\mathcal{F}_0$ to $\mathcal{F}_1$ (or in the opposite direction).

Theorem 5.3.5.6. Let $\mathcal{C}$ be a category. Then the weighted nerve functor $\mathcal{F} \mapsto N^{\mathcal{F}}_\bullet(\mathcal{C})$ induces a bijection

$$\{\text{Diagrams } \mathcal{C} \to \mathbf{QCat}\}/\text{Levelwise Equivalence} \to \{\text{Cocartesian Fibrations } \mathcal{E} \to N_\bullet(\mathcal{C})\}/\text{Equivalence}.$$
The inverse bijection carries (the equivalence class of) a cocartesian fibration $U : \mathcal{E} \to N\bullet(C)$ to (the equivalence class of) the strict transport representation $s\text{Tr}_{\mathcal{E}/C}$.

We will deduce Theorem 5.3.5.6 from the following result, which we prove at the end of this section:

**Theorem 5.3.5.7.** Let $\mathcal{C}$ be a category, let $\mathcal{F} : \mathcal{C} \to \text{Set}_\Delta$ be a functor, and suppose we are given a commutative diagram of simplicial sets

\[
\begin{align*}
\holim(\mathcal{F}) & \xrightarrow{\lambda} \mathcal{E} \\
\downarrow & \\
N\bullet(C) & \xrightarrow{U} \mathcal{E}
\end{align*}
\]

where $\mathcal{E}$ is an $\infty$-category. The following conditions are equivalent:

1. The functor $U$ is a cocartesian fibration and $\lambda$ is a scaffold.
2. The morphism $\lambda$ is a categorical equivalence of simplicial sets.

**Corollary 5.3.5.8.** Let $\mathcal{C}$ be a category, let $U : \mathcal{E} \to N\bullet(C)$ be a cocartesian fibration of $\infty$-categories, and let $s\text{Tr}_{\mathcal{E}/C}$ denote the strict transport representation of Construction 5.3.1.5. Then the universal scaffold $\lambda_u : \holim(s\text{Tr}_{\mathcal{E}/C}) \to \mathcal{E}$ of Construction 5.3.4.7 is a categorical equivalence of simplicial sets.

**Proof.** Combine Theorem 5.3.5.7 with Proposition 5.3.4.8.

**Corollary 5.3.5.9.** Let $\mathcal{F} : \mathcal{C} \to \text{Set}_\Delta$ be a diagram of simplicial sets. Then the morphism $\lambda_t : \holim(\mathcal{F}) \to N\bullet(\mathcal{C})$ of Construction 5.3.4.11 is a categorical equivalence of simplicial sets.

**Proof.** Using Proposition 4.1.3.2 we can choose a diagram of $\infty$-categories $\mathcal{F}' : \mathcal{C} \to \text{QCat}$ and a levelwise categorical equivalence $\alpha : \mathcal{F} \to \mathcal{F}'$. We then have a commutative diagram of simplicial sets

\[
\begin{align*}
\holim(\mathcal{F}) & \xrightarrow{\lambda_t} N\bullet(C) \\
\downarrow & \\
\holim(\mathcal{F}') & \xrightarrow{\lambda_t'} N\bullet'(C)
\end{align*}
\]
where the horizontal maps are given by Construction \([5.3.4.11]\) and the vertical maps are induced by the natural transformation \(\alpha\). Since \(\alpha\) is a levelwise categorical equivalence, Variant \([5.3.2.19]\) and Corollary \([5.3.3.17]\) guarantee that the vertical maps are categorical equivalences of simplicial sets. Consequently, to show that \(\lambda_t\) is a categorical equivalence, it will suffice to show that \(\lambda'_t\) is a categorical equivalence. This is a special case of Theorem \([5.3.5.7]\), since \(\lambda'_t\) is a scaffold of the cocartesian fibration \(N_\mathcal{F}'(\mathcal{C}) \to N_\bullet(\mathcal{C})\) (Proposition \([5.3.4.17]\)).

\(\square\)

**Example 5.3.5.10.** In the special case \(\mathcal{C} = [1]\), Theorem \([5.3.5.7]\) is a restatement of Theorem \([5.2.4.1]\) and Corollary \([5.3.5.9]\) is a restatement of Proposition \([5.2.4.4]\).

**Proof of Theorem 5.3.5.6.** Let \(\mathcal{C}\) be a category. It follows from Proposition \([5.3.5.2]\) that the construction \(F \mapsto N_\mathcal{F}(\mathcal{C})\) determines an injective function

\[
\{\text{Diagrams } \mathcal{C} \to \text{QCat}\} / \text{Levelwise Equivalence} \quad \Phi \quad \{\text{Cocartesian Fibrations } \mathcal{E} \to N_\bullet(\mathcal{C})\} / \text{Equivalence}
\]

Moreover, the construction \((U : \mathcal{E} \to N_\bullet(\mathcal{C})) \mapsto \text{sTr}_{\mathcal{E}/\mathcal{C}}\) carries equivalences of cocartesian fibrations over \(N_\bullet(\mathcal{C})\) to levelwise categorical equivalences, and therefore induces a function

\[
\{\text{Cocartesian Fibrations } \mathcal{E} \to N_\bullet(\mathcal{C})\} / \text{Equivalence} \quad \Psi \quad \{\text{Diagrams } \mathcal{C} \to \text{QCat}\} / \text{Levelwise Equivalence}
\]

in the opposite direction. We will show that \(\Phi \circ \Psi\) is equal to the identity; it will then follow that \(\Phi\) is a bijection and that \(\Psi = \Phi^{-1}\) is the inverse bijection.

Fix a cocartesian fibration \(U : \mathcal{E} \to N_\bullet(\mathcal{C})\), let \(\mathcal{F} = \text{sTr}_{\mathcal{E}/\mathcal{C}}\) denote its strict transport representation, and let \(U' : N_\mathcal{F}(\mathcal{C}) \to N_\bullet(\mathcal{C})\) be the projection map. We wish to show that \(U\) and \(U'\) are equivalent as cocartesian fibrations over \(N_\bullet(\mathcal{C})\). Let \(\lambda_u : \text{holim}(\mathcal{F}) \to \mathcal{E}\) denote the universal scaffold (Construction \([5.3.4.7]\)) and let \(\lambda_t : \text{holim}(\mathcal{F}) \to N_\mathcal{F}(\mathcal{C})\) denote the taut scaffold (Construction \([5.3.4.11]\)). Then \(\lambda_t\) is a categorical equivalence of simplicial sets (Corollary \([5.3.5.9]\)). Applying Corollary \([4.5.2.28]\) we see that precomposition with \(\lambda_t\) induces an equivalence of \(\infty\)-categories

\[
\text{Fun}_{/ N_\bullet(\mathcal{C})}(N_\mathcal{F}(\mathcal{C}), \mathcal{E}) \to \text{Fun}_{/ N_\bullet(\mathcal{C})}(\text{holim}(\mathcal{F}), \mathcal{E}).
\]
In particular, there exists a morphism $T : N_{\mathcal{E}}(\mathcal{C}) \to \mathcal{E}$ such that $U \circ T = U'$ and $T \circ \lambda_t$ is isomorphic to $\lambda_u$ (as an object of the ∞-category $\text{Fun}/N_{\bullet}(\mathcal{C})(\text{holim}(\mathcal{F}), \mathcal{E})$). Since $\lambda_u$ is a categorical equivalence of simplicial sets (Corollary 5.3.5.8), it follows that $T \circ \lambda_t$ is also a categorical equivalence of simplicial sets (Corollary 4.5.3.9). Applying the two-out-of-three property, we see that $T$ is an equivalence of ∞-categories (Remark 4.5.3.5) and therefore an equivalence of cocartesian fibrations over $N_{\bullet}(\mathcal{C})$ (Proposition 5.1.6.5).

Proof of Theorem 5.3.5.7. We first show that (1) implies (2). Assume that $U : \mathcal{E} \to N_{\bullet}(\mathcal{C})$ is a cocartesian fibration of simplicial sets and let $\lambda : \text{holim}(\mathcal{F}) \to \mathcal{E}$ be a scaffold of $U$; we wish to show that $\lambda$ is a categorical equivalence of simplicial sets. By virtue of Corollary 4.5.7.3, it will suffice to show that for every $n$-simplex $\sigma : \Delta^n \to N_{\bullet}(\mathcal{C})$, the induced map $\Delta^n \times N_{\bullet}(\mathcal{C}) \text{holim}(\mathcal{F}) \to \Delta^n \times N_{\bullet}(\mathcal{C}) \mathcal{E}$ is a categorical equivalence of simplicial sets. We may therefore assume without loss of generality that the category $\mathcal{C}$ is a linearly ordered set of the form $[n] = \{0 < 1 < \cdots < n\}$ for some $n \geq 0$.

We proceed by induction on $n$. If $n = 0$, the result is clear. Let us therefore assume that $n > 0$. Let $S = N_{\bullet}(\{1 < \cdots < n\})$ be the 0th face of the simplex $\Delta^n$ and set $\mathcal{E}_+ = S \times \Delta^n \mathcal{E}$. Let $\mathcal{F}_+$ denote the restriction of $\mathcal{F}$ to the subcategory $\{1 < \cdots < n\} \subset [n]$, so that our inductive hypothesis guarantees that $\lambda$ restricts to a categorical equivalence $\lambda_+ : \text{holim}(\mathcal{F}_+) \to \mathcal{E}_+$. Note that Remark 5.3.2.12 supplies an isomorphism of simplicial sets 
\[
(\Delta^n \times \mathcal{F}(0)) \coprod_{(S \times \mathcal{F}(0))} \text{holim}(\mathcal{F}_+) \to \text{holim}(\mathcal{F}).
\]

Let $V : \Delta^n \to \Delta^1$ be the morphism given on vertices by the formula $V(i) = \begin{cases} 0 & \text{if } i = 0 \\ 1 & \text{if } i > 0. \end{cases}$ Then $V$ is a cocartesian fibration of simplicial sets, and the edge $N_{\bullet}(\{0 < 1\}) \subseteq \Delta^n$ is $V$-cocartesian. It follows that, for every vertex $x$ of the simplicial set $\mathcal{F}(0)$, the composite map $\Delta^1 \times \{x\} \hookrightarrow \Delta^n \times \mathcal{F}(0) \to \text{holim}(\mathcal{F}) \xrightarrow{\lambda} \mathcal{E}$ is a $(V \circ U)$-cocartesian edge of $\mathcal{E}$. Applying Theorem 5.2.4.1 to the cocartesian fibration $V \circ U$, we deduce that the composition
\[
(\Delta^1 \times \mathcal{F}(0)) \coprod_{(\{1\} \times \mathcal{F}(0))} \text{holim}(\mathcal{F}_+) \xrightarrow{\lambda} (\Delta^n \times \mathcal{F}(0)) \coprod_{(S \times \mathcal{F}(0))} \text{holim}(\mathcal{F}_+)
\]
\[
\simeq \text{holim}(\mathcal{F}) \xrightarrow{\lambda} \mathcal{E}.
\]
is a categorical equivalence of simplicial sets. Consequently, to show that \( \lambda \) is a categorical equivalence of simplicial sets, it will suffice to show that \( \iota \) is inner anodyne. By construction, \( \iota \) is a pushout of the inclusion map

\[
(\Delta^1 \coprod_{\{1\}} S) \times \mathcal{F}(0) \to \Delta^n \times \mathcal{F}(0).
\]

By virtue of Lemma 5.3.5.11, it will suffice to show that the inclusion map \( \Delta^1 \coprod_{\{1\}} S \hookrightarrow \Delta^n \) is inner anodyne. This is a special case of Example 4.3.6.5, since the inclusion \( \{1\} \hookrightarrow S \) is left anodyne (Lemma 4.3.7.8).

We now show that (2) implies (1). Let \( U : \mathcal{E} \to N_\bullet(\mathcal{C}) \) be a functor of \( \infty \)-categories, and suppose that \( \lambda : \mathrm{holim}(\mathcal{F}) \to \mathcal{E} \) is a categorical equivalence of simplicial sets such that \( U \circ \lambda \) is equal to the projection map \( \mathrm{holim}(\mathcal{F}) \to N_\bullet(\mathcal{C}) \). We first claim that \( U \) is an isofibration of \( \infty \)-categories. Since \( \mathcal{E} \) is an \( \infty \)-category, the morphism \( U \) is an inner fibration (Proposition 5.3.4.10). It will therefore suffice to show that, for each object \( \bar{C} \in \mathcal{E} \) having image \( C = U(\bar{C}) \in \mathcal{C} \) and every isomorphism \( e : C \to D \) of \( C \), there exists an isomorphism \( \bar{e} : \bar{C} \to \bar{D} \) in \( \mathcal{E} \) satisfying \( U(\bar{e}) = e \). Since \( \lambda \) is a categorical equivalence, we can choose a vertex \( v \) of \( \mathrm{holim}(\mathcal{F}) \) and an isomorphism \( \bar{f} : \bar{C} \to \lambda(v) \in \mathcal{E} \). Let us identify \( v \) with a pair \( (C', X) \), where \( C' \) is an object of \( \mathcal{C} \) and \( X \) is a vertex of the simplicial set \( \mathcal{F}(C') \). Then \( f = U(\bar{f}) \) is an isomorphism from \( C \) to \( C' \) in the category \( \mathcal{C} \). Replacing \( v \) by the pair \( (C, \mathcal{F}(f^{-1})(X)) \), we can reduce to the case where \( C' = C \) and \( f = \text{id}_C \) so that \( \bar{f} \) is an isomorphism in the \( \infty \)-category \( \mathcal{E}_C \). In this case, we can take \( \bar{e} \) to be any composition of \( \bar{f} \) with the morphism \( \lambda(e, \text{id}_X) : \lambda(C, X) \to \lambda(D, \mathcal{F}(e)(X)) \) of \( \mathcal{E} \). This completes the proof that \( U : \mathcal{E} \to N_\bullet(\mathcal{C}) \) is an isofibration.

Using Corollary 5.3.4.18, we can choose a cocartesian fibration \( U' : \mathcal{E}' \to N_\bullet(\mathcal{C}) \) and a scaffold \( \lambda' : \mathrm{holim}(\mathcal{F}) \to \mathcal{E}' \). Then \( U' \) is an isofibration, so composition with \( \lambda \) induces a categorical equivalence \( \mathrm{Fun}_{/N_\bullet(\mathcal{C})}(\mathcal{E}, \mathcal{E}') \to \mathrm{Fun}_{/N_\bullet(\mathcal{C})}(\mathrm{holim}(\mathcal{F}), \mathcal{E}') \) (Corollary 4.5.2.28). It follows that there exists a functor \( F : \mathcal{E} \to \mathcal{E}' \) satisfying \( U' \circ F = U \) such that \( F \circ \lambda \) is isomorphic to \( \lambda' \) as an object of the \( \infty \)-category \( \mathrm{Fun}_{/N_\bullet(\mathcal{C})}(\mathrm{holim}(\mathcal{F}), \mathcal{E}') \). Since \( \lambda' \) is a categorical equivalence of simplicial sets, the morphism \( F \circ \lambda \) is also a categorical equivalence of simplicial sets (Corollary 4.5.3.9). Applying the two-out-of-three property (Remark 4.5.3.5), we deduce that \( F \) is an equivalence of \( \infty \)-categories. It follows that \( U \) is also a cocartesian fibration (Corollary 5.1.5.2) and that \( \lambda \) is a scaffold of \( U \) (Remark 5.3.4.6). \( \square \)

We close this section by recording another consequence of Theorem 5.3.5.7.

**Corollary 5.3.5.11.** Let \( \mathcal{C} \) be a category, let \( U : \mathcal{E} \to N_\bullet(\mathcal{C}) \) be a cocartesian fibration of \( \infty \)-categories, and let \( U' : \mathcal{E}' \to N_\bullet(\mathcal{C}) \) be an isofibration of \( \infty \)-categories. Then the composite
5.3. FIBRATIONS OVER ORDINARY CATEGORIES

map

\[
\begin{align*}
\text{Fun}_{/ \mathcal{N}(\mathcal{C})}(\mathcal{E}, \mathcal{E}') & \to \text{Hom}_{\text{Fun}(\mathcal{C}, \text{Set}_\Delta)}(\text{wTr}_{\mathcal{E}/\mathcal{C}}, \text{wTr}_{\mathcal{E}'/\mathcal{C}}) \\
& \to \text{Hom}_{\text{Fun}(\mathcal{C}, \text{Set}_\Delta)}(\text{sTr}_{\mathcal{E}/\mathcal{C}}, \text{wTr}_{\mathcal{E}'/\mathcal{C}})
\end{align*}
\]

is an equivalence of \(\infty\)-categories.

Proof. Using Corollary 5.3.2.23 we can identify \(\theta\) with the functor

\[
\begin{align*}
\text{Fun}_{/ \mathcal{N}(\mathcal{C})}(\mathcal{E}, \mathcal{E}') & \to \text{Fun}_{/ \mathcal{N}(\mathcal{C})}(\text{holim}(\text{sTr}_{\mathcal{E}/\mathcal{C}}), \mathcal{E}')
\end{align*}
\]

given by precomposition with the universal scaffold \(\lambda_u\). The desired result now follows by combining Corollaries 5.3.5.8 and 4.5.2.28. \(\Box\)

Corollary 5.3.5.12. Let \(\mathcal{C}\) be a category and let \(U : \mathcal{E} \to \mathcal{N}(\mathcal{C})\) and \(U' : \mathcal{E}' \to \mathcal{N}(\mathcal{C})\) be cocartesian fibrations of \(\infty\)-categories, having strict transport representations \(\text{sTr}_{\mathcal{E}/\mathcal{C}}\) and \(\text{sTr}_{\mathcal{E}'/\mathcal{C}}\), respectively. Then the tautological map

\[
\begin{align*}
\text{Fun}^{\text{CCart}}_{/ \mathcal{N}(\mathcal{C})}(\mathcal{E}, \mathcal{E}') & \to \text{Hom}_{\text{Fun}(\mathcal{C}, \text{Set}_\Delta)}(\text{sTr}_{\mathcal{E}/\mathcal{C}}, \text{sTr}_{\mathcal{E}'/\mathcal{C}})
\end{align*}
\]

is an equivalence of \(\infty\)-categories.

Proof. By virtue of Remark 5.3.4.10 we have a pullback diagram of \(\infty\)-categories

\[
\begin{align*}
\text{Fun}^{\text{CCart}}_{/ \mathcal{N}(\mathcal{C})}(\mathcal{E}, \mathcal{E}') & \to \text{Hom}_{\text{Fun}(\mathcal{C}, \text{Set}_\Delta)}(\text{sTr}_{\mathcal{E}/\mathcal{C}}, \text{sTr}_{\mathcal{E}'/\mathcal{C}}) \\
\text{Fun}_{/ \mathcal{N}(\mathcal{C})}(\mathcal{E}, \mathcal{E}') & \to \text{Hom}_{\text{Fun}(\mathcal{C}, \text{Set}_\Delta)}(\text{sTr}_{\mathcal{E}/\mathcal{C}}, \text{wTr}_{\mathcal{E}'/\mathcal{C}})
\end{align*}
\]

where the vertical maps are inclusions of replete full subcategories (and are therefore isofibrations; see Example 4.4.1.11). Since the bottom horizontal map is an equivalence of \(\infty\)-categories (Corollary 5.3.5.11), it follows that the upper horizontal map is also an equivalence of \(\infty\)-categories (Corollary 4.5.2.23). \(\Box\)

5.3.6 Application: Direct Image Fibrations

We now apply Theorem 5.3.5.7 to study the direct image construction of §4.5.9. Our starting point is the following:
Proposition 5.3.6.1. Let $U : E \to C$ be a functor of $\infty$-categories which is either a cartesian fibration or a cocartesian fibration. Then $U$ is exponentiable (in the sense of Definition 4.5.9.10). That is, if we are given any diagram of simplicial sets

$$
\begin{array}{ccc}
E'' & \xrightarrow{F} & E' \\
\downarrow & & \downarrow \\
C'' & \xrightarrow{\bar{F}} & C'
\end{array}
\xrightarrow{U}
\begin{array}{ccc}
E & \xrightarrow{F} & E \\
\downarrow & & \downarrow \\
C & \xrightarrow{\bar{F}} & C
\end{array}
$$

where both squares are pullbacks and $\bar{F}$ is a categorical equivalence, then $F$ is also a categorical equivalence.

Remark 5.3.6.2. In the statement of Proposition 5.3.6.1, the hypothesis that $C$ is an $\infty$-category is not necessary: see Corollary 5.7.7.6.

Our proof of Proposition 5.3.6.1 will require some preliminaries.

Lemma 5.3.6.3. Let $\mathcal{F} : C \to \text{Set}_\Delta$ be a diagram of simplicial sets and suppose we are given morphisms of simplicial sets $A \xrightarrow{f} B \xrightarrow{g} N_\bullet(C)$, where $f$ is inner anodyne. Then the induced map

$$
\theta_g : A \times_{N_\bullet(C)} \text{holim}(\mathcal{F}) \to B \times_{N_\bullet(C)} \text{holim}(\mathcal{F})
$$

is inner anodyne.

Proof. Let $S$ be the collection of all morphisms of simplicial sets $f : A \to B$ having the property that, for every morphism $g : B \to N_\bullet(C)$, the map $\theta_g$ is inner anodyne. It follows immediately from the definitions that $S$ is weakly saturated (in the sense of Definition 1.4.4.15). Consequently, to show that every inner anodyne morphism belongs to $S$, it will suffice to prove that $S$ contained every inner horn inclusion $f : \Lambda^a_i \to \Delta^n, 0 < i < n$. Using Remark 5.3.2.3, we can reduce to the case where $C = [n]$ and $g : \Delta^n \to N_\bullet(C)$ is the identity map. In this case, Remark 5.3.2.14 shows that $\theta_g$ is a pushout of the inclusion map $\Lambda^a_i \times \mathcal{F}(0) \hookrightarrow \Delta^n \times \mathcal{F}(0)$, which is inner anodyne by virtue of Lemma 1.4.7.5.

Lemma 5.3.6.4. Let $\mathcal{F} : C \to \text{Set}_\Delta$ be a diagram of simplicial sets, let $U : E \to N_\bullet(C)$ be a cocartesian fibration of $\infty$-categories, and let $\lambda : \text{holim}(\mathcal{F}) \to E$ be a scaffold. Then, for every morphism of simplicial sets $S \to N_\bullet(C)$, the induced map

$$
\lambda_S : S \times_{N_\bullet(C)} \text{holim}(\mathcal{F}) \to S \times_{N_\bullet(C)} E
$$

is a categorical equivalence of simplicial sets.
5.3. FIBRATIONS OVER ORDINARY CATEGORIES

Proof. By virtue of Corollary 4.5.7.3, we may assume without loss of generality that $S = \Delta^n$ is a standard simplex. Replacing $\mathcal{C}$ by the category $[n] = \{0 < 1 < \cdots < n\}$, we are reduced to proving that $\lambda$ is a categorical equivalence, which follows from Theorem 5.3.5.7.

Lemma 5.3.6.5. Suppose we are given a pullback diagram of simplicial sets

\[ \begin{array}{ccc}
\mathcal{E}' & \xrightarrow{F} & \mathcal{E} \\
\uparrow & & \uparrow \\
\mathcal{C}' & \xrightarrow{F} & \mathcal{C},
\end{array} \]

where $F$ is inner anodyne. If $U$ is either a cartesian fibration or a cocartesian fibration, then $F$ is a categorical equivalence of simplicial sets.

Proof. We will give the proof under the assumption that $U$ is a cocartesian fibration; the proof when $U$ is a cartesian fibration is similar. Let $S$ be the collection of all monomorphisms of simplicial sets $f : A \to B$ with the following property: for every morphism of simplicial sets $B \to C$, the induced map $A \times_C \mathcal{E} \to B \times_C \mathcal{E}$ is a categorical equivalence. To complete the proof, it will suffice to show that the morphism $\overline{F} : \mathcal{C}' \to \mathcal{C}$ belongs to $S$. In fact, we claim that every inner anodyne morphism of simplicial sets belongs to $S$. Using Remark 4.5.3.6, Corollary 4.5.7.2, and Remark 4.5.4.13, we see that $S$ is weakly saturated (see Definition 1.4.4.15). It will therefore suffice to show that $S$ contains every inner horn inclusion $\Lambda^n_i \to \Delta^n$, $0 < i < n$. In particular, we are reduced to proving Lemma 5.3.6.5 in the special case where $\mathcal{C} = N_\bullet(C_0)$ is the nerve of a category $C_0$. Applying Corollary 5.3.4.9, we deduce that there exists a diagram of $\infty$-categories $\mathcal{G} : C_0 \to Q\text{Cat}$ and a scaffold $\lambda : \text{holim}(\mathcal{G}) \to \mathcal{E}$. We then have a commutative diagram of simplicial sets

\[ \begin{array}{ccc}
\mathcal{C}' \times_{\text{holim}(\mathcal{G})} \overline{F} & \xrightarrow{\lambda} & \text{holim}(\mathcal{G}) \\
\downarrow & & \downarrow \\
\mathcal{E}' & \xrightarrow{F} & \mathcal{E},
\end{array} \]

where the vertical maps are categorical equivalences (Lemma 5.3.6.4). Consequently, to show that $F$ is a categorical equivalence, it will suffice to show that $\overline{F}$ is a categorical equivalence, which follows from Lemma 5.3.6.3.

Proof of Proposition 5.3.6.1 Without loss of generality we may assume that $U : \mathcal{E} \to \mathcal{C}$ is a cocartesian fibration of $\infty$-categories. Suppose we are given a commutative diagram of
where both squares are pullbacks and $\overline{F}$ is a categorical equivalence. We wish to show that $F$ is also a categorical equivalence. By virtue of Proposition 4.1.3.2, the morphism $\overline{G}$ factors as a composition $C' \xrightarrow{\overline{G}} B \xrightarrow{\overline{G}'} C$, where $\overline{G}'$ is inner anodyne and $\overline{G}''$ is an inner fibration. Note that the projection map $V : B \times_C \mathcal{E} \to B$ is a cocartesian fibration of $\infty$-categories. We may therefore replace $C$ by $B$ and thereby reduce to the special case where $\overline{G}$ is inner anodyne. In this case, the morphism $G : \mathcal{E}' \to \mathcal{E}$ is a categorical equivalence of simplicial sets (Lemma 5.3.6.5). Consequently, to show that $F$ is a categorical equivalence of simplicial sets, it will suffice to show that the composite map $(G \circ F) : \mathcal{E}'' \to \mathcal{E}$ is a categorical equivalence of simplicial sets (Remark 4.5.3.5).

Since $\overline{F}$ is a categorical equivalence and $\overline{G}$ is inner anodyne, it follows that the composite map $\overline{G} \circ \overline{F} : \mathcal{C}'' \to \mathcal{C}$ is also a categorical equivalence. Applying Proposition 4.1.3.2, we can factor $\overline{G} \circ \overline{F}$ as a composition $\mathcal{C}'' \xrightarrow{\overline{F}_0} \mathcal{C}'_0 \xrightarrow{\overline{G}_0} \mathcal{C}$, where $\overline{F}_0$ is inner anodyne and $\overline{G}_0$ is an inner fibration. Since $\mathcal{C}$ is an $\infty$-category, it follows that $\mathcal{C}'_0$ is also an $\infty$-category (Remark 4.1.1.9). Set $\mathcal{E}'_0 = \mathcal{C}'_0 \times_C \mathcal{E}$, so that we have a commutative diagram

$$
\begin{array}{ccc}
\mathcal{E}'' & \xrightarrow{F_0} & \mathcal{E}'_0 & \xrightarrow{G_0} & \mathcal{E} \\
\downarrow & & \downarrow & & \downarrow \\
\mathcal{C}'' & \xrightarrow{\overline{F}_0} & \mathcal{C}'_0 & \xrightarrow{\overline{G}_0} & \mathcal{C}
\end{array}
$$

satisfying $G \circ F = G_0 \circ F_0$. Since $U$ is an isofibration (Proposition 5.1.4.8) and $\overline{G}_0$ is an equivalence of $\infty$-categories, it follows that $G_0$ is an equivalence $\infty$-categories (Corollary 4.5.2.23). Applying Lemma 5.3.6.5 to the square on the left, we see that $F_0$ is a categorical equivalence of simplicial sets. Invoking Remark 4.5.3.5 we deduce that $G \circ F = G_0 \circ F_0$ is also a categorical equivalence, as desired.

We now formulate the main result of this section. In what follows, we assume that the reader is familiar with the direct image construction of Notation 5.3.1.10.

**Proposition 5.3.6.6.** Let $U : \mathcal{D} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets, let $V : \mathcal{E} \to \mathcal{D}$ be a cartesian fibration of simplicial sets, and let $\text{Res}_{\mathcal{D}/\mathcal{C}}(\mathcal{E})$ denote the direct
image of $\mathcal{E}$ along $U$ (see Construction 4.5.9.1). Then the projection map $\pi : \text{Res}_{D/C}(\mathcal{E}) \to \mathcal{C}$ is a cartesian fibration of simplicial sets. Moreover, an edge $e$ of $\text{Res}_{D/C}(\mathcal{E})$ is $\pi$-cartesian if and only if it satisfies the following condition:

\textbf{(*)} Form a commutative diagram

\[
\begin{array}{cccccc}
\Delta^1 \times_C \mathcal{E} & \xrightarrow{V_e} & \Delta^1 \times_C \mathcal{D} & \xrightarrow{U_e} & \Delta^1 \\
\downarrow & & \downarrow & & \downarrow \\
\mathcal{E} & \xrightarrow{V} & \mathcal{D} & \xrightarrow{U} & \mathcal{C},
\end{array}
\]

so that the edge $e$ can be identified with a morphism of simplicial sets $F_e : \Delta^1 \times_C \mathcal{D} \to \Delta^1 \times_C \mathcal{E}$ such that $V_e \circ F_e$ is the identity. Then the morphism $F_e$ carries $U_e$-cocartesian morphisms of $\Delta^1 \times_C \mathcal{D}$ to $V_e$-cartesian morphisms of $\Delta^1 \times_C \mathcal{E}$.

We will carry out the proof of Proposition 5.3.6.6 in several steps.

\textbf{Lemma 5.3.6.7.} Let $U : D \to C$ be a cocartesian fibration of simplicial sets, let $V : \mathcal{E} \to D$ be a cartesian fibration of simplicial sets, and let $e$ be an edge of the simplicial set $\text{Res}_{D/C}(\mathcal{E})$ which satisfies condition $\textbf{(*)}$ of Proposition 5.3.6.6. Then $e$ is $\pi$-cartesian, where $\pi : \text{Res}_{D/C}(\mathcal{E}) \to \mathcal{C}$ denotes the projection map.

\textbf{Proof.} Let $n \geq 2$ and suppose we are given a lifting problem

\[
\begin{array}{cccccc}
\Lambda^n & \xrightarrow{\sigma_0} & \text{Res}_{D/C}(\mathcal{E}) \\
\downarrow & & \downarrow \\
\Delta^n & \xrightarrow{\sigma} & C,
\end{array}
\]

where $\sigma_0$ carries the final edge $N_\bullet(\{n - 1 < n\}) \subseteq \Lambda^n$ to $e$; we wish to show that this lifting problem admits a solution. Replacing $U$ and $V$ with the projection maps $\Delta^n \times_C D \to \Delta^n$ and $\Delta^n \times_C \mathcal{E} \to \Delta^n \times_C \mathcal{D}$, we can assume without loss of generality that $C = \Delta^n$ is a standard simplex and that $\sigma : \Delta^n \to \mathcal{C}$ is the identity map. Set $D_0 = \Lambda^n \times \Delta^n$ and $\mathcal{E}_0 = \Lambda^n \times \Delta^n \mathcal{E}$. Invoking the universal property of the simplicial set $\text{Res}_{D/C}(\mathcal{E})$ (Proposition 4.5.9.2), we can rewrite (5.17) as a lifting problem

\[
\begin{array}{cccccc}
D_0 & \xrightarrow{F_0} & \mathcal{E} \\
\downarrow & \xRightarrow{F} & \downarrow \\
D & \xrightarrow{\text{id}_D} & D.
\end{array}
\]
Note that since the edge \( e \) satisfies condition (\(*\)), the diagram \( F_0 \) satisfies the following condition:

\((\star')\) If \( u \) is a \( U \)-cocartesian edge of \( \mathcal{D} \) lying over the final edge \( N_\bullet(\{n - 1 < n\}) \subseteq \mathcal{C} \), then \( F_0(u) \) is a \( V \)-cartesian edge of \( \mathcal{E} \).

Using Corollary 5.3.4.9, we can choose a diagram of \( \infty \)-categories \( \mathcal{F} : [n] \rightarrow \text{QCat} \) and a scaffold \( \lambda : \text{holim}(\mathcal{F}) \rightarrow \mathcal{D} \). Set \( \mathcal{D}' = \text{holim}(\mathcal{F}) \) and \( \mathcal{D}'_0 = \Delta^n_\times \Delta^w \mathcal{D}' \), so that \( \lambda \) restricts to a map \( \lambda_0 : \mathcal{D}'_0 \rightarrow \mathcal{D}_0 \). We then have a commutative diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\text{Fun}_{/\mathcal{D}}(\mathcal{D}, \mathcal{E}) & \xrightarrow{\circ \lambda} & \text{Fun}_{/\mathcal{D}}(\mathcal{D}', \mathcal{E}) \\
\downarrow & & \downarrow \\
\text{Fun}_{/\mathcal{D}}(\mathcal{D}_0, \mathcal{E}) & \xrightarrow{\circ \lambda} & \text{Fun}_{/\mathcal{D}}(\mathcal{D}'_0, \mathcal{E}).
\end{array}
\]

(5.19)

Since \( V \) is an isofibration (Proposition 5.1.4.8), the vertical maps in this diagram are isofibrations (Proposition 4.5.5.14). Since \( \lambda \) and \( \lambda_0 \) are categorical equivalences of simplicial sets (Lemma 5.3.6.4), the horizontal maps are equivalences of \( \infty \)-categories. Applying Corollary 4.5.2.26, we deduce that the upper horizontal map in the diagram (5.19) restricts to an equivalence from each fiber of the left vertical map to the corresponding fiber of the right vertical map. Consequently, we can replace (5.18) with the lifting problem

\[
\begin{array}{ccc}
\mathcal{D}'_0 & \xrightarrow{F_0 \circ G_0} & \mathcal{E} \\
\downarrow & & \downarrow V \\
\mathcal{D}' & \xrightarrow{G} & \mathcal{D}.
\end{array}
\]

(5.20)

Using Remark 5.3.2.12 we obtain a pushout square

\[
\begin{array}{ccc}
\Lambda^n_\times \mathcal{F}(0) & \xrightarrow{H_0} & \mathcal{D}'_0 \\
\downarrow & & \downarrow \\
\Delta^n_\times \mathcal{F}(0) & \xrightarrow{H} & \mathcal{D}'.
\end{array}
\]

Let us identify \( F_0 \circ G_0 \circ H_0 \) with a morphism of simplicial sets \( \tau_0 : \Lambda^n_\rightarrow \text{Fun}(\mathcal{F}(0), \mathcal{E}) \), and \( G \circ H \) with an \( n \)-simplex \( \tau \) of \( \text{Fun}(\mathcal{F}(0), \mathcal{D}) \), so that we can rewrite (5.20) again as a lifting
To show that this lifting problem admits a solution, it will suffice to show that \( \tau_0 \) carries the final edge \( N_n(\{n - 1 < n\}) \) of \( \Lambda^n_0 \) to a \( V' \)-cocartesian edge of \( \text{Fun}(\mathcal{F}(0), \mathcal{E}) \). Since \( \lambda \) is a scaffold, this follows by combining (\( \ast' \)) with the criterion of Theorem 5.2.1.1.

\[ \begin{array}{ccc}
\Lambda^n_0 & \xrightarrow{\tau_0} & \text{Fun}(\mathcal{F}(0), \mathcal{E}) \\
\downarrow & & \downarrow \\
\Delta^n & \xrightarrow{\tau} & \text{Fun}(\mathcal{F}(0), \mathcal{D}) \\
\end{array} \]

**Lemma 5.3.6.8.** Let \( U : \mathcal{D} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets and let \( V : \mathcal{E} \to \mathcal{D} \) be a cartesian fibration of simplicial sets, and let \( \pi : \text{Res}_{\mathcal{D}/\mathcal{C}}(\mathcal{E}) \to \mathcal{C} \) denote the projection map. Suppose we are given a vertex \( Y \) of the simplicial set \( \text{Res}_{\mathcal{D}/\mathcal{C}}(\mathcal{E}) \) having image \( \bar{Y} = \pi(Y) \), and an edge \( \bar{e} : \bar{X} \to \bar{Y} \) of the simplicial set \( \mathcal{C} \). Then we can write \( \bar{e} = \pi(e) \) for some edge \( e : X \to Y \) of \( \text{Res}_{\mathcal{D}/\mathcal{C}}(\mathcal{E}) \) which satisfies condition (\( \ast' \)) of Proposition 5.3.6.6.

**Proof.** As in the proof of Lemma 5.3.6.7, we may assume without loss of generality that \( \mathcal{C} = \Delta^1 \) and that \( \bar{e} \) is the nondegenerate edge of \( \mathcal{C} \). Let \( \mathcal{D}(0) \) and \( \mathcal{D}(1) \) denote the fibers of \( \mathcal{D} \) over the vertices \( X = 0 \) and \( Y = 1 \), respectively, and let us identify \( Y \) with a morphism of simplicial sets \( \mathcal{D}(1) \to \mathcal{E} \). Applying Proposition 5.2.2.8 we can choose a functor \( F : \mathcal{D}(0) \to \mathcal{D}(1) \) and a diagram

\[ \begin{array}{ccc}
\Delta^1 \times \mathcal{D}(0) & \xrightarrow{H} & \mathcal{D} \\
\downarrow & & \downarrow \mathcal{U} \\
\Delta^1 & \xrightarrow{\pi} & \mathcal{C} \\
\end{array} \]

which exhibits \( F = H|_{\{1\} \times \mathcal{D}(0)} \) as given by covariant transport along \( \bar{e} \). Applying Lemma 5.2.1.4 to the cartesian fibration \( V \), we deduce that the lifting problem

\[ \begin{array}{ccc}
\{1\} \times \mathcal{D}(0) & \xrightarrow{Y \circ F} & \mathcal{E} \\
\downarrow \mathcal{H} & & \downarrow \mathcal{V} \\
\Delta^1 \times \mathcal{D}(0) & \xrightarrow{H} & \mathcal{D} \\
\end{array} \]

admits a solution with the property that, for every object \( D \) of the \( \infty \)-category \( \mathcal{D}(0) \), the restriction \( \mathcal{H}|_{\Delta^1 \times \{D\}} \) is a \( V \)-cartesian morphism of \( \mathcal{E} \).
Let $\mathcal{D}' = (\Delta^1 \times \mathcal{D}(0)) \coprod_{\{1\} \times \mathcal{D}(0)} \mathcal{D}(1)$ denote the mapping cylinder of the functor $F$. Amalgamating $H$ with the inclusion map $\mathcal{D}(1) \to \mathcal{D}$, we obtain a morphism of simplicial sets $H' : \mathcal{D}' \to \mathcal{D}$, which is a categorical equivalence by virtue of Corollary 5.2.4.2. Amalgamating $\tilde{H}$ with $Y$, we obtain a diagram $\tilde{H}' : \mathcal{D}' \to \mathcal{E}$ satisfying $V \circ \tilde{H}' = \tilde{H}'$. We have a commutative diagram of $\infty$-categories

$$
\begin{array}{ccc}
\text{Fun}_{/\mathcal{D}}(\mathcal{D}, \mathcal{E}) & \overset{\circ G}{\longrightarrow} & \text{Fun}_{/\mathcal{D}}(\mathcal{D}', \mathcal{E}) \\
\downarrow & & \downarrow \\
\text{Fun}_{/\mathcal{D}}(\mathcal{D}(1), \mathcal{E}) & = & \text{Fun}_{/\mathcal{D}}(\mathcal{D}(1), \mathcal{E}),
\end{array}
$$

where the horizontal maps are equivalences of $\infty$-categories. Since $V$ is an isofibration (Proposition 5.1.4.8), the vertical maps in this diagram are isofibrations (Proposition 4.5.5.14). Applying Corollary 4.5.2.26, we deduce that the upper horizontal map in the diagram restricts to an equivalence of the fibers of the vertical maps over the object $Y \in \text{Fun}_{/\mathcal{D}}(\mathcal{D}(1), \mathcal{E})$. It follows that there there exists a functor $E : \mathcal{D} \to \mathcal{E}$ such that $V \circ E = \text{id}_\mathcal{D}$, $E|_{\mathcal{D}(1)} = Y$, and $E \circ G$ is isomorphic to $\tilde{H}'$ as an object of the $\infty$-category $\text{Fun}_{/\mathcal{D}}(\mathcal{D}', \mathcal{E})$. By construction, we can identify $E$ with an edge $e : X \to Y$ of $\text{Res}_{/\mathcal{C}}(\mathcal{E})$ satisfying $\pi(e) = \bar{e}$.

To complete the proof, it will suffice to show that $e$ satisfies condition $(\ast)$ of Proposition 5.3.6.6. Let $u : D \to D'$ be a $U$-cocartesian edge of $\mathcal{D}$ satisfying $\pi(u) = \bar{e}$; we wish to show that $E(u)$ is a $V$-cartesian edge of $\mathcal{E}$. By virtue of Remark 5.1.3.8, we can assume without loss of generality that $u : D \to F(D)$ is the $U$-cocartesian morphism given by the restriction $\tilde{F}|_{\Delta^1 \times (D)}$. In this case, $E(u)$ is isomorphic (as an object of the $\infty$-category $\text{Fun}(\Delta^1, \mathcal{E})$) to the $V$-cartesian morphism $\tilde{H}|_{\Delta^1 \times (D)}$, and is therefore also $V$-cartesian (Corollary 5.1.2.5). \qed

**Proof of Proposition 5.3.6.6.** Let $U : \mathcal{D} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets and let $V : \mathcal{E} \to \mathcal{D}$ be a cartesian fibration of simplicial sets. We first claim that the projection map $\pi : \text{Res}_{/\mathcal{C}}(\mathcal{E}) \to \mathcal{C}$ is an inner fibration of $\infty$-categories. To prove this, we may assume without loss of generality that $\mathcal{C} = \Delta^n$ is a standard simplex; in particular, we can assume that $\mathcal{C}$ is an $\infty$-category. In this case, $\mathcal{D}$ and $\mathcal{E}$ are also $\infty$-categories (Remark 4.1.1.9), the functor $V$ is an isofibration (Proposition 5.1.4.8), and $U$ is exponentiable (Proposition 5.3.6.1). Applying Corollary 4.5.9.18, we deduce that $\pi$ is an isofibration of simplicial sets, and therefore an inner fibration (Remark 4.5.5.7).

Let us say that an edge $e$ of $\text{Res}_{/\mathcal{C}}(\mathcal{E})$ is special if it satisfies condition $(\ast)$ of Proposition 5.3.6.6. Lemma 5.3.6.7 guarantees that every special edge of $\text{Res}_{/\mathcal{C}}(\mathcal{E})$ is $\pi$-cartesian. Moreover, if $Y$ is a vertex of $\text{Res}_{/\mathcal{C}}(\mathcal{E})$ and $e : X \to \pi(Y)$ is an edge of $\mathcal{C}$, then Lemma 5.3.6.8 guarantees that there exists a special edge $e : X \to Y$ of $\text{Res}_{/\mathcal{C}}(\mathcal{E})$ satisfying $\pi(e) = \bar{e}$. It follows that $\pi$ is a cartesian fibration of simplicial sets.
To complete the proof of Proposition 5.3.6.6, we must show that every $\pi$-cartesian edge $e : X \to Y$ of $\text{Res}_{\mathcal{D}/\mathcal{C}}(\mathcal{E})$ is special. Without loss of generality we may assume that $\mathcal{C} = \Delta^1$ and that $\pi(e)$ is the nondegenerate edge of $\mathcal{C}$, so that we can identify $e$ with a functor $E : \mathcal{D} \to \mathcal{E}$ satisfying $V \circ E = \text{id}_{\mathcal{D}}$. Using Lemma 5.3.6.8, we can choose a special edge $e' : X' \to Y$ of $\text{Res}_{\mathcal{D}/\mathcal{C}}(\mathcal{E})$ satisfying $\pi(e') = \pi(e)$, corresponding to another functor $E' : \mathcal{D} \to \mathcal{E}$. Since $e'$ is also $\pi$-cartesian, it is isomorphic to $e$ as an object of the $\infty$-category $\text{Fun}_{\Delta^1}(\Delta^1, \text{Res}_{\mathcal{D}/\mathcal{C}}(\mathcal{E}))$, so that $E'$ is isomorphic to $E$ as an object of the $\infty$-category $\text{Fun}_{\mathcal{D}}(\mathcal{D}, \mathcal{E})$. If $u$ is a $U$-cocartesian edge of $\mathcal{D}$, then $E(u)$ is isomorphic to the $V$-cartesian morphism $E'(u)$ (as an object of the $\infty$-category $\text{Fun}(\Delta^1, \mathcal{E})$), and is therefore also $V$-cartesian (Corollary 5.1.2.5).

5.3.7 Application: Path Fibrations

Recall that every morphism of Kan complexes $f : X \to Y$ admits a canonical factorization

$$X \xrightarrow{\delta} P(f) \xrightarrow{\pi} Y,$$

where $\delta$ is a homotopy equivalence and $\pi$ is the path fibration

$$P(f) = X \times_{\text{Fun}(\{0\}, Y)} \text{Fun}(\Delta^1, Y) \to \text{Fun}(\{1\}, Y) \simeq Y$$

of Example 3.1.7.9. Note that the simplicial set $P(f) = X \times_Y Y$ is an example of an oriented fiber product (Definition 4.6.4.1), which is defined for any morphism of simplicial sets $f : X \to Y$. Beware that if $X$ and $Y$ are not Kan complexes, then $\delta$ need not be a homotopy equivalence and $\pi$ need not be a Kan fibration. However, if $X = \mathcal{C}$ and $Y = \mathcal{D}$ are $\infty$-categories, then we have the following weaker statements:

(a) The functor $\delta : \mathcal{C} \to \mathcal{C} \times_{\mathcal{D}} \mathcal{D}$ is fully faithful, and its essential image is the homotopy fiber product $\mathcal{C} \times^h_{\mathcal{D}} \mathcal{D}$ of Construction 4.5.2.1 (Proposition 5.3.7.4).

(b) The functor $\pi : \mathcal{C} \times_{\mathcal{D}} \mathcal{D} \to \mathcal{D}$ is a cocartesian fibration of $\infty$-categories (Proposition 5.3.7.1).

Moreover, the oriented fiber product $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}$ can be characterized by a universal mapping property: roughly speaking, the diagonal map $\delta$ exhibits the cocartesian fibration $\pi$ as freely generated by the functor $f$ (Theorem 5.3.7.7).

Proposition 5.3.7.1. Let $F : \mathcal{C} \to \mathcal{E}$ and $G : \mathcal{D} \to \mathcal{E}$ be morphisms of simplicial sets and let $\mathcal{C} \times^h_{\mathcal{E}} \mathcal{D}$ denote the oriented fiber product of Definition 4.6.4.1, so that evaluation at the vertices $0, 1 \in \Delta^1$ determines maps

$$\mathcal{C} \xleftarrow{e^e} \mathcal{C} \times^h_{\mathcal{E}} \mathcal{D} \xrightarrow{\pi} \mathcal{D}.$$  

Then:
(1) If $\mathcal{C}$ and $\mathcal{E}$ are $\infty$-categories, then the evaluation map $\pi : \mathcal{C} \times_{\mathcal{E}} \mathcal{D} \to \mathcal{D}$ is a cocartesian fibration of simplicial sets. Moreover, an edge $e$ of the simplicial set $\mathcal{C} \times_{\mathcal{E}} \mathcal{D}$ is $\pi$-cocartesian if and only if $\pi'(e)$ is an isomorphism in the $\infty$-category $\mathcal{C}$.

(2) If $\mathcal{D}$ and $\mathcal{E}$ are $\infty$-categories, then the evaluation map $\pi' : \mathcal{C} \times_{\mathcal{E}} \mathcal{D} \to \mathcal{C}$ is a cartesian fibration of simplicial sets. Moreover, an edge $e$ of the simplicial set $\mathcal{C} \times_{\mathcal{E}} \mathcal{D}$ is $\pi'$-cartesian if and only if $\pi(e)$ is an isomorphism in the $\infty$-category $\mathcal{D}$.

Example 5.3.7.2. Let $\mathcal{C}$ be an $\infty$-category. Applying Proposition 5.3.7.1 in the case where both $F$ and $G$ are the identity functor $\text{id} : \mathcal{C} \to \mathcal{C}$, we deduce that the evaluation functor

$$\text{Fun}(\Delta^1, \mathcal{C}) \to \text{Fun}(\{0\}, \mathcal{C}) \simeq \mathcal{C}$$

is a cartesian fibration of $\infty$-categories, and the evaluation functor

$$\text{Fun}(\Delta^1, \mathcal{C}) \to \text{Fun}(\{1\}, \mathcal{C}) \simeq \mathcal{C}$$

is a cocartesian fibration of $\infty$-categories.

Proof of Proposition 5.3.7.1 We will prove assertion (1); the proof of (2) is similar. Note that the oriented fiber product $(\mathcal{C} \times_{\mathcal{E}} \mathcal{D})$ fits into a pullback diagram

$$\begin{array}{ccc}
\mathcal{C} \times_{\mathcal{E}} \mathcal{D} & \to & \mathcal{C} \times_{\mathcal{E}} \mathcal{E} \\
\pi \downarrow & & \downarrow \\
\mathcal{D} & \to & \mathcal{E}.
\end{array}$$

By virtue of Remark 5.1.4.6 we can replace $\mathcal{D}$ by $\mathcal{E}$ and thereby reduce to the case where $\mathcal{D} = \mathcal{E}$ and $G$ is the identity functor $\text{id}_\mathcal{D}$. It follows from Proposition 4.6.4.2 that the map $(\pi', \pi) : \mathcal{C} \times_{\mathcal{D}} \mathcal{D} \to \mathcal{C} \times \mathcal{D}$ is an isofibration of $\infty$-categories, so that $\pi : \mathcal{C} \times_{\mathcal{D}} \mathcal{D} \to \mathcal{D}$ is also an isofibration. Let us say that a morphism $e$ of the $\infty$-category $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}$ is special if $\pi'(e)$ is an isomorphism in the $\infty$-category $\mathcal{C}$. Proposition 5.3.7.1 is an immediate consequence of the following three assertions:

(a) For object $x$ in the $\infty$-category $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}$ and every morphism $\overline{e} : \pi(x) \to \overline{y}$ in the $\infty$-category $\mathcal{D}$, there exists a special morphism $e : x \to y$ in $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}$ satisfying $\pi(e) = \overline{e}$.

(b) Every special morphism of $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}$ is $\pi$-cocartesian.

(c) Every $\pi$-cocartesian morphism of $\mathcal{C} \times_{\mathcal{D}} \mathcal{D}$ is special.
We begin with the proof of (a). Let \( x \) be an object of the \( \infty \)-category \( \mathcal{C} \times_D \mathcal{D} \), which we identify with a triple \( (\pi', \pi, u) \) where \( \pi' = \pi'(x) \) is an object of \( \mathcal{C} \), \( \pi = \pi(x) \) is an object of \( \mathcal{D} \), and \( u : F(\pi') \to \pi \) is a morphism of \( \mathcal{D} \). Since \( \mathcal{D} \) is an \( \infty \)-category, we can choose a 2-simplex \( \sigma \) of \( \mathcal{E} \) satisfying \( d_0(\sigma) = e \) and \( d_2(\sigma) = f \). Set \( g = d_1(\sigma) \). Then the 2-simplices \( \sigma \) and \( s_0(g) \) together determine a commutative diagram

\[
\begin{array}{ccc}
F(\pi') & \xrightarrow{f} & \pi \\
\downarrow{\text{id}_{F(\pi')}} & \text{ } & \downarrow{\pi} \\
F(\pi') & \xrightarrow{g} & \pi
\end{array}
\]

in the \( \infty \)-category \( \mathcal{D} \), which we can identify with an edge \( e : x \to y \) of the \( \infty \)-category \( \mathcal{C} \times_D \mathcal{D} \) satisfying \( \pi'(e) = \text{id}_{\pi'} \) and \( \pi(e) = e \).

We now prove (b). Let \( n \geq 2 \) and suppose that we are given a lifting problem

\[
\begin{array}{ccc}
\Lambda^n_0 & \xrightarrow{\tau_0} & \mathcal{C} \times_D \mathcal{D} \\
\downarrow{\tau} & \text{ } & \downarrow{\pi} \\
\Delta^n & \xrightarrow{\pi} & \mathcal{D}
\end{array}
\]

for which the composite map

\[
\Delta^1 \simeq N_\bullet(\{0 < 1\}) \hookrightarrow \Lambda^n_0 \xrightarrow{\tau_0} \mathcal{C} \times_D \mathcal{D}
\]

is a special edge of \( \mathcal{C} \times_D \mathcal{D} \). Then \( \pi' \circ \tau_0 \) carries the initial edge of \( \Lambda^n_0 \) to an isomorphism in the \( \infty \)-category \( \mathcal{C} \), and can therefore be extended to an \( n \)-simplex \( \rho : \Delta^n \to \mathcal{C} \). Let \( X(0) \) denote the simplicial subset of \( \Delta^1 \times \Delta^n \) given by the union of \( \{0\} \times \Delta^n \), \( \{1\} \times \Delta^n \), and \( \Delta^1 \times \Lambda^n_0 \). The morphisms \( \rho \), \( \pi \), and \( \tau_0 \) can then be amalgamated to a morphism of simplicial sets \( h_0 : X(0) \to \mathcal{D} \). We wish to show that \( h_0 \) can be extended to a map \( h : \Delta^1 \times \Delta^n \to \mathcal{D} \).

Choose a filtration

\[
X(0) \subset X(1) \subset X(2) \subset \cdots \subset X(t) = \Delta^1 \times \Delta^n
\]

satisfying the requirements of Lemma \[4.4.4.7\]. We will complete the proof of (b) by showing that, for each \( s \leq t \), the morphism \( h_0 \) admits an extension \( h_s : X(s) \to \mathcal{D} \). The proof proceeds by induction on \( s \), the case \( s = 0 \) being vacuous. Let us therefore assume that \( 0 < s \leq t \) and that \( h_0 \) has already been extended to a morphism of simplicial sets \( h_{s-1} : X(s - 1) \to \mathcal{D} \).
By construction, we have a pushout diagram of simplicial sets

\[
\begin{array}{ccc}
\Lambda^q_p & \xrightarrow{\varphi} & X(s-1) \\
\downarrow & & \downarrow \\
\Delta^q & \xrightarrow{e} & X(s)
\end{array}
\]

for some \( q \geq 2 \) and \( 0 \leq p < q \). Consequently, to prove the existence of \( h_s \), it will suffice to show that \( h_{s-1} \circ \varphi \) can be extended to a \( q \)-simplex of \( D \). For \( p \neq 0 \), the existence of this extension follows from our assumption that \( D \) is an \( \infty \)-category. In the case \( p = 0 \), Lemma 4.4.4.7 guarantees that the morphism \( \varphi \) carries the initial edge of \( \Delta^q \) to the edge \((0,0) \to (0,1)\) of \( \Delta^1 \times \Delta^n \), so that \( h_{s-1} \circ \varphi \) carries the initial edge of \( \Delta^q \) to an isomorphism in \( D \). In this case, the existence of the desired extension follows from Theorem 4.4.2.6.

We now prove \((c)\). Let \( e : x \to z \) be a \( \pi \)-cocartesian morphism in the \( \infty \)-category \( \mathcal{C} \times_D \mathcal{D} \); we wish to show that \( e \) is special. By virtue of \((a)\), there exists a special morphism \( e' : x \to y \) of \( \mathcal{C} \times_D \mathcal{D} \) satisfying \( \pi(e) = \pi(e') \). It follows from \((b)\) that \( e' \) is also \( \pi \)-cocartesian. Applying Remark 5.1.3.8 we deduce that there exists a commutative diagram

in the \( \infty \)-category \( \mathcal{C} \times_D \mathcal{D} \), where \( e'' \) is an isomorphism. Then \( \pi'(e') \) and \( \pi'(e'') \) are isomorphisms in the \( \infty \)-category \( \mathcal{C} \), so that \( \pi'(e) \) is also an isomorphism in \( \mathcal{C} \) (Remark 1.3.6.3). It follows that \( e \) is a special morphism of \( \mathcal{C} \times_D \mathcal{D} \), as desired. \qed

**Corollary 5.3.7.3.** Let \( \mathcal{C} \) be an \( \infty \)-category and let \( K \) be a simplicial set. Then:

1. The restriction map \( U : \text{Fun}(K^a, \mathcal{C}) \to \text{Fun}(K, \mathcal{C}) \) is a cocartesian fibration. Moreover, a morphism \( e \) of \( \text{Fun}(K^a, \mathcal{C}) \) is \( U \)-cocartesian if and only if it carries the cone point \( 0 \in K^a \) to an isomorphism in \( \mathcal{C} \).

2. The restriction map \( V : \text{Fun}(K^o, \mathcal{C}) \to \text{Fun}(K, \mathcal{C}) \) is a cartesian fibration. Moreover, a morphism \( e \) of \( \text{Fun}(K^o, \mathcal{C}) \) is \( U \)-cartesian if and only if it carries the cone point \( 1 \in K^o \) to an isomorphism in \( \mathcal{C} \).

**Proof.** We will prove \((1)\); the proof of \((2)\) is similar. Let \( \Delta^0 \circ K \) denote the blunt join of Notation 4.5.8.3 and let \( c : \Delta^0 \circ K \to \Delta^0 \ast K = K^a \) be the categorical equivalence of
5.3. FIBRATIONS OVER ORDINARY CATEGORIES

Theorem 4.5.8.8. We have a commutative diagram of ∞-categories

\[
\begin{array}{ccc}
\text{Fun}(K^0, \mathcal{C}) & \xrightarrow{\sigma_c} & \text{Fun}(\Delta^0 \circ K, \mathcal{C}) \\
\downarrow U & & \downarrow U' \\
\text{Fun}(K, \mathcal{C}) & \xrightarrow{} & \text{Fun}(K, \mathcal{C})
\end{array}
\]

where the horizontal map is an equivalence of ∞-categories (Proposition 4.5.3.8) and the vertical maps are isofibrations (Corollary 4.4.5.3). Unwinding the definitions, we can identify Fun(Δ^0 ⋄ K, C) with the oriented fiber product \( C_\sim \times_{\text{Fun}(K, \mathcal{C})} \text{Fun}(K, \mathcal{C}) \). Under this identification, the functor \( U' \) is given by projection onto the second factor, and is therefore a cocartesian fibration (Proposition 5.3.7.1). Applying Corollary 5.1.5.2, we deduce that \( U \) is also a cocartesian fibration. Moreover, a morphism \( e \) of Fun(\( K^0, \mathcal{C} \)) is \( U \)-cocartesian if and only if its image in Fun(Δ^0 ⋄ K, C) is \( U' \)-cocartesian (Proposition 5.1.5.6). Using the criterion of Proposition 5.3.7.1, we see that this is equivalent to the requirement that \( e \) carries the cone point \( 0 \in K^0 \) to an isomorphism in \( \mathcal{C} \).

Proposition 5.3.7.4. Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of ∞-categories and let

\[
\delta : \mathcal{C} \to \mathcal{C} \times_{\mathcal{D}} \mathcal{D} = \mathcal{C} \times_{\text{Fun}(\{0\}, \mathcal{D})} \text{Fun}(\Delta^1, \mathcal{D})
\]

be map induced by the diagonal embedding \( c : \mathcal{D} \to \text{Fun}(\Delta^1, \mathcal{D}) \). Then \( \delta \) is fully faithful, and its essential image is the homotopy fiber product \( \mathcal{C} \times_{\mathcal{D}}^h \mathcal{D} \) of Construction 4.5.2.1.

Proof. Let us identify the objects of \( \mathcal{C} \times_{\mathcal{D}} \mathcal{D} \) with triples \((C, D, u)\), where \( C \) is an object of \( \mathcal{C} \), \( D \) is an object of \( \mathcal{D} \), and \( u : F(C) \to D \) is a morphism in \( \mathcal{D} \). By definition, \( \mathcal{C} \times_{\mathcal{D}}^h \mathcal{D} \) is the full subcategory of \( \mathcal{C} \times_{\mathcal{D}} \mathcal{D} \) spanned by those triples \((C, D, u)\) where \( u \) is an isomorphism in \( \mathcal{D} \). The functor \( \delta \) is given on objects by the formula \( \delta(C) = (C, F(C), \text{id}_{F(C)}) \), and therefore factors through \( \mathcal{C} \times_{\mathcal{D}}^h \mathcal{D} \). To complete the proof, it will suffice to show that the functor \( \delta : \mathcal{C} \to \mathcal{C} \times_{\mathcal{D}}^h \mathcal{D} \) is an equivalence of ∞-categories. Equivalently, we wish to show that the diagram

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{\text{id}} & \mathcal{C} \\
\downarrow F & & \downarrow F \\
\mathcal{D} & \xrightarrow{\text{id}} & \mathcal{D}
\end{array}
\]

is a categorical pullback square, which is a special case of Proposition 4.5.2.19. \( \square \)
Corollary 5.3.7.5. Let \( f : K \to D \) be a morphism of simplicial sets, where \( D \) is an \( \infty \)-category. Then \( f \) factors as a composition \( K \xrightarrow{j} C \xrightarrow{U} D \), where \( U \) is an isofibration of \( \infty \)-categories and \( j \) is both a monomorphism and a categorical equivalence.

Proof. Using Proposition 4.1.3.2, we can factor \( f \) as a composition \( K \xrightarrow{i} K \xrightarrow{F} D \), where \( i \) is inner anodyne and \( F \) is an inner fibration. Note that the simplicial set \( K \) is an \( \infty \)-category (Remark 4.1.1.9), and that \( i \) is a categorical equivalence of simplicial sets (Corollary 4.5.3.14). We may therefore replace \( f \) by \( F \), and thereby reduce to the special case where \( K = K \) is an \( \infty \)-category. Let \( C \) denote the homotopy fiber product \( K \times_{hD} D \). Then \( F \) factors as a composition \( K \xrightarrow{\delta} K \xrightarrow{U} D \), where the diagonal embedding \( \delta \) is an equivalence of \( \infty \)-categories (Proposition 5.3.7.4) and \( U \) is an isofibration (see Remark 4.5.2.2).

Remark 5.3.7.6. In the situation of Corollary 5.3.7.5, it is not necessary to assume that \( D \) is an \( \infty \)-category: every morphism of simplicial sets \( f : X \to Z \) admits a factorization \( X \xrightarrow{f'} Y \xrightarrow{f''} Z \), where \( f'' \) is an isofibration and \( f' \) both a monomorphism and a categorical equivalence (Proposition [?]). However, the proof is somewhat more difficult.

Theorem 5.3.7.7. Let \( F : C \to D \) be a functor of \( \infty \)-categories, let \( \pi : C \xleftarrow{\delta} D \to D \) be given by projection onto the second factor, let \( \delta : C \hookrightarrow C \xleftarrow{\delta} D \) be the diagonal map. For every cocartesian fibration \( U : E \to D \), precomposition with \( \delta \) induces a trivial Kan fibration of \( \infty \)-categories

\[
\text{Fun}_{/D}^{CCart}(C \xleftarrow{\delta} D, E) \to \text{Fun}_{/D}(C, E).
\]

To prove Theorem 5.3.7.7, we will need a variant of the direct image construction studied in §4.5.9.

Notation 5.3.7.8 (Cocartesian Direct Images). Let \( U : D \to C \) and \( V : E \to D \) be morphisms of simplicial sets, and let \( \text{Res}_{D/C}(E) \) be the simplicial set of Construction 4.5.9.1. Using Remark 4.5.9.8, we can identify vertices of the simplicial set \( \text{Res}_{D/C}(E) \) with pairs \((C, F)\), where \( C \) is a vertex of \( C \) and

\[
F : D_C = \{C\} \times_C D \to \{C\} \times_C E = E_C
\]

is a section of the map \( V|_{E_C} : E_C \to D_C \). If \( V \) is a cocartesian fibration, we let \( \text{Res}_{D/C}^{CCart}(E) \) denote the full simplicial subset of \( \text{Res}_{D/C}(E) \) spanned by those vertices \((C, F)\) where \( F \) carries each edge of \( D_C \) to \( V|_{E_C}\)-cocartesian edge of \( E_C \). We will refer to \( \text{Res}_{D/C}^{CCart}(E) \) as the cocartesian direct image of \( E \) along \( U \).
Remark 5.3.7.9. Let $U : D \to C$ be a morphism of simplicial sets and let $V : \mathcal{E} \to D$ be a cocartesian fibration of simplicial sets. Then the projection map $\pi : \text{Res}_{D/C}(\mathcal{E}) \to \mathcal{C}$ restricts to a projection map $\pi^{\mathbb{C} \text{cart}} : \text{Res}_{D/C}^{\mathbb{C} \text{cart}}(\mathcal{E}) \to \mathcal{C}$. Moreover, for each vertex $C \in \mathcal{C}$, the isomorphism $\{C\} \times_{\mathcal{C}} \text{Res}_{D/C}(\mathcal{E}) \simeq \text{Fun}_{D/C}(D_C, E_C)$ of Remark 4.5.9.8 restricts to an isomorphism of full subcategories $\{C\} \times_{\mathcal{C}} \text{Res}_{D/C}^{\mathbb{C} \text{cart}}(\mathcal{E}) \simeq \text{Fun}_{D/C}^{\mathbb{C} \text{cart}}(D_C, E_C)$.

Proposition 5.3.7.10. Let $V : \mathcal{E} \to D$ be a cocartesian fibration of simplicial sets, let $U : D \to C$ be a cartesian fibration of simplicial sets. Then:

1. The projection map $\pi : \text{Res}_{D/C}(\mathcal{E}) \to \mathcal{C}$ is a cocartesian fibration of simplicial sets.
2. Let $e : X \to Y$ be a $\pi$-cocartesian edge of the simplicial set $\text{Res}_{D/C}(\mathcal{E})$. If $X$ belongs to the simplicial subset $\text{Res}_{D/C}^{\mathbb{C} \text{cart}}(\mathcal{E})$, then $Y$ also belongs to the simplicial subset $\text{Res}_{D/C}^{\mathbb{C} \text{cart}}(\mathcal{E})$.
3. The morphism $\pi$ restricts to a cocartesian fibration $\pi^{\mathbb{C} \text{cart}} : \text{Res}_{D/C}^{\mathbb{C} \text{cart}}(\mathcal{E}) \to \mathcal{C}$.
4. An edge of the simplicial set $\text{Res}_{D/C}^{\mathbb{C} \text{cart}}(\mathcal{E})$ is $\pi^{\mathbb{C} \text{cart}}$-cocartesian if and only if it is $\pi$-cocartesian.

Proof. Assertion (1) follows from Proposition 5.3.6.6 (after passing to opposite simplicial sets). To prove (2), we may assume without loss of generality that $\mathcal{C} = \Delta^1$ and $\pi(e)$ is the nondegenerate edge of $\mathcal{C}$. In this case, the simplicial sets $D$ and $\mathcal{E}$ are $\infty$-categories, and we can identify the edge $e$ with a morphism of simplicial sets $f : D \to \mathcal{E}$ satisfying $V \circ f = \text{id}_D$. Let $u : D \to D'$ be a morphism in the $\infty$-category $D_1 = \{1\} \times_\mathcal{C} D$; we wish to show that $E(u)$ is a $V$-cocartesian morphism of $\mathcal{E}$. To prove this, let $G : D_1 \to D_0 = \{0\} \times_\mathcal{C} D$ be given by contravariant transport along the nondegenerate edge of $\mathcal{C}$, so that we have a commutative diagram

\[
\begin{array}{ccc}
G(D) & \longrightarrow & D \\
\downarrow G(u) & & \downarrow u \\
G(D') & \longrightarrow & D' 
\end{array}
\]

in the $\infty$-category where the horizontal maps are $U$-cartesian. Our assumption that $e$ is $\pi$-cocartesian guarantees that the functor $E$ carries $U$-cartesian morphisms of $D$ to $V$-cocartesian morphisms of $\mathcal{E}$ (Proposition 5.3.6.6). We therefore obtain a commutative
diagram

\[
\begin{array}{ccc}
(E \circ G)(D) & \longrightarrow & E(D) \\
\downarrow & & \downarrow \\
(E \circ G)(u) & \longrightarrow & E(u)
\end{array}
\]

\[
\begin{array}{ccc}
(E \circ G)(D') & \longrightarrow & E(D') \\
\downarrow & & \downarrow \\
(E \circ G)(D'') & \longrightarrow & E(u)
\end{array}
\]

where the horizontal maps are \(V\)-cocartesian. By virtue of Corollary 5.1.2.4, it will suffice to show that the morphism \((E \circ G)(u)\) is \(V\)-cocartesian, which follows from our assumption that \(X\) belongs to \(\text{Res}^{\text{CCart}}_{D/C}(E)\). This completes the proof of (2); assertions (3) and (4) then follow by applying Proposition 5.1.4.16.

In the situation of Proposition 5.3.7.10, the cocartesian direct image \(\text{Res}^{\text{CCart}}_{D/C}(E)\) can be characterized by a universal property:

**Proposition 5.3.7.11.** Let \(V : E \to D\) be a cocartesian fibration of simplicial sets and let \(U : D \to C\) be a cartesian fibration of simplicial sets. For every cocartesian fibration of simplicial sets \(W : C' \to C\), the isomorphism

\[\text{Fun}_{/C}(C', \text{Res}_{D/C}(E)) \cong \text{Fun}_{/D}(C' \times_C D, E)\]

of Remark 4.5.9.3 restricts to an isomorphism of full simplicial subsets

\[\text{Fun}^{\text{CCart}}_{/C}(C', \text{Res}^{\text{CCart}}_{D/C}(E)) \cong \text{Fun}^{\text{CCart}}_{/D}(C' \times_C D, E).\]

**Proof.** Let \(\pi : \text{Res}_{D/C}(E) \to C\) denote the projection map and let \(f : C' \to \text{Res}_{D/C}(E)\) be a morphism satisfying \(\pi \circ f = W\), corresponding to a morphism of simplicial sets \(F : C' \times_C D \to E\) for which \(V \circ F\) is given by projection to the second factor. Note that we can regard \(F\) as a vertex of the simplicial subset \(\text{Fun}^{\text{CCart}}_{/D}(C' \times_C D, E)\) if and only if it satisfies the following condition:

(a) For every edge \((e', e)\) of the fiber product \(C' \times_C D\) for which \(e'\) is a \(W\)-cocartesian edge of \(C'\), the image \(F(e', e)\) is a \(V\)-cocartesian edge of \(E\).

We wish to show that (a) is equivalent to the following pair of conditions:

(b) The morphism \(f\) factors through the full simplicial subset \(\text{Res}^{\text{CCart}}_{D/C}(E) \subseteq \text{Res}_{D/C}(E)\).

In other words, for every edge \((e', e)\) of the fiber product \(C' \times_C D\) for which \(e'\) is a degenerate edge of \(C'\), the image \(F(e', e)\) is a \(V\)-cocartesian edge of \(E\).

(c) For every \(W\)-cocartesian edge \(e'\) of \(C'\), the image \(f(e')\) is a \(\pi|_{\text{Res}^{\text{CCart}}_{D/C}(E)}\)-cocartesian edge of \(\text{Res}^{\text{CCart}}_{D/C}(E)\). By virtue of Propositions 5.3.7.10 and 5.3.6.6, this is equivalent to the assertion that for every edge \((e', e)\) of the fiber product \(C' \times_C D\) where \(e'\) is \(W\)-cocartesian and \(e\) is \(U\)-cartesian, the image \(F(e', e)\) is a \(V\)-cocartesian edge of \(E\).
The implications \((a) \Rightarrow (b)\) and \((a) \Rightarrow (c)\) are clear. For the converse, suppose that \((b)\) and \((c)\) are satisfied; we wish to prove \((a)\). Let \((e', e) : (X', X) \to (Z', Z)\) be an edge of the fiber product \(C' \times_C D\), where \(e' : X' \to Z'\) is \(W\)-cocartesian. Let \(\bar{e} = U(e) = W(e')\) denote the corresponding edge of \(C\). Since \(U\) is a cartesian fibration, there exists a \(U\)-cartesian morphism \(f : Y \to Z\) satisfying \(U(f) = \bar{e}\). Let \(\sigma\) denote the left-degenerate 2-simplex \(s_0(e')\).

Since \(f\) is \(U\)-cartesian, we can lift \(\sigma\) to a 2-simplex of \(D\) as indicated in the diagram:

\[
\begin{array}{ccc}
Y & \xleftarrow{f} & Z \\
\downarrow{e} & & \downarrow{e} \\
X & \xrightarrow{f} & Z
\end{array}
\]

Writing \(\sigma'\) for the left-degenerate 2-simplex \(s_0(e')\) of \(C'\), we obtain a 2-simplex \(\tau = F(\sigma', \sigma)\) of \(E\). It follows from assumption \((b)\) that the restriction \(\tau|_{N^\bullet(\{0 < 1\})}\) is a \(V\)-cocartesian edge of \(E\), and from assumption \((c)\) that the restriction \(\tau|_{N^\bullet(\{1 < 2\})}\) is a \(V\)-cocartesian edge of \(E\).

Applying Proposition 5.1.4.12, we conclude that \(F(e', e) = \tau|_{N^\bullet(\{0 < 2\})}\) is also a \(V\)-cocartesian edge of \(E\).

\[\square\]

**Proof of Theorem 5.3.7.7.** Let \(F : C \to D\) be a functor of \(\infty\)-categories, let \(U : E \to D\) be a cocartesian fibration of \(\infty\)-categories, and let \(\delta : C \to C \times_D D\) be the diagonal embedding. Since \(U\) is an isofibration (Proposition 5.1.4.8), the restriction map \(\overline{\theta} : \text{Fun}^\text{CCart}_{/D}(C \times_D D, E) \to \text{Fun}^\text{CCart}_{/D}(C, E)\) is also an isofibration (Corollary 4.5.5.16). Because \(\text{Fun}^\text{CCart}_{/D}(C \times_D D, E)\) is a replete full subcategory of \(\text{Fun}^\text{CCart}_{/D}(C \times_D D, E)\), it follows that \(\overline{\theta}\) restricts to an isofibration \(\theta : \text{Fun}^\text{CCart}_{/D}(C \times_D D, E) \to \text{Fun}^\text{CCart}_{/D}(C, E)\). To prove Theorem 5.3.7.7, we will show that \(\theta\) is an equivalence of \(\infty\)-categories (it is then automatically a trivial Kan fibration of simplicial sets: see Proposition 4.5.5.20).

Note that the functor \(U : E \to D\) induces cocartesian fibrations \(U' : C \times_D E \to C \times_D D\) and \(U'' : C \times_D D \to C\). Let \(\pi' : C \times_D D \to C\) be given by projection onto the first factor, so that \(\pi'\) is a cartesian fibration (Proposition 5.3.7.1). Let \(M\) denote the cocartesian direct image \(\text{Res}_{C \times_D D/\text{Fun}^\text{CCart}_{/D}(C, D)}(C \times_D E)\) and let \(T : M \to C\) be the projection map. Precomposition with the diagonal embedding \(\delta : C \to C \times_D D\) induces a restriction functor

\[\delta^* : M \to \text{Res}_{C/\text{Fun}^\text{CCart}_{/D}(C \times_D E)} = C \times_D E\]

which fits into a commutative diagram:

\[
\begin{array}{ccc}
M & \xrightarrow{\delta^*} & C \times_D E \\
\downarrow{T} & & \downarrow{U''} \\
C & & C \times_D E
\end{array}
\]
It follows from Proposition 5.3.7.10 that \( T \) is a cocartesian fibration and that \( \delta^* \) carries \( T \)-cocartesian morphisms of \( \mathcal{M} \) to \( U'' \)-cocartesian morphisms of \( \mathcal{C} \times \mathcal{D} \mathcal{E} \). Using Proposition 5.3.7.11, we can identify \( \theta \) with the map

\[
\text{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{M}) \to \text{Fun}_{/\mathcal{C}}(\mathcal{C} \times \mathcal{D} \mathcal{E}) \cong \text{Fun}_{/\mathcal{D}}(\mathcal{C}, \mathcal{E})
\]

given by postcomposition with \( \delta^* \). Consequently, to show that \( \theta \) is an equivalence of \( \infty \)-categories, it will suffice to show that \( \delta^* \) is an equivalence of cocartesian fibrations over \( \mathcal{C} \). By virtue of Proposition 5.1.6.14, this can be checked fiberwise: that is, it suffices to show that for each object \( C \in \mathcal{C} \), the induced map of fibers

\[
\delta^*_C : \{C\} \times_{\mathcal{C}} \mathcal{M} \cong \text{Fun}_{/\mathcal{D}}^{\text{Cart}}(\{C\} \times_{\mathcal{D}} \mathcal{D} \mathcal{E}) \to \{C\} \times_{\mathcal{D}} \mathcal{E}
\]

is an equivalence of \( \infty \)-categories. This is a special case of Corollary 5.3.1.22, since \( \delta(C) \) is an initial object of the \( \infty \)-category \( \{C\} \times_{\mathcal{D}} \mathcal{D} \) (Proposition 4.6.6.23).

5.4 Size Conditions on \( \infty \)-Categories

Recall that a small category \( \mathcal{C} \) consists of the following data:

- A set \( \text{Ob}(\mathcal{C}) \), whose elements are referred to as objects of \( \mathcal{C} \).
- For every pair of objects \( X, Y \in \mathcal{C} \), a set \( \text{Hom}_{\mathcal{C}}(X, Y) \), whose elements are referred to as morphisms from \( X \) to \( Y \).
- For every triple of objects \( X, Y, Z \in \mathcal{C} \), a composition law

\[
\circ : \text{Hom}_{\mathcal{C}}(Y, Z) \times \text{Hom}_{\mathcal{C}}(X, Y) \to \text{Hom}_{\mathcal{C}}(X, Z)
\]

which is required to be unital and associative.

This definition treats categories as algebraic objects akin to groups (though somewhat more general), which is perfectly adequate for many purposes. However, it is often useful to apply the theory to categories which are not small, such as the category of sets \( \mathcal{C} = \text{Set} \). In this case, \( \text{Ob}(\mathcal{C}) \) is the collection of all sets, and must be treated with a bit of care to avoid paradoxes.

**Example 5.4.0.1.** When speaking informally, it is common to say that the category \( \text{Set} \) has all limits and colimits. A more precise statement is that the category \( \text{Set} \) has all small limits and colimits; that is, every diagram \( F : \mathcal{J} \to \text{Set} \) indexed by a small category \( \mathcal{J} \) has a limit and colimit. Here the size restriction on \( \mathcal{J} \) cannot be omitted. For example, if \( \{S_j\}_{j \in J} \) is a collection of sets indexed by another set \( J \), then it is permissible to form the coproduct \( \coprod_{j \in J} S_j \). However, it is not permissible to form the coproduct \( \coprod_{S \in \text{Ob}(\text{Set})} S \) of all sets.
In the setting of higher category theory, one encounters similar issues. In §1.3, we defined an \( \infty \)-category to be a simplicial set \( C \) which satisfies a filling condition for inner horns (Definition 1.3.0.1). By analogy with the discussion above, we might be better to refer to such objects as small \( \infty \)-categories. However, we will often want to apply the ideas developed in this book to \( \infty \)-categories \( C \) which are not small, because the collections \( n \)-simplices \( C_n \) are “too big” to be sets (this situation arises, for example, if \( C \) is the nerve of a large category). For the most part, we will ignore the set-theoretic issues which are raised by allowing such objects into our discourse. However, this is not always possible: as Example 5.4.0.1 illustrates, it is sometimes important to track the distinction between “large” and “small.”

The first goal of this section is to introduce some language for quantifying the sizes of category-theoretic objects. Let \( \kappa \) be an infinite cardinal. We will say that a set is \( \kappa \)-small if its cardinality is strictly smaller than \( \kappa \) (Definition 5.4.3.1). We will say that a simplicial set \( S \) is \( \kappa \)-small if the collection of nondegenerate simplices of \( S \) is \( \kappa \)-small (Definition 5.4.4.1). We summarize the basic properties of \( \kappa \)-small sets and simplicial sets in §5.4.3 and §5.4.4, respectively. Beware that \( \kappa \)-smallness is not a homotopy invariant condition: that is, it is possible for a \( \kappa \)-small \( \infty \)-category to be equivalent to an \( \infty \)-category which is not \( \kappa \)-small. In §5.4.5, we address this point by introducing the notion of essential smallness. If \( \kappa \) is an uncountable cardinal, we say that an \( \infty \)-category \( C \) is essentially \( \kappa \)-small if it is equivalent to a \( \kappa \)-small \( \infty \)-category (Definition 5.4.5.1). One can formulate this condition also in the case \( \kappa = \aleph_0 \), but it is poorly behaved: it is very rare for finite simplicial sets to be \( \infty \)-categories (see Warning 5.4.5.6).

The second goal of this section is to provide a concrete criterion which can be used to test if an \( \infty \)-category is essentially \( \kappa \)-small. For simplicity, let us assume that \( \kappa \) is an (uncountable) regular cardinal. We say that an \( \infty \)-category \( C \) is locally \( \kappa \)-small if, for every pair of objects \( C, D \in C \), the Kan complex \( \text{Hom}_C(C, D) \) is essentially \( \kappa \)-small (Definition 5.4.8.1). In §5.4.8, we show that \( C \) is essentially \( \kappa \)-small if and only if it locally \( \kappa \)-small and the set of isomorphism classes \( \pi_0(C^\simeq) \) is \( \kappa \)-small (Proposition 5.4.8.8). We are therefore reduced to the problem of testing essential \( \kappa \)-smallness of Kan complexes. In §5.4.7, we address this problem by showing that a Kan complex \( X \) is essentially \( \kappa \)-small if and only if the set \( \pi_0(X) \) is \( \kappa \)-small and the homotopy groups \( \{ \pi_n(X, x) \}_{n \geq 0} \) are \( \kappa \)-small for every vertex \( x \in X \) (Proposition 5.4.7.1).

The proofs of Propositions 5.4.8.8 and 5.4.7.1 will use a common strategy. In both cases, the hard part is to show that if \( C \) is an \( \infty \)-category for which certain homotopy-invariant quantities are bounded in size, then \( C \) is equivalent to an \( \infty \)-category \( C_0 \) for which the collection of simplices is bounded in size. We will prove this using the theory of minimal models. We say that an \( \infty \)-category \( C_0 \) is minimal if the datum of a simplex \( \sigma : \Delta^n \to C \) is determined by its homotopy class relative to the boundary \( \partial \Delta^n \) (see Definition 5.4.6.1). In
§5.4.6 we will prove the following:

- For every $\infty$-category $\mathcal{C}$, there exists an equivalence of $\infty$-categories $\mathcal{C}_0 \to \mathcal{C}$, where $\mathcal{C}_0$ is minimal (Proposition 5.4.6.12). Moreover, $\mathcal{C}_0$ is uniquely determined up to isomorphism (Corollary 5.4.6.11).

- If $\mathcal{C}_0$ is a minimal $\infty$-category, then every equivalence of $\infty$-categories $\mathcal{C}_0 \to \mathcal{C}$ is a monomorphism of simplicial sets (Lemma 5.4.6.8). Consequently, $\mathcal{C}_0$ is essentially $\kappa$-small if and only if it is $\kappa$-small (Corollary 5.4.6.9).

**Remark 5.4.0.2.** Throughout this section, we will need some elementary properties of cardinals and cardinal arithmetic. For the reader’s convenience, we briefly review the set-theoretic prerequisites in §5.4.1 and §5.4.2.

**Remark 5.4.0.3.** The notion of minimal $\infty$-category was introduced by Joyal in [29]. In the setting of Kan complexes, the theory of minimal models is much older (see [2]).

**Remark 5.4.0.4.** Let $\kappa$ be an uncountable regular cardinal. We will see later that the essentially $\kappa$-small $\infty$-categories admit a more intrinsic characterization: they are precisely the $\kappa$-compact objects of the $\infty$-category $\mathcal{QC}$ of $\infty$-categories (see Proposition [?]).

**Remark 5.4.0.5.** Throughout this book, we will make reference to a dichotomy between “small” and “large” mathematical objects. We will generally take a somewhat informal view of this dichotomy, taking care only to avoid maneuvers which are obviously illegitimate (see Example 5.4.0.1). However, the reader who wishes to adopt a more scrupulous approach could proceed (within the framework of Zermelo-Fraenkel set theory) as follows:

- Assume the existence of an uncountable strongly inaccessible cardinal $\kappa$ (see Definition 5.4.3.20).

- Declare that an $\infty$-category $\mathcal{C}$ is small (essentially small, locally small) if it is $\kappa$-small (essentially $\kappa$-small, locally $\kappa$-small), and apply similar conventions to other mathematical objects of interest (such as sets and categories).

### 5.4.1 Ordinals and Well-Orderings

In this section, we review some standard facts about ordinals and well-ordered sets.

**Definition 5.4.1.1.** Let $(S, \leq)$ be a partially ordered set. We say that $(S, \leq)$ is well-founded if every nonempty subset $S_0 \subseteq S$ contains a minimal element: that is, an element $s \in S_0$ for which the set $\{t \in S_0 : t < s\}$ is empty.

**Exercise 5.4.1.2.** Let $(S, \leq)$ be a partially ordered set. Show that the following conditions are equivalent:
5.4. SIZE CONDITIONS ON $\infty$-CATEGORIES

(1) The partial order $\leq$ is well-founded: that is, every nonempty subset of $S$ contains a minimal element.

(2) The set $Q$ does not contain an infinite descending sequence $s_0 > s_1 > s_2 > \cdots$.

Example 5.4.1.3. Every finite partially ordered set $(S, \leq)$ is well-founded.

Example 5.4.1.4. Let $S$ be any set, and let $\leq$ be the discrete partial ordering of $S$: that is, we have $s \leq t$ if and only if $s = t$. Then $(S, \leq)$ is well-founded.

Remark 5.4.1.5. Let $(S, \leq)$ be a well-founded partially ordered set. Then every subset $S_0 \subseteq S$ is also well-founded (when endowed with the partial order given by the restriction of $\leq$).

Definition 5.4.1.6. Let $(S, \leq)$ be a linearly ordered set. We say that $(S, \leq)$ is well-ordered if it is well-founded when regarded as a partially ordered set: that is, if every nonempty subset $S_0 \subseteq S$ contains a smallest element. In this case, we will refer to the relation $\leq$ as a well-ordering of the set $S$.

Definition 5.4.1.7 (Ordinals). An ordinal is an isomorphism class of well-ordered sets. If $(S, \leq)$ is a well-ordered set, then its isomorphism class is an ordinal which we will refer to as the order type of $S$.

Notation 5.4.1.8. We will typically use lower-case Greek letters to denote ordinals.

Example 5.4.1.9 (Finite Ordinals). Let $n$ be a nonnegative integer. Up to isomorphism, there is a unique linearly ordered set $S$ having exactly $n$ elements, which we can identify with the set $\{0 < 1 < \cdots < n-1\}$. We will abuse notation by identifying $n$ with the order type of the linearly ordered set $S$. By means of this convention, we can view every nonnegative integer as an ordinal. We say that an ordinal $\alpha$ is finite if it arises in this way (that is, if it is the order type of a finite linearly ordered set), and infinite if it does not.

Example 5.4.1.10. The set of nonnegative integers $\mathbb{Z}_{\geq 0} = \{0 < 1 < 2 < \cdots\}$ is well-ordered (with respect to its usual ordering). Its order type is an infinite ordinal, which we denote by $\omega$.

By definition, well-ordered sets $(S, \leq)$ and $(T, \leq)$ have the same order type if there is an order-preserving bijection $f : S \to T$. We will show in a moment that in this case, the bijection $f$ is uniquely determined (Corollary 5.4.1.12). First, let us introduce a bit of additional terminology.

Definition 5.4.1.11. Let $(S, \leq)$ be a linearly ordered set. We say that a subset $S_0 \subseteq S$ is an initial segment if it is closed downwards: that is, for every pair of elements $s \leq s'$ of $S$, if $s'$ is contained in $S_0$, then $s$ is also contained in $S_0$. If $(T, \leq)$ is another linearly ordered set, we say that a function $f : S \hookrightarrow T$ is an initial segment embedding if it is an isomorphism (of linearly ordered sets) from $S$ to an initial segment of $T$. 
Example 5.4.1.12. Let \((S, \leq)\) be a linearly ordered set. Then the identity morphism \(\text{id}_S : S \xrightarrow{\sim} S\) is an initial segment embedding.

**Remark 5.4.1.13** (Transitivity). Let \((R, \leq), (S, \leq),\) and \((T, \leq)\) be linearly ordered sets. Suppose that \(f : R \hookrightarrow S\) and \(g : S \hookrightarrow T\) are initial segment embeddings. Then the composition \((g \circ f) : R \hookrightarrow T\) is also an initial segment embedding.

**Proposition 5.4.1.14.** Let \((S, \leq)\) and \((T, \leq)\) be linearly ordered sets, and let \(f, f' : S \hookrightarrow T\) be strictly increasing functions. Suppose that \(S\) is well-ordered and that \(f\) is an initial segment embedding. Then, for each \(s \in S\), we have \(f(s) \leq f'(s)\).

**Proof.** Set \(S_0 = \{s \in S : f'(s) < f(s)\}\). We wish to show that \(S_0\) is empty. Assume otherwise. Since \(S\) is well-ordered, there is a least element \(s \in S_0\). Since \(f\) is an initial segment embedding, the inequality \(f'(s) < f(s)\) implies that we can write \(f'(s) = f(t)\) for some \(t < s\). Then \(t \notin S_0\), so we must have \(f(t) \leq f'(t)\). It follows that \(f'(s) \leq f'(t)\), contradicting our assumption that the function \(f'\) is strictly increasing.

**Corollary 5.4.1.15** (Rigidity). Let \((S, \leq)\) and \((T, \leq)\) be linearly ordered sets, and let \(f, f' : S \hookrightarrow T\) be initial segment embeddings. If \(S\) is well-ordered, then \(f = f'\).

**Corollary 5.4.1.16.** Let \((S, \leq)\) and \((T, \leq)\) be well-ordered sets. If there exists an order-preserving bijection \(f : S \xrightarrow{\sim} T\), then \(f\) is unique.

**Corollary 5.4.1.17.** Let \((S, \leq)\) and \((T, \leq)\) be well-ordered sets. Then one of the following conditions is satisfied:

1. There exists an initial segment embedding \(f : S \hookrightarrow T\).

2. There exists an initial segment embedding \(g : T \hookrightarrow S\).

**Proof.** For each element \(s \in S\), let \(S_{\leq s}\) denote the initial segment \(\{s' \in S : s' \leq s\}\). Let \(S_0 \subseteq S\) denote the collection of elements \(s \in S\) for which there exists an initial segment embedding \(f_{\leq s} : S_{\leq s} \hookrightarrow T\). Note that, if this condition is satisfied, then the morphism \(f_{\leq s}\) is uniquely determined (Corollary 5.4.1.15). Moreover, if \(s' \leq s\), then composite map \(S_{\leq s'} \subseteq S_{\leq s} \xrightarrow{f_{\leq s}} T\) is also an initial segment embedding; it follows that \(s'\) belongs to \(S_0\), and \(f|_{S_{\leq s'}}\) is the restriction of \(f|_{S_{\leq s}}\) to \(S_{\leq s'}\). Consequently, the construction \(s \mapsto f_s(s)\) determines a function \(f : S_0 \to T\), which is an isomorphism of \(S_0\) with an initial segment \(T_0 \subseteq T\). If \(S_0 = S\), then \(f\) is an initial segment embedding from \(S\) to \(T\). If \(T_0 = T\), then \(g = f^{-1}\) is an initial segment embedding from \(T\) to \(S\). Assume that neither of these conditions is satisfied: that is, the sets \(S \setminus S_0\) and \(T \setminus T_0\) are both nonempty. Let \(s\) be a least element of \(S \setminus S_0\), and let \(t\) be a least element of \(T \setminus T_0\). Then \(f\) extends uniquely to an initial segment embedding

\[
    f_{\leq s} : S_{\leq s} = S_0 \cup \{s\} \xrightarrow{\sim} T_0 \cup \{t\} \subseteq T, \quad s \mapsto t.
\]

The existence of \(f_{\leq s}\) shows that \(s\) belongs to \(S_0\), which is a contradiction.
Remark 5.4.1.18. In the situation of Corollary 5.4.1.17, suppose that conditions (1) and (2) are both satisfied: that is, there exist initial segment embeddings \( f : S \to T \) and \( g : T \to S \). Then \( g \circ f \) is an initial segment embedding of \( S \) into itself, and therefore coincides with \( \text{id}_S \) (Corollary 5.4.1.16). The same argument shows that \( f \circ g = \text{id}_T \), so that \( f \) and \( g \) are mutually inverse bijections. In particular, \( S \) and \( T \) have the same order type.

Definition 5.4.1.19. Let \( \alpha \) and \( \beta \) be ordinals, given by the order types of well-ordered sets \( (S, \leq) \) and \( (T, \leq) \). We write \( \alpha \leq \beta \) if there exists an initial segment embedding from \( (S, \leq) \) to \( (T, \leq) \) (note that this condition depends only on the order types of \( S \) and \( T \)).

Proposition 5.4.1.20. The relation \( \leq \) of Definition 5.4.1.19 determines a linear ordering on the collection of ordinals.

Proof. The reflexivity of the relation \( \leq \) follows from Example 5.4.1.12, and the transitivity follows from Remark 5.4.1.13. Let \( \alpha \) and \( \beta \) be ordinals, which we identify with the order types of well-ordered sets \( (S, \leq) \) and \( (T, \leq) \), respectively. Invoking Corollary 5.4.1.17, we deduce that \( \alpha \leq \beta \) or \( \beta \leq \alpha \). Moreover, if both conditions are satisfied, then Remark 5.4.1.18 shows that \( \alpha = \beta \).

Remark 5.4.1.21. Let \( (S, \leq) \) and \( (T, \leq) \) be well-ordered sets. The following conditions are equivalent:

1. There exists an initial segment embedding \( f : S \to T \).
2. There exists a strictly increasing function \( f : S \to T \).

The implication (1) \( \Rightarrow \) (2) is immediate from the definitions. To prove the converse, let \( f : S \to T \) be a strictly increasing function, and suppose that there is no initial segment embedding from \( S \) to \( T \). Invoking Corollary 5.4.1.17, we deduce that there is an initial segment embedding \( g : T \to S \). The composition \( (g \circ f) : S \to S \) is strictly increasing, and therefore satisfies \( (g \circ f)(s) \geq s \) for each \( s \in S \) (Proposition 5.4.1.14). Since the image of \( g \) is an initial segment \( S_0 \subseteq S \), it follows that \( S_0 = S \), so that \( g^{-1} : S \Rightarrow T \) is an isomorphism of linearly ordered sets.

We now show that, for every ordinal \( \alpha \), there is a preferred candidate for a well-ordered set of order type \( \alpha \): namely, the collection \( \text{Ord}_{<\alpha} \) of ordinals smaller than \( \alpha \).

Proposition 5.4.1.22. Let \( (S, \leq) \) be a well-ordered set, and let \( \alpha \) denote its order type. Then there is a unique order-preserving bijection \( S \to \text{Ord}_{<\alpha} \), which carries each element \( s \in S \) to the order type of the well-ordered set \( S_{<s} = \{ s' \in S : s' < s \} \).

Proof. We will prove existence; uniqueness then follows from Corollary 5.4.1.16. For each \( s \in S \), let \( \alpha_s \) denote the order type of the set \( S_{<s} \) (which is well-ordered, by virtue of Remark
Note that, since there is an initial segment embedding $S_{<s} \hookrightarrow S$ which is not bijective, we must have $\alpha_s < \alpha$ (Remark 5.4.1.18). Consequently, the construction $s \mapsto \alpha_s$ determines a function $S \rightarrow \text{Ord}_{<\alpha}$. If $s < t$ in $S$, then there is an initial segment embedding from $S_{<s}$ to $S_{<t}$ which is not bijective, so that $\alpha_s < \alpha_t$ (again by Remark 5.4.1.18). To complete the proof, it will suffice to show that the function $s \mapsto \alpha_s$ is surjective. Let $\beta$ be an ordinal which is strictly smaller than $\alpha$. Then $\beta$ is the order type of some initial segment $S_0 \subseteq S$. Since $S$ is well-ordered, the set $S \setminus S_0$ has a smallest element $s$. It follows that $S_0 = S_{<s}$, so that $\beta = \alpha_s$.

**Corollary 5.4.1.23.** For every ordinal $\alpha$, $\text{Ord}_{<\alpha}$ is a well-ordered set of order type $\alpha$.

**Corollary 5.4.1.24.** Let $S$ be any nonempty collection of ordinals. Then $S$ has a least element.

*Proof.* Choose an ordinal $\alpha \in S$. If $\alpha$ is a least element of $S$, then we are done. Otherwise, we can replace $S$ by the nonempty subset $S_{<\alpha} = \{ \beta \in S : \beta < \alpha \}$. Note that $S_{<\alpha}$ is a nonempty subset $\text{Ord}_{<\alpha}$, and therefore has a smallest element by virtue of Corollary 5.4.1.23.

**Warning 5.4.1.25** (The Burali-Forti Paradox). One can informally summarize Corollary 5.4.1.24 by saying that the collection $\text{Ord}$ of all ordinals is well-ordered (with respect to the order relation of Definition 5.4.1.19). Beware that one must treat this statement with some care to avoid paradoxes. The proof of Proposition 5.4.1.22 shows that the order type of $\text{Ord}$ is strictly larger than $\alpha$, for each ordinal $\alpha \in \text{Ord}$. This paradox has a standard remedy: we regard the collection $\text{Ord}$ as “too large” to form a set (so that its order type is not regarded as an ordinal).

**Definition 5.4.1.26.** Let $(S, \leq)$ and $(T, \leq)$ be linearly ordered sets. We say that a function $f : S \rightarrow T$ is cofinal if it is nondecreasing and, for every element $t \in T$, there exists an element $s \in S$ satisfying $f(s) \geq t$.

**Proposition 5.4.1.27.** Let $(T, \leq)$ be a linearly ordered set. There exists a well-ordered subset $S \subseteq T$ for which the inclusion map $S \hookrightarrow T$ is cofinal.

*Proof.* Let $\{ S_q \}_{q \in Q}$ be the collection of all well-ordered subsets of $T$. We regard $Q$ as a partially ordered set, where $q \leq q'$ if the set $S_q$ is an initial segment of $S_{q'}$. This partial ordering satisfies the hypotheses of Zorn’s lemma, and therefore contains a maximal element $S_{\text{max}}$. To complete the proof, it will suffice to show that the inclusion $S_{\text{max}} \hookrightarrow T$ is cofinal. Assume otherwise: then there exists an element $t \in T$ satisfying $s < t$ for each $s \in S_{\text{max}}$. Then $S_{\text{max}}$ is an initial segment of the well-ordered subset $S_{\text{max}} \cup \{ t \} \subseteq T$, contradicting the maximality of $S_{\text{max}}$. 

\[ \square \]
**Definition 5.4.1.28** (Cofinality). Let \((T, \leq)\) be a linearly ordered set. We let \(\text{cf}(T)\) denote the smallest ordinal \(\alpha\) for which there exists a well-ordered set \((S, \leq)\) of order type \(\alpha\) and a cofinal function \(f : S \to T\). We refer to \(\text{cf}(T)\) as the *cofinality* of the linearly ordered set \(T\).

If \(\beta\) is an ordinal, let \(\text{cf}(\beta)\) denote the cofinality \(\text{cf}(T)\), where \((T, \leq)\) is any well-ordered set of order type \(\beta\). We refer to \(\text{cf}(\beta)\) as the cofinality of \(\beta\).

**Remark 5.4.1.29.** For any linearly ordered set \((T, \leq)\), the identity map \(\text{id} : T \to T\) is cofinal. Consequently, if \(T\) is a well-ordered set of order type \(\alpha\), then we have \(\text{cf}(\alpha) = \text{cf}(T) \leq \alpha\). Beware that the inequality is often strict.

**Example 5.4.1.30.** Let \((T, \leq)\) be a linearly ordered set. Then \(\text{cf}(T) = 0\) if and only if \(T\) is empty.

**Example 5.4.1.31.** Let \((T, \leq)\) be a nonempty linearly ordered set. The following conditions are equivalent:

- The cofinality \(\text{cf}(T)\) is a positive integer.
- The cofinality \(\text{cf}(T)\) is equal to 1.
- The linearly ordered set \(T\) contains a largest element.

**Example 5.4.1.32.** Let \((T, \leq)\) be a linearly ordered sets. Then the cofinality \(\text{cf}(T)\) is equal to \(\omega\) if and only if \(T\) contains an unbounded increasing sequence \(\{t_0 < t_1 < t_2 < \cdots\}\).

**Proposition 5.4.1.33.** Let \((T, \leq)\) be a linearly ordered set. Then the cofinality \(\text{cf}(T)\) is the smallest ordinal with the following property:

\((*)\) There exists a well-ordered set \((S, \leq)\) of order type \(\alpha\) and a function \(f : S \to T\) which is unbounded (that is, every element \(t \in T\) satisfies \(t \leq f(s)\) for some \(s \in S\)). Here we do not require \(f\) to be nondecreasing.

*Proof.* It is clear that the cofinality \(\text{cf}(T)\) satisfies condition \((*)\). For the converse, assume that \((S, \leq)\) is a well-ordered set of order type \(\alpha\) and that \(f : S \to T\) is an unbounded function. Let us say that an element \(s \in S\) is *good* if, for every element \(s' < s\) of \(S\), we have \(f(s') < f(s)\). Let \(S_0\) be the collection of good elements of \(S\), and set \(f_0 = f|_{S_0}\). By construction, the function \(f_0\) is strictly increasing. Moreover, the order type of \(S_0\) is \(\leq \alpha\) (Remark 5.4.1.21). To complete the proof, it will suffice to show that \(f_0 : S_0 \hookrightarrow T\) is cofinal. Fix an element \(t \in T\), and set \(S_{\geq t} = \{s \in S : t \leq f(s)\}\). We wish to show that the intersection \(S_{\geq t} \cap S_0\) is nonempty. We first observe that \(S_{\geq t}\) is nonempty (by virtue of our assumption that \(f\) is unbounded). Since \((S, \leq)\) is well-ordered, the set \(S_{\geq t}\) contains a least element \(s\). We claim that \(s\) belongs to \(S_0\). Assume otherwise: then there exists some \(s' < s\) satisfying \(f(s') \geq f(s)\). It follows that \(s'\) belongs to \(S_{\geq t}\), contradicting the minimality of \(s\). \[\square\]
We conclude this section by observing that well-orderings exist in abundance.

**Theorem 5.4.1.34 (The Well-Ordering Theorem).** Every set $S$ admits a well-ordering.

By virtue of Example 5.4.1.4, Theorem 5.4.1.34 is a special case of the following more refined result:

**Proposition 5.4.1.35.** Let $(S, \preceq)$ be a well-founded partially ordered set. Then there exists a well-ordering $\leq$ on $S$ which refines $\preceq$ in the following sense: for every pair of elements $s, t \in S$ satisfying $s \preceq t$, we also have $s \leq t$.

**Proof.** Let $Q$ denote the set of ordered pairs $(T, \leq_T)$, where $T$ is a subset of $S$ which is closed downward with respect to $\preceq$ and $\leq_T$ is a well-ordering of $T$ which refines $\preceq$. We regard $Q$ as a partially ordered set, where $(T, \leq_T) \leq (T', \leq_{T'})$ if $T$ is an initial segment of $T'$ (with respect to the ordering $\leq_{T'}$), and the ordering $\leq_T$ coincides with the restriction of $\leq_{T'}$. The partially ordered set $Q$ satisfies the hypotheses of Zorn’s lemma, and therefore contains a maximal element $(T_{\text{max}}, \leq_{T_{\text{max}}})$. To complete the proof, it will suffice to show that $T_{\text{max}} = S$. Suppose otherwise. Then the set $S \setminus T_{\text{max}}$ is nonempty, and therefore contains an element $s$ which is minimal with respect to the ordering $\preceq$. Set $T' = T_{\text{max}} \cup \{s\}$, and extend $\leq_{T_{\text{max}}}$ to a linear ordering $\leq_{T'}$ on $T'$ by declaring $s$ to be a largest element. Then $(T', \leq_{T'})$ is an element of $Q$, contradicting the maximality of the pair $(T_{\text{max}}, \leq_{T_{\text{max}}})$.

## 5.4.2 Cardinals and Cardinality

Let $S$ and $T$ be sets. We say that $S$ and $T$ have the same cardinality if there exists a bijection $S \sim T$. This is an equivalence relation on the collection of sets, whose equivalence classes are called **cardinals**. Following a standard convention in set theory, it will be convenient to view a cardinal as a special type of ordinal.

**Definition 5.4.2.1.** Let $S$ be a set. We let $|S|$ denote the smallest ordinal $\alpha$ for which there exists a well-ordering of $S$ having order type $\alpha$. We will refer to $|S|$ as the **cardinality** of the set $S$. A **cardinal** is an ordinal $\kappa$ which has the form $|S|$, for some set $S$.

**Remark 5.4.2.2.** Let $S$ be a set, and let $A$ be the collection of all ordinals which arise as the order types of well-orderings on $S$. The collection $A$ is nonempty (Theorem 5.4.1.34), and therefore contains a smallest element (Corollary 5.4.1.24). It follows that the cardinality $|S|$ is well-defined.

**Proposition 5.4.2.3.** Let $S$ and $T$ be sets. Then $|S| \leq |T|$ if and only if there exists a monomorphism $f : S \hookrightarrow T$.

**Proof.** Choose well-orderings $(S, \leq_S)$ and $(T, \leq_T)$ having order types $|S|$ and $|T|$, respectively. If $|S| \leq |T|$, then there is an isomorphism of $(S, \leq_S)$ with an initial segment of $(T, \leq_T)$; this
isomorphism in particular gives a monomorphism of sets $S \hookrightarrow T$. For the converse, suppose that there exists a monomorphism $f : S \rightarrow T$. Then there is a unique linear ordering $\leq'_S$ on the set $S$ for which $f$ defines a strictly increasing function $(S, \leq'_S) \rightarrow (T, \leq_T)$. Then $\leq'_S$ is a well-ordering (Remark 5.4.1.5); let $\alpha$ denote its order type. We then have $|S| \leq \alpha \leq |T|$, where the second inequality follows from Remark 5.4.1.21.

**Corollary 5.4.2.4.** Let $S$ and $T$ be sets. Then $S$ and $T$ have the same cardinality if and only if there exists a bijection $S \sim T$.

*Proof.* Choose well-orderings $(S, \leq_S)$ and $(T, \leq_T)$ having order types $|S|$ and $|T|$, respectively. If $|S| = |T|$, then there is an isomorphism of linearly ordered sets $(S, \leq_S) \simeq (T, \leq_T)$, and therefore a bijection $S \sim T$. The converse follows from Proposition 5.4.2.3.

**Corollary 5.4.2.5.** Let $(S, \leq)$ be a well-ordered set of order type $\alpha$. Then the cardinality $\kappa = |S|$ is the largest cardinal which satisfies $\kappa \leq \alpha$.

*Proof.* The inequality $\kappa \leq \alpha$ follows immediately from the definition of $|S|$. Let $\lambda$ be another cardinal satisfying $\lambda \leq \alpha$. Then $\lambda$ is the order type of an initial segment $S_0 \subseteq S$, so we have $\lambda = |S_0| \leq |S| = \kappa$.

**Remark 5.4.2.6.** Let $\kappa$ be an ordinal. The following conditions are equivalent:

1. The ordinal $\kappa$ is a cardinal. That is, there exists a set $S$ such that $\kappa = |S|$.
2. For every well-ordered set $(S, \leq)$ of order type $\kappa$, we have $\kappa = |S|$.
3. The set of ordinals $\text{Ord}_{<\kappa}$ has cardinality $\kappa$.

See Corollary 5.4.1.23.

**Example 5.4.2.7** (Finite Cardinals). Let $n$ be a nonnegative integer. Then a set $S$ has cardinality $n$ (in the sense of Definition 5.4.2.1) if and only if it has exactly $n$ elements: that is, there exists a set $S \simeq \{0 < 1 < \cdots < n - 1\}$. In particular, $n$ is a cardinal. We will say that a cardinal $\kappa$ is *finite* if it arises in this way (that is, if it is the cardinality of a finite set); otherwise, we say that $\kappa$ is *infinite*.

**Proposition 5.4.2.8** (Cantor’s Diagonal Argument). Let $S$ be a set, and let $P(S)$ denote the collection of all subsets of $S$. Then $|S| < |P(S)|$.

*Proof.* The construction $s \mapsto \{s\}$ determines an injection from $S$ to $P(S)$, which shows that $|S| \leq |P(S)|$. To show that the inequality is strict, it suffices to observe that no function $f : S \rightarrow P(S)$ can be surjective, since the set $T = \{s \in S : s \notin f(s)\}$ is an element of $P(S)$ which does not belong to the image of $f$. 

\[\square\]
CHAPTER 5. FIBRATIONS OF $\infty$-CATEGORIES

Remark 5.4.2.9. The collection of cardinals is well-ordered. That is, if $S$ is any nonempty collection of cardinals, then $S$ contains a smallest element (see Corollary 5.4.1.24).

Example 5.4.2.10 (The First Infinite Cardinal). We let $\aleph_0$ denote the smallest infinite cardinal. Alternatively, $\aleph_0$ can be defined as the ordinal $\omega$ of Example 5.4.1.10 (the order type of the linearly ordered set $\{0 < 1 < 2 < \cdots\}$). A set $S$ has cardinality $\aleph_0$ if and only if it is countably infinite.

Example 5.4.2.11 (Successor Cardinals). Let $\kappa$ be a cardinal. Proposition 5.4.2.8 implies that there exists another cardinal $\lambda$ such that $\kappa < \lambda$. By virtue of Remark 5.4.2.9, there is a smallest cardinal with this property. We denote this cardinal by $\kappa^+$ and refer to it as the successor of $\kappa$.

Example 5.4.2.12 (The First Uncountable Cardinal). We say that a cardinal $\kappa$ is uncountable if it is strictly larger than $\aleph_0$. By virtue of Remark 5.4.2.9, there is a smallest uncountable cardinal, which we denote by $\aleph_1$. In other words, $\aleph_1$ is the successor cardinal $\aleph_0^+$.

Remark 5.4.2.13 (The Continuum Hypothesis). Let $\mathbb{R}$ be the set of real numbers. Then $|\mathbb{R}|$ is an uncountable cardinal (it is also the cardinality of the power set $P(\mathbb{Z})$). The continuum hypothesis is the assertion that $|\mathbb{R}|$ coincides with the smallest uncountable cardinal $\aleph_1$. This was a central question in the early days of set theory (and first of Hilbert’s celebrated list of problems for the mathematics of the 20th century). It is now known to be neither provable nor disprovable from the axioms of Zermelo-Fraenkel set theory (assuming that they are consistent), thanks to the work of Gödel ([25]) and Cohen ([8], [9]).

Proposition 5.4.2.14. Let $(T, \leq)$ be a linearly ordered set and let $\kappa = \text{cf}(T)$ be its cofinality (Definition 5.4.1.28). Then $\kappa$ is a cardinal.

Proof. Choose a well-ordered set $(S, \leq)$ of order type $\kappa$ and a cofinal function $f : S \to T$. If $\kappa$ is not a cardinal, then we can choose another well-ordering $\leq'$ of $S$ having order type $\alpha < \kappa$. Applying Proposition 5.4.1.33 we obtain $\text{cf}(T) \leq \alpha < \kappa$, which is a contradiction.

5.4.3 Smallness of Sets

We now introduce some terminology which will be useful for measuring the sizes of various mathematical objects.

Definition 5.4.3.1. Let $\kappa$ be a cardinal. We say that a set $S$ is $\kappa$-small if the cardinality $|S|$ is strictly smaller than $\kappa$.

Example 5.4.3.2. Let $\aleph_0$ denote the first infinite cardinal (Example 5.4.2.10). Then a set $S$ is $\aleph_0$-small if and only if it is finite.
Example 5.4.3.3. Let $\aleph_1$ denote the first uncountable cardinal (Example 5.4.2.12). Then a set $S$ is $\aleph_1$-small if and only if it is countable.

Remark 5.4.3.4. Let $\kappa$ be a cardinal and let $T$ be a $\kappa$-small set. Then:

- Any subset of $T$ is also $\kappa$-small (see Proposition 5.4.2.3).
- The set $T$ is $\lambda$-small for every cardinal $\lambda \geq \kappa$.
- For every surjective morphism of sets $T \to S$, the set $S$ is also $\kappa$-small.

Proposition 5.4.3.5. Let $\kappa$ be an infinite cardinal. Then the collection of $\kappa$-small sets is closed under finite products.

Proof. We first note that the collection of finite sets is closed under finite products. It will therefore suffice to show that, for every infinite cardinal $\lambda$, the following condition is satisfied:

$(*)_\lambda$ If $S$ and $T$ are sets of cardinality $\leq \lambda$, then the product $S \times T$ has cardinality $\leq \lambda$.

By virtue of Remark 5.4.2.9 we may assume that condition $(*)_\mu$ is satisfied for every cardinal $\mu < \lambda$. Without loss of generality, we may assume that $S = \text{Ord}_{<\lambda} = T$, where $\text{Ord}_{<\lambda}$ denotes the collection of ordinals smaller than $\lambda$. Given a pair of elements $(\alpha, \beta), (\alpha', \beta') \in S \times T$, let us write $(\alpha', \beta') \preceq (\alpha, \beta)$ if either $\max(\alpha', \beta') < \max(\alpha, \beta)$, or $\max(\alpha', \beta') = \max(\alpha, \beta)$ and $\alpha' < \alpha$, or $\max(\alpha', \beta') = \max(\alpha, \beta)$ and $\alpha' = \alpha$ and $\beta' \leq \beta$. The relation $\preceq$ defines a well-ordering of the set $S \times T$. To prove $(*)_\lambda$, it will suffice to show this well ordering has order type $\leq \lambda$. Assume otherwise. Then there exists an element $(\alpha, \beta) \in S \times T$ such that $\lambda$ is the order type of the initial segment $K = \{(\alpha', \beta') \in S \times T : (\alpha', \beta') \prec (\alpha, \beta)\}$. Note that $K$ is a subset of the product $\text{Ord}_{<\alpha} \times \text{Ord}_{<\beta}$. Our inductive hypothesis guarantees that $K$ has cardinality $< \lambda$, contradicting Corollary 5.4.2.5.

Corollary 5.4.3.6. Let $\kappa$ be an infinite cardinal. Then the collection of $\kappa$-small sets is closed under finite coproducts.

Proof. Let $\{S_i\}_{i \in I}$ be a finite collection of $\kappa$-small sets. Then the disjoint union $\coprod_{i \in I} S_i$ can be identified with a subset of the product $\prod_{i \in I} (S_i \coprod \{i\})$, which is $\kappa$-small by virtue of Proposition 5.4.3.5.

We will need the following generalization of Corollary 5.4.3.6:

Proposition 5.4.3.7. Let $\kappa$ and $\lambda$ be cardinals, where $\lambda$ is infinite. The following conditions are equivalent:

1. The cardinal $\kappa$ is strictly smaller than the cofinality $\text{cf}(\lambda)$ (see Definition 5.4.1.28).
(2) Let \( \{T_s\}_{s \in S} \) be a collection of \( \lambda \)-small sets indexed by a set \( S \) of cardinality \( \leq \kappa \). Then the coproduct \( \coprod_{s \in S} T_s \) is \( \lambda \)-small.

**Proof.** Assume first that condition (1) is satisfied. Let \( \{T_s\}_{s \in S} \) be a collection of \( \lambda \)-small sets indexed by a set \( S \) of cardinality \( \leq \kappa \); we wish to show that the coproduct \( T = \coprod_{s \in S} T_s \) is \( \lambda \)-small. Using Theorem 5.4.1.14, we can choose a well-ordering \( \leq_S \) on the set \( S \), and a well-ordering \( \leq_s \) on the set \( T_s \) for each \( s \in S \). For elements \( t \in T_s \) and \( t' \in T_{s'} \), write \( t \leq_T t' \) if either \( s <_S s' \), or \( s = s' \) and \( t \leq_s t' \). Then \( \leq_T \) is a well-ordering of the set \( T \). If \( T \) is not \( \lambda \)-small, then it has an initial segment of order type \( \lambda \). Passing to subsets, we may assume without loss of generality that \( T \) itself has order type \( \lambda \). Moreover, we may assume without loss of generality that each of the sets \( T_s \) is nonempty, and therefore contains a smallest element \( t_s \). We consider two cases:

- Suppose that \( S \) contains a largest element \( s \). In this case, we can write \( T \) as the disjoint union of the initial segment \( T' = \coprod_{s <_s T_s} T_s \) with the set \( T_s \). Since \( T_s \) is nonempty, \( T' \) has order type smaller than \( \lambda \), and is therefore \( \lambda \)-small. Applying Corollary 5.4.3.6, we deduce that \( T = T' \coprod T_s \) is also \( \lambda \)-small.

- Suppose that \( S \) does not have a largest element. In this case, the construction \( (s \in S) \mapsto (t_s \in T) \) is a cofinal function from \( S \) to \( T \). It follows that the order type of \( (S, \leq_S) \) is greater than or equal to the cofinality \( \text{cf}(T) = \text{cf}(\lambda) \), contradicting assumption (1).

We now prove the reverse implication. Assume that condition (2) is satisfied. Choose a well-ordering \( (S, \leq_S) \) of order type \( \text{cf}(\lambda) \) and a cofinal map \( f : S \to \text{Ord}_{<\lambda} \). If \( \kappa \geq \text{cf}(\lambda) \), then condition (2) implies that the disjoint union \( \coprod_{s \in S} \text{Ord}_{<f(s)} \) is \( \lambda \)-small. Since \( f \) is cofinal, the tautological map \( \coprod_{s \in S} \text{Ord}_{<f(s)} \to \text{Ord}_{<\lambda} \) is surjective. It follows that \( \text{Ord}_{<\lambda} \) is \( \lambda \)-small, which is a contradiction. \( \square \)

**Corollary 5.4.3.8.** Let \( \lambda \) be an infinite cardinal. Then \( \kappa = \text{cf}(\lambda) \) is the smallest cardinal for which there exists a set \( S \) of cardinality \( \kappa \) and a collection of \( \lambda \)-small sets \( \{T_s\}_{s \in S} \), where the coproduct \( \coprod_{s \in S} T_s \) is not \( \lambda \)-small.

**Proof.** Proposition 5.4.2.14 guarantees that \( \kappa \) is a cardinal. The characterization is a restatement of Proposition 5.4.3.7. \( \square \)

**Corollary 5.4.3.9.** Let \( \lambda \) be an infinite cardinal and let \( \kappa = \text{cf}(\lambda) \) be its cofinality. Suppose we are given a collection of \( \lambda \)-small sets \( \{T_s\}_{s \in S} \). If the index set \( S \) is \( \kappa \)-small, then coproduct \( \coprod_{s \in S} T_s \) is \( \lambda \)-small.

**Definition 5.4.3.10** (Regular Cardinals). Let \( \kappa \) be a cardinal. We say that \( \kappa \) is regular if it is infinite and \( \text{cf}(\kappa) = \kappa \). Here \( \text{cf}(\kappa) \) denotes the cofinality of \( \kappa \) (Definition 5.4.1.28). We say that \( \kappa \) is singular if it is infinite but not regular.
Remark 5.4.3.11. Let \( \kappa \) be an infinite cardinal. Then \( \kappa \) is regular if and only if the collection of \( \kappa \)-small sets is closed under \( \kappa \)-small coproducts (this is a special case of Corollary 5.4.3.8).

Example 5.4.3.12. Let \( \aleph_0 \) denote the first infinite cardinal (Example 5.4.2.10). Then \( \aleph_0 \) is regular: that is, the collection of finite sets is closed under finite coproducts.

Example 5.4.3.13 (Successor Cardinals). Let \( \kappa \) be an infinite cardinal and let \( \kappa^+ \) be its successor (Example 5.4.2.11). Then a set \( S \) is \( \kappa^+ \)-small if and only if it has cardinality \( \leq \kappa \). It follows that \( \kappa^+ \) is a regular cardinal. That is, if \( \{T_s\}_{s \in S} \) is a collection of sets of cardinality \( \leq \kappa \) indexed by a set \( S \) of cardinality \( \leq \kappa \), then the disjoint union \( \bigsqcup_{s \in S} T_s \) also has cardinality \( \leq \kappa \). To prove this, choose a collection of monomorphisms \( \{i_s : T_s \to T\}_{s \in S} \), where \( T \) is a set of cardinality \( \kappa \). We then obtain a monomorphism

\[
\bigsqcup_{s \in S} T_s \to S \times T \quad (x \in T_s) \mapsto (s, i_s(x)),
\]

where the set \( S \times T \) has cardinality \( \leq \kappa \) by virtue of Proposition 5.4.3.5.

Example 5.4.3.14. Let \( \aleph_1 \) denote the first uncountable cardinal (Example 5.4.2.12). Then \( \aleph_1 \) is regular: that is, the collection of countable sets is closed under the formation of countable disjoint unions. This is a special case of Example 5.4.3.13, since \( \aleph_1 = \aleph_0^+ \).

Example 5.4.3.15. Let \( (T, \leq) \) be a nonempty linearly ordered set with no largest element. Then the cofinality \( \kappa = \text{cf}(T) \) is a regular cardinal. To see this, choose a well-ordered set \( (S, \leq) \) of order type \( \kappa \) and a cofinal function \( f : S \to T \). Proposition 5.4.2.14 guarantees that \( \kappa \) is a cardinal, and Example 5.4.1.31 shows that \( \kappa \) is infinite. If it is not regular, then there exists a cofinal map \( g : R \to S \), where \( (R, \leq) \) is a well-ordered set of order type \( \alpha < \kappa \). This contradicts the definition of \( \kappa = \text{cf}(T) \), since the composite map \( (f \circ g) : R \to T \) is cofinal.

It will be convenient to introduce the following bit of nonstandard terminology:

Definition 5.4.3.16. Let \( \lambda \) be an infinite cardinal. We let \( \text{ecf}(\lambda) \) denote the least cardinal \( \kappa \) with the following property: there exists a set \( S \) of cardinality \( \kappa \) and a collection of \( \lambda \)-small sets \( \{T_s\}_{s \in S} \) for which the product \( \prod_{s \in S} T_s \) is not \( \lambda \)-small. We will refer to \( \text{ecf}(\lambda) \) as the exponential cofinality of \( \lambda \).

Remark 5.4.3.17. Let \( \lambda \) be an infinite cardinal. Then the exponential cofinality \( \text{ecf}(\lambda) \) satisfies \( \aleph_0 \leq \text{ecf}(\lambda) \leq \text{cf}(\lambda) \). In particular, we have \( \text{ecf}(\lambda) \leq \lambda \). The inequality \( \aleph_0 \leq \text{ecf}(\lambda) \) is a reformulation of the fact that the collection of \( \lambda \)-small sets is closed under finite products (Proposition 5.4.3.5). To prove the other inequality, choose a set \( S \) of cardinality \( \text{cf}(\lambda) \) and a collection of \( \lambda \)-small sets \( \{T_s\}_{s \in S} \) for which the coproduct \( T = \bigsqcup_{s \in S} T_s \) is not \( \lambda \)-small. We now observe that \( T \) can be identified with a subset of the product \( \prod_{s \in S} (T_s \bigsqcup \{s\}) \). Since each of the sets \( T_s \bigsqcup \{s\} \) is also \( \lambda \)-small, we obtain \( \text{ecf}(\lambda) \leq \text{cf}(\lambda) \).
CHAPTER 5. FIBRATIONS OF ∞-CATEGORIES

Remark 5.4.3.18. Let $\kappa$ and $\lambda$ be infinite cardinals. Then $\kappa \leq \text{ecf}(\lambda)$ if and only if the following condition is satisfied: for every collection of $\lambda$-small sets $\{T_s\}_{s \in S}$ indexed by a $\kappa$-small set $S$, the product $\prod_{s \in S} T_s$ is also $\lambda$-small.

Remark 5.4.3.19. Let $\kappa$ be an infinite cardinal. Then there are arbitrarily large regular cardinals $\lambda$ satisfying $\text{ecf}(\lambda) > \kappa$. To see this, it will suffice (by enlarging $\kappa$) to show that there exists some regular cardinal $\lambda$ of exponential cofinality $\geq \kappa$. Let $S$ be a set of cardinality $\kappa$ and let $2^\kappa$ denote the cardinality of the power set $P(S) = \{S_0 : S_0 \subseteq S\}$. Proposition 5.4.3.5 implies that the product $S \times S$ also has cardinality $\kappa$, so that $P(S \times S) \simeq \prod_{s \in S} P(S)$ also has cardinality $2^\kappa$. It follows that the collection of sets of cardinality $\leq 2^\kappa$ is closed under the formation of products indexed by sets of cardinality $\leq \kappa$, so that $\lambda = (2^\kappa)^+$ has exponential cofinality $> \kappa$.

Definition 5.4.3.20. Let $\kappa$ be an infinite cardinal. We say that $\kappa$ is strongly inaccessible if $\kappa = \text{ecf}(\kappa)$. In other words, $\kappa$ is strongly inaccessible if the collection of $\kappa$-small sets is closed under the formation of $\kappa$-small products.

Example 5.4.3.21. Let $\aleph_0$ be the least infinite cardinal. Then $\aleph_0$ is strongly inaccessible. That is, the collection of finite sets is closed under finite products.

Remark 5.4.3.22. Let $\kappa$ be a strongly inaccessible cardinal. Then $\kappa$ is regular: this follows immediately from the inequality $\text{ecf}(\kappa) \leq \text{cf}(\kappa)$ of Remark 5.4.3.17.

Warning 5.4.3.23. The existence of uncountable strongly inaccessible cardinals cannot be proven from the axioms of Zermelo-Fraenkel set theory (assuming those axioms are consistent).

Proposition 5.4.3.24. Let $\lambda$ be an infinite cardinal and let $\kappa = \text{ecf}(\lambda)$ be the exponential cofinality of $\lambda$. Then $\kappa$ is a regular cardinal.

Proof. Suppose that $\kappa$ is not regular: that is, there is a collection of $\kappa$-small sets $\{T_s\}_{s \in S}$ indexed by a $\kappa$-small set $S$ such that $T = \prod_{s \in S} T_s$ has cardinality $\geq \kappa$. Choose a collection of $\lambda$-small sets $\{U_t\}_{t \in T}$ for which the product $U = \prod_{t \in T} U_t$ is not $\lambda$-small. For each $s \in S$, let $U_s$ denote the product $\prod_{t \in T_s} U_t$. Since $T_s$ is $\text{ecf}(\lambda)$-small, the set $U_s$ is $\lambda$-small. Since $S$ is also $\text{ecf}(\lambda)$-small, it follows that $U \simeq \prod_{s \in S} U_s$ is also $\lambda$-small, which is a contradiction. \qed

5.4.4 Small Simplicial Sets

Definition 5.4.3.1 has a counterpart in the setting of simplicial sets.

Definition 5.4.4.1. Let $\kappa$ be an infinite cardinal. We say that a simplicial set $S$ is $\kappa$-small if the collection of nondegenerate simplices of $S$ is $\kappa$-small.
Remark 5.4.4.2. In the situation of Definition 5.4.4.1, the dimension of the simplices under consideration is not fixed. That is, a simplicial set $S_\bullet$ is $\kappa$-small if and only if the disjoint union $\coprod_{m \geq 0} S_m^{\text{nd}}$ is a $\kappa$-small set, where $S_m^{\text{nd}} \subseteq S_m$ denotes the set of nondegenerate $m$-simplices of $S_\bullet$.

Remark 5.4.4.3. Let $\kappa$ be an infinite cardinal. Then a simplicial set $S$ is $\kappa$-small if and only if the opposite simplicial set $S^\text{op}$ is $\kappa$-small.

Example 5.4.4.4. A simplicial set $S$ is $\aleph_0$-small (in the sense of Definition 5.4.4.1) if and only if it is finite (Definition 3.5.1.1).

Remark 5.4.4.5 (Coproducts). Let $\kappa$ be an infinite cardinal and let $\{S_i\}_{i \in I}$ be a collection of $\kappa$-small simplicial sets. Suppose that the cardinality of the index set $I$ is smaller than the cofinality $\text{cf}(\kappa)$. Then the coproduct $\coprod_{i \in I} S_i$ is also $\kappa$-small (see Corollary 5.4.3.9). In particular:

- The collection of $\kappa$-small simplicial sets is closed under finite coproducts.
- If $\kappa$ is regular, then the collection of $\kappa$-small simplicial sets is closed under $\kappa$-small coproducts.

Remark 5.4.4.6 (Colimits). Let $\kappa$ be an infinite cardinal and let $\{S_i\}_{i \in I}$ be a diagram of simplicial sets indexed by a category $I$. Suppose that the set of objects $\text{Ob}(I)$ has cardinality smaller than the cofinality of $\kappa$. Then the colimit $\varinjlim_{i \in I} S_i$ is also $\kappa$-small (since it can be realized as a quotient of the coproduct $\coprod S_i$, which is $\kappa$-small by virtue of Remark 5.4.4.5).

Remark 5.4.4.7. Let $S$ be a simplicial set. Then there is a least infinite cardinal $\kappa$ for which $S$ is $\kappa$-small. If $S$ is finite, then $\kappa = \aleph_0$. If $S$ is not finite, then $\kappa = \lambda^+$, where $\lambda$ is the cardinality of the set of all nondegenerate simplices of $S$. In particular, $\kappa$ is always a regular cardinal.

Remark 5.4.4.8. Let $\kappa$ be an infinite cardinal and let $T$ be a $\kappa$-small simplicial set. Then:

- Every simplicial subset of $T$ is $\kappa$-small.
- The simplicial set $T$ is $\lambda$-small for each $\lambda \geq \kappa$.
- For every epimorphism of simplicial sets $T \to S$, the simplicial set $S$ is also $\kappa$-small.

See Remark 5.4.3.4.

Proposition 5.4.4.9. Let $\kappa$ be an infinite cardinal and $S_\bullet$ be a simplicial set. Assume that the cofinality of $\kappa$ is larger than $\aleph_0$ (this condition is satisfied, for example, if $\kappa$ is uncountable and regular). The following conditions are equivalent:
CHAPTER 5. FIBRATIONS OF ∞-CATEGORIES

(1) The simplicial set $S_\bullet$ is $\kappa$-small.

(2) For every integer $n \geq 0$, the set $S_n$ is $\kappa$-small.

(3) For every finite simplicial set $K$, the set $\text{Hom}_{\text{Set}_\Delta}(K, S_\bullet)$ is $\kappa$-small.

Proof. We first show that (1) implies (2). Assume that $S_\bullet$ is $\kappa$-small and let $n \geq 0$ be an integer. For each integer $m \geq 0$, let $S_m$ denote the set of nondegenerate $m$-simplices of $X$. Using Proposition 1.1.3.4, we can identify $S_n$ with the coproduct $\coprod_{\alpha: [n] \to [m]} S_{m}^{nd}$, where $\alpha$ ranges over all surjective maps of linearly ordered sets $[n] \to [m]$. Our assumption that $S_\bullet$ is $\kappa$-small guarantees that each of the sets $S_m$ is $\kappa$-small, so that $S_n$ is also $\kappa$-small (Corollary 5.4.3.6).

We now show that (2) implies (1). Assume that, for each $n \geq 0$, the set $S_n$ is $\kappa$-small. Since $\kappa$ has cofinality $> \aleph_0$ it follows that the coproduct $\coprod_{n \geq 0} S_n$ is also $\kappa$-small. In particular, the coproduct $\coprod_{n \geq 0} S_n$ is $\kappa$-small: that is, the simplicial set $S_\bullet$ is $\kappa$-small.

The implication (3) $\Rightarrow$ (2) is immediate from the definition. We will complete the proof by showing that (2) $\Rightarrow$ (3). Assume that, for each $n \geq 0$, the set $S_n$ is $\kappa$-small, and let $K$ be a finite simplicial set. By virtue of Proposition 3.5.1.7, there exists an epimorphism $f: K' \to K$, where $K' = \coprod_{i \in I} \Delta^n_i$ is a disjoint union of finitely many standard simplices. Then precomposition with $f$ induces a monomorphism

$$\text{Hom}_{\text{Set}_\Delta}(K, S_\bullet) \hookrightarrow \text{Hom}_{\text{Set}_\Delta}(K', S_\bullet) \simeq \coprod_{i \in I} S_{n_i}.$$ 

Since the collection of $\kappa$-small sets is closed under finite products and passage to subsets (Proposition 5.4.3.5 and Remark 5.4.3.4), it follows that the set $\text{Hom}_{\text{Set}_\Delta}(K, S_\bullet)$ is also $\kappa$-small. $\square$

Warning 5.4.4.10. The implications (1) $\Rightarrow$ (2) $\Leftrightarrow$ (3) of Proposition 5.4.4.9 are valid for an arbitrary infinite cardinal $\kappa$. However, the implication (2) $\Rightarrow$ (1) is false if $\kappa$ has countable cofinality (for example, if $\kappa = \aleph_0$).

Corollary 5.4.4.11. Let $\kappa$ be an infinite cardinal. Then the collection of $\kappa$-small simplicial sets is closed under finite products.

Proof. Let $\{S_i\}_{i \in I}$ be a collection of $\kappa$-small simplicial sets indexed by a finite set $I$; we wish to show that the product $S = \prod_{i \in I} S_i$ is $\kappa$-small. Without loss of generality, we may assume that $\kappa$ is the least infinite cardinal for which each of the simplicial sets $X_i$ is $\kappa$-small. Then $\kappa$ is regular (Remark 5.4.4.7). If $\kappa = \aleph_0$, then the desired result follows from Remark 3.5.1.6. We may therefore assume that $\kappa$ is uncountable. In this case, the desired result follows from the criterion of Proposition 5.4.4.9, since the collection of $\kappa$-small sets is closed under finite products (Proposition 5.4.3.5). $\square$
Corollary 5.4.4.12. Let $\kappa$ be an uncountable cardinal, let $S$ be a $\kappa$-small simplicial set, and let $K$ be a finite simplicial set. Then the simplicial set $\text{Fun}(K, S)$ is $\kappa$-small.

Proof. Without loss of generality, we may assume that $\kappa$ is the least uncountable cardinal for which $S$ is $\kappa$-small. In particular, $\kappa$ is regular (Remark 5.4.4.7). By virtue of Proposition 5.4.4.9, it will suffice to show that for every finite simplicial set $L$, the set $\text{Hom}_{\text{Set}^\Delta}(L, \text{Fun}(K, S)) \simeq \text{Hom}_{\text{Set}^\Delta}(K \times L, S)$ is $\kappa$-small. This is a special case of Proposition 5.4.4.9, since the simplicial set $K \times L$ is finite (Remark 3.5.1.6). \hfill \Box

Warning 5.4.4.13. The assertion of Corollary 5.4.4.12 is false in the case $\kappa = \aleph_0$. That is, if $K$ and $S$ are finite simplicial sets, then the simplicial set $\text{Fun}(K, S)$ need not be finite.

We close by recording stronger forms of Corollaries 5.4.4.11 and 5.4.4.12.

Corollary 5.4.4.14. Let $\lambda$ be an infinite cardinal and let $\kappa = \text{ecf}(\lambda)$ be its exponential cofinality (Definition 5.4.3.16). Then the collection of $\lambda$-small simplicial sets is closed under $\kappa$-small products.

Proof. Let $\{S_i\}_{i \in I}$ be a collection of $\lambda$-small simplicial sets indexed by a $\kappa$-small set $I$; we wish to show that the product $S = \prod_{i \in I} S_i$ is $\lambda$-small. If $\kappa = \aleph_0$, this follows from Corollary 5.4.4.11. We may therefore assume that $\kappa$ is uncountable. Then the cofinality $\text{cf}(\lambda)$ is also uncountable (Remark 5.4.3.17). The desired result now follows from the criterion of Proposition 5.4.4.9 since the collection of $\lambda$-small sets is closed under $\kappa$-small products. \hfill \Box

Corollary 5.4.4.15. Let $\lambda$ be an infinite cardinal and let $\kappa = \text{ecf}(\lambda)$ be its exponential cofinality. If $S$ is a $\lambda$-small simplicial set and $K$ be a $\kappa$-small simplicial set. Then $\text{Fun}(K, S)$ is $\lambda$-small.

Proof. Since $K$ is $\kappa$-small, we can choose an epimorphism of simplicial sets $\coprod_{i \in I} \Delta^n_i \to K$, where $I$ is a $\kappa$-small set. It follows that $\text{Fun}(K, S)$ can be identified with a simplicial subset of the product $\prod_{i \in I} \text{Fun}(\Delta^n_i, S)$. Corollary 5.4.4.12 guarantees that each factor $\text{Fun}(\Delta^n_i, S)$ is $\lambda$-small, so that the product $\prod_{i \in I} \text{Fun}(\Delta^n_i, S)$ is $\lambda$-small by virtue of Corollary 5.4.4.14. \hfill \Box

5.4.5 Essential Smallness

Let $\kappa$ be an infinite cardinal. Beware that the condition that a simplicial set is $\kappa$-small is not invariant under categorical equivalence. For this reason, it is useful to consider the following variant of Definition 5.4.4.1.

Definition 5.4.5.1. Let $\kappa$ be an uncountable cardinal. We will say that a simplicial set $C$ is essentially $\kappa$-small if there exists a categorical equivalence of simplicial sets $C \to \mathcal{D}$, where $\mathcal{D}$ is a $\kappa$-small $\infty$-category.
Remark 5.4.5.2. Let \( \kappa \) be an uncountable cardinal, and let \( F : C \to D \) be a categorical equivalence of simplicial sets. Then \( C \) is essentially \( \kappa \)-small if and only if \( D \) is essentially \( \kappa \)-small.

Remark 5.4.5.3. Let \( \kappa \) be an uncountable cardinal. Then a simplicial set \( C \) is essentially \( \kappa \)-small if and only if the opposite simplicial set \( C^{\text{op}} \) is essentially \( \kappa \)-small. See Remark 5.4.4.3.

Variant 5.4.5.4. Let \( C \) be a simplicial set. We say that \( C \) is essentially small if there exists a categorical equivalence \( C \to D \), where \( D \) is a small \( \infty \)-category.

Proposition 5.4.5.5. Let \( \kappa \) be an uncountable cardinal and let \( C \) be a \( \kappa \)-small simplicial set. Then there exists an inner anodyne morphism \( C \to D \), where \( D \) is a \( \kappa \)-small \( \infty \)-category. In particular, \( C \) is essentially \( \kappa \)-small.

Proof. Without loss of generality, we may assume that \( \kappa \) is the least uncountable cardinal for which \( C \) is \( \kappa \)-small, so that \( \kappa \) is regular (Remark 5.4.4.7). We proceed as in the proof of Proposition 4.1.3.2. We will construct \( D \) as the colimit of a diagram of inner anodyne morphisms

\[
C = C(0) \hookrightarrow C(1) \hookrightarrow C(2) \hookrightarrow C(3) \hookrightarrow \cdots
\]

where each transition map fits into a pushout diagram

\[
\begin{array}{ccc}
\prod_{s \in S(n)} \Lambda_{i_s}^{n_s} & \xrightarrow{\{u_s\}_{s \in S(n)}} & C(n) \\
\downarrow & & \downarrow \\
\prod_{s \in S(n)} \Delta_{i_s}^{n_s} & \rightarrow & C(n + 1);
\end{array}
\]

here the coproducts are indexed by the collection \( \{u_s : \Lambda_{i_s}^{n_s} \to C(n)\}_{s \in S(n)} \) of all inner horns in the simplicial set \( C(n) \). Note that if the simplicial set \( C(n) \) is \( \kappa \)-small, then the set \( S(n) \) is also \( \kappa \)-small (Proposition 5.4.4.9), so that \( C(n + 1) \) is also \( \kappa \)-small. Since \( \kappa \) is regular and uncountable, it follows that the colimit \( C = \lim_{\to} C(n) \) is \( \kappa \)-small (Remark 5.4.4.6).

Warning 5.4.5.6. The statement of Proposition 5.4.5.5 is false in the case \( \kappa = \aleph_0 \). If \( S \) is a finite simplicial set, we generally cannot choose a categorical equivalence \( f : S \to D \), where \( D \) is an \( \infty \)-category which is also a finite simplicial set. For example, take \( S = \Delta^2 / \partial \Delta^2 \), so that the geometric realization \( |S| \) is homeomorphic to a sphere of dimension 2. Since every edge of \( S \) is degenerate, the homotopy category \( hS \) is a groupoid. Consequently, if \( f \) is a categorical equivalence from \( S \) to an \( \infty \)-category \( D \), then \( D \) is a Kan complex (Proposition 4.4.2.1), which is homotopy equivalent to the singular simplicial set \( \text{Sing}_\bullet(|S|) \) (Theorem...
It follows that \( \pi_2(D) \) is an infinite cyclic group (generated by the homotopy class \([f]\)), so that the Kan complex \( D \) must contain infinitely many 2-simplices.

**Remark 5.4.5.7** (Coproducts). Let \( \kappa \) be an uncountable cardinal and let \( \{C_i\}_{i \in I} \) be a collection of essentially \( \kappa \)-small simplicial sets. Suppose that the cardinality of the index set \( I \) is smaller than the cofinality \( \text{cf}(\kappa) \). Then the coproduct \( \coprod_{i \in I} C_i \) is also essentially \( \kappa \)-small. This follows by combining Remark 5.4.5. with Corollary 4.5.3.10. In particular:

- The collection of essentially \( \kappa \)-small simplicial sets is closed under finite coproducts.
- If \( \kappa \) is regular, then the collection of essentially \( \kappa \)-small simplicial sets is closed under \( \kappa \)-small coproducts.

**Remark 5.4.5.8** (Products). Let \( \kappa \) be an uncountable cardinal and let \( \{C_i\}_{i \in I} \) be a finite collection of simplicial sets which are essentially \( \kappa \)-small. Then the product \( \prod_{i \in I} C_i \) is essentially \( \kappa \)-small. This follows by combining Corollary 5.4.4.14 since the collection of categorical equivalences is stable under the formation of finite products (Remark 4.5.3.7).

**Variant 5.4.5.9.** Let \( \kappa \) be an uncountable cardinal and let \( \{C_i\}_{i \in I} \) be a collection of essentially \( \kappa \)-small \( \infty \)-categories. Suppose that the cardinality of the index set \( I \) has smaller than the exponential cofinality \( \text{ecf}(\kappa) \). Then the product \( \prod_{i \in I} C_i \) is also essentially \( \kappa \)-small. This follows by combining Corollary 5.4.4.14 with Remark 4.5.1.17.

**Remark 5.4.5.10.** Let \( \lambda \) be an uncountable cardinal, let \( \mathcal{C} \) be an \( \infty \)-category which is essentially \( \lambda \)-small, and let \( K \) be a simplicial set. Suppose that \( K \) is \( \kappa \)-small, where \( \kappa = \text{ecf}(\lambda) \) is the exponential cofinality of \( \lambda \). Then the \( \infty \)-category \( \text{Fun}(K, \mathcal{C}) \) is essentially \( \lambda \)-small. To prove this, we can use Remark 4.5.1.16 to reduce to the case where \( \mathcal{C} \) is \( \lambda \)-small, in which case it follows from Corollary 5.4.4.12. Moreover, if \( \kappa \) is uncountable, then it suffices to assume that \( K \) is essentially \( \kappa \)-small.

**Proposition 5.4.5.11.** Let \( \kappa \) be an uncountable cardinal and let \( \mathcal{C} \) be an \( \infty \)-category which is essentially \( \kappa \)-small. Then any replete subcategory \( \mathcal{C}_0 \subseteq \mathcal{C} \) is also essentially \( \kappa \)-small.

**Proof.** Choose an equivalence of \( \infty \)-categories \( F : \mathcal{D} \to \mathcal{C} \), where \( \mathcal{D} \) is \( \kappa \)-small. Then the inverse image \( \mathcal{D}_0 = F^{-1}(\mathcal{C}_0) \) is \( \kappa \)-small (Remark 5.4.4.8), and the functor \( F \) restricts to an equivalence of \( \infty \)-categories \( \mathcal{D}_0 \to \mathcal{C}_0 \) (Corollary 4.5.2.23).

**Corollary 5.4.5.12.** Let \( \kappa \) be an uncountable cardinal and let \( \mathcal{C} \) be an \( \infty \)-category which is essentially \( \kappa \)-small. Then the core \( \mathcal{C}^{\simeq} \) is an essentially \( \kappa \)-small Kan complex.

**Proof.** Since \( \mathcal{C}^{\simeq} \) is a replete subcategory of \( \mathcal{C} \) (Proposition 4.4.3.6), this is a special case of Proposition 5.4.5.11.
Corollary 5.4.5.13. Let $\kappa$ be an uncountable cardinal and let $\mathcal{C}$ be an $\infty$-category which is essentially $\kappa$-small. Then any full subcategory $\mathcal{C}_0 \subseteq \mathcal{C}$ is essentially $\kappa$-small.

Proof. Let $\mathcal{C}_1 \subseteq \mathcal{C}$ be the full subcategory spanned by those objects $X \in \mathcal{C}$ which are isomorphic to an object of $\mathcal{C}_0$. Proposition 5.4.5.11 guarantees that $\mathcal{C}_1$ is essentially $\kappa$-small. Since the inclusion $\mathcal{C}_0 \hookrightarrow \mathcal{C}_1$ is an equivalence of $\infty$-categories, it follows that $\mathcal{C}_0$ is also essentially $\kappa$-small (Remark 5.4.5.2).

Proposition 5.4.5.14. Let $F_0 : \mathcal{C}_0 \rightarrow \mathcal{C}$ and $F_1 : \mathcal{C}_1 \rightarrow \mathcal{C}$ be functors of $\infty$-categories and let $\kappa$ be an uncountable cardinal. If $\mathcal{C}_0$, $\mathcal{C}_1$, and $\mathcal{C}$ are essentially $\kappa$-small, then the oriented fiber product $\mathcal{C}_0 \hat{\times}_\mathcal{C} \mathcal{C}_1$ is also essentially $\kappa$-small.

Proof. Choose equivalences of $\infty$-categories

$$D_0 \rightarrow \mathcal{C}_0 \quad \mathcal{C} \rightarrow \mathcal{D} \quad D_1 \rightarrow \mathcal{C}_1,$$

where $D_0$, $D_1$, and $\mathcal{D}$ are $\kappa$-small. By virtue of Remark 4.6.4.4 the induced maps

$$\mathcal{C}_0 \hat{\times}_\mathcal{C} \mathcal{C}_1 \leftarrow D_0 \hat{\times}_\mathcal{C} D_1 \rightarrow D_0 \hat{\times}_\mathcal{D} D_1$$

are equivalences of $\infty$-categories. It will therefore suffice to show that the $\infty$-category $D_0 \hat{\times}_\mathcal{D} D_1$ is $\kappa$-small. This follows from Corollaries 5.4.4.12 and 5.4.4.11 since $D_0 \hat{\times}_\mathcal{D} D_1$ can be identified with a simplicial subset of the product $D_0 \times \text{Fun}(\Delta^1, \mathcal{D}) \times D_1$.

Corollary 5.4.5.15. Let $F_0 : \mathcal{C}_0 \rightarrow \mathcal{C}$ and $F_1 : \mathcal{C}_1 \rightarrow \mathcal{C}$ be functors of $\infty$-categories and let $\kappa$ be an uncountable cardinal. If $\mathcal{C}_0$, $\mathcal{C}_1$, and $\mathcal{C}$ are essentially $\kappa$-small, then the homotopy fiber product $\mathcal{C}_0 \times^h_\mathcal{C} \mathcal{C}_1$ is essentially $\kappa$-small.

Proof. Since $\mathcal{C}_0 \times^h_\mathcal{C} \mathcal{C}_1$ is a full subcategory of the oriented fiber product $\mathcal{C}_0 \hat{\times}_\mathcal{C} \mathcal{C}_1$, this follows from Proposition 5.4.5.14 and Corollary 5.4.5.13.

Corollary 5.4.5.16. Let $\kappa$ be an uncountable cardinal and suppose we are given a categorical pullback diagram of $\infty$-categories

$$\begin{align*}
\mathcal{C}_0 & \rightarrow \mathcal{C}_0 \\
\downarrow & \\
\mathcal{C}_1 & \rightarrow \mathcal{C}.
\end{align*}$$

(5.21)

If $\mathcal{C}_0$, $\mathcal{C}$, and $\mathcal{C}_1$ are essentially $\kappa$-small, then $\mathcal{C}_{01}$ is essentially $\kappa$-small.

Proof. Combine Remark 5.4.5.2 with Corollary 5.4.5.15.
5.4. SIZE CONDITIONS ON ∞-CATEGORIES

5.4.6 Minimal ∞-Categories

Let κ be an uncountable cardinal. An ∞-category D is essentially κ-small if and only if there exists an equivalence C → D, where C is a κ-small ∞-category. Our goal in this section is to show that, if this condition is satisfied, then there is a preferred choice for the ∞-category C which is characterized (up to noncanonical isomorphism) by the requirement that it is minimal.

**Definition 5.4.6.1.** Let C be an ∞-category. We say that C is minimal if it satisfies the following condition, for each n ≥ 0:

\((*n)\) Let σ and σ' be n-simplices of C. Suppose that there exists an isomorphism \(h : \sigma \rightarrow \sigma'\) in the ∞-category \(\text{Fun}(\Delta^n, C)\), and that the image of \(h\) in the ∞-category \(\text{Fun}(\partial\Delta^n, C)\) is an identity morphism. Then \(\sigma = \sigma'\).

**Remark 5.4.6.2.** Let C be an ∞-category. Then C satisfies condition \((*0)\) of Definition 5.4.6.1 if and only if, for every pair of isomorphic objects \(X, Y \in C\), we have \(X = Y\).

**Remark 5.4.6.3.** Let C be an ∞-category. Then C satisfies condition \((*1)\) of Definition 5.4.6.1 if and only if, for every pair of objects \(X, Y \in C\) and every pair of morphisms \(f, g : X \rightarrow Y\) which are homotopic, we have \(f = g\) (see Corollary 1.3.3.7).

**Exercise 5.4.6.4.** Let C be a category. Show that the nerve \(N^\bullet(C)\) automatically satisfies condition \((*n)\) of Definition 5.4.6.1 for \(n > 0\). Consequently, the ∞-category \(N^\bullet(C)\) is minimal if and only if, for every pair of isomorphic objects \(X, Y \in C\), we have \(X = Y\).

**Remark 5.4.6.5.** Let C be a minimal ∞-category, and let \(C_0 \subseteq C\) be a simplicial subset. If \(C_0\) is an ∞-category, then it is also minimal.

**Remark 5.4.6.6.** Let \(\{C_i\}_{i \in I}\) be a collection of minimal ∞-categories. Then the product \(\prod_{i \in I} C_i\) and the coproduct \(\bigsqcup_{i \in I} C_i\) are also minimal ∞-categories.

**Warning 5.4.6.7.** The collection of minimal ∞-categories has poor closure properties:

- If C is a minimal ∞-category and \(K\) is a simplicial set, then the ∞-category \(\text{Fun}(K, C)\) need not be minimal (even in the case \(K = \Delta^1\)).

- If C is a minimal ∞-category and \(q : K \rightarrow C\) is a diagram, then the ∞-categories \(C/q\) and \(C_{q/}\) need not be minimal (even in the case \(K = \Delta^0\)).

- If C is a minimal ∞-category and \(D\) is equivalent to \(C\), then \(D\) need not be minimal.

Our main goal in this section is to show that every ∞-category \(D\) admits a minimal model: that is, a minimal ∞-category \(C\) equipped with an equivalence \(F : C \rightarrow D\). Moreover, the ∞-category \(C\) is uniquely determined up to isomorphism (Corollary 5.4.6.13). Our first step is to show that, in this case, the functor \(F\) is automatically a monomorphism.
**Lemma 5.4.6.8.** Let $F : C \to D$ be an equivalence of $\infty$-categories. If $C$ is minimal, then $F$ is a monomorphism of simplicial sets.

**Proof.** Let $\sigma, \sigma' : \Delta^n \to C$ be $n$-simplices of $C$ satisfying $F(\sigma) = F(\sigma')$; we wish to show that $\sigma = \sigma'$. Our proof proceeds by induction on $n$. Set $\tau = F(\sigma) = F(\sigma')$ and $\sigma_0 = \sigma|_{\partial \Delta^n}$, so that our inductive hypothesis guarantees that $\sigma_0 = \sigma'|_{\partial \Delta^n}$.

Fix a functor $G : D \to C$ which is homotopy inverse to $F$, so that there exists a 2-simplex

$$
\begin{array}{ccc}
\text{id}_C & \xrightarrow{\text{id}} & \text{id}_C \\
\alpha \downarrow & & \beta \\
G \circ F & \xrightarrow{\tau} & \text{id}_C
\end{array}
$$

in the $\infty$-category $\text{Fun}(C, C)$, where $\alpha$ and $\beta$ are (mutually inverse) isomorphisms. Precomposing with the morphism $\sigma_0 : \partial \Delta^n \to C$, we obtain a 2-simplex

$$
\begin{array}{ccc}
\sigma_0 & \xrightarrow{\text{id}} & \sigma_0 \\
\alpha(\sigma_0) \downarrow & & \beta(\sigma_0) \\
(G \circ F)(\sigma_0) & \xrightarrow{(G \circ F)(\tau)} & \text{id}_C
\end{array}
$$

(5.22)

in the $\infty$-category $\text{Fun}(\partial \Delta^n, C)$. Since $C$ is an $\infty$-category, Theorem 1.4.6.1 guarantees that we can lift (5.22) to a 2-simplex

$$
\begin{array}{ccc}
\sigma & \xrightarrow{\gamma} & \sigma' \\
\alpha(\sigma) \downarrow & & \beta(\sigma') \\
G(\tau) & \xrightarrow{G(\tau)} & \text{id}_C
\end{array}
$$

in the $\infty$-category $\text{Fun}(\Delta^n, C)$. By construction, $\gamma$ is an isomorphism whose image in $\text{Fun}(\partial \Delta^n, C)$ is an identity morphism. Invoking our assumption that $C$ is minimal, we deduce that $\sigma = \sigma'$.

**Corollary 5.4.6.9.** Let $C$ be a minimal $\infty$-category and let $\kappa$ be an uncountable cardinal. Then $C$ is essentially $\kappa$-small if and only if it is $\kappa$-small.

**Proof.** Suppose that $C$ is essentially $\kappa$-small. Then there exists an equivalence of $\infty$-categories $F : C \to D$, where $D$ is $\kappa$-small. Since $C$ is minimal, the functor $F$ is a monomorphism of simplicial sets (Lemma 5.4.6.8), so that $C$ is also $\kappa$-small (Remark 5.4.4.8).
Proposition 5.4.6.10 (Uniqueness). Let $F : \mathcal{C} \to \mathcal{D}$ be an equivalence of $\infty$-categories. If $\mathcal{C}$ and $\mathcal{D}$ are minimal, then $F$ is an isomorphism of simplicial sets.

Proof. Let $G : \mathcal{D} \to \mathcal{C}$ be a homotopy inverse to $F$. It follows from Lemma 5.4.6.8 that $F$ and $G$ are monomorphisms of simplicial sets. We will complete the proof by showing that the composite map $(F \circ G) : \mathcal{D} \to \mathcal{D}$ is an epimorphism of simplicial sets (so that, in particular, $F$ is an epimorphism). Let $\sigma$ be an $n$-simplex of $\mathcal{D}$; we wish to show that $\sigma$ belongs to the image of $F \circ G$. The proof proceeds by induction on $n$. Set $\sigma_0 = \sigma|_{\partial \Delta^n}$; our inductive hypothesis then guarantees that we can write $\sigma_0 = (F \circ G)(\tau_0)$ for some morphism $\tau_0 : \partial \Delta^n \to \mathcal{D}$.

Choose a 2-simplex

\[
\begin{array}{ccc}
F \circ G & \xrightarrow{id_{F \circ G}} & F \circ G \\
\downarrow \alpha & & \downarrow \beta \\
\downarrow \beta & & \downarrow \beta \\
\downarrow \alpha & & \downarrow \alpha \\
id_{\mathcal{D}} & & nid_{\mathcal{D}}
\end{array}
\]

in the $\infty$-category $\text{Fun}(\mathcal{D}, \mathcal{D})$, where $\alpha$ and $\beta$ are isomorphisms. Precomposing with $\tau_0 : \partial \Delta^n \to \mathcal{D}$, we obtain a 2-simplex

\[
\begin{array}{ccc}
\sigma_0 & \xrightarrow{id} & \sigma_0 \\
\downarrow \alpha(\tau_0) & & \downarrow \beta(\tau_0) \\
\downarrow \tau_0 & & \downarrow \tau_0 \\
\downarrow \alpha(\tau_0) & & \downarrow \beta(\tau_0) \\
\end{array}
\] (5.23)

in the $\infty$-category $\text{Fun}(\partial \Delta^n, \mathcal{D})$. Using Corollary 4.4.5.9, we can lift $\alpha(\tau_0)$ to an isomorphism $\tilde{\alpha} : \sigma \to \tau$ in the $\infty$-category $\text{Fun}(\Delta^n, \mathcal{D})$. Since $\mathcal{D}$ is an $\infty$-category, Theorem 1.4.6.1 guarantees that we can lift (5.23) to a 2-simplex

\[
\begin{array}{ccc}
\sigma & \xrightarrow{\gamma} & (F \circ G)(\tau) \\
\downarrow \tilde{\alpha} & & \downarrow \beta(\tau) \\
\downarrow \sigma & & \downarrow \tau \\
\end{array}
\]

in the $\infty$-category $\text{Fun}(\Delta^n, \mathcal{D})$. By construction, $\gamma$ is an isomorphism whose image in $\text{Fun}(\partial \Delta^n, \mathcal{D})$ is an identity morphism. Our assumption that $\mathcal{D}$ is minimal then guarantees that $\sigma = (F \circ G)(\tau)$ belongs to the image of $F \circ G$. \qed
Corollary 5.4.6.11. Let $\mathcal{C}$ and $\mathcal{D}$ be minimal $\infty$-categories. Then $\mathcal{C}$ and $\mathcal{D}$ are equivalent if and only if they are isomorphic.

We now prove the existence of minimal models.

Proposition 5.4.6.12 (Existence). Let $\mathcal{D}$ be an $\infty$-category. Then there exists an equivalence of $\infty$-categories $F : \mathcal{C} \to \mathcal{D}$, where $\mathcal{C}$ is minimal.

Corollary 5.4.6.13. The construction

$$\{\text{Minimal } \infty\text{-Categories}\}/\text{Isomorphism} \to \{\infty\text{-Categories}\}/\text{Equivalence}$$

is a bijection.

Proof. Injectivity is a restatement of Corollary 5.4.6.11 and surjectivity follows from Proposition 5.4.6.12.

Corollary 5.4.6.14. Let $\mathcal{C}$ be a simplicial set. Then there is a least uncountable cardinal $\kappa$ for which $\mathcal{C}$ is essentially $\kappa$-small. Moreover, $\kappa$ is always a successor cardinal.

Proof. By virtue of Proposition 5.4.6.12, we may assume that $\mathcal{C}$ is a minimal $\infty$-category. In this case, the desired result follows by combining Corollary 5.4.6.9 with Remark 5.4.4.7.

Proof of Proposition 5.4.6.12. Let $\sigma, \sigma' : \Delta^n \to \mathcal{D}$ be $n$-simplices of $\mathcal{D}$. We write $\sigma \sim \sigma'$ if there exists an isomorphism $\sigma \to \sigma'$ in the $\infty$-category $\text{Fun}(\Delta^n, \mathcal{D})$ whose image in $\text{Fun}(\partial \Delta^n, \mathcal{D})$ is an identity morphism. Note that, if this condition is satisfied, then we must have $\sigma|_{\partial \Delta^n} = \sigma'|_{\partial \Delta^n}$. In particular, if $\sigma$ and $\sigma'$ are both degenerate, we must have $\sigma = \sigma'$.

Let $R(n)$ denote a collection of $n$-simplices of $\mathcal{D}$ which contains all degenerate $n$-simplices, and contains exactly one element of every $\sim$-class. We let $\mathcal{C} \subseteq \mathcal{D}$ denote the simplicial subset consisting of all simplices $\tau : \Delta^m \to \mathcal{D}$ having the property that, for every morphism of linearly ordered sets $\alpha : [n] \to [m]$, the $n$-simplex $\Delta^n \to \Delta^m \xrightarrow{\tau} \mathcal{D}$ belongs to $R(n)$ (by construction, it suffices to check this in the case where $\alpha$ is injective). To complete the proof, it will suffice to establish the following:

1. The simplicial set $\mathcal{C}$ is an $\infty$-category.
2. The $\infty$-category $\mathcal{C}$ is minimal.
3. The inclusion map $\mathcal{C} \hookrightarrow \mathcal{D}$ is an equivalence of $\infty$-categories.

We begin by proving (1). Suppose we are given integers $0 < i < n$ and a morphism of simplicial sets $\sigma_0 : \Lambda^n_i \to \mathcal{C}$; we wish to show that $\sigma_0$ can be extended to an $n$-simplex $\sigma$ of $\mathcal{C}$. Since $\mathcal{D}$ is an $\infty$-category, we can extend $\sigma_0$ to an $n$-simplex $\sigma'' : \Delta^n \to \mathcal{D}$. Let $\overline{\sigma'} = d_i(\sigma'')$ denote the $i$th face of $\sigma''$. Then there is a unique element $\overline{\sigma'} \in R(n - 1)$ satisfying $\overline{\sigma'} \sim \overline{\sigma''}$. \[\overline{\sigma'} = d_i(\sigma'') \vdash \overline{\sigma''}.\]
Choose an isomorphism $\alpha : \sigma' \to \sigma''$ in the $\infty$-category $\text{Fun}(\Delta^{n-1}, \mathcal{D})$ whose image in $\text{Fun}(\partial \Delta^{n-1}, \mathcal{D})$ is an identity morphism. Then $\alpha$ can be lifted uniquely to an isomorphism $\tilde{\alpha} : \sigma'|_{\partial \Delta^n} \to \sigma''$ in the $\infty$-category $\text{Fun}(\partial \Delta^{n-1}, \mathcal{D})$ whose image in $\text{Fun}(\Lambda^n_1, \mathcal{D})$ is an identity morphism. Applying Proposition 4.4.5.8, we can lift $\tilde{\alpha}$ to an isomorphism $\alpha : \sigma' \to \sigma''$ in the $\infty$-category $\text{Fun}(\Delta^n, \mathcal{D})$. By construction, the restriction $\sigma'|_{\partial \Delta^n}$ factors through $\mathcal{C}$. Let $\sigma$ be the unique $n$-simplex of $\mathcal{D}$ which belongs to $R(n)$ and satisfies $\sigma \sim \sigma'$. Then $\sigma$ is an $n$-simplex of $\mathcal{C}$ satisfying $\sigma|_{\Delta^n_0} = \sigma'|_{\Delta^n_0} = \sigma''|_{\Delta^n_0} = \sigma_0$. This completes the proof of (1).

We now prove (2). Let $\sigma$ and $\sigma'$ be $n$-simplices of $\mathcal{C}$, and suppose that there exists an isomorphism $\sigma \to \sigma'$ in $\text{Fun}(\Delta^n, \mathcal{C})$ whose image in $\text{Fun}(\partial \Delta^n, \mathcal{C})$ is an identity morphism. It follows that, when regarded as $n$-simplices of $\mathcal{D}$, we have $\sigma \sim \sigma'$. Since $\sigma$ and $\sigma'$ both belong to $R(n)$, we conclude that $\sigma = \sigma'$.

To prove (3), we will show that $\mathcal{C}$ is a deformation retract of $\mathcal{C}$; that is, there exists a functor $H : \Delta^1 \times \mathcal{C} \to \mathcal{D}$ satisfying the following conditions:

(i) The restriction $H|_{\{0\} \times \mathcal{D}}$ is the identity functor $\text{id}_\mathcal{D}$.

(ii) The restriction $H|_{\{1\} \times \mathcal{D}}$ factors through $\mathcal{C}$.

(iii) The restriction $H|_{\Delta^1 \times \mathcal{C}}$ coincides with the projection map $\Delta^1 \times \mathcal{C} \to \mathcal{C} \subseteq \mathcal{D}$.

(iv) For each object $D \in \mathcal{D}$, the restriction $H|_{\Delta^1 \times \{D\}}$ is an isomorphism in $\mathcal{D}$.

Note that these conditions guarantee that the functor $H|_{\{1\} \times \mathcal{D}} : \mathcal{D} \to \mathcal{C}$ is a homotopy inverse to the inclusion map $\mathcal{C} \hookrightarrow \mathcal{D}$.

Let $Q$ denote the set of pairs $(S, H_S)$, where $S \subseteq \mathcal{D}$ is a simplicial subset which contains $\mathcal{C}$ and $H_S : \Delta^1 \times S \to \mathcal{D}$ is a morphism of simplicial sets which satisfies the analogues of conditions (i) through (iv). We regard $Q$ as a partially ordered set, where $(S, H_S) \leq (S', H_{S'})$ if $S \subseteq S'$ and $H_S = H_{S'}|_{\Delta^1 \times S}$. This partially ordered set satisfies the hypotheses of Zorn’s lemma, and therefore contains a maximal element $(S_{\text{max}}, H_{\text{max}})$. To complete the proof, it will suffice to show that $S_{\text{max}} = \mathcal{D}$. Assume otherwise. Then there is some $n$-simplex $\tau : \Delta^n \to \mathcal{D}$ which is not contained in $S_{\text{max}}$. Choose $n$ as small as possible, so that $\tau_0 = \tau|_{\partial \Delta^n}$ factors through $S_{\text{max}}$. Then the composite map

$$\Delta^1 \times \partial \Delta^n \xrightarrow{\text{id} \times \tau_0} \Delta^1 \times S_{\text{max}} \xrightarrow{H_{\text{max}}} \mathcal{D}$$

can be viewed as an isomorphism $\alpha_0 : \tau_0 \to \tau_0'$ in the $\infty$-category $\text{Fun}(\partial \Delta^n, \mathcal{D})$, where $\tau_0'$ belongs to $\text{Fun}(\partial \Delta^n, \mathcal{C})$. Using Proposition 4.4.5.8, we can lift $\alpha_0$ to an isomorphism $\tau \to \tau'$ in the $\infty$-category $\text{Fun}(\Delta^n, \mathcal{D})$. Let $\tau''$ be the unique $n$-simplex of $\mathcal{D}$ which belongs to $R(n)$ and satisfies $\tau' \sim \tau''$. Then there exists an isomorphism $\beta : \tau' \to \tau''$ in the $\infty$-category $\mathcal{D}$.
Fun(Δ^n, D) whose image in Fun(∂Δ^n, D) is an identity morphism. Using Theorem 1.4.6.1, we can lift the degenerate 2-simplex

\[
\begin{array}{ccc}
\tau' & \xrightarrow{\alpha_0} & \tau_0' \\
\downarrow{\text{id}} & & \downarrow{\text{id}} \\
\tau_0 & \xrightarrow{\alpha_0} & \tau_0'
\end{array}
\]

of Fun(∂Δ^n, D) to a 2-simplex

\[
\begin{array}{ccc}
\tau' & \xrightarrow{\alpha} & \tau'' \\
\downarrow{\beta} & & \downarrow{\gamma} \\
\tau & \xrightarrow{\gamma} & \tau''
\end{array}
\]

in the \(\infty\)-category Fun(Δ^n, D). Let \(S\) denote the simplicial subset of \(D\) given by the union of \(S_{\text{max}}\) with the image of \(\tau\). Then \(H_{\text{max}}\) extends uniquely to a morphism \(H_S : \Delta^1 \times S \to D\) for which the composite map

\[
\Delta^1 \times \Delta^n \xrightarrow{\text{id} \times \tau} \Delta^1 \times S \xrightarrow{H_S} D
\]

coincides with \(\gamma\). By construction, the pair \((S, H_S)\) is an element of \(Q\) satisfying \((S, H_S) > (S_{\text{max}}, H_{\text{max}})\), contradicting the maximality of \((S_{\text{max}}, H_{\text{max}})\). \(\square\)

5.4.7 Small Kan Complexes

In the setting of Kan complexes, essential \(\kappa\)-smallness can be tested at the level of homotopy groups.

**Proposition 5.4.7.1.** Let \(X\) be a Kan complex and let \(\kappa\) be an uncountable regular cardinal. Then \(X\) is essentially \(\kappa\)-small if and only if it satisfies the following pair of conditions:

1. The set \(\pi_0(X)\) is \(\kappa\)-small.
2. For each vertex \(x \in X\) and each integer \(n > 0\), the homotopy group \(\pi_n(X, x)\) is \(\kappa\)-small.

**Proof.** By virtue of Proposition 5.4.6.12, we may assume without loss of generality that the Kan complex \(X\) is minimal. If \(X\) is essentially \(\kappa\)-small, then it is \(\kappa\)-small (Corollary 5.4.6.9), so that conditions (1) and (2) follow immediately from the definitions. Conversely, suppose that (1) and (2) are satisfied; we wish to show that \(X\) is \(\kappa\)-small. By virtue of
Proposition 5.4.4.9 it will suffice to show that the collection of \( n \)-simplices of \( X \) is \( \kappa \)-small, for each \( n \geq 0 \). Our proof proceeds by induction on \( n \). Using our inductive hypothesis (together with Remark 5.4.3.4 and Proposition 5.4.3.5), we see that the set \( \text{Hom}_{\text{Set}_\Delta}(\Delta^n, X) \) is \( \kappa \)-small. Since \( \kappa \) is regular, it will suffice to show that each fiber of the restriction map \( \text{Hom}_{\text{Set}_\Delta}(\Delta^n, X) \to \text{Hom}_{\text{Set}_\Delta}(\partial \Delta^n, X) \) is \( \kappa \)-small.

Set \( E = \text{Fun}(\Delta^n, X) \) and \( B = \text{Fun}(\partial \Delta^n, X) \), so that the inclusion map \( \partial \Delta^n \hookrightarrow \Delta^n \) induces a Kan fibration \( q : E \to B \) (Corollary 3.1.3.3). For each vertex \( b \in B \), let \( E_b \) denote the fiber \( \{ b \} \times_B E \); we wish to show that the set of vertices of \( E_b \) is \( \kappa \)-small. Since the Kan complex \( X \) is minimal, each vertex of \( E_b \) belongs to a different connected component. It will therefore suffice to show that the set \( \pi_0(E_b) \) is \( \kappa \)-small. If \( n = 0 \), this follows from condition (1). Let us therefore assume that \( n > 0 \), and identify \( b \) with a morphism of simplicial sets \( \partial \Delta^n \to X \). If this morphism is not nullhomotopic, then the Kan complex \( E_b \) is empty and there is nothing to prove. We may therefore assume that there is a homotopy from \( b \) to a constant map \( b' : \partial \Delta^n \to \{ x \} \hookrightarrow X \). In this case, Proposition 5.2.2.18 supplies a homotopy equivalence of \( E_b \) with \( E_{b'} \). We are therefore reduced to proving that the set \( \pi_0(E_{b'}) \simeq \pi_n(X, x) \) is \( \kappa \)-small, which follows from condition (2). \( \square \)

**Corollary 5.4.7.2.** Let \( \kappa \) be an uncountable regular cardinal and let \( f : X \to Y \) be a Kan fibration between Kan complexes, where \( Y \) is essentially \( \kappa \)-small. The following conditions are equivalent:

(a) The Kan complex \( X \) is essentially \( \kappa \)-small.

(b) For each vertex \( y \in Y \), the fiber \( X_y = \{ y \} \times_Y X \) is essentially \( \kappa \)-small.

**Proof.** The implication \( (a) \Rightarrow (b) \) follows from Corollary 5.4.16 (and does not require the regularity of \( \kappa \)). Assume that condition \( (b) \) is satisfied; we will show that \( X \) satisfies the criteria of Proposition 5.4.7.1

1. Let \( y \) be a vertex of \( Y \) and let \([y]\) denote its image in \( \pi_0(Y) \). Since \( f \) is a Kan fibration, the tautological map \( \pi_0(X_y) \to \{ [y] \} \times_{\pi_0(Y)} \pi_0(X) \) is a surjection. Assumption \( (b) \) guarantees that \( \pi_0(X_y) \) is \( \kappa \)-small, so that the fiber \( \{ [y] \} \times_{\pi_0(Y)} \pi_0(X) \) is also \( \kappa \)-small. Since \( \pi_0(Y) \) is \( \kappa \)-small, the regularity of \( \kappa \) guarantees that \( \pi_0(X) \) is also \( \kappa \)-small.

2. Fix a vertex \( x \in X \) having image \( y = f(x) \), and let \( n > 0 \) be a positive integer. For each integer \( n > 0 \), Proposition 3.2.5.2 supplies an exact sequence of groups

\[
\pi_n(X_y, x) \to \pi_n(X, x) \xrightarrow{\pi_n(f)} \pi_n(Y, y).
\]

Consequently, every nonempty fiber of the group homomorphism \( \pi_n(f) \) carries a transitive action of the \( \kappa \)-small group \( \pi_n(X_y, x) \), and is therefore \( \kappa \)-small. Since the group \( \pi_n(Y, y) \) is \( \kappa \)-small, the regularity of \( \kappa \) guarantees that \( \pi_n(X, x) \) is \( \kappa \)-small.
Exercise 5.4.7.3. Let $\kappa$ be an uncountable regular cardinal and let $f : X \to Y$ be Kan fibration between Kan complexes. Suppose that $X$ is essentially $\kappa$-small, that each fiber $X_y = \{y\} \times_Y X$ is essentially $\kappa$-small, and that the morphism $\pi_0(f) : \pi_0(X) \to \pi_0(Y)$ is surjective. Show that $Y$ is also essentially $\kappa$-small.

5.4.8 Local Smallness

In mathematical practice, it is very common to encounter categories $\mathcal{C}$ which are not small but are nonetheless locally small: that is, for every pair of objects $X, Y \in \mathcal{C}$, the set $\text{Hom}_\mathcal{C}(X, Y)$ is small. We now consider a quantitative counterpart of this condition in the $\infty$-categorical setting.

Definition 5.4.8.1. Let $\kappa$ be an uncountable cardinal. We say that an $\infty$-category $\mathcal{C}$ is locally $\kappa$-small if, for every pair of objects $X, Y \in \mathcal{C}$, the Kan complex $\text{Hom}_\mathcal{C}(X, Y)$ is essentially $\kappa$-small.

Example 5.4.8.2. Let $\kappa$ be an uncountable cardinal and let $\mathcal{C}$ be a category. Then the $\infty$-category $N_{\bullet}(\mathcal{C})$ is locally $\kappa$-small if and only if, for every pair of objects $X, Y \in \mathcal{C}$, the set $\text{Hom}_\mathcal{C}(X, Y)$ is $\kappa$-small.

Example 5.4.8.3. Let $\kappa$ be an uncountable regular cardinal and let $X$ be a Kan complex. Then $X$ is locally $\kappa$-small if and only if, for every vertex $x \in X$ and every integer $n > 0$, the homotopy group $\pi_n(X, x)$ is $\kappa$-small.

Example 5.4.8.4. Let $\kappa$ be an uncountable cardinal and let $\mathcal{C}$ be an $\infty$-category which is essentially $\kappa$-small. Then $\mathcal{C}$ is locally $\kappa$-small: that is, for every pair of objects $X, Y \in \mathcal{C}$, the Kan complex $\text{Hom}_\mathcal{C}(X, Y)$ is essentially $\kappa$-small. This is a special case of Proposition 5.4.5.14, since $\text{Hom}_\mathcal{C}(X, Y)$ can be identified with the oriented fiber product $\{X\} \times_C \{Y\}$.

Remark 5.4.8.5 (Homotopy Invariance). Let $\kappa$ be an uncountable cardinal and let $F : \mathcal{C} \to \mathcal{D}$ be an equivalence of $\infty$-categories. Then $\mathcal{C}$ is locally $\kappa$-small if and only if $\mathcal{D}$ is locally $\kappa$-small.

Variant 5.4.8.6. Let $\mathcal{C}$ be an $\infty$-category. We say that $\mathcal{C}$ is locally small if, for every pair of objects $X, Y \in \mathcal{C}$, the Kan complex $\text{Hom}_\mathcal{C}(X, Y)$ is essentially small (that is, it is homotopy equivalent to a small Kan complex: see Variant 5.4.5.4).

Proposition 5.4.8.7. Let $\kappa$ be an uncountable regular cardinal and let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of $\infty$-categories. Assume that $\mathcal{C}$ is locally $\kappa$-small and that, for each object $C \in \mathcal{C}$, the fiber $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ is locally $\kappa$-small. Then $\mathcal{E}$ is locally $\kappa$-small.
Proof. Let $X$ and $Y$ be objects of $E$, and set $X = U(X)$ and $Y = U(Y)$. We wish to show that the Kan complex $\text{Hom}_C(X,Y)$ is essentially $\kappa$-small. By virtue of Proposition 4.6.1.19, the functor $U$ induces a Kan fibration $\theta : \text{Hom}_E(X,Y) \to \text{Hom}_C(X,Y)$. Our assumption that Condition (2) is satisfied; we wish to show that the Kan complex $\text{Hom}_C(X,Y)$ is essentially $\kappa$-small. By virtue of Corollary 5.4.7.2, it will suffice to show that for every morphism $\pi : X \to Y$ in $C$, the Kan complex $\text{Hom}_C(X,Y)_\pi = \{\pi\} \times_{\text{Hom}_C(X,Y)} \text{Hom}_C(X,Y)$ is essentially $\kappa$-small.

Since $U$ is a cocartesian fibration, we can lift $\pi$ to a $U$-cocartesian morphism $e : X \to Y'$ of $E$. Proposition 5.1.3.11 then supplies a homotopy equivalence of $\text{Hom}_E(X,Y)_\pi$ with the mapping space $\text{Hom}_{C_{/Y'}}(Y',Y)$ which is essentially $\kappa$-small by virtue of our assumption that $E_{/Y}$ is locally $\kappa$-small. □

Proposition 5.4.8.8. Let $\kappa$ be an uncountable regular cardinal and let $C$ be an $\infty$-category. The following conditions are equivalent:

(1) The $\infty$-category $C$ is essentially $\kappa$-small.

(2) The $\infty$-category $C$ is locally $\kappa$-small and the set of isomorphism classes $\pi_0(C^\sim)$ is $\kappa$-small.

(3) The Kan complex $\text{Fun}(\Delta^1,C)^\sim$ is essentially $\kappa$-small.

(4) For every finite simplicial set $K$, the Kan complex $\text{Fun}(K,C)^\sim$ is essentially $\kappa$-small.

(5) For every integer $n \geq 0$, the set $\pi_0(\text{Fun}(\Delta^n,C)^\sim)$ is $\kappa$-small. Moreover, for every map $b : \partial \Delta^n \to C$, the fundamental group $\pi_1(\text{Fun}(\partial \Delta^n,C)^\sim,b)$ is $\kappa$-small.

Proof. The implication (1) $\Rightarrow$ (2) follows from Example 5.4.8.4. We next show that (2) $\Rightarrow$ (3). Assume that condition (2) is satisfied; we wish to show that the Kan complex $\text{Fun}(\Delta^1,C)^\sim$ is essentially $\kappa$-small. Corollary 4.4.5.4 implies that the restriction map

$$\theta : \text{Fun}(\Delta^1,C)^\sim \to \text{Fun}(\partial \Delta^1,C)^\sim \simeq C^\sim \times C^\sim$$

is a Kan fibration. Moreover, for each vertex $(X,Y) \in C^\sim \times C^\sim$, the fiber $\theta^{-1}\{(X,Y)\}$ can be identified with the morphism space $\text{Hom}_C(X,Y)$, which is essentially $\kappa$-small by virtue of (2). Using Corollary 5.4.7.2 and Remark 5.4.5.8, we are reduced to proving that the Kan complex $C^\sim$ is essentially $\kappa$-small. Fix a vertex $X \in C^\sim$. For $n \geq 2$, Example 4.6.1.12 supplies an isomorphism $\pi_n(C^\sim,X) \simeq \pi_{n-1}(\text{Hom}_C(X,X),\text{id}_X)$, so that the homotopy group $\pi_n(C^\sim,X)$ is essentially small by virtue of assumption (2). Similarly, the fundamental group $\pi_1(C^\sim,X)$ can be identified with the subset of $\pi_0(\text{Hom}_C(X,X))$ spanned by the homotopy classes of isomorphisms, which is also $\kappa$-small. Since $\pi_0(C^\sim)$ is $\kappa$-small by virtue of assumption (2), Proposition 5.4.7.1 implies that the Kan complex $C^\sim$ is essentially $\kappa$-small.

We now show that (3) implies (4). Assume that the Kan complex $\text{Fun}(\Delta^1,C)^\sim$ is essentially $\kappa$-small and let $K$ be a finite simplicial set; we wish to show that $\text{Fun}(K,C)^\sim$ is
also essentially $\kappa$-small. We proceed by induction on the dimension $n$ of $K$ and the number
of nondegenerate $n$-simplices of $K$. If $K$ is empty, there is nothing to prove. Otherwise,
there exists a pushout square of simplicial sets
\[
\begin{array}{ccc}
\partial \Delta^n & \rightarrow & \Delta^n \\
\downarrow & & \downarrow \\
K' & \rightarrow & K.
\end{array}
\]
Since the horizontal maps are monomorphisms, this diagram is also a categorical pushout
square (Example 4.5.4.12) and therefore induces a homotopy pullback diagram of Kan
complexes
\[
\begin{array}{ccc}
\text{Fun}(\partial \Delta^n, \mathcal{C}) \sim & \leftarrow & \text{Fun}(\Delta^n, \mathcal{C}) \sim \\
\downarrow & & \downarrow \\
\text{Fun}(K', \mathcal{C}) \sim & \leftarrow & \text{Fun}(K, \mathcal{C}) \sim
\end{array}
\]
Our inductive hypothesis guarantees that $\text{Fun}(\partial \Delta^n, \mathcal{C}) \sim$ and $\text{Fun}(K', \mathcal{C}) \sim$ are essentially
$\kappa$-small. It will therefore suffice to show that the Kan complex $\text{Fun}(\Delta^n, \mathcal{C}) \sim$ is essentially
$\kappa$-small (Corollary 5.4.5.16). If $n = 1$, this follows from assumption (3). If $n \geq 2$, then the
inclusion map $\Lambda^n_0 \hookrightarrow \Delta^n$ induces a homotopy equivalence $\text{Fun}(\Delta^n, \mathcal{C}) \sim \rightarrow \text{Fun}(\Lambda^n_0, \mathcal{C}) \sim$, so
that the desired result again follows from our inductive hypothesis. It will therefore suffice
to treat the case $n = 0$: that is, to show that the Kan complex $\mathcal{C} \sim$ is essentially $\kappa$-small.
This follows from Corollary 5.4.5.13, since $\mathcal{C} \sim$ is homotopy equivalent to the summand
$\text{Isom}(\mathcal{C}) \sim \subseteq \text{Fun}(\Delta^1, \mathcal{C}) \sim$ (see Corollary 4.4.5.10).

The implication (4) $\Rightarrow$ (5) follows from Proposition 5.4.7.1. We will complete the proof
by showing that (5) implies (1). Assume that condition (5) is satisfied; we will show that $\mathcal{C}$ is
essentially $\kappa$-small. We now proceed as in the proof of Proposition 5.4.7.1. Using Proposition
5.4.6.12 we can reduce to the case where $\mathcal{C}$ is minimal. In this case, we wish to show that
$\mathcal{C}$ is $\kappa$-small. By virtue of Proposition 5.4.4.9 it will suffice to show that the collection of
$n$-simplices of $\mathcal{C}$ is $\kappa$-small, for each $n \geq 0$. Our proof proceeds by induction on $n$. Using
our inductive hypothesis (together with Remark 5.4.3.4 and Proposition 5.4.3.5), we see that
the set $\text{Hom}_{\text{Set}_{\Delta}}(\partial \Delta^n, \mathcal{C})$ is $\kappa$-small. Since $\kappa$ is regular, it will suffice to show that each fiber
of the restriction map $\text{Hom}_{\text{Set}_{\Delta}}(\Delta^n, \mathcal{C}) \rightarrow \text{Hom}_{\text{Set}_{\Delta}}(\partial \Delta^n, \mathcal{C})$ is $\kappa$-small.

Set $E = \text{Fun}(\Delta^n, \mathcal{C}) \sim$ and $B = \text{Fun}(\partial \Delta^n, \mathcal{C}) \sim$, so that the inclusion map $\partial \Delta^n \hookrightarrow \Delta^n$
duces a Kan fibration $q : E \rightarrow B$ (Corollary 4.4.5.4). Fix a vertex $b \in B$ and set
$E_b = \{b\} \times_B E$; we wish to show that the the set of vertices of $E_b$ is $\kappa$-small. Since $\mathcal{C}$ is
minimal, each vertex of $E_b$ belongs to a different connected component. It will therefore suffice to show that the set of connected components $\pi_0(E_b)$ is $\kappa$-small. Assumption (5) guarantees that the set $\pi_0(E)$ is $\kappa$-small. Moreover Corollary 3.2.5.5 shows that every nonempty fiber of the map $\pi_0(E_b) \to \pi_0(E)$ is equipped with a transitive action of the fundamental group $\pi_1(B,b)$, which is also $\kappa$-small. Since $\kappa$ is regular, it follows that the set $\pi_0(E_b)$ is also $\kappa$-small, as desired.

**Corollary 5.4.8.9.** Let $\kappa$ be an infinite cardinal, let $\lambda$ be an uncountable cardinal of exponential cofinality $\geq \kappa$ (Definition 5.4.3.16), and let $\mathcal{C}$ be an $\infty$-category which is locally $\lambda$-small. Then, for every $\kappa$-small simplicial set $K$, the $\infty$-category $\text{Fun}(K,\mathcal{C})$ is locally $\lambda$-small. Moreover, if $\kappa$ is uncountable, then it suffices to assume that $K$ is essentially $\kappa$-small.

**Proof.** Let $F,F' : K \to \mathcal{C}$ be diagrams; we wish to show that the morphism space $\text{Hom}_{\text{Fun}(K,\mathcal{C})}(F,F')$ is essentially $\lambda$-small. Let $\mathcal{C}_0 \subseteq \mathcal{C}$ be the full subcategory spanned by the essential images of $F$ and $F'$. Proposition 5.4.8.8 guarantees that $\mathcal{C}_0$ is essentially $\lambda$-small. It will therefore suffice to show that $\text{Fun}(K,\mathcal{C}_0)$ is locally $\lambda$-small, which follows immediately from Remark 5.4.5.10.

**Corollary 5.4.8.10.** Let $\mathcal{C}$ and $\mathcal{D}$ be $\infty$-categories. If $\mathcal{C}$ is essentially small and $\mathcal{D}$ is locally small, then the $\infty$-category $\text{Fun}(\mathcal{C},\mathcal{D})$ is locally small.

We now prove a generalization of Corollary 5.4.7.2.

**Corollary 5.4.8.11.** Let $\kappa$ be an uncountable regular cardinal, let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets, and suppose that $\mathcal{C}$ is essentially $\kappa$-small. The following conditions are equivalent:

1. The $\infty$-category $\mathcal{E}$ is essentially $\kappa$-small.
2. For every vertex $C \in \mathcal{C}$, the $\infty$-category $\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}$ is essentially $\kappa$-small.

**Proof.** Using Corollary 4.1.3.3, we can choose an inner anodyne morphism $\mathcal{C} \hookrightarrow \mathcal{C}'$, where $\mathcal{C}'$ is an $\infty$-category. Using Proposition 5.7.7.2, we can write $U$ as the pullback of a cocartesian fibration $U' : \mathcal{E}' \to \mathcal{C}'$. Proposition 5.3.6.1 then guarantees that the inclusion map $\mathcal{E} \hookrightarrow \mathcal{E}'$ is a categorical equivalence of simplicial sets. Since the inclusion $\mathcal{C} \hookrightarrow \mathcal{C}'$ is bijective on vertices, every fiber of $U'$ can also be regarded as a fiber of $U$. We can therefore replace $U$ by $U'$, and thereby reduce to proving Corollary 5.4.8.11 in the special case where $U$ is a cocartesian fibration of $\infty$-categories.
Note that $U$ is an isofibration (Proposition 5.1.4.8). Consequently, for each object $C \in C$, the diagram

```
\begin{array}{ccc}
E_C & \longrightarrow & E \\
\downarrow & & \downarrow U \\
\{C\} & \longrightarrow & C
\end{array}
```

is a categorical pullback diagram of simplicial sets (Corollary 4.5.2.21). The implication (1) $\Rightarrow$ (2) now follows from Corollary 5.4.5.16 (and does not require the assumption that $\kappa$ is regular). To prove the reverse implication, we first note that the $\infty$-category $C$ and each fiber $E_C$ are locally $\kappa$-small (Example 5.4.8.4). Applying Proposition 5.4.8.7, we see that $E$ is locally $\kappa$-small. It will therefore suffice to show that the set of isomorphism classes $\pi_0(E_C)\simeq$ is $\kappa$-small (Proposition 5.4.8.8). The functor $U$ induces a map $\theta : \pi_0(E_C)\simeq \rightarrow \pi_0(C)\simeq$, whose target is $\kappa$-small. Invoking the regularity of $\kappa$, we are reduced to showing that for every element $[C] \in \pi_0(C)\simeq$, the inverse image $\theta^{-1}\{[C]\}$ is a $\kappa$-small set. Let us identify $[C]$ with the isomorphism class of an object $C \in C$. Then there is a surjective map $\pi_0(E_C)\simeq \rightarrow \theta^{-1}\{[C]\}$. Since the $\infty$-category $E_C$ is essentially $\kappa$-small, the set $\pi_0(E_C)\simeq$ is $\kappa$-small, so that the quotient $\theta^{-1}\{[C]\}$ is also $\kappa$-small (Remark 5.4.3.4). 

**Warning 5.4.8.12.** The implication (2) $\Rightarrow$ (1) of Corollary 5.4.8.11 is generally false if we assume only that $U$ is an isofibration. For example, let $S$ be a set and let $E$ be the category containing a pair of objects $X$ and $Y$, with morphisms given by

$\text{Hom}_E(X, X) = \{\text{id}_X\} \quad \text{Hom}_E(Y, Y) = \{\text{id}_Y\}$

$\text{Hom}_E(X, Y) = S \quad \text{Hom}_E(Y, X) = \emptyset$.

Then there is a unique isofibration $U : N_\bullet(E) \rightarrow \Delta^1$ satisfying $U(X) = 0$ and $U(Y) = 1$. The $\infty$-categories $\Delta^1, U^{-1}\{0\},$ and $U^{-1}\{1\}$ are finite simplicial sets (and are therefore essentially $\kappa$-small for every uncountable cardinal $\kappa$). However, the $\infty$-category $N_\bullet(E)$ is essentially $\kappa$-small if and only if the set $S$ is $\kappa$-small.

### 5.5 $(\infty, 2)$-Categories

In §1.3 we defined an $\infty$-category to be a simplicial set $C$ which satisfies the weak Kan extension condition: for $0 < i < n$, every morphism of simplicial sets $\Lambda_i^n \rightarrow C$ can be extended to an $n$-simplex of $C$ (Definition 1.3.0.1). Beware that this terminology is potentially confusing, because the theory of $\infty$-categories does not generalize the classical theory of 2-categories. For every 2-category $E$, the Duskin nerve $N_\bullet^D(E)$ is a simplicial set.
which determines $\mathcal{E}$ up to isomorphism (Theorem 2.3.4.1). However, the simplicial set $\mathcal{N}_\bullet^D(\mathcal{E})$ is an $\infty$-category if and only if $\mathcal{E}$ is a $(2,1)$-category: that is, every 2-morphism in $\mathcal{E}$ is invertible (Theorem 2.3.2.1). Consequently, one can view the notions of 2-category and $\infty$-category as mutually incomparable extensions of the notion of $(2,1)$-category. Our goal in this section is to show that these extensions admit a common generalization: a class of simplicial sets which we will refer to as $(\infty,2)$-categories.

Our starting point is the notion of a thin 2-simplex, which was introduced in §2.3.2. Recall that if $\mathcal{C}$ is a simplicial set, then a 2-simplex $\sigma$ of $\mathcal{C}$ is thin if every morphism of simplicial sets $\tau_0 : \Lambda^n_i \to \mathcal{C}$ can be extended to an $n$-simplex of $\mathcal{C}$, provided that $0 < i < n$, $n \geq 3$, and the 2-simplex $\tau_0|_{\mathcal{N}_\bullet((i-1<i<i+1))}$ is equal to $\sigma$ (Definition 2.3.2.3). By virtue of Example 2.3.2.4, $\mathcal{C}$ is an $\infty$-category if and only if it satisfies the following pair of conditions:

1. Every morphism of simplicial sets $\Lambda^2_1 \to \mathcal{C}$ can be extended to a 2-simplex of $\mathcal{C}$.
2. Every 2-simplex of $\mathcal{C}$ is thin.

We will obtain the notion of $(\infty,2)$-category by weakening (2) to the requirement that degenerate 2-simplices of $\mathcal{C}$ are thin, but strengthening (1) to require that every map $\Lambda^2_1 \to \mathcal{C}$ can be extended to a thin 2-simplex of $\mathcal{C}$. We will also add additional axioms that guarantee the ability to fill outer horns of $\mathcal{C}$ in certain special circumstances (see Definition 5.5.1.3).

Every $\infty$-category is an $(\infty,2)$-category (Proposition 5.5.1.4), and every 2-category can be regarded as an $(\infty,2)$-category by passing to its Duskin nerve (Proposition 5.5.1.7). The situation is summarized in the following diagram:

\[
\begin{array}{ccc}
\{\text{Groupoids}\} & \subset & \{\text{Categories}\} \\
\cap & & \cap \\
\{\text{2-Groupoids}\} & \subset & \{(2,1)\text{-Categories}\} & \subset & \{\text{2-Categories}\} \\
& \downarrow \mathcal{N}_\bullet^D & & \downarrow \mathcal{N}_\bullet^D & \\
\{\text{Kan Complexes}\} & \subset & \{\infty\text{-Categories}\} & \subset & \{(\infty,2)\text{-Categories}\},
\end{array}
\]

where none of the inclusions is reversible.

Let $\mathcal{C}$ be a simplicial set containing a pair of objects $X$ and $Y$, and let $\text{Hom}_\mathcal{C}^L(X,Y)$ and $\text{Hom}_\mathcal{C}^R(X,Y)$ denote the pinched morphism spaces of Construction 4.6.5.1. If $\mathcal{C}$ is an $\infty$-category, then the simplicial sets $\text{Hom}_\mathcal{C}^L(X,Y)$ and $\text{Hom}_\mathcal{C}^R(X,Y)$ are Kan complexes (Proposition 4.6.5.4). In §5.5.3 we prove an analogous result: if $\mathcal{C}$ is an $(\infty,2)$-category, then the simplicial sets $\text{Hom}_\mathcal{C}^L(X,Y)$ and $\text{Hom}_\mathcal{C}^R(X,Y)$ are $\infty$-categories (Corollary 5.5.3.5).
CHAPTER 5. FIBRATIONS OF $\infty$-CATEGORIES

Recall that $\text{Hom}_L^C(X,Y)$ is defined as the fiber over $Y$ of the projection map $q : C_X \to C$, and $\text{Hom}_R^C(X,Y)$ is defined as the fiber over $X$ of the projection map $q' : C_Y \to C$. When $C$ is an $\infty$-category, the morphism $q$ is a left fibration of simplicial sets and the morphism $q'$ is a right fibration of simplicial sets (Corollary 4.3.6.11). Beware that, in the case where $C$ is an $(\infty, 2)$-category, the morphisms $q$ and $q'$ are generally not inner fibrations. Nevertheless, we will deduce that the fibers of $q$ and $q'$ are $\infty$-categories by showing that $q$ and $q'$ are interior fibrations (Definition 5.5.2.1), a class of morphisms which we introduce and study in §5.5.2. From this we deduce also that the simplicial sets $C_X$ and $C_Y$ are $(\infty, 2)$-categories; moreover, an analogous result holds more generally for the slice and coslice constructions associated to any diagram $f : K \to C$ (Corollary 5.5.3.4).

Suppose that we are given a 2-simplex $\sigma$ of a simplicial set $C$, whose 1-skeleton we indicate in the diagram

```
X \arrow{dr}{h} \arrow{rr}{f} & & Y \arrow{ur}{g} \\
& Z
```

Writing $q : C_X \to C$ for the projection map, we can identify $\sigma$ with an edge $\tilde{g}$ of the simplicial set $C_X$ satisfying $q(\tilde{g}) = g$. It follows immediately from the definition that if the 2-simplex $\sigma$ is thin, then the edge $\tilde{g}$ is $q$-cocartesian (in the sense of Definition 5.1.1.1); in particular, it is locally $q$-cocartesian. In §5.5.4 we prove that if $C$ is an $(\infty, 2)$-category, then the converse holds: every locally $q$-cocartesian edge of $C_X$ is thin when viewed as a 2-simplex of $C$ (Theorem 5.5.4.1). Roughly speaking, one can think of $\tilde{g}$ as encoding the datum of a morphism $\gamma$ from $g \circ f$ to $h$ in the $\infty$-category $\text{Hom}_L^C(X,Z)$; Theorem 5.5.4.1 confirms the heuristic that $\gamma$ is an isomorphism if and only if $\sigma$ is thin (in the case where $C$ is the Duskin nerve of a 2-category, this is also the content of Theorem 2.3.2.5).

Let $C$ be an $(\infty, 2)$-category. We define the pith of $C$ to be the simplicial subset $\text{Pith}(C) \subseteq C$ consisting of those simplices $\Delta^m \to C$ which carry each 2-simplex of $\Delta^m$ to a thin 2-simplex of $C$ (Construction 5.5.5.1). In §5.5.6 we show that Pith$(C)$ is an $\infty$-category (Proposition 5.5.6.1) whose pinched morphism spaces $\text{Hom}_{\text{Pith}(C)}^L(X,Y)$ and $\text{Hom}_{\text{Pith}(C)}^R(X,Y)$ can be identified with the cores of the $\infty$-categories $\text{Hom}_C^L(X,Y)$ and $\text{Hom}_C^R(X,Y)$, respectively (Proposition 5.5.6.12). Roughly speaking, one can think of the $\infty$-category Pith$(C)$ as obtained from the $(\infty, 2)$-category by “discarding” its noninvertible 2-morphisms. In particular, when $C$ is the Duskin nerve of a 2-category $E$, we can identify Pith$(C)$ with the Duskin nerve of the $(2, 1)$-category Pith$(E)$ introduced in Construction 2.2.8.9 (Example 5.5.5.4).

Let $C$ and $D$ be $(\infty, 2)$-categories. We define a functor from $C$ to $D$ to be a morphism of simplicial sets $F : C \to D$ which carries thin 2-simplices of $C$ to thin 2-simplices of $D$...
5.5. \((\infty, 2)\)-CATEGORIES

(Definition 5.5.7.1). This definition can be somewhat cumbersome to work with in practice, because it requires us to check a condition for every thin 2-simplex of \(C\). In §5.5.7, we show that this is unnecessary: to verify that a morphism of simplicial sets \(F : C \to D\) is a functor, it suffices to show that every morphism \(\sigma_0 : \Lambda^2_2 \to C\) can be extended to a thin 2-simplex \(\sigma\) of \(C\) for which \(F(\sigma)\) is a thin 2-simplex of \(D\) (Proposition 5.5.7.8). Here we can think of \(\sigma_0\) as given by a pair of morphisms \(X \overset{f}{\rightarrow} Y \overset{g}{\rightarrow} Z\), and the thinness assumption on \(F(\sigma)\) corresponds heuristically to the requirement that \(F\) “preserves” the composition of \(f\) and \(g\) (up to isomorphism). Our proof will make use of a certain closure property enjoyed by the thin 2-simplices of an \((\infty, 2)\)-category which we refer to as the four-out-of-five property, which we formulate and study in §5.5.6 (see Definition 5.5.6.8 and Proposition 5.5.6.11).

Recall that a 2-category \(E\) is strict if its unit and associativity constraints are identity morphisms (Example 2.2.1.4); in this case, we can view \(E\) as an ordinary category which is enriched over \(\text{Cat}\) (see Definition 2.2.0.1). This notion has a counterpart in the setting of \((\infty, 2)\)-categories. Let \(\text{Set}_\Delta\) denote the ordinary category of simplicial sets, and let \(\text{QCat}\) denote the full subcategory of \(\text{Set}_\Delta\) whose objects are \(\infty\)-categories. Let \(E\) be a \(\text{QCat}\)-enriched category: that is, a simplicial category with the property that, for every pair of objects \(X, Y \in C\), the simplicial set \(\text{Hom}_C(X, Y)_\bullet\) is an \(\infty\)-category. In §5.5.8, we show that the homotopy coherent nerve \(N^\text{hc}\) of \(\text{QCat}\) is an \((\infty, 2)\)-category (Theorem 5.5.8.1). The construction \(E \mapsto N^\text{hc}(E)\) can be regarded as a generalization of the inclusion from strict 2-categories into general 2-categories (recall that if \(E\) is a strict 2-category, then its Duskin nerve can be identified with the homotopy coherent nerve of the associated simplicial category; see Example 2.4.3.11). Beware that not every \((\infty, 2)\)-category \(C\) is isomorphic to the homotopy coherent nerve of a \(\text{QCat}\)-enriched category. Nevertheless, we will later prove a coherence theorem which guarantees that \(C\) is equivalent to the homotopy coherent nerve of a \(\text{QCat}\)-enriched category: see Theorem [?].

**Remark 5.5.0.1.** The ideas presented in this section are closely related to the work of Verity, who has proposed a simplicial framework for studying higher categories with noninvertible morphisms at all levels. We refer the reader to [53], [54], and [52] for Verity’s work, and to [23] for a discussion of its relationship to the theory of \((\infty, 2)\)-categories presented here.

5.5.1 Definitions

We begin by introducing some terminology.

**Definition 5.5.1.1.** Let \(X\) be a simplicial set and let \(\sigma : \Delta^2 \rightarrow X\) be a 2-simplex of \(X\). We will say that \(\sigma\) is left-degenerate if it factors through the map \(\sigma^0 : \Delta^2 \rightarrow \Delta^1\) given on vertices by \(\sigma^0(0) = 0 = \sigma^0(1)\) and \(\sigma^0(2) = 1\) (Notation 1.1.1.9). We say that \(\sigma\) is right-degenerate if it factors through the map \(\sigma^1 : \Delta^2 \rightarrow \Delta^1\) given on vertices \(\sigma^1(0) = 0\) and \(\sigma^1(1) = 1 = \sigma^1(2)\).

**Remark 5.5.1.2.** Let \(X\) be a simplicial set. Then:
• A 2-simplex $\sigma$ of $X$ is degenerate (in the sense of Definition 1.1.3.2) if and only if it is either left-degenerate or right-degenerate.

• A 2-simplex $\sigma$ of $X$ is constant (that is, factors through the projection map $\Delta^2 \to \Delta^0$) if and only if it is both left-degenerate and right-degenerate.

• A 2-simplex $\sigma$ of $X$ is left-degenerate if and only if it is right-degenerate when viewed as a 2-simplex of the opposite simplicial set $X^\text{op}$.

**Definition 5.5.1.3.** Let $C$ be a simplicial set. We will say that $C$ is an $(\infty, 2)$-category if it satisfies the following axioms:

1. Every morphism of simplicial sets $\Lambda^2_1 \to C$ can be extended to a thin 2-simplex of $C$.
2. Every degenerate 2-simplex of $C$ is thin.
3. Let $n \geq 3$ and let $\sigma_0 : \Lambda^n_0 \to C$ be a morphism of simplicial sets with the property that the 2-simplex $\sigma_0 |_{N^\bullet(\{0 < 1 < n\})}$ is left-degenerate. Then $\sigma_0$ can be extended to an $n$-simplex of $C$.
4. Let $n \geq 3$ and let $\sigma_0 : \Lambda^n_0 \to C$ be a morphism of simplicial sets with the property that the 2-simplex $\sigma_0 |_{N^\bullet(\{0 < n-1 < n\})}$ is right-degenerate. Then $\sigma_0$ can be extended to an $n$-simplex of $C$.

**Proposition 5.5.1.4.** Let $C$ be an $\infty$-category. Then $C$ is an $(\infty, 2)$-category.

**Proof.** Our assumption that $C$ is an $\infty$-category guarantees that every 2-simplex of $C$ is thin (Example 2.3.2.4). Consequently, condition (2) of Definition 5.5.1.3 is automatic, and condition (1) follows immediately from the definition. Conditions (3) and (4) follow from Theorem 4.4.2.6 (since every degenerate edge of $C$ is an isomorphism).

**Remark 5.5.1.5.** Let $C$ be an $(\infty, 2)$-category. We will refer to vertices of $C$ as objects, and to the edges of $C$ as morphisms. If $f$ is an edge of $C$ satisfying $d_1(f) = X$ and $d_0(f) = Y$, then we say that $f$ is a morphism from $X$ to $Y$ and write $f : X \to Y$.

Suppose we are given morphisms $f : X \to Y$, $g : Y \to Z$, and $h : X \to Z$ of $C$. We will say that a 2-simplex $\sigma$ witnesses $h$ as a composition of $f$ and $g$ if it is thin and satisfies $d_0(\sigma) = g$, $d_1(\sigma) = h$, and $d_2(\sigma) = f$, as indicated in the diagram

```
\begin{tikzpicture}
  \node (X) at (0,0) {$X$};
  \node (Y) at (2,2) {$Y$};
  \node (Z) at (4,0) {$Z$};
  \draw[->] (X) -- node[below] {$h$} (Z);
  \draw[->] (X) -- node[above] {$f$} (Y);
  \draw[->] (Y) -- node[above] {$g$} (Z);
\end{tikzpicture}
```

Note that:
5.5. \((\infty,2)\text{-CATEGORIES}\)

- When \(\mathcal{C}\) is an \(\infty\)-category, this recovers the terminology of Definition \[1.3.4.1\] (since the 2-simplex \(\sigma\) is automatically thin).

- If \(\mathcal{C}\) is the Duskin nerve of a 2-category \(\mathcal{E}\), the 2-simplex \(\sigma\) can be identified with a 2-morphism \(\gamma : g \circ f \Rightarrow h\) of \(\mathcal{E}\), which is invertible if and only if \(\sigma\) is thin. In other words, \(\sigma\) witnesses \(h\) as a composition of \(f\) and \(g\) if and only if it encodes the datum of an isomorphism \(g \circ f \cong h\) in the category \(\text{Hom}_\mathcal{E}(X,Z)\).

- Axiom (1) of Definition \[5.5.1.3\] asserts that the composition of 1-morphisms in \(\mathcal{C}\) is defined (albeit not uniquely). More precisely, it asserts that for every pair of morphisms \(f : X \to Y\) and \(g : Y \to Z\), there exists a morphism \(h : X \to Z\) and a 2-simplex which witnesses \(h\) as a composition of \(f\) and \(g\).

**Remark 5.5.1.6.** Let \(\mathcal{C}\) be a simplicial set. Then \(\mathcal{C}\) is an \((\infty,2)\)-category if and only if the opposite simplicial set \(\mathcal{C}^{op}\) is an \((\infty,2)\)-category.

**Proposition 5.5.1.7.** Let \(\mathcal{C}\) be a 2-category. Then the Duskin nerve \(N^D(\mathcal{C})\) is an \((\infty,2)\)-category.

**Proof.** Condition (1) of Definition \[5.5.1.3\] follows immediately from Theorem \[2.3.2.5\] and condition (2) from Corollary \[2.3.2.7\]. We will verify (4); the proof of (3) is similar. Suppose we are given an integer \(n \geq 3\) and a map \(\sigma_0 : \Lambda^n_3 \to N^D(\mathcal{C})\). for which the restriction \(\sigma_0|_{N^+\{0<\cdots<n\}}\) is right-degenerate. We wish to show that \(\sigma_0\) can be extended to an \(n\)-simplex of \(N^D(\mathcal{C})\). We now consider three cases:

- Suppose that \(n = 3\). Then \(\sigma_0\) can be identified with a collection of objects \(\{X_i\}_{0 \leq i \leq 3}\), 1-morphisms \(\{f_{ji} : X_i \to X_j\}_{0 \leq i, j \leq 3}\), and 2-morphisms

\[
\mu_{321} : f_{32} \circ f_{21} \Rightarrow f_{31} \quad \mu_{320} : f_{32} \circ f_{20} \Rightarrow f_{30} \quad \mu_{310} : f_{31} \circ f_{10} \Rightarrow f_{30}
\]

in the 2-category \(\mathcal{C}\). The assumption that \(\sigma_0|_{N^+\{0<\cdots<n\}}\) is right-degenerate guarantees that \(X_2 = X_3\), that \(f_{20} = f_{30}\), that the 1-morphism \(f_{32}\) is the identity \(id_{X_2}\), and that \(\mu_{320}\) is the left unit constraint \(\lambda_{f_{20}}\). To extend \(\sigma_0\) to a 3-simplex of \(N^D\), we must
show that there exists a 2-morphism \( \mu_{210} : f_{21} \circ f_{10} \Rightarrow f_{20} \) for which the diagram

\[
\begin{array}{ccc}
\mu_{320} \circ \mu_{210} & \sim & \mu_{321} \circ \text{id}_{f_{10}} \\
\downarrow & & \downarrow \\
f_{32} \circ f_{20} & \Rightarrow & f_{31} \circ f_{10}
\end{array}
\]

is commutative, where \( \alpha = \alpha_{f_{32}, f_{21}, f_{10}} \) is the associativity constraint for the composition of 1-morphisms in \( \mathcal{C} \) (Proposition \textbf{2.3.1.9}). This commutativity can be rewritten as an equation

\[
\mu_{320}(\text{id}_{f_{32}} \circ \mu_{210}) = \mu_{310}(\mu_{321} \circ \text{id}_{f_{10}}) \alpha.
\]

This equation has a unique solution, because \( \mu_{320} \) is invertible and horizontal composition with \( f_{32} \) induces an equivalence of categories \( \text{Hom}_\mathcal{C}(X_0, X_2) \to \text{Hom}_\mathcal{C}(X_0, X_3) \).

- Suppose that \( n = 4 \). The restriction of \( \sigma_0 \) to the 2-skeleton of \( \Delta^4 \) can be identified with a collection of objects \( \{X_i\}_{0 \leq i \leq 4} \), 1-morphisms \( \{f_{ji} : X_i \to X_j\}_{0 \leq i < j \leq 4} \), and 2-morphisms \( \{\mu_{kji} : f_{kj} \circ f_{ji} \Rightarrow f_{ki}\}_{0 \leq i < j < k \leq 4} \) in the 2-category \( \mathcal{C} \). The assumption that \( \sigma_0|_{N_\bullet(\{0 < n-1 < n\})} \) is right-degenerate guarantees that \( X_3 = X_4 \), that \( f_{30} = f_{40} \), that the 1-morphism \( f_{43} \) is the identity \( \text{id}_{X_3} \), and that \( \mu_{430} \) is the left unit constraint.
Consider the diagram

\[
\begin{array}{c}
\mu_{310} \quad \mu_{320} \\
\mu_{430} \\
\mu_{431} \\
\mu_{421}
\end{array}
\]

in the category \(\text{Hom}_C(X_0, X_4)\), where the unlabeled 2-morphisms are given by the associativity constraints. Note that the 4-cycles in this diagram commute by functoriality, and the central 5-cycle commutes by the pentagon identity of \(C\). Our assumption that \(\sigma_0\) is defined on the horn \(\Lambda^4_4\) guarantees that pentagonal cycles on the right and bottom of the diagram are commutative and that the outer cycle commutes. Since the 2-morphism \(\mu_{430}\) is invertible, a diagram chase shows that the pentagonal cycle on the left of the diagram also commutes. Since \(f_{43}\) is an identity 1-morphism, horizontal composition with \(f_{43}\) is isomorphic to the identity (via the left unit constraint of Construction 2.2.1.11) and is therefore faithful. It follows that the diagram (5.24) is commutative, so that \(\sigma_0\) extends (uniquely) to a 4-simplex of \(N^D_\bullet(C)\).

- If \(n \geq 5\), then the horn \(\Lambda^n_0\) contains the 3-skeleton of \(\Delta^n\). In this case, the morphism \(\sigma_0 : \Lambda^n_0 \to N^D_\bullet(C)\) extends uniquely to an \(n\)-simplex of \(N^D_\bullet(C)\) by virtue of Corollary 2.3.1.10.

5.5.2 Interior Fibrations

Recall that a morphism of simplicial sets \(q : C \to D\) is an inner fibration if it has the right lifting property with respect to the horn inclusion \(\Lambda^i_0 \to \Delta^n\) for every pair of integers \(0 < i < n\). In the setting of \((\infty, 2)\)-categories, it will be convenient to consider a variant of this condition.
CHAPTER 5. FIBRATIONS OF ∞-CATEGORIES

Definition 5.5.2.1. Let $\mathcal{D}$ be an $(\infty, 2)$-category and let $q : \mathcal{C} \to \mathcal{D}$ be a morphism of simplicial sets. We will say that $q$ is an interior fibration if it satisfies the following conditions:

- Every lifting problem

\[
\begin{array}{ccc}
\Lambda^n_i & \xrightarrow{\sigma_0} & \mathcal{C} \\
\downarrow & & \downarrow q \\
\Delta^n & \xrightarrow{\sigma} & \mathcal{D}
\end{array}
\]

admits a solution, provided that $0 < i < n$ and the restriction $\sigma|_{\Delta^n(i-1 < i < i+1)}$ is a thin 2-simplex of $\mathcal{D}$.

- For every vertex $X \in \mathcal{C}$, the degenerate edge $\text{id}_X$ is $q$-cartesian and $q$-cocartesian.

Example 5.5.2.2. Let $\mathcal{D}$ be an $\infty$-category and let $q : \mathcal{C} \to \mathcal{D}$ be a morphism of simplicial sets. The following conditions are equivalent:

1. The morphism $q$ is an interior fibration (in the sense of Definition 5.5.2.1).
2. The morphism $q$ is an inner fibration (in the sense of Definition 4.1.1.1).

The implication $(1) \Rightarrow (2)$ follows from the observation that every 2-simplex of $\mathcal{D}$ is thin, and the implication $(2) \Rightarrow (1)$ follows from Corollary 5.1.1.9. In particular, if either of these conditions is satisfied, then $\mathcal{C}$ is an $\infty$-category.

Remark 5.5.2.3. Let $\mathcal{D}$ be an $(\infty, 2)$-category and let $q : \mathcal{C} \to \mathcal{D}$ be a morphism of simplicial sets. Then $q$ is an interior fibration if and only if the opposite morphism $q^{\text{op}} : \mathcal{C}^{\text{op}} \to \mathcal{D}^{\text{op}}$ is an interior fibration.

Remark 5.5.2.4. Suppose we are given a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{C}' & \xrightarrow{q'} & \mathcal{C} \\
\downarrow & & \downarrow q \\
\mathcal{D}' & \xrightarrow{F} & \mathcal{D}.
\end{array}
\]

Assume that $\mathcal{D}$ and $\mathcal{D}'$ are $(\infty, 2)$-categories and that the morphism $F$ carries thin 2-simplices of $\mathcal{D}'$ to thin 2-simplices of $\mathcal{D}$ (that is, that $F$ is a functor of $(\infty, 2)$-categories; see Definition 5.5.7.1). If $q$ is an interior fibration, then $q'$ is an interior fibration.
Remark 5.5.2.5. Let \( D \) be an \((\infty, 2)\)-category and let \( q : C \to D \) be an interior fibration. Then, for every object \( X \in D \), the fiber \( C_X = \{ X \} \times_D C \) is an \( \infty \)-category (this follows by combining Example 5.5.2.2 with Remark 5.5.2.4).

Our goal in this section is to show that, if \( D \) is an \((\infty, 2)\)-category and \( q : C \to D \) is an interior fibration of simplicial sets, then \( C \) is also an \((\infty, 2)\)-category (Proposition 5.5.2.8). To prove this, we must exhibit a sufficiently large collection of thin 2-simplices of \( C \).

Lemma 5.5.2.6. Let \( D \) be an \((\infty, 2)\)-category, let \( q : C \to D \) be an interior fibration of simplicial sets, and let \( \sigma \) be a 2-simplex of \( C \). If \( q(\sigma) \) is a thin 2-simplex of \( D \), then \( \sigma \) is a thin 2-simplex of \( C \).

Proof. Suppose we are given a morphism of simplicial sets \( \tau_0 : \Lambda_i^2 \to C \), where \( n \geq 3 \), \( 0 < i < n \), and \( \tau_0 \) carries \( N_\bullet(\{ i-1 < i < i+1 \}) \) to the 2-simplex \( \sigma \). We wish to show that \( \tau_0 \) can be extended to an \( n \)-simplex \( \tau \) of \( C \). Let \( \tau_0 : \Lambda_i^n \to D \) be the composition \( q \circ \tau_0 \). Since \( q(\sigma) \) is a thin 2-simplex of \( D \), we can extend \( \tau_0 \) to an \( n \)-simplex \( \tau : \Delta^n \to D \). To complete the proof, it suffices to find a solution to the lifting problem

\[
\begin{array}{ccc}
\Lambda_i^2 & \xrightarrow{\tau_0} & C \\
\downarrow \downarrow & & \downarrow q \\
\Delta^n & \xleftarrow{\tau} & D \\
\end{array}
\]

which exists by virtue of our assumption that \( q \) is an interior fibration. \(\square\)

Remark 5.5.2.7. In the situation of Lemma 5.5.2.6, we will see later that the converse assertion is also true: if \( \sigma \) is a thin 2-simplex of \( C \), then \( q(\sigma) \) is a thin 2-simplex of \( D \) (Proposition 5.5.7.9).

Proposition 5.5.2.8. Let \( D \) be an \((\infty, 2)\)-category and let \( q : C \to D \) be an interior fibration of simplicial sets. Then \( C \) is also an \((\infty, 2)\)-category.

Proof. We must verify that the simplicial set \( C \) satisfies each of the axioms of Definition 5.5.1.3:

1. Let \( f : X \to Y \) and \( g : Y \to Z \) be edges of the simplicial set \( C \); we wish to show that there exists a thin 2-simplex \( \Delta^2 \to C \) satisfying \( d_2(\sigma) = f \) and \( d_0(\sigma) = g \), as indicated in the diagram

\[
\begin{array}{ccc}
& Y & \\
& \searrow f & \nearrow g \\
X & \downarrow & Z \\
\end{array}
\]
We first invoke our assumption that $\mathcal{D}$ is an $(\infty, 2)$-category to choose a thin 2-simplex $\sigma$ of $\mathcal{D}$ satisfying $d_2(\sigma) = q(f)$ and $d_0(\sigma) = q(g)$. Since $\sigma$ is thin, our assumption that $q$ is an interior fibration guarantees that the lifting problem

\[
\Lambda^2 \overset{(g \bullet f)}{\rightarrow} \mathcal{C} \quad \downarrow q \\
\Delta^2 \overset{\sigma}{\rightarrow} \mathcal{D}
\]

admits a solution. It follows from Lemma 5.5.2.6 that $\sigma$ is a thin 2-simplex of $\mathcal{C}$.

(2) Let $\sigma$ be a degenerate 2-simplex of $\mathcal{C}$. Then $q(\sigma)$ is a degenerate 2-simplex of $\mathcal{D}$. Since $\mathcal{D}$ is an $(\infty, 2)$-category, $q(\sigma)$ is a thin 2-simplex of $\mathcal{D}$. Applying Lemma 5.5.2.6, we conclude that $\sigma$ is a thin 2-simplex of $\mathcal{C}$.

(3) Let $n \geq 3$ and let $\tau_0 : \Lambda^n_0 \rightarrow \mathcal{C}$ be a morphism of simplicial sets with the property that the 2-simplex $\tau_0|_{N_\bullet(\{0 < 1 < n\})}$ is left-degenerate; we wish to show that $\tau_0$ can be extended to an $n$-simplex $\tau$ of $\mathcal{C}$. Let $\tau_0 : \Lambda^n_0 \rightarrow \mathcal{D}$ denote the composition $q \circ \tau_0$. Since $\mathcal{D}$ is an $(\infty, 2)$-category, we can extend $\tau_0$ to an $n$-simplex $\tau : \Delta^n \rightarrow \mathcal{D}$. To complete the proof, it will suffice to show that the lifting problem

\[
\Lambda^n \overset{\tau_0}{\rightarrow} \mathcal{C} \quad \downarrow q \\
\Delta^n \overset{\tau}{\rightarrow} \mathcal{D}
\]

admits a solution. We conclude by observing that the edge $\tau_0|_{N_\bullet(\{0 < 1\})}$ is degenerate and is therefore $q$-cocartesian by virtue of our assumption that $q$ is an interior fibration.

(4) Let $n \geq 3$ and let $\tau_0 : \Lambda^n_0 \rightarrow \mathcal{C}$ be a morphism of simplicial sets with the property that the 2-simplex $\tau_0|_{N_\bullet(\{0 < n-1 < n\})}$ is right-degenerate; we wish to show that $\tau_0$ can be extended to an $n$-simplex $\tau$ of $\mathcal{C}$. This follows by the argument given above, applied to the opposite interior fibration $q^{\op} : \mathcal{C}^{\op} \rightarrow \mathcal{D}^{\op}$.

\[\square\]

**Proposition 5.5.2.9.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ and $G : \mathcal{D} \rightarrow \mathcal{E}$ be interior fibrations of $(\infty, 2)$-categories. Then the composition $(G \circ F) : \mathcal{C} \rightarrow \mathcal{E}$ is also an interior fibration.
Proof. Suppose we are given an integer \( n \geq 2 \) and a lifting problem

\[
\begin{array}{c}
\Lambda^n_i \quad \sigma_0 \\
\downarrow \sigma \quad \uparrow \downarrow \\
\Delta^n \quad \pi \\
\end{array} 
\rightarrow 
\begin{array}{c}
C \\
\downarrow G \circ F \\
E. \\
\end{array}
\]

We wish to show that this lifting problem admits a solution if one of the following conditions is satisfied:

(a) The integer \( i \) is equal to 0 and \( \sigma_0|_{N_{\bullet}((0<1))} \) is a degenerate edge of \( C \).

(b) The integer \( i \) satisfies \( 0 < i < n \) and the restriction \( \sigma|_{N_{\bullet}((i-1<i<i+1))} \) is a thin 2-simplex of \( E \).

(c) The integer \( i \) is equal to \( n \) and \( \sigma_0|_{N_{\bullet}((n-1<n))} \) is a degenerate edge of \( C \).

Since \( G \) is an interior fibration, any of these hypotheses guarantee the existence of a solution to the associated lifting problem

\[
\begin{array}{c}
\Lambda^n_i \quad F \circ \sigma_0 \\
\downarrow \tau \quad \uparrow \downarrow \\
\Delta^n \quad \pi \\
\end{array} 
\rightarrow 
\begin{array}{c}
D \\
\downarrow G \\
E. \\
\end{array}
\]

It will therefore suffice to construct a solution to the lifting problem

\[
\begin{array}{c}
\Lambda^n_i \quad \sigma_0 \\
\downarrow \sigma \quad \uparrow \downarrow \\
\Delta^n \quad \tau \\
\end{array} 
\rightarrow 
\begin{array}{c}
C \\
\downarrow F \\
D. \\
\end{array}
\]

In cases (a) and (c), our assumption that \( F \) is an interior fibration immediately guarantees the existence of \( \sigma \). In case (b), it suffices to verify that the restriction \( \tau|_{N_{\bullet}((i-1<i<i+1))} \) is a thin 2-simplex of \( D \), which follows from Lemma 5.5.2.6.

\[\square\]
(1) The induced map of left-pinched morphism spaces \( \text{Hom}_C^L(X,Y) \rightarrow \text{Hom}_D^L(F(X),F(Y)) \) is a right fibration of simplicial sets.

(2) The induced map of right-pinched morphism spaces \( \text{Hom}_C^R(X,Y) \rightarrow \text{Hom}_D^R(F(X),F(Y)) \) is a left fibration of simplicial sets.

**Proof.** We will prove (2); assertion (1) follows from a similar argument. We wish to show that, for every pair of integers \( 0 \leq i < n \), every lifting problem

\[
\begin{align*}
\Lambda_i^n \longrightarrow & \quad \sigma_0 \quad \rightarrow \quad \text{Hom}_C^R(X,Y) \\
\downarrow & \quad \sigma \quad \quad \downarrow \\
\Delta^n \longrightarrow & \quad \tau \quad \rightarrow \quad \text{Hom}_D^R(F(X),F(Y))
\end{align*}
\]  

admits a solution. Unwinding the definitions, we can rewrite (5.25) as a lifting problem

\[
\begin{align*}
\Lambda_i^{n+1} \longrightarrow & \quad \tau_0 \quad \rightarrow \quad C \\
\downarrow & \quad \tau \quad \quad \downarrow \\
\Delta^{n+1} \longrightarrow & \quad \tau \quad \rightarrow \quad D,
\end{align*}
\]

where the restriction \( \tau_0|_{N^*\{0<1\}} \) is the constant map taking the value \( X \). If \( i = 0 \), then this lifting problem admits a solution because the edge \( \tau_0|_{N^*\{0<1\}} \) is degenerate (and therefore \( F \)-cocartesian, by virtue of our assumption that \( F \) is an interior fibration). If \( 0 < i < n \), the solution exists by virtue of the fact that \( F \) is an interior fibration and \( \tau|_{N^*\{i-1<i+1\}} \) is a degenerate 2-simplex of \( D \) (and therefore thin).

**5.5.3 Slices of \((\infty,2)\)-Categories**

The slice and coslice constructions of §4.3 provide many examples of interior fibrations of \((\infty,2)\)-categories.

**Proposition 5.5.3.1.** Let \( \mathcal{C} \) be an \((\infty,2)\)-category and let \( f : K \rightarrow \mathcal{C} \) be a morphism of simplicial sets. Then the projection maps

\[
\mathcal{C}_{f/} \rightarrow \mathcal{C} \quad \mathcal{C}/f \rightarrow \mathcal{C}
\]

are interior fibrations.
**Warning 5.5.3.2.** In the situation of Proposition 5.5.3.1, the projection maps
\[ C_f/ \rightarrow C \quad C/f \rightarrow C \]
are generally not inner fibrations of simplicial sets.

**Remark 5.5.3.3.** Let \( C \) be a simplicial set. Then axioms (3) and (4) of Definition 5.5.1.3 can be stated as follows:

(3') Let \( X \) be any vertex of \( C \) and let \( q : C_{/X} \rightarrow C \) be the projection map. Then every degenerate edge of \( C_{/X} \) is \( q \)-cocartesian.

(4') Let \( X \) be any vertex of \( C \) and let \( q' : C_{X/} \rightarrow C \) be the projection map. Then every degenerate edge of \( C_{X/} \) is \( q' \)-cartesian.

Note that (3') and (4') appear as special cases of the conclusion of Proposition 5.5.3.1.

**Corollary 5.5.3.4.** Let \( C \) be an \((\infty, 2)\)-category and let \( f : K \rightarrow C \) be a morphism of simplicial sets. Then the simplicial sets \( C_f/ \) and \( C/f \) are \((\infty, 2)\)-categories.

**Proof.** Combine Proposition 5.5.3.1 with Proposition 5.5.2.8.

**Corollary 5.5.3.5.** Let \( C \) be an \((\infty, 2)\)-category. For every pair of objects \( X \) and \( Y \), the pinched morphism spaces \( \text{Hom}_L^C(X, Y) \) and \( \text{Hom}_R^C(X, Y) \) of Construction 4.6.5.1 are \( \infty \)-categories.

**Proof.** By definition, the left-pinched morphism space \( \text{Hom}_L^C(X, Y) \) is the fiber over \( Y \) of the projection map \( \pi : C_{X/} \rightarrow C \). Since \( \pi \) is an interior fibration (Proposition 5.5.3.1), each of its fibers is an \( \infty \)-category (Remark 5.5.2.5). A similar argument shows that \( \text{Hom}_R^C(X, Y) \) is an \( \infty \)-category.

**Warning 5.5.3.6.** Let \( C \) be an \((\infty, 2)\)-category containing objects \( X \) and \( Y \). Then the simplicial set \( \text{Hom}_C(X, Y) \) of Construction 4.6.1.1 is generally not an \( \infty \)-category (see Warning 8.1.5.1).

**Remark 5.5.3.7.** Let \( C \) be an \((\infty, 2)\)-category containing \( X \) and \( Y \). We will see later that the \( \infty \)-category \( \text{Hom}^L_C(X, Y) \) is naturally equivalent to the opposite of the \( \infty \)-category \( \text{Hom}^R_C(X, Y) \) (Proposition [?]). When \( C \) is the Duskin nerve of a 2-category, we can do better: the \( \infty \)-category \( \text{Hom}^L_C(X, Y) \) is isomorphic to the opposite of \( \text{Hom}^R_C(X, Y) \); see Example 4.6.5.12.

We will deduce Proposition 5.5.3.1 from the following more precise result:
Proposition 5.5.3.8. Let $f : K \to C$ be a morphism of simplicial sets and let $f_0 : K_0 \to C$ be the restriction of $f$ to a simplicial subset $K_0 \subseteq K$. Then every lifting problem admits a solution provided that $m \geq 2$ and one of the following additional conditions is satisfied:

(a) The simplicial set $C$ is an $(\infty, 2)$-category, $i = 0$, and the composition

$$\Delta^1 \simeq N_\bullet(\{0 < 1\}) \subseteq \Lambda^m_i \xrightarrow{\sigma_0} C_f$$

is a degenerate edge of $C_f$.

(b) The integer $i$ satisfies $0 < i < m$ and the composite map

$$\Delta^2 \simeq N_\bullet(\{i - 1 < i < i + 1\}) \subseteq \Delta^m \xrightarrow{\sigma} C_{f_0} \to C$$

is a thin 2-simplex of $C$.

(c) The integer $i$ is equal to $m$ and, for every vertex $x \in K$, the composite map

$$\Delta^2 \simeq N_\bullet(\{m - 1 < m\}) \star \{x\} \hookrightarrow \Lambda^m_i \star K \xrightarrow{\sigma} C$$

is a thin 2-simplex of $C$.

Proof. Unwinding the definitions, we can identify the diagram with a morphism of simplicial sets

$$\overline{f} : (\Lambda^m_i \star K) \coprod_{(\Lambda^m_i \star K_0)} (\Delta^m \star K_0) \to C,$$

and we wish to show that $\overline{f}$ can be extended to a morphism $\Delta^m \star K \to C$. Let $P$ be the collection of all pairs $(L, g)$, where $L$ is a simplicial subset of $K$ containing $K_0$ and $g : \Delta^m \star L \to C$ is a morphism satisfying

$$g|_{\Delta^m \star K_0} = \overline{f}|_{\Delta^m \star K_0} \quad g|_{\Lambda^m_i \star L} = \overline{f}|_{\Lambda^m_i \star L}.$$

We regard $P$ as a partially ordered set, with $(L, g) \leq (L', g')$ if $L$ is contained in $L'$ and $g = g'|_{\Delta^m \star L}$. The partially ordered set $P$ satisfies the hypotheses of Zorn’s lemma and
therefore admits a maximal element \((L_{\text{max}}, g_{\text{max}})\). We will complete the proof by showing that \(L_{\text{max}} = K\) (so that \(g_{\text{max}}\) is the desired extension of \(\overline{f}\)). Suppose otherwise. Then there is some nondegenerate simplex \(\rho : \Delta^n \to K\) which is not contained in \(L_{\text{max}}\). Choosing \(\rho\) so that \(n\) is as small as possible, we may assume without loss of generality that \(\rho\) carries the boundary \(\partial \Delta^n\) into \(L_{\text{max}}\). Let \(L' \subseteq K\) be the simplicial subset given by the union of \(L_{\text{max}}\) together with the image of \(\rho\), so that \(\rho\) determines a pushout diagram

\[
\begin{array}{ccc}
\partial \Delta^n & \to & L_{\text{max}} \\
\downarrow & & \downarrow \\
\Delta^n & \to & L'.
\end{array}
\]

We will show that \(g_{\text{max}}\) can be extended to a morphism of simplicial sets \(g' : \Delta^m \star L' \to \mathcal{C}\) satisfying \(g'|_{\Lambda_i^m \star L'} = f|_{\Lambda_i^m \star L'}\); thereby contradicting the maximality of \((L_{\text{max}}, g_{\text{max}})\) and completing the proof of Proposition 5.5.3.8. Note that the composite maps

\[
\Lambda_i^m \star \Delta^n \xrightarrow{id \star \rho} \Lambda_i^m \star K \xrightarrow{\overline{f}} \mathcal{C}
\]

\[
\Delta^m \star \partial \Delta^n \xrightarrow{id \star \rho} \Delta^m \star L_{\text{max}} \xrightarrow{g_{\text{max}}} \mathcal{C}
\]

can be amalgamated to a morphism of simplicial sets

\[
\tau_0 : (\Lambda_i^m \star \Delta^n) \coprod_{(\Delta^m \star \partial \Delta^n)} (\Delta^m \star \partial \Delta^n) \to \mathcal{C},
\]

whose source can be identified with the horn \(\Lambda_i^{m+1+n} \subseteq \Delta^{m+1+n}\) (Lemma 4.3.6.14). We wish to show that \(\tau_0\) can be extended to a map

\[
\tau : \Delta^m \star \Delta^n \simeq \Delta^{m+1+n} \to \mathcal{C}.
\]

If \(0 < i \leq m\), the desired extension exists because the composite map

\[
\Delta^2 \simeq N_{\bullet}(\{i-1 < i < i+1\}) \subseteq \Lambda_i^{m+1+n} \xrightarrow{\tau_0} \mathcal{C}
\]

is a thin 2-simplex of \(\mathcal{C}\) (by virtue of assumption (b) when \(i < m\) or (c) in the case \(i = m\)). If \(i = 0\), then the desired extension exists because assumption (a) guarantees that \(\mathcal{C}\) is an \((\infty, 2)\)-category and the 2-simplex

\[
\Delta^2 \simeq N_{\bullet}(\{0 < m+1+n\}) \subseteq \Lambda_i^{m+1+n} \xrightarrow{\tau_0} \mathcal{C}
\]

is left-degenerate. \(\square\)
Proof of Proposition 5.5.3.1 Let \( \mathcal{C} \) be an \((\infty, 2)\)-category and let \( f : K \to \mathcal{C} \) be a morphism of simplicial sets. We will show that the projection map \( q : \mathcal{C}/f \to \mathcal{C} \) is an interior fibration; the analogous assertion for the coslice simplicial set \( \mathcal{C}/f \) follows by a similar argument. Let \( m \geq 2 \) and suppose that we are given a lifting problem

\[
\begin{array}{ccc}
\Lambda^m_i & \xrightarrow{\sigma_0} & \mathcal{C}/f \\
\downarrow & & \downarrow \\
\Delta^m & \xrightarrow{\pi} & \mathcal{C}
\end{array}
\]

We wish to show that a solution exists under any of the following additional assumptions:

(a) The integer \( i \) is equal to zero and the restriction \( \sigma_0|_{\mathcal{N}_\bullet(\{0 < 1\})} \) is a degenerate edge of \( \mathcal{C}/f \).

(b) The integer \( i \) satisfies \( 0 < i < m \) and the composite map

\[
\Delta^2 \cong \mathcal{N}_\bullet(\{i - 1 < i < i + 1\}) \subseteq \Delta^m \xrightarrow{\pi} \mathcal{C}/f_0 \to \mathcal{C}
\]

is a thin 2-simplex of \( \mathcal{C} \).

(c) The integer \( i \) is equal to \( m \) and the restriction \( \sigma_0|_{\mathcal{N}_\bullet(\{m - 1 < m\})} \) is a degenerate edge of \( \mathcal{C}/f \).

In cases (a) and (b), this follows immediately from Proposition 5.5.3.8. In case (c), we observe that for every vertex \( x \in K \), the composite map

\[
\Delta^2 \cong \mathcal{N}_\bullet(\{m - 1 < m\}) \star \{x\} \hookrightarrow \Lambda^m_i \star K \xrightarrow{\sigma_0} \mathcal{C}
\]

is a left-degenerate 2-simplex of \( \mathcal{C} \). Since \( \mathcal{C} \) is an \((\infty, 2)\)-category, this degenerate 2-simplex is thin, so that existence of the desired extension again follows from Proposition 5.5.3.8.

In the situation of Proposition 5.5.3.1, the interior fibration \( \mathcal{C}/f \to \mathcal{C} \) behaves like a cartesian fibration (with the caveat that it need not be an inner fibration).

Proposition 5.5.3.9. Let \( \mathcal{C} \) be an \((\infty, 2)\)-category, let \( f : K \to \mathcal{C} \) be a morphism of simplicial sets, and let \( q : \mathcal{C}/f \to \mathcal{C} \) be the projection map. Let \( Y \) be an object of the \((\infty, 2)\)-category \( \mathcal{C}/f \), and let \( \overline{u} : \overline{X} \to q(Y) \) be a morphism in the \((\infty, 2)\)-category \( \mathcal{C} \). Then \( \overline{u} \) can be lifted to a morphism \( u : X \to Y \) of \( \mathcal{C}/f \) with the following property:

(*) For every vertex \( z \in K \), the image of \( u \) in \( \mathcal{C}/f(z) \) is a thin 2-simplex of \( \mathcal{C} \).
Remark 5.5.3.10. In the situation of Proposition 5.5.3.9, condition (*) guarantees that $u$ is a $q$-cartesian morphism of $\mathcal{C}_f$ (this follows immediately from Proposition 5.5.3.8). In §5.5.4, we will prove the converse: every $q$-cartesian morphism of $\mathcal{C}_f$ satisfies condition (*) (Corollary 5.5.4.2).

Proposition 5.5.3.11. Let $\mathcal{C}$ be an $(\infty, 2)$-category, let $f : K \to \mathcal{C}$ be a morphism of simplicial sets, and let $f_0 : K_0 \to \mathcal{C}$ be the restriction of $f$ to a simplicial subset $K_0 \subseteq K$. Let $q : \mathcal{C}_f \to \mathcal{C}_{f_0}$ denote the projection map, and suppose we are given a lifting problem

$\begin{array}{c}
\Delta^1 \\
\sigma \\
\sigma_0 \\
\mathcal{C}_f \\
\mathcal{C}_{f_0}
\end{array}$

with the following property:

(*0) For every vertex $x \in K_0$, the composition

$$\Delta^2 \simeq \Delta^1 \ast \{x\} \hookrightarrow \Delta^1 \ast K_0 \xrightarrow{\sigma} \mathcal{C}$$

is a thin 2-simplex of $\mathcal{C}$.

Then there exists an edge $\sigma : \Delta^1 \to \mathcal{C}_f$ which solves the lifting problem problem (5.27) and which satisfies the following stronger version of (*0):

(*) For every vertex $x \in K$, the composition

$$\Delta^2 \simeq \Delta^1 \ast \{x\} \hookrightarrow \Delta^1 \ast K \xrightarrow{\sigma} \mathcal{C}$$

is a thin 2-simplex of $\mathcal{C}$.

Proof. Arguing as in the proof of Proposition 5.5.3.8, we can reduce to the case where $K = \Delta^n$ is a standard simplex and $K_0 = \partial \Delta^n$ is its boundary. In this case, the lifting problem (5.27) determines a morphism of simplicial sets

$$\tau_0 : (\{1\} \ast \Delta^n) \coprod_{(1) \ast \partial \Delta^n} (\Delta^1 \ast \partial \Delta^n) \to \mathcal{C},$$

whose source can be identified with the horn $\Lambda^n_{1,2} \subseteq \Delta^{n+2}$. (Lemma 4.3.6.14) and we wish to extend $\tau$ to an $(n + 2)$-simplex of $\mathcal{C}$. If $n > 0$, then the desired extension exists because $\tau_0$ carries $N_{\bullet}(\{0 < 1 < 2\})$ to a thin 2-simplex of $\mathcal{C}$ (by virtue of assumption (*0)). If $n = 0$, then our assumption that $\mathcal{C}$ is an $(\infty, 2)$-category allows us to extend $\tau_0$ to a thin 2-simplex of $\mathcal{C}$. \qed
5.5.4 The Local Thinness Criterion

Let $\mathcal{C}$ be an $(\infty,2)$-category and let $\sigma$ be a 2-simplex of $\mathcal{C}$, whose restriction to the 1-skeleton of $\Delta^2$ we indicate in the diagram

```
Y
 / \ / \\
/  \ / \\
X \quad \quad \quad \quad \quad \quad Z
```

Roughly speaking, we can think of $\sigma$ as encoding a 2-morphism $\gamma : v \circ u \Rightarrow w$, and we can think of the condition that $\sigma$ is thin as corresponding to the requirement that $\gamma$ is invertible. In the case where $\mathcal{C}$ is the Duskin nerve of a 2-category, this is the content of Theorem 2.3.2.5. For a general $(\infty,2)$-category, we can formulate this heuristic more precisely as follows:

**Theorem 5.5.4.1 (Local Thinness Criterion).** Let $\mathcal{C}$ be an $(\infty,2)$-category and let $\sigma$ be a 2-simplex of $\mathcal{C}$, which we represent by the diagram

```
Y
 / \ / \\
/  \ / \\
X \quad \quad \quad \quad \quad \quad Z
```

The following conditions are equivalent:

1. The 2-simplex $\sigma$ is thin.
2. Let $q : \mathcal{C}/Z \to \mathcal{C}$ denote the projection map. Then $\sigma$ is $q$-cartesian when viewed as an edge of the simplicial set $\mathcal{C}/Z$.
3. The 2-simplex $\sigma$ is locally $q$-cartesian when viewed as an edge of the simplicial set $\mathcal{C}/Z$.
4. Let $q' : \mathcal{C}_{X/} \to \mathcal{C}$ denote the projection map. Then $\sigma$ is $q'$-cocartesian when viewed as an edge of the simplicial set $\mathcal{C}_{X/}$.
5. The 2-simplex $\sigma$ is locally $q'$-cocartesian when viewed as an edge of the simplicial set $\mathcal{C}_{X/}$.

**Proof.** We will prove that (1) $\iff$ (2) $\iff$ (3); the proof that (1) $\iff$ (4) $\iff$ (5) follows by applying the same argument to the opposite $(\infty,2)$-category $\mathcal{C}^{\text{op}}$. The implication (1) $\Rightarrow$ (2) follows from Proposition 5.1.3.9, and the implication (2) $\Rightarrow$ (3) is immediate (see Remark 5.1.3.11). For each integer $n \geq 3$, consider the following weaker version of condition (1):
For every integer $0 < i < n$ and every morphism of simplicial sets $\mu_0 : \Lambda^n_i \to C$ for which the composition
\[
\Delta^2 \simeq N_*\{i - 1 < i < i + 1\} \hookrightarrow \Lambda^n_i \xrightarrow{\mu_0} C
\]
is equal to $\sigma$, there exists a map $\mu : \Delta^n \to C$ extending $\mu_0$.

Note that $\sigma$ satisfies condition (1) if and only if it satisfies condition $(1_n)$ for each $n \geq 3$. We will complete the proof by showing that $(3) \Rightarrow (1_n)$, using a fairly elaborate induction on $n$.

Assume that $\sigma$ is locally $q$-cartesian when viewed as a morphism in the $(\infty, 2)$-category $C/Z$. Since $C$ is an $\infty$-category, we can choose a thin 2-simplex $\sigma'$ satisfying $d_0(\sigma') = d_0(\sigma)$ and $d_2(\sigma') = d_2(\sigma)$, which we represent as a diagram
\[
\begin{array}{ccc}
X & \xrightarrow{w'} & Z \\
\downarrow{u} \quad \quad \quad & & \downarrow{v} \\
Y & & \end{array}
\]
The implication $(1) \Rightarrow (3)$ shows that $\sigma'$ is also locally $q$-cartesian when viewed as an edge of the simplicial set $C/Z$. Let us regard the edge $u$ as a morphism of simplicial sets $\Delta^1 \to C$, and let $E$ denote the fiber product $\Delta^1 \times_C C/Z$. Since $q$ is an interior fibration, it follows from Remark 5.5.2.4 and Example 5.5.2.2 that the projection map $\pi : E \to \Delta^1$ is an inner fibration. Moreover, we can identify $\sigma$ and $\sigma'$ with $\pi$-cartesian edges of $E$ having nondegenerate images under $\pi$. Applying Remark 5.1.3.8, we see that there exists a 2-simplex of $E$ which exhibits $\sigma'$ as a composition of $\sigma$ with an isomorphism in $E$. The image of this 2-simplex under the projection map $E \to C/Z$ can be identified with a 3-simplex $\rho$ of $C$ such that $d_0(\rho) = \sigma$, $d_1(\rho) = \sigma'$, and $d_3(\rho) = s_0(u)$ is left-degenerate; the restriction of $\rho$ to the 1-skeleton of $\Delta^3$ we can represent by the diagram
\[
\begin{array}{ccc}
X & \xrightarrow{w'} & Z \\
\downarrow{u} \quad \quad \quad & & \downarrow{v} \\
Y & & \end{array}
\]
\[
\begin{array}{ccc}
X & \xrightarrow{id_X} & Y \\
\downarrow{u} \quad \quad \quad & & \downarrow{w} \\
X & & \end{array}
\]
\[
\begin{array}{ccc}
X & \xrightarrow{w'} & Z \\
\downarrow{u} \quad \quad \quad & & \downarrow{v} \\
Y & & \end{array}
\]
By construction, the remaining face $\sigma'' = d_2(\rho)$ is an isomorphism when viewed as a morphism in the $\infty$-category $\text{Hom}^R(X, Z) = \{X\} \times_C C/Z$, and is therefore locally $q$-cartesian (Example 5.1.3.6). In particular, our inductive hypothesis guarantees that the simplex $\sigma''$ satisfies condition $(1_m)$ for $3 \leq m < n$. 

CHAPTER 5. FIBRATIONS OF ∞-CATEGORIES

Fix a morphism of simplicial sets $\mu_0 : \Lambda_i^n \to C$ as in condition $(1_n)$; we wish to show that $\mu_0$ can be extended to an $n$-simplex $\mu$ of $C$. Let $\delta^{i-1} : \Delta^n \hookrightarrow \Delta^{n+1}$ denote the inclusion of the $(i - 1)$st face, given on vertices by the formula

$$\delta^{i-1}(j) = \begin{cases} j & \text{if } j < i - 1 \\ j + 1 & \text{if } j \geq i - 1. \end{cases}$$

We will construct an $(n + 1)$-simplex $\nu : \Delta^{n+1} \to C$ which satisfies the following conditions:

(a) The composite map

$$\Lambda_i^n \hookrightarrow \Delta^n \xrightarrow{\delta^{i-1}} \Delta^{n+1} \xrightarrow{\nu} C$$

is equal to $\mu_0$.

(b) The composite map

$$\Delta^3 \simeq N_\bullet(\{i - 1 < i < i + 1 < i + 2\}) \hookrightarrow \Delta^{n+1} \xrightarrow{\nu} C$$

is equal to the 3-simplex $\rho$.

(c) For every integer $0 \leq j < i - 1$, the 2-simplex

$$\Delta^2 \simeq N_\bullet(\{j < i - 1 < i\}) \hookrightarrow \Delta^{n+1} \xrightarrow{\nu} C$$

is right-degenerate (in particular, it is thin).

(d) For every integer $i + 2 < j \leq n + 1$, the 2-simplex

$$\Delta^2 \simeq N_\bullet(\{i - 1 < i < j\}) \hookrightarrow \Delta^{n+1} \xrightarrow{\nu} C$$

is left-degenerate (in particular, it is thin).

Assuming that this construction is possible, we complete the proof by observing that $\mu = \nu \circ \delta^{i-1}$ provides the desired extension of $\mu_0$ (by virtue of assumption (a)).

The construction of the $(n + 1)$-simplex $\nu$ will take place in several steps. We define simplicial subsets

$$K_0 \subsetneq K_1 \subsetneq K_2 \subsetneq K_3 \subsetneq K_4 \subsetneq \Delta^{n+1}$$

and maps $\nu_j : K_j \to C$ as follows:

- Let $K_0 \subsetneq \Delta^{n+1}$ be the image of the horn $\Lambda_i^n$ under $\delta^{i-1}$, so that $\delta^{i-1}$ induces an isomorphism $\Lambda_i^n \simeq K_0$. It follows that there is a unique morphism of simplicial sets $\nu_0 : K_0 \to C$ satisfying $\mu_0 = \nu_0 \circ \delta^{i-1}|_{\Lambda_i^n}$. By construction, the map $\nu_0$ satisfies condition (a).
5.5. \((\infty, 2)\)-CATEGORIES

- Let \(K_1 \subseteq \Delta^{n+1}\) be the union of \(K_0\) with the 3-simplex \(N_\bullet\{i - 1 < i < i + 1 < i + 2\}\). It follows from the identity \(d_0(\rho) = \sigma\) that \(\nu_0\) extends uniquely to a map \(\nu_1 : K_1 \to \mathcal{C}\) satisfying condition (b).

- Let \(K_2\) be the simplicial subset of \(\Delta^{n+1}\) obtained by removing those nondegenerate simplices which contain all of the vertices \(\{0 < 1 < \cdots < i - 2 < i + 2 < i + 3 < \cdots < n + 1\}\) and at least one of the vertices \(\{i - 1, i\}\). We will prove below that \(\nu_1\) can be extended to a map \(\nu_2 : K_2 \to \mathcal{C}\) which satisfies conditions (c) and (d).

- Let \(\delta^i : \Delta^n \hookrightarrow \Delta^{n+1}\) denote the inclusion of the \(i\)th face, given on vertices by the formula
  \[
  \delta^i(j) = \begin{cases} 
  j & \text{if } j < i \\
  j + 1 & \text{if } j \geq i.
  \end{cases}
  \]

Let \(K_3\) be the union of \(K_2\) with the image of \(\delta^i\). Note that \(\delta^i\) determines a pushout diagram of simplicial sets

\[
\begin{array}{cccc}
\Lambda^n_i & \rightarrow & K_2 \\
\downarrow & & \downarrow \\
\Delta^n & \rightarrow & K_3.
\end{array}
\]

Let \(\alpha_0\) denote the composite map \(\Lambda^n_i \rightarrow K_2 \xrightarrow{\nu_2} \mathcal{C}\). Since \(\nu_1\) satisfies condition (b), \(\alpha_0\) carries \(N_\bullet\{i - 1 < i < i + 1\}\) to the thin 2-simplex \(\sigma^i\) of \(\mathcal{C}\), and can therefore be extended to an \(n\)-simplex \(\alpha\) of \(\mathcal{C}\). It follows that \(\nu_2\) extends uniquely to a morphism of simplicial sets \(\nu_3 : K_3 \to \mathcal{C}\) satisfying \(\nu_3 \circ \delta^i = \alpha\).

- Let \(K_4\) denote the horn \(\Lambda^{n+1}_{i-1} \subseteq \Delta^n\). Note that \(K_4\) can be written as the union of \(K_3\) with the image of the face inclusion \(\delta^{i+1} : \Delta^n \hookrightarrow \Delta^{n+1}\), given on vertices by the formula
  \[
  \delta^{i+1}(j) = \begin{cases} 
  j & \text{if } j \leq i \\
  j + 1 & \text{if } j > i.
  \end{cases}
  \]

Moreover, we have a pushout diagram

\[
\begin{array}{cccc}
\Lambda^n_{i-1} & \rightarrow & K_3 \\
\downarrow & & \downarrow \\
\Delta^n & \rightarrow & K_4.
\end{array}
\]
Let $\beta_0$ denote the composite map

$$A_{i-1}^n \overset{\delta^{i+1}}{\longrightarrow} K_3 \overset{\nu_3}{\longrightarrow} C.$$ 

If $i > 1$, then condition (c) guarantees that the restriction $\beta_0|_{N_\bullet((i-2<i-1<i))}$ is a right-degenerate 2-simplex of $C$. If $i = 1$, then condition (d) guarantees that the restriction $\beta_0|_{N_\bullet((0<1<n))}$ is a left-degenerate 2-simplex of $C$. In either case, our assumption that $C$ is an $(\infty,2)$-category guarantees that $\beta_0$ can be extended to an $n$-simplex $\beta$ of $C$, so that $\nu_3$ can be extended uniquely to a map $\nu_4: K_4 \to C$ satisfying $\nu_4 \circ \delta^{i+1} = \beta$.

- If $i > 1$, then condition (c) guarantees that the map $\nu_4: A_{i-1}^{n+1} \to C$ carries $N_\bullet(\{i-2 < i-1 < i\})$ to a right-degenerate 2-simplex of $C$. If $i = 1$, then condition (d) guarantees that $\nu_4$ carries $N_\bullet(\{0 < 1 < n + 1\})$ to a left-degenerate 2-simplex of $C$. In either case, our assumption that $C$ is an $(\infty,2)$-category guarantees that we can extend $\nu_4$ to an $(n + 1)$-simplex $\nu: \Delta^{n+1} \to C$, thereby completing the proof of Theorem 5.5.4.1.

It remains to show that $\nu_4$ admits an extension $\nu_2: K_2 \to C$ which satisfies conditions (c) and (d). Let us say that a simplex $\tau: \Delta^m \to K_2$ is free if it is nondegenerate, not contained in $K_1$, and there exists an integer $0 \leq j \leq m$ satisfying $\tau(j) = i$. Note that in this case, we automatically have $j > 0$ and $\tau(j-1) = i - 1$ (otherwise, $\tau$ would be contained in $K_1$). Moreover, if $\tau$ is any nondegenerate $m$-simplex of $K_2$ which is not contained in $K_1$, then $\tau$ is either free or can be realized uniquely as a face of a free $(m+1)$-simplex $\tau': \Delta^{m+1} \to K_2$ (obtained by adjoining $i$ to the image of $\tau$).

Let $\{\tau_1, \tau_2, \cdots, \tau_t\}$ be an enumeration of the collection of all free simplices of $K_2$, chosen so $\dim(\tau_1) \leq \dim(\tau_2) \leq \cdots \leq \dim(\tau_t)$. For $0 \leq s \leq t$, let $K_2(s)$ denote the union of $K_1$ with the images of the maps $\{\tau_1, \tau_2, \cdots, \tau_s\}$, so that we have inclusions of simplicial sets

$$K_1 = K_2(0) \subset K_2(1) \subset K_2(2) \subset \cdots \subset K_2(t) = K_2.$$ 

We will complete the proof by inductively constructing a compatible sequence of maps $\nu_2(s): K_2(s) \to C$ satisfying $\nu_2(0) = \nu_1$ together with the following translation of conditions (c) and (d):

(*s) If the simplex $\tau_s$ has dimension 2, then the 2-simplex $\nu_2 \circ \tau_s$ of $C$ is left-degenerate if $\tau_s(1) = i$ and right-degenerate if $\tau_s(2) = i$.

Assume that $s > 0$ and that the map $\nu_2(s-1)$ has already been constructed. Set $\tau = \tau_s: \Delta^m \to K_2$, so that there is a unique integer $1 \leq j \leq m$ satisfying $\tau(j) = i$. Note that for $0 \leq k \leq m$ with $k \neq j$, the face $d_k(\tau)$ is either free or belongs to $K_1$; in either case, it belongs to $K_2(s-1)$. Moreover, the face $d_j(\tau)$ is neither free, nor contained in $K_1$, nor contained as
a face of any other free \( m \)-simplex of \( K_2 \). It follows that \( \tau \) determines a pushout diagram of simplicial sets

\[
\begin{array}{ccc}
\Lambda_j^m & \longrightarrow & K_2(s - 1) \\
\downarrow & & \downarrow \\
\Delta^m & \longrightarrow & K_2(s).
\end{array}
\]

Let \( \xi_0 : \Lambda_j^m \to C \) denote the composite map \( \Lambda_j^m \to K_2(s - 1) \to C \); we wish to show that \( \xi_0 \) can be extended to an \( m \)-simplex of \( C \). If \( m = 2 \), then there is a unique such extension which satisfies condition \((\ast_s)\) (since, by construction, the morphism \( \nu_1 \) carries \( N_\bullet(\{i - 1 < i\}) \) to the degenerate edge \( \text{id}_X \) of \( C \)). We may therefore assume that \( m \geq 3 \). We consider several cases:

- If \( j = m \), then it follows from assumption \((\ast_{s'})\) for \( s' < s \) that \( \xi_0 \) carries \( N_\bullet(\{0 < m - 1 < m\}) \) to a right-degenerate 2-simplex of \( C \), so the desired extension exists by virtue of our assumption that \( C \) is an \((\infty, 2)\)-category.

- If \( j < m \) and \( \tau(j + 1) = i + 1 \), then it follows from \((b)\) that \( \xi_0 \) carries \( N_\bullet(\{j - 1 < j < j + 1\}) \) to the left-degenerate 2-simplex \( d_3(\rho) \). Since \( C \) is an \((\infty, 2)\)-category, this 2-simplex is thin so that \( \xi_0 \) can be extended to an \( m \)-simplex of \( C \).

- If \( j < m \) and \( \tau(j + 1) > i + 2 \), then it follows from assumption \((\ast_{s'})\) for \( s' < s \) that \( \xi_0 \) carries \( N_\bullet(\{j - 1 < j < j + 1\}) \) to a left-degenerate 2-simplex of \( C \). Since \( C \) is an \((\infty, 2)\)-category, this 2-simplex is thin so that \( \xi_0 \) can be extended to an \( m \)-simplex of \( C \).

- If \( j < m \) and \( \tau(j + 1) = i + 2 \), then it follows from \((b)\) that \( \xi_0 \) carries \( N_\bullet(\{j - 1 < j < j + 1\}) \) to the 2-simplex \( \sigma'' \) of \( C \). In this case, our assumption that \( \tau \) belongs to \( K_2 \) guarantees that \( m < n \), so the existence of the desired extension follows the fact that \( \sigma'' \) satisfies condition \((1_m)\) (by virtue of our inductive hypothesis).

\[\square\]

Theorem \[5.5.4.1\] immediately generalizes to other slice constructions:

\[\textbf{Corollary 5.5.4.2.}\] Let \( C \) be an \((\infty, 2)\)-category, let \( f : K \to C \) be a morphism of simplicial sets, and let \( q : C_{/f} \to C \) denote the projection map. Let \( u : X \to Y \) be a morphism in the \((\infty, 2)\)-category \( C_{/f} \). The following conditions are equivalent:

1. For every vertex \( z \in K \), the composite map

\[
\Delta^2 \simeq \Delta^1 \star \{z\} \hookrightarrow \Delta^1 \star K \xrightarrow{u} C
\]

is a thin 2-simplex of \( C \).
(2) The morphism $u$ is $q$-cartesian.

(3) The morphism $u$ is locally $q$-cartesian.

**Proof.** The implication (1) $\Rightarrow$ (2) follows from Proposition 5.5.3.8, and the implication (2) $\Rightarrow$ (3) is immediate (see Remark 5.1.3.3). We will show that (3) $\Rightarrow$ (1). Fix a vertex $z \in K$; we wish to show that the composite map

$$\Delta^2 \simeq \Delta^1 \star \{z\} \hookrightarrow \Delta^1 \star K \xrightarrow{u} C$$

is a thin 2-simplex of $C$. Set $Z = f(z) \in C$, so that $q$ factors as a composition

$$C/f \xrightarrow{q'} C/Z \xrightarrow{q''} C.$$ 

By virtue of Theorem 5.5.4.1, it will suffice to show that the $q'(u)$ is a locally $q''$-cartesian morphism of the $(\infty, 2)$-category $C/Z$.

Set $\pi = q(u)$, which we regard as a morphism $\pi : X \to Y$ in the $(\infty, 2)$-category $C$. By virtue of Proposition 5.5.3.9, we can lift $\pi$ to a morphism $u' : X' \to Y$ in $C/f$ which satisfies condition (1) (and therefore also satisfies (3)). Regard $\pi$ as a 1-simplex of $C$ and let $\mathcal{E}$ denote the fiber product $\Delta^1 \times_C C/f$. Since $q$ is an interior fibration (Proposition 5.5.3.1), the projection map $\pi : \mathcal{E} \to \Delta^1$ is also an interior fibration (Remark 5.5.2.4) and therefore an inner fibration (Example 5.5.2.2). Let us abuse notation by identifying $u$ and $u'$ with morphisms in the $\infty$-category $\mathcal{E}$ lying over the unique nondegenerate edge of $\Delta^1$. Assumption (3) then guarantees that $u$ and $u'$ are $\pi$-cartesian. Invoking Remark 5.1.3.8, we deduce that there exists a 2-simplex $\rho : \Delta^2 \to \mathcal{E}$, which we display as a diagram

$$\begin{array}{ccc}
X' & \xrightarrow{u'} & Y \\
\downarrow{v} & & \downarrow{u} \\
X & \xrightarrow{u} & Y,
\end{array}$$

where $v$ is an isomorphism in the $\infty$-category $\{0\} \times_{\Delta^1} \mathcal{E} \simeq \{X\} \times_C C/f$. It follows that $q'(v)$ is an isomorphism in the $\infty$-category $\{X\} \times_C C/f$. Since $u'$ satisfies condition (1), Theorem 5.5.4.1 guarantees that $q'(u')$ is locally $q''$-cartesian. Invoking Remark 5.1.3.8 again, we deduce that $q'(u)$ is locally $q''$-cartesian, as desired. \hfill $\square$

### 5.5.5 The Pith of an $(\infty, 2)$-Category

Let $C$ be a 2-category. Recall that the *pith of $C$* is the subcategory $\text{Pith}(C) \subseteq C$ obtained by removing the non-invertible 2-morphisms of $C$ (Construction 2.2.8.9). In this section, we generalize this definition to the setting of $(\infty, 2)$-categories.
Construction 5.5.5.1. Let $\mathcal{C}$ be an $(\infty, 2)$-category. We let $\text{Pith}(\mathcal{C}) \subseteq \mathcal{C}$ denote the simplicial subset consisting of those simplices $\sigma : \Delta^n \to \mathcal{C}$ which carry every 2-simplex of $\Delta^n$ to a thin 2-simplex of $\mathcal{C}$. We will refer to $\text{Pith}(\mathcal{C})$ as the pith of $\mathcal{C}$.

Remark 5.5.5.2. Let $\mathcal{C}$ be an $(\infty, 2)$-category. Then every degenerate 2-simplex of $\mathcal{C}$ is thin. Consequently, to check that a simplex $\sigma : \Delta^n \to \mathcal{C}$ belongs to the pith $\text{Pith}(\mathcal{C})$, it suffices to check that $\sigma$ carries every nondegenerate 2-simplex of $\Delta^n$ to a thin 2-simplex of $\mathcal{C}$. In particular:

- Every object of $\mathcal{C}$ belongs to $\text{Pith}(\mathcal{C})$.
- Every morphism of $\mathcal{C}$ belongs to $\text{Pith}(\mathcal{C})$.
- A 2-simplex $\sigma$ of $\mathcal{C}$ belongs to $\text{Pith}(\mathcal{C})$ if and only if it is thin.

Remark 5.5.5.3. Let $\mathcal{C}$ be an $(\infty, 2)$-category. Then $\text{Pith}(\mathcal{C})$ is the largest simplicial subset of $\mathcal{C}$ which does not contain any non-thin 2-simplices of $\mathcal{C}$.

Example 5.5.5.4. Let $\mathcal{C}$ be a 2-category and let $\text{Pith}(\mathcal{C})$ denote its pith (Construction 2.2.8.9). Then the inclusion $\text{Pith}(\mathcal{C}) \hookrightarrow \mathcal{C}$ induces an isomorphism of simplicial sets $\text{N}_\bullet(\text{Pith}(\mathcal{C})) \simeq \text{Pith}(\text{N}_\bullet(\mathcal{C}))$. This is an immediate consequence of Theorem 2.3.2.5.

Example 5.5.5.5. Let $\mathcal{C}$ be an $\infty$-category. Then $\text{Pith}(\mathcal{C}) = \mathcal{C}$ (see Example 2.3.2.4).

Proposition 5.5.5.6. Let $\mathcal{C}$ be an $(\infty, 2)$-category. Then $\text{Pith}(\mathcal{C})$ is an $\infty$-category.

Our proof of Proposition 5.5.5.6 will make use of a closure property of the collection of thin 2-simplices of an $(\infty, 2)$-category $\mathcal{C}$.

Definition 5.5.5.7. Let $\mathcal{C}$ be a simplicial set and let $T$ be a collection of 2-simplices of $\mathcal{C}$. We will say that $T$ has the inner exchange property if the following condition is satisfied:

$(\ast)$ Let $\sigma : \Delta^3 \to \mathcal{C}$ be a 3-simplex of $\mathcal{C}$. For every triple of integers $0 \leq i < j < k \leq 3$, let $\sigma_{kji}$ be the face of $\sigma$ given by the restriction $\sigma|_{N_\bullet(\{i < j < k\})}$. Assume that the outer faces $\sigma_{210}$ and $\sigma_{321}$ belong to $T$. Then $\sigma_{310}$ belongs to $T$ if and only if $\sigma_{320}$ belongs to $T$.

Remark 5.5.5.8. Let $\mathcal{C}$ be a simplicial set, let $T$ be a collection of 2-simplices of $\mathcal{C}$, and let $T^{\text{op}}$ denote the set $T$, regarded as a collection of simplices of the opposite simplicial set $\mathcal{C}^{\text{op}}$. Then $T$ has the inner exchange property if and only if $T^{\text{op}}$ has the inner exchange property.

Remark 5.5.5.9. Let $F : \mathcal{C} \to \mathcal{D}$ be a morphism of simplicial sets and let $T$ be a collection of 2-simplices of $\mathcal{D}$. If $T$ has the inner exchange property, then the inverse image $F^{-1}(T)$ has the inner exchange property.
Proposition 5.5.5.10 (Inner Exchange). Let \( C \) be an \((\infty, 2)\)-category. Then the collection of thin 2-simplices of \( C \) has the inner exchange property (Definition 5.5.5.7).

Remark 5.5.5.11. To get a feeling for the content of Proposition 5.5.5.10, let us specialize to the case where \( C = N_D^\bullet(D) \) is the Duskin nerve of a 2-category \( D \). In this case, we can identify a 3-simplex \( \sigma : \Delta^3 \to C \) with a collection of objects \( \{X_i\}_{0 \leq i \leq 3} \) of \( D \), a collection of 1-morphisms \( \{f_{ji} : X_i \to X_j\}_{0 \leq i < j \leq 3} \), and a collection of 2-morphisms \( \{\mu_{kji} : f_{kj} \circ f_{ji} \Rightarrow f_{ki}\} \) for which the diagram

\[
\begin{array}{ccc}
  f_{32} \circ (f_{21} \circ f_{10}) & \overset{\alpha}{\Rightarrow} & (f_{32} \circ f_{21}) \circ f_{10} \\
  \downarrow \text{id}_{f_{32}} \circ \mu_{210} & & \downarrow \mu_{321} \circ \text{id}_{f_{10}} \\
  f_{32} \circ f_{20} & & f_{31} \circ f_{10} \\
  \downarrow \mu_{320} & & \downarrow \mu_{310} \\
  f_{30} & & f_{30}
\end{array}
\]

is commutative, where \( \alpha = \alpha_{f_{32}, f_{21}, f_{10}} \) is the associativity constraint for the composition of 1-morphisms in \( C \) (Proposition 2.3.1.9). The assumption that the outer faces of \( \sigma \) are thin guarantees that the 2-morphisms \( \mu_{321} \) and \( \mu_{210} \) are isomorphisms. In this case, Proposition 5.5.5.10 asserts that \( \mu_{320} \) is an isomorphism if and only if \( \mu_{310} \) is an isomorphism, which follows by inspection.

Proof of Proposition 5.5.5.10. Let \( C \) be an \((\infty, 2)\)-category, let \( \sigma : \Delta^3 \to C \) be a 3-simplex of \( C \) and let \( C = \sigma(3) \in C \) be the image of the final vertex. Let us regard the face \( \sigma_{210} = \sigma|_{\Delta^4_{(0<1<2)}} \) as a morphism of simplicial sets from \( \Delta^2 \) to \( C \), and let \( \mathcal{E} \) denote the pullback \( \Delta^2 \times_C C/\mathcal{C} \). Note that the projection map \( C/\mathcal{C} \to C \) is an interior fibration (Proposition 5.5.3.1). If \( \sigma_{210} \) is thin, then the projection map \( \pi : \mathcal{E} \to \Delta^2 \) is also an interior fibration (Remark 5.5.2.4); since \( \Delta^2 \) is an \( \infty \)-category, it is an inner fibration (Example 5.5.2.2). Unwinding the definitions, we can identify \( \sigma \) with a 2-simplex of \( \mathcal{E} \) lying over the unique nondegenerate 2-simplex of \( \Delta^2 \), which we display as a diagram

\[
\begin{array}{ccc}
  & Y & \\
  X & \downarrow h & Z \\
  & f & \uparrow g
\end{array}
\]
If \( \sigma_{321} = \sigma|_{\mathcal{N}_\ast(\{1<2<3\})} \) is a thin 2-simplex of \( \mathcal{C} \), then the “easy direction” of Theorem 5.5.4.1 guarantees that \( g \) is \( \pi \)-cartesian. It follows that \( f \) is \( \pi \)-cartesian if and only if \( h \) is \( \pi \)-cartesian (Corollary 5.1.2.4). Equivalently, \( f \) is locally \( \pi \)-cartesian if and only if \( h \) is locally \( \pi \)-cartesian (see Remark 5.1.3.4). Applying the “hard direction” of Theorem 5.5.4.1, we conclude that the 2-simplex \( \sigma_{310} = \sigma|_{\mathcal{N}_\ast(\{0<1<3\})} \) is thin if and only if the 2-simplex \( \sigma_{320} = \sigma|_{\mathcal{N}_\ast(\{0<2<3\})} \) is thin.

**Proof of Proposition 5.5.5.6.** Let \( \mathcal{C} \) be an \((\infty, 2)\)-category. Suppose we are given integers \( 0 < i < n \) and a morphism of simplicial sets \( \sigma_0 : \Lambda^n_i \to \Pith(\mathcal{C}) \); we wish to show that \( \sigma_0 \) can be extended to an \( n \)-simplex \( \sigma : \Delta^n \to \Pith(\mathcal{C}) \). If \( n = 2 \), then condition (1) of Definition 5.5.1.3 guarantees that we can extend \( \sigma_0 \) to a thin 2-simplex of \( \mathcal{C} \), which then belongs to \( \Pith(\mathcal{C}) \) by virtue of Remark 5.5.5.2. We may therefore assume that \( n \geq 3 \). In this case, we observe that the composite map

\[
\Delta^2 \simeq \mathcal{N}_\ast(\{i - 1 < i < i + 1\}) \hookrightarrow \Lambda^n_i \xrightarrow{\sigma_0} \Pith(\mathcal{C}) \to \mathcal{C}
\]

is a thin 2-simplex of \( \mathcal{C} \), so that we can extend \( \sigma_0 \) to an \( n \)-simplex \( \sigma : \Delta^n \to \mathcal{C} \). To complete the proof, it will suffice to show that \( \sigma \) carries each 2-simplex of \( \Delta^n \) to a thin 2-simplex of \( \mathcal{C} \). If \( n \geq 4 \), this is automatic (since every 2-simplex of \( \Delta^n \) is contained in the horn \( \Lambda^n_i \)). In the case \( n = 3 \), it follows from our assumption that the collection of thin 2-simplices of \( \mathcal{C} \) has the inner exchange property (Proposition 5.5.10).

Let \( \mathcal{C} \) be an \((\infty, 2)\)-category. Heuristically, one can think of the \( \infty \)-category \( \Pith(\mathcal{C}) \) as obtained from \( \mathcal{C} \) by removing its noninvertible 2-morphisms, just as the core \( \mathcal{E}^\leq \) of an \( \infty \)-category \( \mathcal{E} \) is obtained by removing its noninvertible morphisms (see Construction 4.4.3.1). We now make this heuristic more precise (see Corollary 5.5.7.11 for a relative version):

**Proposition 5.5.5.12.** Let \( \mathcal{C} \) be an \((\infty, 2)\)-category containing objects \( X \) and \( Y \). Then the inclusion \( \Pith(\mathcal{C}) \hookrightarrow \mathcal{C} \) induces isomorphisms of simplicial sets

\[
\Hom^L_{\Pith(\mathcal{C})}(X,Y) \simeq \Hom^L_{\mathcal{C}}(X,Y) \simeq \Hom^R_{\Pith(\mathcal{C})}(X,Y) \simeq \Hom^R_{\mathcal{C}}(X,Y).
\]

**Proof.** Let \( \sigma \) be an \( n \)-simplex of the simplicial set \( \Hom^R_{\mathcal{C}}(X,Y) \), which we view as a morphism of simplicial sets \( \tau : \Delta^{n+1} \to \mathcal{C} \) whose restriction to the face \( \Delta^n \subseteq \Delta^{n+1} \) equal to the constant map \( \Delta^n \to \{X\} \hookrightarrow \mathcal{C} \). Then \( \sigma \) belongs to the simplicial subset \( \Hom^R_{\Pith(\mathcal{C})}(X,Y) \subseteq \Hom^R_{\mathcal{C}}(X,Y) \) if and only if, for every 2-simplex \( \rho : \Delta^2 \to \Delta^{n+1} \), the composition \( \tau \circ \rho \) is a thin 2-simplex of \( \mathcal{C} \). Note that this condition is automatically satisfied if \( \rho \) is degenerate, or takes values in the subset \( \Delta^n \subseteq \Delta^{n+1} \) (since every degenerate 2-simplex of \( \mathcal{C} \) is thin). Consequently, it suffices to verify this condition in the case where \( \rho \) is the right cone of a map \( \rho_0 : \Delta^1 \to \Delta^n \). In this case, \( \tau \circ \rho \) is thin if and only if the edge \( \Delta^1 \xrightarrow{\rho_0} \Delta^n \xrightarrow{\sigma} \Hom^R_{\mathcal{C}}(X,Y) \) is an isomorphism in the \( \infty \)-category \( \Hom^R_{\mathcal{C}}(X,Y) \) (Theorem 5.5.4.1). Allowing \( \tau_0 \) to vary,
we obtain the identification $\text{Hom}^R_{\text{Pith}(C)}(X,Y) \simeq \text{Hom}^R_C(X,Y) \simeq$; the proof of the analogous statement for left-pinched morphism spaces is similar.

**Proposition 5.5.5.13.** Let $C$ be an $(\infty,2)$-category and let $f : K \to C$ be a morphism of simplicial sets. Then:

1. The projection map $\pi : C/f \times_C \text{Pith}(C) \to \text{Pith}(C)$ is a cartesian fibration of $\infty$-categories. Moreover, a morphism $u$ of $C/f \times_C \text{Pith}(C)$ is $\pi$-cartesian if and only if, for every vertex $z \in K$, the composite map
   \[ \Delta^2 \simeq \Delta^1 \star \{z\} \hookrightarrow \Delta^1 \star K \xrightarrow{u} C \]
   is a thin 2-simplex of $C$.

2. The projection map $\pi' : C/f \times_C \text{Pith}(C) \to \text{Pith}(C)$ is a cocartesian fibration of $\infty$-categories. Moreover, a morphism $v$ of $C/f \times_C \text{Pith}(C)$ is $\pi'$-cocartesian if and only if, for every vertex $x \in K$, the composite map
   \[ \Delta^2 \simeq \{x\} \star \Delta^1 \hookrightarrow K \star \Delta^1 \xrightarrow{v} C \]
   is a thin 2-simplex of $C$.

**Proof.** We will prove (1); the proof of (2) is similar. It follows from Remark 5.5.2.4 that $\pi$ is an interior fibration. Since $\text{Pith}(C)$ is an $\infty$-category (Proposition 5.5.5.6), it is an inner fibration of $\infty$-categories (Example 5.5.2.2). Let us say that a morphism $u$ of $C/f \times_C \text{Pith}(C)$ is special if, for every vertex $z \in K$, the composite map
   \[ \Delta^2 \simeq \Delta^1 \star \{z\} \hookrightarrow \Delta^1 \star K \xrightarrow{u} C \]
   is a thin 2-simplex of $C$. Let $\pi : C/f \to C$ be the projection map. It follows from Corollary 5.5.4.2 that every special morphism of $C/f \times_C \text{Pith}(C)$ is $\pi$-cartesian when viewed as a morphism of $C/f$, and therefore also $\pi$-cartesian (Remark 5.1.1.11). Conversely, any $\pi$-cartesian morphism of $C/f \times_C \text{Pith}(C)$ is locally $\pi$-cartesian when viewed as a morphism of $C/f$, and therefore special (again by Corollary 5.5.4.2). To complete the proof, it will suffice to show that if $Y$ is an object of $C/f$, then any morphism $\overline{\pi} : \overline{X} \to q(\overline{Y})$ in $\text{Pith}(C)$ can be lifted to a special morphism $u : X \to Y$ of $C/f \times_C \text{Pith}(C)$, which follows from Proposition 5.5.3.9.

**5.5.6 The Four-out-of-Five Property**

Let $C$ be an $\infty$-category. Recall that the collection of isomorphisms in $C$ has the “two-out-of-three” property: if $f : X \to Y$ and $g : Y \to Z$ are composable morphisms of $C$ and any two of the morphisms $f$, $g$, and $g \circ f$ is an isomorphism, then so is the third (Remark 1.3.6.3). This can be regarded as a special case of a more general closure property.
Definition 5.5.6.1. Let \( C \) be a simplicial set and let \( W \) be a collection of edges of \( C \). We will say that \( W \) has the \textit{two-out-of-six property} if it satisfies the following condition:

\[(\ast) \text{ Let } \sigma \text{ be a 3-simplex of } C \text{ and, for every pair of integers } 0 \leq i < j \leq 3, \text{ let } \sigma_{ij} \text{ denote the edge of } C \text{ given by } \sigma|_{N_{\bullet}(\{i<j\})}. \text{ If the edges } \sigma_{20} \text{ and } \sigma_{31} \text{ belong to } W, \text{ then the edges } \sigma_{10}, \sigma_{21}, \sigma_{32}, \text{ and } \sigma_{30} \text{ also belong to } W.\]

Exercise 5.5.6.2. Let \( C \) be a simplicial set and let \( W \) be a collection of edges of \( C \) which has the two-out-of-six property. Show that \( W \) has the two-out-of-three property. That is, for any 2-simplex \( \sigma \) of \( C \), if any two of the faces \( d_0(\sigma), d_1(\sigma), \text{ and } d_2(\sigma) \) belong to \( W \), then so does the third.

Remark 5.5.6.3. Let \( C \) be an \( \infty \)-category and let \( W \) be a collection of edges of \( C \). We can informally summarize Definition 5.5.6.1 as follows: a collection of morphisms \( W \) of \( C \) has the two-out-of-six property if, for every triple of composable morphisms \( f : A \to B, g : B \to C, \text{ and } h : C \to D \), if the compositions \( g \circ f \) and \( h \circ g \) belong to \( W \), then the morphisms \( f, g, h, \text{ and } h \circ g \circ f \) are \textit{a priori} only well-defined up to homotopy.

Remark 5.5.6.4. Let \( F : C \to D \) be a morphism of simplicial sets and let \( W \) be a collection of edges of \( D \). If \( W \) has the two-out-of-six property, then the inverse image \( F^{-1}(W) \) also has the two-out-of-six property.

Proposition 5.5.6.5 (Two-out-of-Six). Let \( C \) be an \( \infty \)-category and let \( W \) be the collection of isomorphisms in \( C \). Then \( W \) has the two-out-of-six property.

\[\text{Proof.} \text{ By definition, a morphism } f \text{ of } C \text{ is an isomorphism if and only if its homotopy class } [f] \text{ is an isomorphism in the homotopy category } hC \text{ (Definition 1.3.6.1). By virtue of Remark 5.5.6.4, we can replace } C \text{ by the nerve } N_{\bullet}(hC) \text{ and thereby reduce to the case where } C = N_{\bullet}(C') \text{ for some category } C'. \text{ Let } \sigma \text{ be a 3-simplex of } C, \text{ corresponding to a triple of morphisms}
\]

\[A \xrightarrow{f} B \xrightarrow{g} C \xrightarrow{h} D\]

in \( C' \), and suppose that \( g \circ f \) and \( h \circ g \) are isomorphisms. Then \( g \circ f \) admits an inverse \( u : C \to A \). It follows that \( g \circ (f \circ u) = (g \circ f) \circ u = \text{id}_C \), so that \( g \) admits a right inverse. A similar argument shows that \( g \) also admits a left inverse, and is therefore an isomorphism (Remark 1.3.6.7). Applying the two-out-three property, we deduce that \( f \) and \( h \) are also isomorphisms. Since the collection of isomorphisms is closed under composition, it also follows that \( h \circ g \circ f \) is an isomorphism. \]

Proposition 5.5.6.5 admits a converse:
Proposition 5.5.6.6. Let $C$ be an $\infty$-category and let $W$ be a collection of morphisms of $C$ which has the two-out-of-six property. If $W$ contains every identity morphism of $C$, then it contains every isomorphism of $C$.

In other words, the collection of isomorphisms in an $\infty$-category $C$ is the smallest collection of morphisms which contains all identity morphisms and has the two-out-of-six property.

Warning 5.5.6.7. The analogue of Proposition 5.5.6.6 for the two-out-of-three property is false in general. For example, if $C$ is the nerve of a category, then the collection of identity morphisms of $C$ has the two-out-of-three property, but usually does not contain all the isomorphisms of $C$.

Proof of Proposition 5.5.6.6. Let $C$ be an $\infty$-category and let $f : X \to Y$ be an isomorphism in $C$. Then $f$ admits a homotopy inverse $g : Y \to X$. Let $\sigma$ be a 2-simplex of $C$ which witnesses $\text{id}_X$ as a composition $f$ and $g$, and let $\sigma'$ be a 2-simplex of $C$ which witnesses $\text{id}_Y$ as a composition of $g$ and $f$. Then the triple $(\sigma', s_0(f), \bullet, \sigma)$ can be regarded as a morphism of simplicial sets $\tau_0 : \Delta^3 \to C$. Since $C$ is an $\infty$-category, we can extend $\tau_0$ to a 3-simplex $\tau : \Delta^3 \to C$, whose restriction to the 1-skeleton of $\Delta^3$ is indicated in the diagram

It follows that if $W$ is a collection of morphisms of $C$ which contains $\text{id}_X$, $\text{id}_Y$, and has the two-out-of-six property, then $W$ also contains the isomorphism $f$. 

Our goal in this section is to prove analogues of Propositions 5.5.6.5 and Proposition 5.5.6.6 in the setting of $(\infty, 2)$-categories, where we replace the set $W \subseteq \text{Hom}_{\text{Set}}(\Delta^1, C)$ of isomorphisms with the set $T \subseteq \text{Hom}_{\text{Set}}(\Delta^2, C)$ of thin 2-simplices.

Definition 5.5.6.8. Let $C$ be a simplicial set and let $T$ be a collection of 2-simplices of $C$. We say that $T$ has the four-out-of-five property if it satisfies the following condition:

(*) Let $\sigma : \Delta^4 \to C$ be a 4-simplex of $C$. For every triple of integers $0 \leq i < j < k \leq 4$, let $\sigma_{kji}$ denote the 2-simplex of $C$ given by the restriction of $\sigma$ to $N_\bullet([i < j < k])$. If the 2-simplices $\sigma_{310}$, $\sigma_{420}$, $\sigma_{321}$, and $\sigma_{432}$ belong to $T$, then the 2-simplex $\sigma_{430}$ also belongs to $T$. 

Definition 5.5.6.9 is not self-dual. Let $T$ be a collection of 2-simplices of $C$ which satisfies the four-out-of-five property and let $T^{\text{op}}$ denote the same set, regarded as a collection of 2-simplices of the opposite simplicial set $C^{\text{op}}$. Then $T^{\text{op}}$ need not satisfy the four-out-of-five property.

Warning 5.5.6.10. Let $F : C \to D$ be a morphism of simplicial sets and let $T$ be a collection of 2-simplices of $D$. If $T$ has the four-out-of-five property, then the inverse image $F^{-1}(T)$ also has the four-out-of-five property.

Proposition 5.5.6.11 (Four-out-of-Five). Let $C$ be an $(\infty, 2)$-category and let $T$ be the collection of all thin 2-simplices of $C$. Then $T$ has the four-out-of-five property.

Warning 5.5.6.12. Let $C$ be an $(\infty, 2)$-category and let $\sigma : \Delta^4 \to C$ be a 4-simplex of $C$. For $0 \leq i < j < k \leq 4$, let $\sigma_{kji}$ denote the restriction $\sigma|_{N^\text{•}(\{i < j < k\})}$. Proposition 5.5.6.11 asserts that, if the 2-simplices $\sigma_{310}, \sigma_{420}, \sigma_{321},$ and $\sigma_{432}$ are thin, then $\sigma_{430}$ is also thin. Beware that the remaining 2-simplices $\sigma_{210}, \sigma_{410}, \sigma_{320}, \sigma_{421}$, and $\sigma_{431}$ need not be thin.

Example 5.5.6.13. To get a feeling for the content of Proposition 5.5.6.11, let us consider the special case where $C = N^\text{•}(C')$ is the Duskin nerve of a strict 2-category $C'$. Let $\sigma$ be a 4-simplex of $C$, which we identify with a collection of objects $\{X_i\}_{0 \leq i \leq 4}$, 1-morphisms $\{f_{ji} : X_j \to X_i\}_{0 \leq i < j \leq 4}$, and 2-morphisms $\{\mu_{kji} : f_{kj} \circ f_{ji} \Rightarrow f_{ki}\}_{0 \leq i < j < k \leq 4}$ of $C$ satisfying the condition described in Proposition 2.3.1.9. Proposition 5.5.6.11 asserts that if the 2-morphisms $\mu_{310}, \mu_{420}, \mu_{321},$ and $\mu_{432}$ are invertible, then the 2-morphism $\mu_{430}$ is also invertible. This follows by inspecting the cubical diagram:

\[
\begin{array}{cccc}
\begin{array}{c}
f_{43} \circ f_{32} \circ f_{21} \circ f_{10} \\
\mu_{210}
\end{array} & \begin{array}{c}
f_{43} \circ f_{32} \circ f_{20}
\end{array} & \begin{array}{c}
f_{43} \circ f_{32} \circ f_{21} \circ f_{10} \\
\mu_{321}
\end{array} & \begin{array}{c}
f_{43} \circ f_{32} \circ f_{20} \\
\mu_{330}
\end{array} \\
\mu_{432} & \sim & \sim
\end{array}
\]

\[
\begin{array}{cccc}
\begin{array}{c}
f_{43} \circ f_{31} \circ f_{10} \\
\mu_{110}
\end{array} & \begin{array}{c}
f_{43} \circ f_{30}
\end{array} & \begin{array}{c}
f_{43} \circ f_{31} \circ f_{10} \\
\mu_{432}
\end{array} & \begin{array}{c}
f_{43} \circ f_{30} \\
\mu_{440}
\end{array} \\
\sim & \sim & \sim & \sim
\end{array}
\]

\[
\begin{array}{cc}
\begin{array}{c}
f_{42} \circ f_{21} \circ f_{10} \\
\mu_{210}
\end{array} & \begin{array}{c}
f_{42} \circ f_{20}
\end{array} \\
\mu_{421} & \sim
\end{array}
\]

\[
\begin{array}{cc}
\begin{array}{c}
f_{41} \circ f_{10} \\
\mu_{410}
\end{array} & \begin{array}{c}
f_{40}
\end{array} \\
\sim & \sim
\end{array}
\]
in the category $\text{Hom}_{\infty}(X_0, X_4)$ and applying the two-out-of-six property to the chain of 2-morphisms
\[ f_{43} \circ f_{32} \circ f_{21} \circ f_{10} \xrightarrow{\mu_{210}} f_{43} \circ f_{32} \circ f_{20} \xrightarrow{\mu_{320}} f_{43} \circ f_{30} \xrightarrow{\mu_{430}} f_{40}. \]

**Proof of Proposition 5.5.6.11.** Let $\mathcal{C}$ be an $(\infty, 2)$-category and let $\sigma : \Delta^4 \to \mathcal{C}$ be a 4-simplex. For every triple of integers $0 \leq i < j < k \leq 4$, let $\sigma_{kji}$ denote the 2-simplex of $\mathcal{C}$ given by the restriction of $\sigma$ to $N_i \{i < j < k\}$. Assume that the 2-simplices $\sigma_{310}, \sigma_{420}, \sigma_{321}$, and $\sigma_{432}$ are thin. We wish to show that $\sigma_{430}$ is also thin.

Set $X = \sigma(0) \in \mathcal{C}$. Let $\mathcal{E}$ denote the fiber product $\mathcal{C}_{X/} \times_\mathcal{C} \text{Pith}(\mathcal{C})$ and let $\pi : \mathcal{E} \to \text{Pith}(\mathcal{C})$ be the projection map, so that $\pi$ is a cocartesian fibration of $\infty$-categories (Proposition 5.5.5.13). For $1 \leq i \leq 4$, let $\mathcal{E}_i$ denote the $\infty$-category $\{\sigma(i)\} \times_{\text{Pith}(\mathcal{C})} \mathcal{E}$, so that the edge $\sigma|_{N_i \{0 < i\}}$ of $\mathcal{C}$ can be identified with an object $Y_i \in \mathcal{E}_i$. For $1 \leq i < j \leq 4$, let us identify the 2-simplex $\sigma|_{N_i \{0 < i < j\}}$ with a morphism $f_{j,i} : Y_i \to Y_j$ in $\mathcal{E}$. By virtue of Proposition 5.5.5.13, it will suffice to show that the morphism $f_{4,3} : Y_3 \to Y_4$ is $\pi$-cocartesian.

For $2 \leq i \leq 4$, let $F_i : \mathcal{E}_{i-1} \to \mathcal{E}_i$ be given by covariant transport along the edge $\sigma|_{N_i \{i-1 < i\}}$ of $\text{Pith}(\mathcal{C})$ (see Definition 5.2.2.4) so that we have a sequence of functors
\[ \mathcal{E}_1 \xrightarrow{F_2} \mathcal{E}_2 \xrightarrow{F_3} \mathcal{E}_3 \xrightarrow{F_4} \mathcal{E}_4. \]

Let $H_i : \Delta^1 \times \mathcal{E}_{i-1} \to \mathcal{E}$ be a functor which witnesses that $F_i$ is given by covariant transport along $\sigma|_{N_i \{i-1 < i\}}$, so that $h_i = H_i|_{\Delta^1 \times \{Y_{i-1}\}}$ is a $\pi$-cocartesian morphism of $\mathcal{E}$. It follows that the morphism $f_{i,i-1}$ can be written as a composition
\[ Y_{i-1} \xrightarrow{h_i} F_i(Y_{i-1}) \xrightarrow{g_i} Y_i, \]
where $g_i$ is a morphism in the $\infty$-category $\mathcal{E}_i$. To complete the proof, it will suffice to show that the morphism $g_4 : F_4(Y_3) \to Y_4$ is an isomorphism in the $\infty$-category $\mathcal{E}_4$ (see Remark 5.1.3.8).

Note that we have a chain of 1-morphisms
\[ (F_4 \circ F_3 \circ F_2)(Y_1) \xrightarrow{(F_4 \circ F_3)(g_2)} (F_4 \circ F_3)(Y_2) \xrightarrow{F_4(g_3)} F_4(Y_3) \xrightarrow{g_4} Y_4 \]
in the $\infty$-category $\mathcal{E}_4$. Since the collection of isomorphisms in the homotopy category $\text{h}\mathcal{E}_4$ satisfies the two-out-of-six property, it will suffice to prove the following:

(a) The composition
\[ (F_4 \circ F_3 \circ F_2)(Y_1) \xrightarrow{[F_4 \circ F_3](g_2)} (F_4 \circ F_3)(Y_2) \xrightarrow{[F_4(g_3)]} F_4(Y_3) \]
is an isomorphism in the homotopy category $\text{h}\mathcal{E}_4$. 

5.5. $(\infty, 2)$-CATEGORIES

(b) The composition

$$ (F_4 \circ F_3)(Y_2) \xrightarrow{[F_4(g_3)]} F_4(Y_3) \xrightarrow{[g_4]} Y_4 $$

is an isomorphism in the homotopy category $h\mathcal{E}_4$.

We will deduce (a) from the following slightly stronger assertion:

(a') The composition

$$ (F_3 \circ F_2)(Y_1) \xrightarrow{[F_3(g_2)]} F_3(Y_2) \xrightarrow{[g_3]} Y_3 $$

is an isomorphism in the homotopy category $h\mathcal{E}_3$.

To prove (a'), we first note that the 2-simplex $\sigma_{321}$ is thin, and can therefore be regarded as a 2-simplex of $\text{Pith}(\mathcal{C})$. Let $\mathcal{E}'$ denote the fiber product $\mathcal{N}_\bullet(\{1 < 2 < 3\}) \times_{\text{Pith}(\mathcal{C})} \mathcal{E}$, and let $\pi': \mathcal{E}' \to \mathcal{N}_\bullet(\{1 < 2 < 3\})$ be the projection map. In the homotopy category $h\mathcal{E}'$, we have a commutative diagram

$$
\begin{array}{ccc}
Y_1 & \xrightarrow{[h_2]} & F_2(Y_1) \\
| & & | \\
| & & | \\
Y_2 & \xrightarrow{[g_2]} & F_3(Y_2) \\
| & & | \\
| & & | \\
Y_3 & \xrightarrow{[g_3]} & F_3(Y_3) \\
| & & | \\
| & & | \\
Y_3 & \xrightarrow{[h_3]} & F_2(Y_1)
\end{array}
$$

where the upper horizontal composition is the homotopy class of a $\pi'$-cocartesian morphism (Corollary 5.1.2.4). It follows that the vertical composition on the right is an isomorphism if and only if the diagonal composition is also the homotopy class of a $\pi'$-cocartesian morphism (Remark 5.1.3.8). We now observe that the 3-simplex $\sigma_{310}|_{\mathcal{N}_\bullet(\{0 < 1 < 2 < 3\})}$ witnesses the identity $[f_{3,2}] \circ [f_{2,1}] = [f_{3,1}]$ in the homotopy category $h\mathcal{E}'$. It will therefore suffice to show that $f_{3,1}$ is a $\pi'$-cocartesian morphism of the $\infty$-category $\mathcal{E}'$, which follows from Proposition 5.5.5.13 and our assumption that $\sigma_{310}$ is thin. This completes the proof of (a). The proof of (b) follows by the same argument, using the thinness of the 2-simplices $\sigma_{321}$ and $\sigma_{420}$ in place of $\sigma_{321}$ and $\sigma_{310}$.

We now prove a partial converse to Proposition 5.5.6.11, which can be regarded as an $(\infty, 2)$-categorical analogue of Proposition 5.5.6.6.

**Proposition 5.5.6.14.** Let $\mathcal{C}$ be an $(\infty, 2)$-category and let $T$ be a collection of 2-simplices of $\mathcal{C}$. Assume that:

**01Y3**
(1) Every degenerate 2-simplex of \( C \) belongs to \( T \).

(2) For every pair of morphisms \( f : X \to Y \) and \( g : Y \to Z \) in \( C \), there exists a thin 2-simplex \( \sigma \) of \( C \) which belongs to \( T \) and satisfies \( d_2(\sigma) = f \) and \( d_0(\sigma) = g \), as indicated in the diagram

\[
\begin{array}{ccc}
Y & \overset{f}{\longrightarrow} & X \\
| & | & | \\
 & \downarrow{h} & \\
Z & \overset{g}{\longrightarrow} & \end{array}
\]

(3) The collection \( T \) has the inner exchange property (Definition 5.5.5.7).

(4) The collection \( T \) has the four-out-of-five property (Definition 5.5.6.8).

Then every thin 2-simplex of \( C \) belongs to \( T \).

Proof. Let \( \sigma \) be a thin 2-simplex of \( C \), whose 1-skeleton we represent by the diagram

\[
\begin{array}{ccc}
Y & \overset{f}{\longrightarrow} & X \\
| & | & | \\
 & \downarrow{h} & \\
Z & \overset{g}{\longrightarrow} & \end{array}
\]

Applying assumption (2), we can choose a thin 2-simplex \( \sigma' \) of \( C \) which belongs to \( T \) whose restriction to the 1-skeleton of \( \Delta^2 \) is represented by the diagram

\[
\begin{array}{ccc}
Y & \overset{f}{\longrightarrow} & X \\
| & | & | \\
 & \downarrow{h'} & \\
Z & \overset{g}{\longrightarrow} & \end{array}
\]

The edge \( g \) determines a morphism of simplicial sets \( \Delta^1 \to C \). Let \( \mathcal{E} \) denote the fiber product \( \Delta^1 \times^C C_{X/} \). Since the projection map \( C_{X/} \to C \) is an interior fibration (Proposition 5.5.3.1), it follows from Remark 5.5.2.4 and Example 5.5.2.2 that the projection map \( \pi : \mathcal{E} \to \Delta^1 \) is an inner fibration; in particular, \( \mathcal{E} \) is an \( \infty \)-category. Moreover, we can identify the edges \( f, h, \) and \( h' \) of \( C \) with objects \( \tilde{Y}, \tilde{Z}, \) and \( \tilde{Z}' \) of \( \mathcal{E} \), and the 2-simplices \( \sigma \) and \( \sigma' \) with morphisms \( \bar{h} : \tilde{Y} \to \tilde{Z} \) and \( \bar{h}' : \tilde{Y} \to \tilde{Z}' \). Since \( \sigma \) and \( \sigma' \) are both thin, the morphisms \( \bar{h} \) and \( \bar{h}' \) are both \( \pi \)-cocartesian (Theorem 5.5.4.1). It follows that \( \bar{h} \) and \( \bar{h}' \) are isomorphic when
viewed as objects of the ∞-category $\mathcal{E}_{\tilde{Y}/}$ (see Remark 5.1.3.8). We can therefore choose a 2-simplex $\rho$ of $\mathcal{E}_{\tilde{Y}/}$ whose 1-skeleton is given by the diagram

$$
\begin{array}{c}
\tilde{h}'
\end{array}
\begin{array}{c}
\downarrow
\end{array}
\begin{array}{c}
\tilde{h}
\end{array}
\begin{array}{c}
\downarrow
\end{array}
\begin{array}{c}
\tilde{id}_h
\end{array}
\begin{array}{c}
\rightarrow
\end{array}
\begin{array}{c}
\tilde{h}_i
\end{array}
\begin{array}{c}
\rightarrow
\end{array}
\begin{array}{c}
\tilde{h}_j
\end{array}
$$

which we can identify with a 4-simplex $\tau : \Delta^4 \to \mathcal{C}$. For $0 \leq i < j < k \leq 4$, let $\tau_{kij}$ denote the 2-simplex of $\mathcal{C}$ given by $\tau|_{N^\bullet([[i < j < k]])}$. By construction, the 2-simplex $\tau_{310}$ is equal to $\sigma'$, and therefore belongs to $T$. Moreover, the 2-simplices $\tau_{420}$, $\tau_{321}$, $\tau_{431}$, and $\tau_{432}$ are right-degenerate, and therefore belong to $T$ by virtue of assumption (1). Since $T$ has the four-out-of-five-property, it follows that $\tau_{430}$ belongs to $T$. Applying the inner exchange property to the 3-simplex $\tau|_{N^\bullet([0 < 1 < 3 < 4])}$, we deduce that the 2-simplex $\sigma = \tau_{410}$ also belongs to $T$, as desired.

5.5.7 Functors of ($\infty, 2$)-Categories

Let $\mathcal{C}$ and $\mathcal{D}$ be $\infty$-categories. Recall that a functor from $\mathcal{C}$ to $\mathcal{D}$ is a morphism of simplicial sets $F : \mathcal{C} \to \mathcal{D}$ (Definition 1.4.0.1). In this case, it is automatic that $F$ carries isomorphisms in $\mathcal{C}$ to isomorphisms in $\mathcal{D}$ (Remark 1.4.1.6). Beware that the ($\infty, 2$)-categorical analogue of this statement is false: if $\mathcal{C}$ and $\mathcal{D}$ are ($\infty, 2$)-categories, then a morphism of simplicial sets $F : \mathcal{C} \to \mathcal{D}$ will generally not carry thin 2-simplices of $\mathcal{C}$ to thin 2-simplices of $\mathcal{D}$. This motivates the following:

**Definition 5.5.7.1.** Let $\mathcal{C}$ and $\mathcal{D}$ be ($\infty, 2$)-categories. A functor from $\mathcal{C}$ to $\mathcal{D}$ is a morphism of simplicial sets $F : \mathcal{C} \to \mathcal{D}$ which carries thin 2-simplices of $\mathcal{C}$ to thin 2-simplices of $\mathcal{D}$.

**Example 5.5.7.2.** Let $\mathcal{C}$ be an ($\infty, 2$)-category and let $\mathcal{D}$ be an $\infty$-category. Then every 2-simplex of $\mathcal{D}$ is thin, so every morphism of simplicial sets $F : \mathcal{C} \to \mathcal{D}$ is a functor. In particular, when $\mathcal{C}$ and $\mathcal{D}$ are $\infty$-categories, Definition 5.5.7.1 reduces to Definition 1.4.0.1.

**Example 5.5.7.3.** Let $\mathcal{C}$ and $\mathcal{D}$ be 2-categories. By virtue of Theorem 2.3.4.1 and Corollary 2.3.4.5, passage to the Duskin nerve induces a bijection

\[
\{\text{Strictly unitary functors of 2-categories } \mathcal{C} \to \mathcal{D}\} \\
\downarrow \\
\{\text{Functors of } (\infty, 2)\text{-categories } N^\bullet_{\mathcal{D}}(\mathcal{C}) \to N^\bullet_{\mathcal{D}}(\mathcal{D})\}.
\]
Remark 5.5.7.4 (Functoriality). Let \( C \) and \( D \) be \((\infty, 2)\)-categories, and let \( F : C \to D \) be a morphism of simplicial sets. Then \( F \) is a functor (Definition 5.5.7.1) if and only it carries \( \operatorname{Pith}(C) \) into \( \operatorname{Pith}(D) \). If this condition is satisfied, then \( \operatorname{Pith}(F) = F|_{\operatorname{Pith}(C)} \) can be regarded as a functor from the \( \infty \)-category \( \operatorname{Pith}(C) \) to the \( \infty \)-category \( \operatorname{Pith}(D) \).

Remark 5.5.7.5. Let \( C \) be an \( \infty \)-category and let \( D \) be an \((\infty, 2)\)-category. Then every functor \( F : C \to D \) takes values in the pith \( \operatorname{Pith}(D) \subseteq D \). Consequently, the inclusion \( \operatorname{Pith}(D) \hookrightarrow D \) induces a bijection

\[
\{ \text{Functors of } \infty \text{-categories from } C \text{ to } \operatorname{Pith}(D) \} \rightarrow \{ \text{Functors of } (\infty, 2)\text{-categories from } C \text{ to } D \}.
\]

Note that this property (together with Proposition 5.5.5.6) characterize the simplicial set \( \operatorname{Pith}(D) \) up to unique isomorphism.

Remark 5.5.7.6. The existence of morphisms between \((\infty, 2)\)-categories which do not preserve thin 2-simplices should be viewed as a feature of our formalism, rather than a bug. Recall that, if \( C \) and \( D \) are 2-categories, then Theorem 2.3.4.1 supplies a bijection

\[
\{ \text{Strictly unitary lax functors } C \to D \} \sim \{ \text{Morphisms of simplicial sets } N_\bullet(C) \to N_\bullet(D) \}.
\]

Consequently, we can think of general morphisms of simplicial sets as providing a generalization of the notion of (strictly) unitary lax functors to the setting of \((\infty, 2)\)-categories.

Warning 5.5.7.7. For every pair of simplicial sets \( C \) and \( D \), we let \( \operatorname{Fun}(C, D) \) denote the simplicial set introduced in Construction 1.4.3.1. When working with \((\infty, 2)\)-categories, this notation is potentially confusing. By construction, vertices of the simplicial set \( \operatorname{Fun}(C, D) \) can be identified with morphisms of simplicial sets \( F : C \to D \). If \( C \) and \( D \) are \((\infty, 2)\)-categories, then such morphisms need not carry thin 2-simplices of \( C \) to thin 2-simplices of \( D \), and therefore need not correspond to functors from \( C \) to \( D \) in the sense of Definition 5.5.7.1. We will return to this point in §[?].

The following criterion is often useful for checking that a morphism of \((\infty, 2)\)-categories \( F : C \to D \) is a functor:
Proposition 5.5.7.8. Let $\mathcal{C}$ and $\mathcal{D}$ be $(\infty, 2)$-categories and let $F : \mathcal{C} \to \mathcal{D}$ be a morphism of simplicial sets. The following conditions are equivalent:

1. The morphism $F$ is a functor: that is, it carries thin 2-simplices of $\mathcal{C}$ to thin 2-simplices of $\mathcal{D}$.

2. For every pair of morphisms $f : X \to Y$ and $g : Y \to Z$ of $\mathcal{C}$, there exists a thin 2-simplex $\sigma$ of $\mathcal{C}$ with $d_0(\sigma) = g$ and $d_2(\sigma) = f$, as indicated in the diagram

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow & & \downarrow \searrow \\
 & \mathcal{D} & \\
\end{array}
\]

such that $F(\sigma)$ is a thin 2-simplex of $\mathcal{D}$.

Proof. The implication $(1) \Rightarrow (2)$ is immediate. To prove the converse, let $T$ be the collection of all 2-simplices of $\mathcal{C}$ for which $F(\sigma)$ is a thin 2-simplex of $\mathcal{D}$. Since the collection of thin 2-simplices of $\mathcal{D}$ has the four-out-of-five property (Proposition 5.5.6.11), it follows that $T$ also has the four-out-of-five property (Remark 5.5.6.10). Since the collection of thin 2-simplices of $\mathcal{D}$ has the inner exchange property (Proposition 5.5.5.10), $T$ has the inner exchange property (Remark 5.5.5.9). Since $\mathcal{D}$ is an $(\infty, 2)$-category, every degenerate 2-simplex of $\mathcal{D}$ is thin, so every degenerate 2-simplex of $\mathcal{C}$ belongs to $T$. If condition (2) is satisfied, then Proposition 5.5.6.14 guarantees that every thin 2-simplex of $\mathcal{C}$ belongs to $T$, so that $F$ is a functor.

Proposition 5.5.7.9. Let $F : \mathcal{C} \to \mathcal{D}$ be an interior fibration of $(\infty, 2)$-categories (Definition 5.5.2.1). Then:

1. The morphism $F$ is a functor of $(\infty, 2)$-categories: that is, it carries thin 2-simplices of $\mathcal{C}$ to thin 2-simplices of $\mathcal{D}$, and therefore induces a functor $\operatorname{Pith}(F) : \operatorname{Pith}(\mathcal{C}) \to \operatorname{Pith}(\mathcal{D})$.

2. The diagram of simplicial sets

\[
\begin{array}{ccc}
\operatorname{Pith}(\mathcal{C}) & \xrightarrow{F} & \mathcal{C} \\
\downarrow \operatorname{Pith}(F) & & \downarrow F \\
\operatorname{Pith}(\mathcal{D}) & \xrightarrow{F} & \mathcal{D}
\end{array}
\]

is a pullback square.
(3) The functor $Pith(F) : Pith(C) \to Pith(D)$ is an inner fibration of $\infty$-categories.

Proof. We will prove assertion (1) by showing that $F$ satisfies the criterion of Proposition \[5.5.7.8\]. Let $f : X \to Y$ and $g : Y \to Z$ be morphisms of $C$. Since $D$ is an $(\infty, 2)$-category, we can choose a thin 2-simplex $\sigma$ of $D$ satisfying $d_0(\sigma) = F(g)$ and $d_2(\sigma) = F(f)$, which we depict as a diagram

\[
\begin{array}{ccc}
F(Y) & \xrightarrow{F(f)} & F(Z) \\
\downarrow{F(g)} & & \downarrow{F(g)} \\
F(X) & \xrightarrow{F(f)} & F(Z). \\
\end{array}
\]

Since $F$ is an interior fibration, the lifting problem

\[
\begin{array}{ccc}
\Lambda^2_1 & \xrightarrow{(g, \bullet, f)} & C \\
\downarrow{\sigma} & & \downarrow{F} \\
\Delta^2 & \xrightarrow{\sigma} & D
\end{array}
\]

admits a solution. Then $\sigma$ is a thin 2-simplex of $C$ (Lemma \[5.5.2.6\]) for which the image $\bar{\sigma} = F(\sigma)$ is a thin 2-simplex of $D$.

We now prove (2). Let $\tau$ be an $m$-simplex of the simplicial set $C$, and suppose that $F(\tau)$ belongs to the pith $Pith(D)$. We wish to show that $\tau$ belongs to $Pith(C)$: that is, that it carries each 2-simplex of $\Delta^m$ to a thin 2-simplex of $C$. This follows immediately from Lemma \[5.5.2.6\] since the composite map

\[
\Delta^2 \to \Delta^m \xrightarrow{\tau} C \xrightarrow{F} D
\]

is a thin 2-simplex of $D$.

Combining (2) with Remark \[5.5.2.4\], we conclude that the functor $Pith(F) : Pith(C) \to Pith(D)$ is an interior fibration. Since $Pith(D)$ is an $\infty$-category (Proposition \[5.5.5.6\]), it follows that $Pith(F)$ is an inner fibration (Example \[5.5.2.2\]).

\[\square\]

Corollary \[5.5.7.10\]. Let $C$ be an $(\infty, 2)$-category, let $f : K \to C$ be a morphism of simplicial sets, and let

\[
q' : C_f/ \to C \quad q : C_f/ \to C
\]

be the projection maps. Then:
(1) The functor $\text{Pith}(q) : \text{Pith}(\mathcal{C}/f) \to \text{Pith}(\mathcal{C})$ is a cartesian fibration of $\infty$-categories. Moreover, a morphism $u$ of $\text{Pith}(\mathcal{C}/f)$ is $\text{Pith}(q)$-cartesian if and only if, for every vertex $z \in K$, the composite map

$$\Delta^2 \simeq \Delta^1 \ast \{z\} \hookrightarrow \Delta^1 \ast K \xrightarrow{u} \mathcal{C}$$

is a thin 2-simplex of $\mathcal{C}$.

(2) The functor $\text{Pith}(q') : \text{Pith}(\mathcal{C}/f) \to \text{Pith}(\mathcal{C})$ is a cocartesian fibration of $\infty$-categories. Moreover, a morphism $v$ of $\text{Pith}(\mathcal{C}/f)$ is $\text{Pith}(q')$-cocartesian if and only if, for every vertex $x \in K$, the composite map

$$\Delta^2 \simeq \{x\} \ast \Delta^1 \hookrightarrow K \ast \Delta^1 \xrightarrow{v} \mathcal{C}$$

is a thin 2-simplex of $\mathcal{C}$.

Proof. Combine Propositions 5.5.7.9 and 5.5.5.13.

Specializing Corollary 5.5.7.10 to the case $K = \Delta^0$, we obtain the following:

**Corollary 5.5.7.11.** Let $\mathcal{C}$ be an $(\infty, 2)$-category and let $Z$ be an object of $\mathcal{C}$. Then:

1. The projection map $\pi : \mathcal{C}/Z \to \mathcal{C}$ induces a cartesian fibration of $\infty$-categories $\text{Pith}(\pi) : \text{Pith}(\mathcal{C}/Z) \to \text{Pith}(\mathcal{C})$.

2. A morphism $u$ of $\text{Pith}(\mathcal{C}/Z)$ is $\text{Pith}(\pi)$-cartesian if and only if it corresponds to a thin 2-simplex of $\mathcal{C}$ (in this case, it is also $\pi$-cartesian when viewed as a morphism of $\mathcal{C}/Z$).

3. The inclusion $\text{Pith}(\mathcal{C}) \hookrightarrow \mathcal{C}$ induces an isomorphism from $\text{Pith}(\mathcal{C})/Z$ to the (non-full) subcategory of $\text{Pith}(\mathcal{C}/Z)$ spanned by the $\pi$-cartesian morphisms.

Proof. Assertions (1) and (2) follow from Corollary 5.5.7.10, and assertion (3) is an immediate consequence of (2).

**Remark 5.5.7.12.** Recall that every cartesian fibration of simplicial sets $\pi : \mathcal{E} \to \mathcal{D}$ has an underlying right fibration $\pi' : \mathcal{E}' \to \mathcal{D}$, given by restricting $\pi$ to the simplicial subset $\mathcal{E}' \subseteq \mathcal{E}$ spanned by those simplices $\sigma : \Delta^n \to \mathcal{E}$ which carry each edge of $\Delta^n$ to $\pi$-cartesian edge of $\mathcal{E}$. Corollary 5.5.7.11 asserts that, when $\pi$ is the cartesian fibration $\text{Pith}(\mathcal{C}/Z) \to \text{Pith}(\mathcal{C})$ associated to a choice of object $Z$ of an $(\infty, 2)$-category $\mathcal{C}$, then $\pi'$ can be identified with the right fibration $\text{Pith}(\mathcal{C})/Z \to \text{Pith}(\mathcal{C})$ supplied by Corollary 4.3.6.11; compare with Proposition 5.5.3.1.

We can also use Proposition 5.5.7.9 to deduce a relative version of Proposition 5.5.3.1.
Corollary 5.5.7.13. Let \( \mathcal{C} \) be an \((\infty,2)\)-category, let \( f : K \to \mathcal{C} \) be a morphism of simplicial sets, and let \( f_0 = f|_{K_0} \) denote the restriction of \( f \) to a simplicial subset \( K_0 \subseteq K \). Then the projection maps

\[
\mathcal{C}_f \to \mathcal{C}_{f_0} \quad \mathcal{C}/f \to \mathcal{C}/f_0
\]

are interior fibrations of \((\infty,2)\)-categories.

Warning 5.5.7.14. In the situation of Corollary 5.5.7.13, the induced map \( \text{Pith}(\mathcal{C}/f) \to \text{Pith}(\mathcal{C}_{f_0}) \) is generally not a cartesian fibration, and the induced map \( \text{Pith}(\mathcal{C}_f) \to \text{Pith}(\mathcal{C}_{f_0}) \) is generally not a cocartesian fibration.

Proof of Corollary 5.5.7.13. We will show that the map of slice simplicial sets \( q : \mathcal{C}_f \to \mathcal{C}_{f_0} \) is an interior fibration; the analogous statement for coslice simplicial sets follows by a similar argument. We first observe that \( \mathcal{C}_{f_0} \) is an \((\infty,2)\)-category (Corollary 5.5.3.4). Suppose we are given an integer \( n \geq 2 \) and a lifting problem

\[
\begin{array}{ccc}
\Lambda^n_1 & \overset{\sigma_0}{\longrightarrow} & \mathcal{C}_f \\
\downarrow \sigma \downarrow & & \downarrow q \\
\Delta^n & \overset{\pi}{\longrightarrow} & \mathcal{C}_{f_0}
\end{array}
\]

We wish to show that this lifting problem admits a solution provided that one of the following conditions is satisfied:

(a) The integer \( i \) is equal to 0 and \( \sigma_0|_{N_{\bullet}(\{0<1\})} \) is a degenerate edge of \( \mathcal{C}_f \).

(b) The integer \( i \) satisfies \( 0 < i < n \) and the restriction \( \overline{\sigma}|_{N_{\bullet}(\{i-1<i<i+1\})} \) is a thin 2-simplex of \( \mathcal{C}_{f_0} \).

(c) The integer \( i \) is equal to \( n \) and \( \sigma_0|_{N_{\bullet}(\{n-1<n\})} \) is a degenerate edge of \( \mathcal{C}/f \).

In cases (a) and (c), this follows immediately from Proposition 5.5.3.8. In case (b), it suffices (by virtue of Proposition 5.5.3.8) to verify that the composite map

\[
\Delta^2 \simeq N_{\bullet}(\{i-1<i<i+1\}) \subseteq \Delta^n \overset{\pi}{\longrightarrow} \mathcal{C}_{f_0} \to \mathcal{C}
\]

is a thin 2-simplex of \( \mathcal{C} \). This follows from our hypothesis, since the projection map \( \mathcal{C}_{f_0} \to \mathcal{C} \) preserves thin 2-simplices (Proposition 5.5.7.9). \( \square \)
5.5.8 Strict $(\infty,2)$-Categories

Let $\mathcal{C}$ be a simplicial category. If $\mathcal{C}$ is locally Kan, then Theorem 2.4.5.1 guarantees that the homotopy coherent nerve $N^{hc}(\mathcal{C})$ is an $\infty$-category. Our goal in this section is to establish an $(\infty,2)$-categorical variant of this result:

**Theorem 5.5.8.1.** Let $\mathcal{C}$ be a simplicial category. Suppose that, for every pair of objects $X$ and $Y$, the simplicial set $\text{Hom}_\mathcal{C}(X,Y)_\bullet$ is an $\infty$-category. Then the homotopy coherent nerve $N^{hc}(\mathcal{C})$ is an $(\infty,2)$-category.

We will deduce Theorem 5.5.8.1 from the following thinness criterion for 2-simplices of the homotopy coherent nerve $N^{hc}(\mathcal{C})$.

**Proposition 5.5.8.2.** Let $\mathcal{C}$ be a simplicial category. Suppose that, for every pair of objects $X$ and $Y$, the simplicial set $\text{Hom}_\mathcal{C}(X,Y)_\bullet$ is an $\infty$-category. Let $\sigma$ be a 2-simplex of the homotopy coherent nerve $N^{hc}(\mathcal{C})$, which we identify with a (not necessarily commutative) diagram

\[
\begin{array}{ccc}
Y & \rightarrow & \ast \\
\downarrow f & & \downarrow g \\
X & \rightarrow & Z
\end{array}
\]

in $\mathcal{C}$ together with an edge $\mu : g \circ f \rightarrow h$ in the simplicial set $\text{Hom}_\mathcal{C}(X,Z)_\bullet$. If $\mu$ is an isomorphism, then $\sigma$ is thin.

**Proof.** Suppose we are given integers $n \geq 3$, $0 < i < n$, and a morphism of simplicial sets $\tau_0 : \Lambda^n_i \rightarrow N^{hc}(\mathcal{C})$ for which the restriction $\tau_0|_{N_\bullet((i-1)<i<i+1)}$ is the 2-simplex $\sigma$. We wish to show that $\tau_0$ can be extended to an $n$-simplex of $\mathcal{C}$. Let $\text{Path}[n]_\bullet$ be the simplicial category described in Notation 2.4.3.1 and let us identify $\text{Path}[\Lambda^n_i]_\bullet$ with the simplicial subcategory of $\text{Path}[n]_\bullet$ described in Proposition 2.4.5.8. Then $\tau_0$ can be identified with a simplicial functor $F_0 : \text{Path}[\Lambda^n_i]_\bullet \rightarrow \mathcal{C}$, and we wish to show that $\tau_0$ can be extended to a simplicial functor $F : \text{Path}[n]_\bullet \rightarrow \mathcal{C}$.

For $0 \leq j \leq n$, let $C_j$ denote the object of $\mathcal{C}$ given by $F_0(j)$. For $1 \leq j \leq n$, let $u_j : C_{j-1} \rightarrow C_j$ be the morphism in $\mathcal{C}$ obtained by applying $F_0$ to the unique vertex of $\text{Hom}_{\text{Path}[\Lambda^n_i]}(j-1,j)$, so that we have a chain of composable morphisms

\[
C_0 \xrightarrow{u_1} C_1 \xrightarrow{u_2} \cdots \xrightarrow{u_n} C_n
\]

in the simplicial category $\mathcal{C}$. Let $\square^{n-1}$ denote the simplicial cube of dimension $(n-1)$ and let $\square^{n-1}_i \subseteq \square^{n-1}$ denote the hollow cube of Notation 2.4.5.5 so that Remark 2.4.5.4 and Proposition 2.4.5.8 supply isomorphisms

\[
\text{Hom}_{\text{Path}[n]}(0,n)_\bullet \simeq \square^{n-1} \quad \text{Hom}_{\text{Path}[\Lambda^n_i]}(0,n)_\bullet \simeq \square^{n-1}_i.
\]
Let $\lambda_0$ denote the composite map

$$\cap_1^{n-1} \simeq \text{Hom}_{\text{Path}[\Lambda^n_n]}(0,n) \xrightarrow{F_0} \text{Hom}_C(C_0,C_n).$$

By virtue of Corollary 2.4.5.10, it will suffice to show that $\lambda_0$ can be extended to a morphism of simplicial sets $\lambda : \square^{n-1} \to \text{Hom}_C(C_0,C_n).$

Let $I$ denote the set $\{1, 2, \ldots, i-1, i+1, \ldots, n-1\}$, so that we can identify $\square^{n-1}$ with the product $\Delta^1 \times I$. Under this identification, $\cap_1^{n-1}$ corresponds to the pushout

$$(\Delta^1 \times \partial I) \coprod_{(\{0\} \times \partial I)} \bigl(\{0\} \times I\bigr).$$

Let $v \in I$ be the initial vertex (corresponding to the empty subset of $I$), and let $e$ be the edge of $\text{Hom}_C(C_0,C_n)$ given by the composite map

$$\Delta^1 \times \{v\} \hookrightarrow \Delta^1 \times I \hookrightarrow \cap_1^{n-1} \xrightarrow{\lambda_0} \text{Hom}_C(C_0,C_n).$$

Unwinding the definitions, we see that $e$ is the image of $\mu$ under the morphism of simplicial sets

$$\text{Hom}_C(C_{i-1},C_{i+1}) \to \text{Hom}_C(C_0,C_n), \quad \rho \mapsto u_n \circ u_{n-1} \circ \cdots \circ u_{i+2} \circ \rho \circ u_{i-1} \circ \cdots \circ u_1,$$

and is therefore an isomorphism in the $\infty$-category $\text{Hom}_C(C_0,C_n)$. Note that every simplex of $\square^I$ which is not contained in the boundary $\partial I$ has initial vertex $v$. The existence of the desired extension $\lambda$ now follows from Proposition 4.4.5.8.

Example 5.5.8.3. Let $C$ be a simplicial category. Suppose that, for every pair of objects $X$ and $Y$, the simplicial set $\text{Hom}_C(X,Y)$ is an $\infty$-category. Then the inclusion $N\bullet(C) \hookrightarrow N_{\text{hc}}\bullet(C)$ of Remark 2.4.3.8 carries every 2-simplex of the ordinary nerve $N\bullet(C)$ to a thin 2-simplex of the homotopy coherent nerve $N_{\text{hc}}\bullet(C)$.

To verify the outer horn-filling conditions which appear in Definition 5.5.1.3, we will need a variant of Proposition 2.4.5.8.

Proposition 5.5.8.4. Let $n \geq 2$ be an integer and let $F : \text{Path}[\Lambda^n_n] \to \text{Path}[\Delta^n]$ be the simplicial functor induced by the horn inclusion $\Lambda^n_n \hookrightarrow \Delta^n$. Then:

(a) The functor $F$ is bijective on objects; in particular, we can identify the objects of $\text{Path}[\Lambda^n_n]$ with elements of the set $[n] = \{0 < 1 < \cdots < n\}$.

(b) For $(0,n-1) \neq (i,j) \neq (0,n)$, the functor $F$ induces an isomorphism of simplicial sets

$$\text{Hom}_{\text{Path}[\Lambda^n_n]}(i,j) \simeq \text{Hom}_{\text{Path}[\Delta^n]}(i,j).$$
(c) The functor $F$ induces a monomorphism of simplicial sets

$$\text{Hom}_{\text{Path}[\Lambda^n_m]}(0, n-1) \hookrightarrow \text{Hom}_{\text{Path}[\Delta^n]}(0, n-1),$$

whose image can be identified with the boundary

$$\partial \Box^{n-2} \subseteq \Box^{n-2} \simeq \text{Hom}_{\text{Path}[\Delta^n]}(0, n-1),$$

introduced in Notation 2.4.5.5.

(d) The functor $F$ induces a monomorphism of simplicial sets

$$\text{Hom}_{\text{Path}[\Lambda^n_n]}(0, n) \hookrightarrow \text{Hom}_{\text{Path}[\Delta^n]}(0, n),$$

whose image can be identified with the hollow cube

$$\sqcup_{0}^{n-1} \subseteq \Box^{n-1} \simeq \text{Hom}_{\text{Path}[\Delta^n]}(0, n),$$

introduced in Notation 2.4.5.5.

Proof. Assertion (a) is immediate from Theorem 2.4.4.10. To prove the remaining assertions, fix an integer $m \geq 0$. Using Lemma 2.4.4.16, we see that $\text{Path}[\Delta^n]_m$ can be identified with the path category $\text{Path}[G]$ of a directed graph $G$ which can be described concretely as follows:

- The vertices of $G$ are the elements of the set $[n] = \{0 < 1 < \cdots < n\}$.
- For $0 \leq i < j \leq n$, an edge of $G$ with source $j$ and target $k$ is a chain of subsets

  $$\{i, i+1, \ldots, j-1, j\} \supseteq I_0 \supseteq \cdots \supseteq I_m = \{i, j\}$$

Using Theorem 2.4.4.10, we see that $\text{Path}[\Lambda^n_n]_m$ can be identified with the path category of the directed subgraph $G' \subseteq G$ having the same vertices, where an edge $\overrightarrow{T} = (I_0 \supseteq \cdots \supseteq I_m)$ of $G$ belongs to $G'$ if and only if the subset $I_0 \subseteq [n]$ corresponds to a simplex of $\Delta^n$ which belongs to the horn $\Lambda^n_m$: that is, if and only if $[n-1] \not\subseteq I_0$. We now argue as follows:

- For $(0, n-1) \neq (i, j) \neq (0, n)$, every path from $i$ to $j$ in the graph $G$ is also a path in the graph $G'$. This proves (b).
- Let $\tau$ be a morphism from $0$ to $n-1$ in the category $\text{Path}[n]_m$, which we identify with a chain of subsets

  $$[n-1] \supseteq I_0 \supseteq I_1 \supseteq \cdots \supseteq I_m \supseteq \{0, n-1\}.$$ 

Then $\tau$ belongs to $\text{Path}[\Lambda^n_n]_m$ if and only if $I_0 \neq [n-1]$ or $I_m \neq \{0, n-1\}$: that is, if and only if $\tau$ corresponds to an $m$-simplex of the cube $\partial \Box^{n-2} \subseteq \Box^{n-2}$. This proves (c).
Let \( \tau \) be a morphism from 0 to \( n \) in the category \( \text{Path}[n]_m \), which we identify with a chain of subsets

\[
[n] \supseteq I_0 \supseteq I_1 \supseteq \cdots \supseteq I_m \supseteq \{0, n\}.
\]

Then \( \tau \) belongs to \( \text{Path}[\Lambda^n]_m \) if and only if \( I_0 \neq [n] \) or \( \{0, n\} \neq I_m \neq \{0, n - 1, n\} \):

that is, if and only if \( \tau \) corresponds to an \( m \)-simplex of the hollow cube \( \sqcup_{n-1} \subseteq \Box_{n-1} \). This proves (d).

\[\square\]

**Corollary 5.5.8.5.** Let \( \mathcal{C} \) be a simplicial category, let \( n \geq 2 \) be an integer, and let \( \sigma_0 : \Lambda^n \to N^{hc}(\mathcal{C}) \) be a morphism of simplicial sets, which we identify with a simplicial functor \( F : \text{Path}[\Lambda^n]_\bullet \to \mathcal{C} \) inducing a map of simplicial sets

\[
\lambda_0 : \sqcup_{n-1} \simeq \text{Hom}_{\text{Path}[\Lambda^n]}(0, n)_\bullet \to \text{Hom}_\mathcal{C}(F(0), F(n))_\bullet.
\]

Suppose that \( F \) carries the edge \( N_\bullet(\{n - 1 < n\}) \subseteq \Lambda^n \) to an isomorphism in \( \mathcal{C} \). Then the restriction map

\[
\{\text{Maps } \sigma : \Delta^n \to N^{hc}_\bullet(\mathcal{C}) \text{ with } \sigma_0 = \sigma|_{\Lambda^n}\}
\]

\[
\theta
\]

\[
\{\text{Maps } \lambda : \Box^{n-1} \to \text{Hom}_\mathcal{C}(F(0), F(n))_\bullet \text{ with } \lambda_0 = \lambda|_{\sqcup_{n-1}}\}
\]

is bijective.

**Proof.** By virtue of Corollary 2.4.6.13 we can identify \( \theta \) with a pullback of the restriction map

\[
\{\text{Maps } \sigma_1 : \partial \Delta^n \to N^{hc}_\bullet(\mathcal{C}) \text{ with } \sigma_0 = \sigma_1|_{\Lambda^n}\}
\]

\[
\theta'
\]

\[
\{\text{Maps } \lambda_1 : \partial \Box^{n-1} \to \text{Hom}_\mathcal{C}(F(0), F(n))_\bullet \text{ with } \lambda_0 = \lambda_1|_{\sqcup_{n-1}}\}.
\]

It will therefore suffice to show that \( \theta' \) is bijective. Let us identify \( \Delta^{n-1} \) with a simplicial subset of \( \Delta^n \) (via the map which is the identity on vertices), so that the boundary \( \partial \Delta^{n-1} \) is contained in the horn \( \Lambda^n \). Let \( \tau_0 \) denote the restriction of \( \sigma_0 \) to \( \partial \Delta^{n-1} \), let \( \mu_0 \) denote the \( \lambda_0 \) to the simplicial subset \( \partial \Box^{n-2} \times \{0\} \subseteq \sqcup_{n-1} \). Note that \( \mu_0 \) can be written as a composition

\[
\partial \Box^{n-2} \simeq \text{Hom}_{\text{Path}[\partial \Delta^{n-1}]}(0, n - 1)_\bullet \xrightarrow{\iota_0} \text{Hom}_\mathcal{C}(F(0), F(n - 1))_\bullet \xrightarrow{\epsilon_0} \text{Hom}_\mathcal{C}(F(0), F(n))_\bullet.
\]
5.5. $(\infty, 2)$-CATEGORIES

where $\nu_0$ is determined by $\tau_0$. Using the identifications

$$\partial \Delta^n \simeq \Delta^{n-1} \coprod_{\partial \Delta^{n-1}} \Lambda^n_0 \quad \partial \square^{n-1} \simeq (\square^{n-2} \times \{0\}) \coprod_{(\partial \square^{n-2} \times \{0\})} \square^{n-1},$$

we can identify $\theta'$ with composition

$$\{\text{Maps } \tau : \Delta^{n-1} \to \mathcal{N}^{hc}(C) \text{ with } \tau_0 = \tau|_{\partial \Delta^n}\} \quad \downarrow \quad \{\text{Maps } \nu : \square^{n-2} \to \text{Hom}_C(F(0), F(n-1)), \text{ with } \nu = \nu_0|_{\partial \square^{n-2}}\} \quad \downarrow \quad \{\text{Maps } \mu : \square^{n-2} \to \text{Hom}_C(F(0), F(n)), \text{ with } \mu = \mu_0|_{\partial \square^{n-2}}\}.$$

Here the first map is bijective by virtue of Corollary 2.4.6.13 and the second by virtue of our assumption that $e$ is an isomorphism in the simplicial category $C$.

**Proof of Theorem 5.5.8.1** Let $C$ be a simplicial category with the property that, for every pair of objects $X, Y \in C$, the simplicial set $\text{Hom}_C(X, Y)_\bullet$ is an $\infty$-category. Using Example 5.5.8.3 we immediately deduce that every degenerate 2-simplex of the homotopy coherent nerve $\mathcal{N}^{hc}(C)$ is thin, and that every morphism $\Lambda^n_2 \to \mathcal{N}^{hc}(C)$ can be extended to a thin 2-simplex of $\mathcal{N}^{hc}(C)$. We will complete the proof that $\mathcal{N}^{hc}(C)$ is an $(\infty, 2)$-category by showing that, if $n \geq 3$ and $\sigma_0 : \Lambda^n_0 \to \mathcal{N}^{hc}(C)$ is a morphism of simplicial sets for which the 2-simplex $\sigma_0|_{\mathcal{N}^{hc}(\{0 < n-1 < n\})}$ is right-degenerate, then $\sigma_0$ can be extended to an $n$-simplex $\sigma$ of $C$ (the dual assertion regarding extension of maps $\Lambda^n_0 \to \mathcal{N}^{hc}(C)$ follows by the same argument, applied to the opposite simplicial category $C^{op}$). Let us identify $\sigma_0$ with a simplicial functor $F : \text{Path}[\Lambda^n_0]_\bullet \to C$, carrying each element $i \in [n]$ to an object $C_i \in C$.

Let $\square^{n-1}$ denote the simplicial cube of dimension $(n - 1)$ and let $\sqcup_{n-1} \subseteq \square^{n-1}$ denote the hollow cube of Notation 2.4.5.5 so that Remark 2.4.5.4 and Proposition 5.5.8.4 supply isomorphisms

$$\text{Hom}_{\text{Path}[n]}(0, n)_\bullet \simeq \square^{n-1} \quad \text{Hom}_{\text{Path}[\Lambda^n_0]}(0, n) \simeq \sqcup_{n-1}.$$

Let $\lambda_0$ denote the composite map

$$\sqcup_{n-1} \simeq \text{Hom}_{\text{Path}[\Lambda^n_0]}(0, n)_\bullet \overset{F}{\longrightarrow} \text{Hom}_C(C_0, C_n)_\bullet.$$
CHAPTER 5. FIBRATIONS OF $\infty$-CATEGORIES

Note that our degeneracy assumption on $\sigma_0|_{N_n(\{0<\cdot<\cdot\})}$ guarantees that the functor $F$ induces an isomorphism $C_{n-1} \simeq C_n$ in the category $C$. By virtue of Corollary 5.5.8.5, it will suffice to show that $\lambda_0$ can be extended to a morphism of simplicial sets $\lambda : \square^{n-1} \to \text{Hom}_C(C_0, C_n)_\bullet$.

Let us identify $\sqcup_{n-1} \sqcup n-1$ with the pushout $(\partial \square^{n-2} \times \Delta^1) \coprod_{(\partial \square^{n-2} \times \{1\})} (\square^{n-2} \times \{1\})$.

Let $v$ be the final vertex of the cube $\partial \square^{n-2}$ (corresponding to the set $\{1, 2, \ldots, n-2\}$, regarded as a subset of itself). Our assumption that the 2-simplex $\sigma_0|_{N_n(\{0<\cdot<\cdot\})}$ is right-degenerate guarantees that the composite map

$$\{v\} \times \Delta^1 \to \sqcup_{n-1} \sqcup n-1 \xrightarrow{\lambda_0} \text{Hom}_C(C_0, C_n)_\bullet.$$

is a degenerate edge of the $\infty$-category $\text{Hom}_C(C_0, C_n)_\bullet$; in particular, it is an isomorphism of $\text{Hom}_C(C_0, C_n)_\bullet$. Note that every simplex of $\square^{n-2}$ which is not contained in the boundary $\partial \square^{n-2}$ has final vertex $v$. The existence of the desired extension $\lambda$ now follows by applying Proposition 4.4.5.8.

Proposition 5.5.8.6 (Functoriality). Let $F : C \to D$ be a functor of simplicial categories. Assume that:

- For every pair of objects $C, C' \in C$, the simplicial set $\text{Hom}_C(C, C')_\bullet$ is an $\infty$-category.
- For every pair of objects $D, D' \in D$, the simplicial set $\text{Hom}_D(D, D')_\bullet$ is an $\infty$-category.

Then the induced map $N^{hc}_\bullet(F) : N^{hc}_\bullet(C) \to N^{hc}_\bullet(D)$ is a functor of $(\infty, 2)$-categories: that is, it carries thin $2$-simplices of $N^{hc}_\bullet(C)$ to thin $2$-simplices of $N^{hc}_\bullet(D)$.

Proof. It follows from Theorem 5.5.8.1 that the simplicial sets $N^{hc}_\bullet(C)$ and $N^{hc}_\bullet(D)$ are $(\infty, 2)$-categories. We will show that the morphism $N^{hc}_\bullet(F)$ is a functor by verifying the criterion of Proposition 5.5.7.8. Let $f : X \to Y$ and $g : Y \to Z$ be morphisms in the category $C$ (or, equivalently, in the $(\infty, 2)$-category $N^{hc}_\bullet(C)$). Then $f$ and $g$ determine a 2-simplex of the nerve $N_\bullet(C)$, which we identify with 2-simplex $\sigma$ of the homotopy coherent nerve $N^{hc}_\bullet(C)$ (see Remark 2.4.3.8). By virtue of Example 5.5.8.3 $\sigma$ is a thin 2-simplex of $N^{hc}_\bullet(C)$ and its image $N^{hc}_\bullet(F)(\sigma)$ is a thin 2-simplex of $N^{hc}_\bullet(D)$.

We are now equipped to establish the converse of Proposition 5.5.8.2.

Proposition 5.5.8.7. Let $C$ be a simplicial category. Suppose that, for every pair of objects $X$ and $Y$, the simplicial set $\text{Hom}_C(X, Y)_\bullet$ is an $\infty$-category. Let $\sigma$ be a 2-simplex of the
homotopy coherent nerve $N^{\text{hc}}(\mathcal{C})$, which we identify with a (not necessarily commutative) diagram

\[
\begin{array}{ccc}
Y & \xrightarrow{g} & Z \\
\downarrow{f} & & \downarrow{g} \\
X & \xrightarrow{h} & Z
\end{array}
\]

in $\mathcal{C}$ together with an edge $\mu : g \circ f \to h$ in the simplicial set $\text{Hom}_\mathcal{C}(X, Z)_\bullet$. Then $\sigma$ is thin if and only if $\mu$ is an isomorphism in the $\infty$-category $\text{Hom}_\mathcal{C}(X, Z)_\bullet$.

**Proof.** It follows from Proposition 5.5.8.2 that if $\mu$ is an isomorphism, then $\sigma$ is thin. Conversely, assume that $\sigma$ is thin; we wish to show that $\mu$ is an isomorphism. Define a strict 2-category $\mathcal{E}$ as follows:

- The objects of $\mathcal{E}$ are the objects of $\mathcal{C}$.
- For every pair of objects $A, B \in \mathcal{C}$, we define $\text{Hom}_\mathcal{E}(A, B)$ to be the homotopy category of the $\infty$-category $\text{Hom}_\mathcal{C}(A, B)_\bullet$.
- For every triple of objects $A, B, C \in \mathcal{C}$, we define the composition law

\[
\circ : \text{Hom}_\mathcal{E}(B, C)_\bullet \times \text{Hom}_\mathcal{E}(A, B)_\bullet \to \text{Hom}_\mathcal{E}(A, C)_\bullet
\]

as the functor of homotopy categories induced by the composition law $\circ : \text{Hom}_\mathcal{C}(B, C)_\bullet \times \text{Hom}_\mathcal{C}(A, B)_\bullet \to \text{Hom}_\mathcal{C}(A, C)_\bullet$ of the simplicial category $\mathcal{C}$.

Let $\mathcal{D}$ denote the simplicial category obtained by applying the construction of Example 2.4.2.8 to the strict 2-category $\mathcal{E}$: the simplicial category $\mathcal{D}$ has the same objects as $\mathcal{C}$, with simplicial morphism spaces given by

\[
\text{Hom}_\mathcal{D}(A, B)_\bullet = N_\bullet(\text{Hom}_\mathcal{E}(A, B)) = N_\bullet(\text{hHom}_\mathcal{C}(A, B)_\bullet).
\]

There is an evident functor of simplicial categories $F : \mathcal{C} \to \mathcal{D}$, which is the identity on objects and which induces the unit map $\text{Hom}_\mathcal{C}(A, B)_\bullet \to N_\bullet(\text{hHom}_\mathcal{C}(A, B)_\bullet)$ on simplicial morphism spaces. Invoking Proposition 5.5.8.6, we see that the induced map $N_\bullet^{\text{hc}}(F)$ carries $\sigma$ to a thin 2-simplex of the homotopy coherent nerve $N_\bullet^{\text{hc}}(\mathcal{D})$, which we can identify with the Duskin nerve $N_\bullet^{\text{D}}(\mathcal{E})$ of the 2-category $\mathcal{E}$ (Example 2.4.3.11). Using the description of the thin simplices of $N_\bullet^{\text{D}}(\mathcal{E})$ supplied by Theorem 2.3.2.5, we conclude that the homotopy class $[\mu]$ is an isomorphism in the category $\text{Hom}_\mathcal{E}(X, Z)_\bullet = \text{hHom}_\mathcal{C}(X, Z)_\bullet$, so that $\mu$ is an isomorphism in the $\infty$-category $\text{Hom}_\mathcal{C}(X, Z)_\bullet$. \qed
Corollary 5.5.8.8. Let $\mathcal{C}$ be a simplicial category having the property that, for every pair of objects $X, Y \in \mathcal{C}$, the simplicial set $\operatorname{Hom}_\mathcal{C}(X, Y)_\bullet$ is an $\infty$-category. Let $\mathcal{C}'$ denote the simplicial subcategory of $\mathcal{C}$ having the same objects, with morphism simplicial sets given by $\operatorname{Hom}_{\mathcal{C}'}(X, Y)_\bullet = \operatorname{Hom}_\mathcal{C}(X, Y)_\bullet$. Then the inclusion of simplicial categories $\mathcal{C}' \hookrightarrow \mathcal{C}$ induces an isomorphism of $\infty$-categories $\mathcal{N}^{hc}(\mathcal{C}') \simeq \operatorname{Pith}(\mathcal{N}^{hc}(\mathcal{C}))$.

Proof. Let $\sigma$ be an $n$-simplex of the homotopy coherent nerve $\mathcal{N}^{hc}(\mathcal{C})$, which we identify with a simplicial functor $F : \operatorname{Path}[n]_\bullet \to \mathcal{C}$ carrying each $i \in [n]$ to an object $C_i \in \mathcal{C}$. If $T \subseteq [n]$ is a nonempty subset having smallest element $i$ and largest element $k$, let us write $F(T)$ for the corresponding vertex of the simplicial set $\operatorname{Hom}_\mathcal{C}(C_i, C_k)_\bullet$. If $S \subseteq T$ is a subset containing $i$ and $k$, let us write $F(S \subseteq T) : F(T) \to F(S)$ for the corresponding edge of the simplicial set $\operatorname{Hom}_\mathcal{C}(C_i, C_k)_\bullet$. Let us abuse notation by identifying $\mathcal{N}^{hc}(\mathcal{C}')$ with a simplicial subset of $\mathcal{N}^{hc}(\mathcal{C})$. Unwinding the definitions, we see that $\sigma$ is contained in $\mathcal{N}^{hc}(\mathcal{C}')$ if and only if the following condition is satisfied:

$\text{(1)}$ For every inclusion $S \subseteq T$ of nonempty subsets of $[n]$ having the same smallest element $i$ and largest element $k$, the edge $F(S \subseteq T) : F(T) \to F(S)$ is an isomorphism in the $\infty$-category $\operatorname{Hom}_\mathcal{C}(C_i, C_k)_\bullet$.

Using the thinness criterion of Proposition 5.5.8.7, we see that $\sigma$ belongs to the pith $\operatorname{Pith}(\mathcal{N}^{hc}(\mathcal{C}))$ if and only if the following $a \text{ priori}$ weaker condition is satisfied:

$\text{(2)}$ For every triple of elements $0 \leq i \leq j \leq k \leq n$, the edge

$$F(\{i, k\} \subseteq \{i, j, k\}) : F(\{i, j, k\}) \to F(\{i, k\})$$

is an isomorphism in the $\infty$-category $\operatorname{Hom}_\mathcal{C}(C_i, C_k)_\bullet$.

To complete the proof, it will suffice to show that (2) $\Rightarrow$ (1). Assume that (2) is satisfied, and suppose that we are given nonempty subsets $S \subseteq T$ of $[n]$ having the same smallest element $i$ and largest element $k$. We wish to show that $F(S \subseteq T)$ is an isomorphism in the $\infty$-category $\operatorname{Hom}_\mathcal{C}(C_i, C_k)_\bullet$. Since the collection of isomorphisms contains all identity morphisms and is closed under composition (Remark 1.3.6.3), we may assume without loss of generality that the difference $T \setminus S$ contains exactly one element $j$. Set $S_- = \{ s \in S : s < j \}$ and $S_+ = \{ s \in S : s > j \}$. Let $i'$ be the largest element of $S_-$, and let $k'$ denote the smallest element of $S_+$. Unwinding the definitions, we see that the edge $F(S \subseteq T)$ is the image of $F(\{i', k'\} \subseteq \{i', j, k'\})$ under the functor

$$\operatorname{Hom}_\mathcal{C}(C_{i'}, C_{k'})_\bullet \xrightarrow{F(S_-) \circ \cdots \circ F(S_-)} \operatorname{Hom}_\mathcal{C}(C_i, C_k)_\bullet,$$

and is therefore an isomorphism by virtue of assumption (2). \qed
5.5.9 Comparison of Homotopy Transport Representations

Let \( C \) be a locally Kan simplicial category containing an object \( X \). Since the homotopy coherent nerve \( N^\bullet_{hc}(C) \) is an \( \infty \)-category (Theorem 2.4.5.1), the projection map \( U : N^\bullet_{hc}(C)_{X/} \to N^\bullet_{hc}(C) \) is a left fibration (Proposition 4.3.6.1). Let \( h\text{Tr}_{N^\bullet_{hc}(C)_{X/}/N^\bullet_{hc}(C)} : \text{hN}^\bullet_{hc}(C) \to \text{hKan} \) denote the homotopy transport representation of \( U \). Combining Example 5.2.8.13 with Corollary 4.6.8.20, we obtain the following concrete description of the functor \( \text{hTr}_{N^\bullet_{hc}(C)_{X/}/N^\bullet_{hc}(C)} \):

Proposition 5.5.9.1. Let \( C \) be locally Kan simplicial category containing an object \( X \), and let \( \Phi : \text{hC} \to \text{hN}^\bullet_{hc}(C) \) be the isomorphism of Proposition 2.4.6.9. Then the diagram of functors

\[
\begin{array}{ccc}
\text{hC} & \stackrel{\sim}{\longrightarrow} & \text{Hom}_C(X, \bullet) \\
\Phi \downarrow & & \downarrow \text{hTr}_{N^\bullet_{hc}(C)_{X/}/N^\bullet_{hc}(C)} \\
\text{hN}^\bullet_{hc}(C) & \longrightarrow & \text{hKan}
\end{array}
\]

commutes up to isomorphism.

Our goal in this section is to formulate and prove a stronger version of Proposition 5.5.9.1, which differs in three respects:

- We drop the assumption that the simplicial category \( C \) is locally Kan, and assume instead that the simplicial set \( \text{Hom}_C(Y, Z)_{\bullet} \) is an \( \infty \)-category for every pair of objects \( Y, Z \in C \). In this case, the nerve \( N^\bullet_{hc}(C) \) need not be an \( \infty \)-category, so the projection map \( U : N^\bullet_{hc}(C)_{X/} \to N^\bullet_{hc}(C) \) need not be a left fibration. However, Theorem 5.5.8.1 guarantees that \( N^\bullet_{hc}(C) \) is an \((\infty, 2)\)-category, so that \( U \) restricts to a cocartesian fibration of \( \infty \)-categories \( \text{Pith}(U) : \text{Pith}(N^\bullet_{hc}(C)_{X/}) \to \text{Pith}(N^\bullet_{hc}(C)) \) (Corollary 5.5.7.10). Note that Proposition 2.4.6.9 and Corollary 5.5.8.8 supply an isomorphism of homotopy categories \( \Phi : \text{hC} \to \text{hPith}(N^\bullet_{hc}(C)) \), where \( C' \subseteq C \) is the locally Kan simplicial subcategory with morphism spaces given by \( \text{Hom}_{C'}(Y, Z)_{\bullet} = \text{Hom}_C(Y, Z)_{\bullet} \).

- Proposition 5.5.9.1 asserts that a certain diagram commutes up to isomorphism. However, it is possible to be more precise. For every pair of objects \( X, Y \in C \), Theorem 4.6.7.9 supplies an equivalence of \( \infty \)-categories

\[
\theta_{X,Y} : \text{Hom}_C(X, Y)_{\bullet} \to \text{Hom}_{N^\bullet_{hc}(C)}(X, Y) = \text{hTr}_{\text{Pith}(N^\bullet_{hc}(C)_{X/})/\text{Pith}(N^\bullet_{hc}(C))}(Y),
\]

so that the homotopy class \([\theta_{X,Y}]\) can be viewed as an isomorphism in the category \( \text{hQCat} \). We will show that \([\theta_{X,Y}]\) depends functorially on \( Y \), so that the construction
CHAPTER 5. FIBRATIONS OF ∞-CATEGORIES

Y ↦→ [θ_{X,Y}] furnishes a natural isomorphism of functors

\[ \text{Hom}_C(X, \bullet) \rightarrow \text{hTr}_{\text{Pith}(N_{hc}^\bullet(C)_X)/\text{Pith}(N_{hc}^\bullet(C))} \circ \Phi \]

- Since Pith\((N_{hc}^\bullet(C))\) is an ∞-category, we can regard the homotopy transport representation

\[ \text{hTr}_{\text{Pith}(N_{hc}^\bullet(C)_X)/\text{Pith}(N_{hc}^\bullet(C))} : \text{hPith}(N_{hc}^\bullet(C)) \rightarrow \text{hQC} \]

as an hKan-enriched functor (Construction 5.2.8.9). Similarly, we can regard Φ as an isomorphism of hKan-enriched categories (Corollary 4.6.8.20), and the construction

\[ Y \mapsto \text{Hom}_C(X, Y, \bullet) \]

determines an hKan-enriched functor from h\(C'\) to hQC. We will show that the natural isomorphism \(Y \mapsto [\theta_Y]\) is compatible with these hKan-enrichments.

Our main result is the following:

**Theorem 5.5.9.2.** Let \(C\) be a simplicial category having the property that, for every pair of objects \(Y, Z \in C\), the simplicial set \(\text{Hom}_C(Y, Z, \bullet)\) is an ∞-category. Let \(X\) be an object of \(C\), let \(\text{hTr}\) denote the (enriched) homotopy transport representation associated to the cocartesian fibration \(\text{Pith}(U) : \text{Pith}(N_{hc}^\bullet(C)_X) \rightarrow \text{Pith}(N_{hc}^\bullet(C))\), and let \(C' \subseteq C\) be the locally Kan simplicial subcategory defined above. Then the diagram of hKan-enriched functors

\[
\begin{align*}
\text{hC}' & \ar{dr}{\text{hTr}} \ar{d}{\Phi} \ar{dr}[swap]{\sim} & \\
\text{hN}_{hc}^\bullet(C) & \ar{r} & \text{hQC} \\
\text{Hom}_C(X, \bullet) & \ar{r} & \text{hTr}_{\text{Pith}(N_{hc}^\bullet(C)_X)/\text{Pith}(N_{hc}^\bullet(C))} \circ \Phi
\end{align*}
\]

commutes up to natural isomorphism, given explicitly by the map

\[ Y \mapsto ([\theta_{X,Y}] : \text{Hom}_C(X, Y, \bullet) \rightarrow \text{Hom}_{N_{hc}^\bullet(C)}^{L}(X, Y)). \]

of Construction 4.6.7.3.

**Proof.** For every object \(Y \in C\), the comparison functor

\[ \theta_{X,Y} : \text{Hom}_C(X, Y, \bullet) \rightarrow \text{Hom}_{N_{hc}^\bullet(C)}^{L}(X, Y) \]

is an equivalence of ∞-categories (Theorem 4.6.7.9), so its homotopy class \([\theta_{X,Y}]\) is an isomorphism when regarded as a morphism in the homotopy category hQC. To complete the proof, it will suffice to show that the construction \(Y \mapsto [\theta_{X,Y}]\) determines a natural
transformation of hKan-enriched functors. Let $Y$ and $Z$ be objects of $\mathcal{C}$, so that the map $\theta_{Y,Z}$ restricts to a homotopy equivalence of Kan complexes $\theta_{Y,Z}^\simeq : \Hom_{\mathcal{C}'}(Y,Z) \to \Hom_{N_{\mathcal{hc}}^\bullet(\mathcal{C}')}^\simeq(Y,Z)$. We wish to show that the diagram of Kan complexes

\[
\begin{array}{cccc}
\Hom_{\mathcal{C}'}(Y,Z) & \longrightarrow & \Fun(\Hom_{\mathcal{C}}(X,Y),\Hom_{\mathcal{C}}(X,Z))^\simeq \\
\downarrow^{\theta_{Y,Z}^\simeq} & & \downarrow^{\theta_{X,Z}^\simeq} & \\
\Hom_{N_{\mathcal{hc}}^\bullet(\mathcal{C}')}^\simeq(Y,Z) & & \Fun(\Hom_{N_{\mathcal{hc}}^\bullet(\mathcal{C}')}^L(X,Y),\Hom_{N_{\mathcal{hc}}^\bullet(\mathcal{C}')}^L(X,Z))^\simeq \\
\downarrow^{\rho} & & \downarrow^{\rho} & \\
\Fun(\Hom_{N_{\mathcal{hc}}^\bullet(\mathcal{C}')}^L(X,Y),\Hom_{N_{\mathcal{hc}}^\bullet(\mathcal{C}')}^L(X,Z))^\simeq & \longrightarrow & \Fun(\Hom_{N_{\mathcal{hc}}^\bullet(\mathcal{C}')}^L(X,Y),\Hom_{N_{\mathcal{hc}}^\bullet(\mathcal{C}')}^L(X,Z))^\simeq
\end{array}
\]

commutes up to homotopy, where $\rho$ is given by parametrized covariant transport for the cocartesian fibration $\Pith(U) : \Pith(N_{\mathcal{hc}}^\bullet(\mathcal{C})_{X/}) \to \Pith(N_{\mathcal{hc}}^\bullet(\mathcal{C})) \simeq N_{\mathcal{hc}}^\bullet(\mathcal{C})'$.

We will show that there exists a functor of $\infty$-categories $H : \Delta^1 \times \Hom_{\mathcal{C}}(X,Y) \times \Hom_{\mathcal{C}}(Y,Z) \to N_{\mathcal{hc}}^\bullet(\mathcal{C})_{X/}$ satisfying the following requirements:

(a) The diagram of simplicial sets

\[
\begin{array}{cccc}
\Delta^1 \times \Hom_{\mathcal{C}}(X,Y) \times \Hom_{\mathcal{C}}(Y,Z) & \longrightarrow & N_{\mathcal{hc}}^\bullet(\mathcal{C})_{X/} \\
\downarrow^{H} & & \downarrow^{U} & \\
\Delta^1 \times \Hom_{\mathcal{C}}(Y,Z)^\simeq & \longrightarrow & \Delta^1 \times \Hom_{N_{\mathcal{hc}}^\bullet(\mathcal{C})}^\simeq(Y,Z) & \longrightarrow N_{\mathcal{hc}}^\bullet(\mathcal{C})
\end{array}
\]

commutes.

(b) The restriction $H_0 = H|_{\{0\} \times \Hom_{\mathcal{C}}(X,Y) \times \Hom_{\mathcal{C}}(Y,Z)}$ is given by the composition

$\Hom_{\mathcal{C}}(X,Y) \times \Hom_{\mathcal{C}}(Y,Z) \to \Hom_{\mathcal{C}}(X,Y) \to \Hom_{N_{\mathcal{hc}}^\bullet(\mathcal{C})}^L(X,Y)$.

(c) The restriction $H_1 = H|_{\{1\} \times \Hom_{\mathcal{C}}(X,Y) \times \Hom_{\mathcal{C}}(Y,Z)}$ is given by the composition

$\Hom_{\mathcal{C}}(X,Y) \times \Hom_{\mathcal{C}}(Y,Z) \to \Hom_{\mathcal{C}}(X,Z) \to \Hom_{N_{\mathcal{hc}}^\bullet(\mathcal{C})}^L(X,Z)$. 

(d) For every pair of morphisms \( f : X \to Y \) and \( g : Y \to Z \) in \( C \), the composite map

\[
\Delta^1 \times \{f\} \times \{g\} \hookrightarrow \Delta^1 \times \operatorname{Hom}_C(X,Y)_\bullet \times \operatorname{Hom}_C(Y,Z)_\bullet \xrightarrow{H} N^{hc}_\bullet(C)_{X/}
\]

is a \( U \)-cocartesian morphism of the \((\infty,2)\)-category \( N^{hc}_\bullet(C)_{X/} \) (that is, it corresponds to a thin 2-simplex of \( N^{hc}_\bullet(C) \); see Theorem 5.5.4.1).

Assume for the moment that there exists a morphism \( H \) satisfying these requirements. Note that the restriction \( H|_{\{1\} \times \operatorname{Hom}_C(X,Y)_\bullet \times \operatorname{Hom}_C(Y,Z)_\bullet} \) can be identified with a map of Kan complexes

\[
\lambda : \operatorname{Hom}_{C'}(Y,Z)_\bullet \to \operatorname{Fun}(\operatorname{Hom}_C(X,Y)_\bullet, \operatorname{Hom}^L_{N^{hc}_\bullet}(X,Z))^{\sim}.
\]

It follows from requirement (c) that \( \lambda \) is given by clockwise composition around the diagram \((5.28)\), and from requirements (a), (b), and (d) that \( \lambda \) is also given (up to homotopy) by counterclockwise composition around the diagram \((5.28)\). It follows that the diagram \((5.28)\) commutes up to homotopy, as desired.

It remains to construct the morphism \( H \). Fix an auxiliary symbol \( e \), let \( n \geq 0 \), and let \( \sigma \) be an \( n \)-simplex of the simplicial set \( \Delta^1 \times \operatorname{Hom}_C(X,Y)_\bullet \times \operatorname{Hom}_C(Y,Z)_\bullet \). We will identify \( \sigma \) with a triple \((\alpha, f_\sigma, g_\sigma)\), where \( \alpha : [n] \to [1] \) is a nondecreasing function, \( f_\sigma \) is an \( n \)-simplex of \( \operatorname{Hom}_C(X,Y)_\bullet \), and \( Fg_\sigma \) is an \( n \)-simplex of \( \operatorname{Hom}_C(Y,Z)_\bullet \). Let \( \operatorname{Path}[\{\{e\} \times [n]\}]_\bullet \) denote the simplicial path category of the linearly ordered set \( \{e\} \times [n] = \{e < 0 < \cdots < n\} \) (see Notation 2.4.3.1). To the \( n \)-simplex \( \sigma \), we associate a simplicial functor \( h_\sigma : \operatorname{Path}[\{e\} \times [n]]_\bullet \to C \) as follows:

- On objects, the functor \( h_\sigma \) is given by the formula

  \[
  h_\sigma(i) = \begin{cases} 
  X & \text{if } i = e \\
  Y & \text{if } 0 \leq i \leq n \text{ and } \alpha(i) = 0 \\
  Z & \text{if } 0 \leq i \leq n \text{ and } \alpha(i) = 1.
  \end{cases}
  \]

- Let \( i < j \) be elements of the linearly ordered set \( \{e\} \times [n] \), so that \( \operatorname{Hom}_{\operatorname{Path}[\{e\} \times [n]]}(i,j)_\bullet \) can be identified with the nerve \( N_\bullet(Q) \), where \( Q \) is the collection of all subsets \( K \subseteq \{e\} \times [n] \) having smallest element \( i \) and largest element \( j \) (and we regard \( Q \) as ordered by reverse inclusion). The simplicial functor \( h_\sigma \) is given on morphisms by a map of simplicial sets \( u_{i,j} : N_\bullet(Q) \to \operatorname{Hom}_C(h_\sigma(i), h_\sigma(j)) \). If \( 0 \leq i < j \leq n \) with \( \alpha(i) = \alpha(j) \), we take \( u_{i,j} \) to be the constant map taking the value \( \operatorname{id}_Y \) (if \( \alpha(i) = 0 \)) or \( \operatorname{id}_Z \) (if \( \alpha(i) = 1 \)). The remaining cases can be described as follows:

  (a') If \( 0 \leq i < j \leq n \) satisfy \( \alpha(i) = 0 \) and \( \alpha(j) = 1 \), then \( u_{i,j} \) is given by the composition

  \[
  N_\bullet(Q) \xrightarrow{r^+} \Delta^n \xrightarrow{g_\sigma} \operatorname{Hom}_C(Y,Z)_\bullet,
  \]

  where \( r^+ \) is given on vertices by the formula \( r^+(K) = \min\{k \in K : \alpha(k) = 1\} \).
(b') If \( i = e \) and \( \alpha(j) = 0 \), then \( u_{i,j} \) is given by the composition

\[
N_\bullet(Q) \xrightarrow{r_-} \Delta^n \xrightarrow{f_\sigma} \text{Hom}_C(X, Y)_\bullet,
\]

where \( r_- \) is given on vertices by the formula \( r_-(K) = \min\{k \in K : k > e\} \).

(c') If \( i = e \) and \( \alpha(j) = 1 \), then \( u_{i,j} \) is given by the composition

\[
N_\bullet(Q) \xrightarrow{(r_+, r_-)} \Delta^n \times \Delta^n \xrightarrow{g_\sigma \times f_\sigma} \text{Hom}_C(Y, Z)_\bullet \times \text{Hom}_C(X, Y)_\bullet \xrightarrow{\circ} \text{Hom}_C(X, Z)_\bullet,
\]

where \( r_- \) and \( r_+ \) are defined as above.

Note that we can identify \( h_\sigma \) with a morphism of simplicial sets \( \{e\} \star \Delta^n \to N^\text{hc}_\bullet(C) \) carrying \( \{e\} \) to the vertex \( X \), which we can view as an \( n \)-simplex \( H(\sigma) \) of the \((\infty, 2)\)-category \( N^\text{hc}_\bullet(C)_{X/} \). The construction \( \sigma \mapsto H(\sigma) \) determines a morphism of simplicial sets

\[
H : \Delta^1 \times \text{Hom}_C(X, Y)_\bullet \times \text{Hom}_C(Y, Z)_\bullet \to N^\text{hc}_\bullet(C)_{X/}.
\]

Requirements (a), (b), and (c) follow immediately from (a'), (b'), and (c') (together with the definitions of the maps \( \theta_{Y,Z} \), \( \theta_{X,Y} \), and \( \theta_{X,Z} \), respectively). Requirement (d) follows from the description of the thin 2-simplices of \( N^\text{hc}_\bullet(C) \) supplied by Proposition 5.5.8.7.

### 5.6 The \( \infty \)-Categories \( S \) and \( QC \)

Let Kan denote the category of Kan complexes and let hKan denote its homotopy category (Construction 3.1.5.10). There is an evident forgetful functor \( U : \text{Kan} \to \text{hKan} \), which carries each Kan complex \( X \) to itself and each morphism of Kan complexes \( f : X \to Y \) to its homotopy class \( [f] \in \pi_0(\text{Fun}(X, Y)) \). Broadly speaking, homotopy theory is concerned with questions about Kan complexes which are invariant under homotopy equivalence. Since a morphism of Kan complexes \( f \) is a homotopy equivalence if and only if its homotopy class \( [f] \) is an isomorphism, it is tempting to characterize homotopy theory as the study of the category hKan. Beware that this characterization is somewhat misleading: many questions belonging to the purview of homotopy theory cannot be formulated at the level of the homotopy category. For example, suppose we are given a commutative diagram of Kan complexes \( \sigma : \)

\[
\begin{array}{ccc}
X' & \xrightarrow{f} & X \\
\Downarrow & & \Downarrow \\
Y' & \xrightarrow{g} & Y
\end{array}
\]
One can then ask if $\sigma$ is a homotopy pullback square (Definition 3.4.1.1). Though the answer to this question depends only on the homotopy type of the diagram $\sigma$ (Corollary 3.4.1.12), it does not depend only on the associated diagram $U(\sigma)$ in the homotopy category $h\text{Kan}$ (see Example 3.4.1.13).

Roughly speaking, the problem is that passage from the category of Kan complexes $\text{Kan}$ to its homotopy category $h\text{Kan}$ destroys too much information. To remedy the situation, it is convenient to consider a refinement of the homotopy category $h\text{Kan}$. Note that $\text{Kan}$ has the structure of a simplicial category (see Example 2.4.2.1). In §5.6.1, we show that the homotopy coherent nerve $N_{\bullet}^{hc}(\text{Kan})$ is an $\infty$-category (Proposition 5.6.1.2), which we will denote by $\mathcal{S}$ and refer to as the $\infty$-category of spaces (Construction 5.6.1.1). After passing to nerves, the forgetful functor $U : \text{Kan} \to h\text{Kan}$ factors as a composition

$$N_{\bullet}(\text{Kan}) \xrightarrow{U'} N_{\bullet}^{hc}(\text{Kan}) = \mathcal{S} \xrightarrow{U''} N_{\bullet}(h\text{Kan})$$

with the following features:

- The functor $U'$ is a monomorphism of simplicial sets which is bijective on vertices and edges. In particular, we can identify objects of the $\infty$-category $\mathcal{S}$ with Kan complexes, and morphisms in the $\infty$-category $\mathcal{S}$ with morphisms of Kan complexes (Remark 5.6.1.3).

- The functor $U''$ exhibits $h\text{Kan}$ as a homotopy category of the $\infty$-category $\mathcal{S}$ (Remark 5.6.1.6). In particular, a map of Kan complexes $f : X \to Y$ is a homotopy equivalence if and only if it is an isomorphism when regarded as a morphism of the $\infty$-category $\mathcal{S}$ (Remark 5.6.1.4).

In §5.6.3, we introduce a variant of the $\infty$-category $\mathcal{S}$ whose objects are pointed Kan complexes $(X, x)$. Here there are (at least) two different ways we might proceed:

- Let $\text{Kan}_*$ denote the category of pointed Kan complexes (Definition 3.2.1.1). Note that $\text{Kan}_*$ can be identified with the coslice category $\text{Kan}_{\Delta^0/}$, where we regard the standard simplex $\Delta^0$ as an object of the category $\text{Kan}$. This identification determines a simplicial enrichment of the category $\text{Kan}_*$, and we can obtain an $\infty$-category $N_{\bullet}^{hc}(\text{Kan}_*)$ by passing to the homotopy coherent nerve.

- If we regard $\Delta^0$ as an object of the $\infty$-category $\mathcal{S}$, then we can instead form the coslice $\infty$-category $\mathcal{S}_{\Delta^0/}$. We will denote this $\infty$-category by $\mathcal{S}_*$ and refer to it as the $\infty$-category of pointed spaces (Construction 5.6.3.1).

Beware that the $\infty$-categories $N_{\bullet}^{hc}(\text{Kan}_*)$ and $\mathcal{S}_*$ are not isomorphic as simplicial sets. However, there is a natural comparison functor $N_{\bullet}^{hc}(\text{Kan}_*) \to \mathcal{S}_*$ which is an equivalence of $\infty$-categories (Proposition 5.6.3.8). This is a special case of a general assertion concerning...
the compatibility of the homotopy coherent nerve with (co)slice constructions (Theorem
5.6.2.21), which we formulate and prove in §5.6.2.

In §5.6.5 we consider an enlargement of the ∞-category \( S \). Let Set\(_\Delta\) denote the category
of simplicial sets and let QCat \( \subseteq \) Set\(_\Delta\) denote the full subcategory spanned by the ∞-
categories, which we again regard as a simplicial category (see Example 2.4.2.1). The
homotopy coherent nerve \( N^{hc}_\bullet(\text{QCat}) \) is an (∞, 2)-category (Proposition 5.6.5.2), which
we will denote by \( \text{QC} \) and refer to as the (∞, 2)-category of ∞-categories (Construction
5.6.5.1). For many applications, it is convenient to work instead with the underlying ∞-
category \( \text{QC} = \text{Pith}(\text{QC}) \), which we study in §5.6.4. Both of these constructions have pointed
analogues, which we introduce and compare in §5.6.6.

\textbf{Warning 5.6.0.1.} The constructions of this section depend on a choice of dichotomy
between “small” and “large” mathematical objects, and we implicitly assume that the
categories Set\(_\Delta\) \( \supseteq \) QCat \( \supseteq \) Kan consist only of small simplicial sets. In particular, the
objects of \( S \) are small Kan complexes, and the objects of \( \text{QC} \) are small ∞-categories. By
contrast, the ∞-categories \( S \) and \( \text{QC} \) are not themselves small. In particular, one cannot
regard \( \text{QC} \) as an object of itself, or the Kan complex \( S \) as an object of \( S \).

\section{5.6.1 The ∞-Category of Spaces}

We begin by introducing a refinement of Construction 3.1.5.10.

\textbf{Construction 5.6.1.1 (The ∞-Category of Spaces).} Let Kan denote the category of Kan
complexes. We view Kan as a simplicial category, with simplicial morphism sets given by
the construction

\[ \text{Hom}_{\text{Kan}}(X, Y)_\bullet = \text{Fun}(X, Y). \]

We let \( S \) denote the homotopy coherent nerve \( N^{hc}_\bullet(\text{Kan}) \) (Definition 2.4.3.5). We will refer
to \( S \) as the ∞-category of spaces.

\textbf{Proposition 5.6.1.2.} The simplicial set \( S \) is an ∞-category.

\textit{Proof.} By virtue of Theorem 2.4.5.1 it suffices to show that the simplicial category Kan is
locally Kan: that is, for every pair of Kan complexes \( X \) and \( Y \), the simplicial set \( \text{Fun}(X, Y) \)
is also a Kan complex. This is a special case of Corollary 3.1.3.4. \( \square \)

\textbf{Remark 5.6.1.3.} Let \( N_\bullet(\text{Kan}) \) denote the nerve of the category of Kan complexes, where
we view Kan as an ordinary category. There is an evident monomorphism of simplicial sets

\[ \iota : N_\bullet(\text{Kan}) \hookrightarrow N^{hc}_\bullet(\text{Kan}) = S, \]

which is bijective on simplices of dimension \( \leq 1 \) (Example 2.4.3.9). In other words:
• The objects of the ∞-category \( \mathcal{S} \) are Kan complexes.

• If \( X \) and \( Y \) are Kan complexes, then morphisms \( f : X \to Y \) in the ∞-category \( \mathcal{S} \) can be identified with morphisms of simplicial sets from \( X \) to \( Y \).

However, \( \iota \) is not bijective on simplices of dimension \( \geq 2 \). For example, 2-simplices of \( \mathcal{S} \) can be identified with diagrams of Kan complexes

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
& \downarrow{\mu} & \\
& \downarrow{g} & \\
& \downarrow{\mu} & \\
& \downarrow{h} & \\
Z & \xrightarrow{\mu} & Z
\end{array}
\]

which commute up to a specified homotopy \( \mu : (g \circ f) \to h \).

**Remark 5.6.1.4.** Let \( f : X \to Y \) be a morphism of Kan complexes. Then \( f \) is a homotopy equivalence (in the sense of Definition 3.1.6.1) if and only if it is an isomorphism when viewed as a morphism of the ∞-category \( \mathcal{S} \).

**Remark 5.6.1.5.** Let \( X \) and \( Y \) be Kan complexes. Then Remark 4.6.7.6 supplies a canonical homotopy equivalence of Kan complexes \( \text{Fun}(X,Y) \to \text{Hom}_\mathcal{S}(X,Y) \). Beware that this homotopy equivalence is generally not an isomorphism.

**Remark 5.6.1.6.** Let \( X \) and \( Y \) be Kan complexes, and let \( f, g : X \to Y \) be morphisms. Then \( f \) and \( g \) are homotopic as morphisms of simplicial sets (that is, they belong to the same connected component of the Kan complex \( \text{Fun}(X,Y) \)) if and only if they are homotopic as morphisms in the ∞-category \( \mathcal{S} \) (Definition 1.3.3.1). Consequently, the category \( \text{hKan} \) of Construction 3.1.5.10 can be identified with the homotopy category of the ∞-category \( \mathcal{S} \) (this is a special case of Proposition 2.4.6.9). Moreover, this identification is compatible (via the homotopy equivalences of Remark 5.6.1.5) with the \( \text{hKan} \)-enrichments supplied by Remark 3.1.5.12 and Construction 4.6.8.13 (see Corollary 4.6.8.20).

**Remark 5.6.1.7** (Comparison with Sets). For every set \( S \), let \( S \) denote the associated constant simplicial set (Construction 1.1.4.2). The construction \( S \mapsto S \) determines a fully faithful embedding from the category of sets to the category of Kan complexes. Passing to homotopy coherent nerves, we obtain a functor of ∞-categories \( N_\bullet(\text{Set}) \to \mathcal{S} \). This functor is fully faithful: in fact, it is an isomorphism from \( N_\bullet(\text{Set}) \) to the full subcategory of \( \mathcal{S} \) spanned by Kan complexes of the form \( S \). We will generally abuse notation by identifying (the nerve of) the category Set with its image in \( \mathcal{S} \): in particular, we will not distinguish between a set \( S \) and the associated constant simplicial set \( S \), viewed as an object of \( \mathcal{S} \). We can summarize the situation informally by saying that the ∞-category \( \mathcal{S} \) is an enlargement of the ordinary category \( \text{Set} \).
Remark 5.6.1.8 (Comparison with Groupoids). Let $\textbf{Cat}$ denote the (strict) 2-category of small categories, let $\textbf{Gpd} \subseteq \textbf{Cat}$ denote the full subcategory spanned by the groupoids, and let $\textbf{Gpd}_\bullet$ denote the associated simplicial category (Example 2.4.2.8), which we can describe concretely as follows:

- The objects of the simplicial category $\textbf{Gpd}_\bullet$ are small groupoids.
- If $\mathcal{C}$ and $\mathcal{D}$ are groupoids, then the simplicial set $\text{Hom}_{\textbf{Gpd}}(\mathcal{C}, \mathcal{D})_\bullet$ is the nerve of the functor category $\text{Fun}(\mathcal{C}, \mathcal{D})$.

Note that if $\mathcal{C}$ is a groupoid, then the nerve $N_\bullet(\mathcal{C})$ is a Kan complex (Proposition 1.2.4.2). By virtue of Proposition 1.4.3.3, the construction $\mathcal{C} \mapsto N_\bullet(\mathcal{C})$ determines a fully faithful embedding of simplicial categories $\textbf{Gpd}_\bullet \hookrightarrow \text{Kan}$. Passing to homotopy coherent nerves and invoking Example 2.4.3.11, we obtain a functor of $\infty$-categories

$$N^D_\bullet(\textbf{Gpd}) \simeq N^\text{hc}_\bullet(\textbf{Gpd}_\bullet) \hookrightarrow N^\text{hc}_\bullet(\text{Kan}) = \mathcal{S},$$

where $N^D_\bullet(\textbf{Gpd})$ is the Duskin nerve of the 2-category $\textbf{Gpd}$ (Construction 2.3.1.1). This functor restricts to an isomorphism of $N^D_\bullet(\textbf{Gpd})$ with the full subcategory of $\mathcal{S}$ spanned by those Kan complexes of the form $N_\bullet(\mathcal{C})$, where $\mathcal{C}$ is a small groupoid. We can informally summarize the situation informally by saying that the $\infty$-category $\mathcal{S}$ is an enlargement of the 2-category of groupoids $\textbf{Gpd}$.

Remark 5.6.1.9 (Comparison with Topological Spaces). Let $\text{Top}$ denote the category of topological spaces and continuous functions, endowed with the simplicial enrichment described in Example 2.4.1.5. The geometric realization construction $X \mapsto |X|$ determines a functor of simplicial categories $|\bullet| : \text{Kan} \to \text{Top}$ (see Construction 3.5.5.1). Moreover, if $X$ and $Y$ are Kan complexes, then Proposition 3.5.5.2 guarantees that the induced map

$$\text{Fun}(X, Y) = \text{Hom}_{\text{Kan}}(X, Y)_\bullet \to \text{Hom}_{\text{Top}}(|X|, |Y|)_\bullet$$

is a homotopy equivalence of Kan complexes. Applying Corollary 4.6.7.8, we deduce that the induced map

$$\mathcal{S} = N^\text{hc}_{\bullet}(\text{Kan}) \hookrightarrow N^\text{hc}_{\bullet}(\text{Top})$$

is a fully faithful functor of $\infty$-categories. The essential image of this embedding is spanned by those topological spaces which have the homotopy type of a CW complex (Proposition 3.5.5.3).

5.6.2 Digression: Slicing and the Homotopy Coherent Nerve
Let $\mathcal{C}$ be a category and let $N_\bullet(\mathcal{C})$ denote its nerve. For every object $X \in \mathcal{C}$, Example 4.3.5.8 supplies canonical isomorphisms
\[ N_\bullet(\mathcal{C}/X) \simeq N_\bullet(\mathcal{C})/X \quad N_\bullet(\mathcal{C}_X/) \simeq N_\bullet(\mathcal{C})_X/. \]

Our goal in this section is to establish a counterpart of this result in the case where $\mathcal{C}$ is a (locally Kan) simplicial category. In this case, the slice and coslice categories $\mathcal{C}/X$ and $\mathcal{C}_X/$ inherit simplicial enrichments (Construction 5.6.2.1), and there are natural comparison maps
\[ N^{hc}_\bullet(\mathcal{C}/X) \hookrightarrow N^{hc}_\bullet(\mathcal{C})/X \quad N^{hc}_\bullet(\mathcal{C}_X/) \hookrightarrow N^{hc}_\bullet(\mathcal{C})_X/. \]

Beware that these maps are generally not isomorphisms at the level of simplicial sets (Warning 5.6.2.19). However, we will show that, under some mild assumptions, they are equivalences of $\infty$-categories (Theorem 5.6.2.21).

Construction 5.6.2.1 (Slices of Simplicial-Categories). Let $\mathcal{C}$ be a simplicial category and let $X$ be an object of $\mathcal{C}$. We define a simplicial category $\mathcal{C}/X$ as follows:

- The objects of $\mathcal{C}/X$ are pairs $(C, f)$, where $C$ is an object of $\mathcal{C}$ and $f : C \to X$ is a vertex of the simplicial set $\text{Hom}_\mathcal{C}(C, X)_\bullet$.

- Let $(C, f)$ and $(D, g)$ be objects of $\mathcal{C}/X$. We let $\text{Hom}_{\mathcal{C}/X}((C, f), (D, g))_\bullet$ denote the simplicial set given by the fiber product
\[ \text{Hom}_\mathcal{C}(C, D)_\bullet \times_{\text{Hom}_\mathcal{C}(C, X)_\bullet} \{ f \}, \]
which we regard as a simplicial subset of $\text{Hom}_\mathcal{C}(C, D)_\bullet$. More precisely, we let $\text{Hom}_{\mathcal{C}/X}((C, f), (D, g))_\bullet$ denote the simplicial subset of $\text{Hom}_\mathcal{C}(C, D)_\bullet$ consisting of those $n$-simplices $\sigma$ for which the composite map $\Delta^n \to \{ f \}$.

- Let $(C, f)$, $(D, g)$, and $(E, h)$ be objects of $\mathcal{C}/X$. Then the composition law
\[ \circ : \text{Hom}_{\mathcal{C}/X}((D, g), (E, h))_\bullet \times \text{Hom}_{\mathcal{C}/X}((C, f), (D, g))_\bullet \to \text{Hom}_{\mathcal{C}/X}((C, f), (E, h))_\bullet \]
for the simplicial category $\mathcal{C}/X$ is given by the restriction of the composition law
\[ \circ : \text{Hom}_\mathcal{C}(D, E)_\bullet \times \text{Hom}_\mathcal{C}(C, D)_\bullet \to \text{Hom}_\mathcal{C}(C, E)_\bullet \]
for the simplicial category $\mathcal{C}$.

Exercise 5.6.2.2. Let $\mathcal{C}$ be a simplicial category containing an object $X$. Show that the simplicial categories $\mathcal{C}/X$ and $\mathcal{C}_X/$ of Construction 5.6.2.1 are well-defined (that is, the composition law of Construction 5.6.2.1 is unital and associative).
5.6. THE ∞-CATEGORIES $S$ AND $QC$

**Variant 5.6.2.3** (Coslices of Simplicial-Categories). Let $C$ be a simplicial category and let $X$ be an object of $C$. We define a simplicial category $C_{X/}$ as follows:

- The objects of $C_{X/}$ are pairs $(C, f)$, where $C$ is an object of $C$ and $f$ is a vertex of the simplicial set $\text{Hom}_C(X, C)$.
- Let $(C, f)$ and $(D, g)$ be objects of $C_{X/}$. We let $\text{Hom}_{C_{X/}}((C, f), (D, g))$ denote the simplicial set given by the fiber product
  \[ \text{Hom}_C(C, D) \times_{\text{Hom}_C(X, D)} \{g\}, \]
  which we regard as a simplicial subset of $\text{Hom}_C(C, D)$.
- Let $(C, f), (D, g),$ and $(E, h)$ be objects of $C_{X/}$. Then the composition law
  \[ \circ : \text{Hom}_{C_{X/}}((D, g), (E, h)) \times \text{Hom}_{C_{X/}}((C, f), (D, g)) \to \text{Hom}_{C_{X/}}((C, f), (E, h)) \]
  for the simplicial category $C_{X/}$ is given by the restriction of the composition law
  \[ \circ : \text{Hom}_C(D, E) \times \text{Hom}_C(C, D) \to \text{Hom}_C(C, E) \]
  for the simplicial category $C$.

**Remark 5.6.2.4.** Let $C$ be a simplicial category containing an object $X$, which we also regard as an object of the opposite simplicial category $C^{\text{op}}$. Then there is a canonical isomorphism of simplicial categories $(C_{X/})^{\text{op}} \simeq (C^{\text{op}})/X$.

**Remark 5.6.2.5.** For every simplicial category $C$, let $C^\circ$ denote the underlying ordinary category of $C$ (Example 2.4.1.4). If $X$ is an object of $C$, then we have canonical isomorphisms

\[ (C_{X/})^\circ \simeq (C^\circ)/X \quad (C_{X/})^\circ \simeq (C^\circ)_{X/}, \]

where the left hand sides are defined using the slice and coslice operations on simplicial categories (Construction 5.6.2.1 and Variant 5.6.2.3) and the right hand sides are defined using the slice and coslice operations on ordinary categories (Construction 4.3.1.1 and Variant 4.3.1.4). In other words, the slice and coslice constructions are compatible with the forgetful functor from simplicial categories to ordinary categories. We can summarize the situation more informally as follows: if $C$ is a category and $X$ is an object of $C$, then any simplicial enrichment of $C$ determines a simplicial enrichment on the slice and coslice categories $C_{X/}$ and $C_{/X}$.

**Remark 5.6.2.6.** Let $C$ be an ordinary category and let $\mathcal{C}$ denote the associated constant simplicial category (Example 2.4.2.4). Then the simplicial categories $C_{/X}$ and $C_{X/}$ of Construction 5.6.2.1 and Variant 5.6.2.3 are also constant, associated to the ordinary categories $C_{/X}$ and $C_{X/}$ of Construction 4.3.1.1 and Variant 4.3.1.4 respectively. In other words, the slice and coslice constructions are compatible with the operation of regarding an ordinary category as a (constant) simplicial category.
Warning 5.6.2.7. Let \( C \) be a simplicial category and let \( hC \) denote the homotopy category of \( C \) (Construction 2.4.6.1). For every object \( X \in C \), there is a natural comparison map \( h(C/X) \to (hC)/X \), which carries an object \((C, f)\) of the slice simplicial category \( C/X \) to the object \((C, [f])\) of the slice category \((hC)/X\), where \([f] \in \pi_0(\text{Hom}_C(C,X)_\bullet)\) denotes the homotopy class of \( f \). Beware that this functor is generally not an equivalence of categories (see Warning 3.2.1.9).

We now characterize the simplicial category \( C/X \) of Construction 5.6.2.1 by a universal property.

Notation 5.6.2.8. Let \( C \) be a simplicial category. We define a simplicial category \( C^e \) as follows:

- The set of objects \( \text{Ob}(C^e) \) is the (disjoint) union \( \text{Ob}(C) \cup \{X_0\} \), where \( X_0 \) is an auxiliary symbol.

- The simplicial morphism sets in \( C^e \) are given by

\[
\text{Hom}_{C^e}(C,D)_\bullet = \begin{cases} 
\text{Hom}_C(C,D)_\bullet & \text{if } C, D \in \text{Ob}(C) \\
\Delta^0 & \text{if } C = X_0 \\
\emptyset & \text{otherwise}.
\end{cases}
\]

- For objects \( C, D, E \in \text{Ob}(C^e) \), the composition law

\[
\circ : \text{Hom}_{C^e}(D,E)_\bullet \times \text{Hom}_{C^e}(C,D)_\bullet \to \text{Hom}_{C^e}(C,E)_\bullet
\]

is given by the composition law on \( C \) in the case where \( C, D, E \in \text{Ob}(C) \), and is otherwise uniquely determined (since either the left hand side is empty or the right hand side is \( \Delta^0 \)).

More informally, the simplicial category \( C^e \) is obtained from \( C \) by adjoining a (new) initial object \( X_0 \). We will refer to \( C^e \) as the left cone on \( C \), and to the object \( X_0 \in C^e \) as the cone point.

Variant 5.6.2.9. Let \( C \) be a simplicial category. We define a simplicial category \( C^\circ \) as follows:

- The set of objects \( \text{Ob}(C^\circ) \) is given by the (disjoint) union \( \text{Ob}(C) \cup \{Y_0\} \), where \( Y_0 \) is an auxiliary symbol.

- The simplicial morphism sets in \( C^\circ \) are given by

\[
\text{Hom}_{C^\circ}(C,D)_\bullet = \begin{cases} 
\text{Hom}_C(C,D)_\bullet & \text{if } C, D \in \text{Ob}(C) \\
\Delta^0 & \text{if } D = Y_0 \\
\emptyset & \text{otherwise}.
\end{cases}
\]
5.6. **THE $\infty$-CATEGORIES $S$ AND $QC$**

- For objects $C, D, E \in \text{Ob}(C^\circ)$, the composition law

  \[ \circ : \text{Hom}_{C^\circ}(D, E) \times \text{Hom}_{C^\circ}(C, D) \to \text{Hom}_{C^\circ}(C, E) \]

  is given by the composition law on $C$ in the case where $C, D, E \in \text{Ob}(C)$, and is otherwise uniquely determined.

More informally, the simplicial category $C^\circ$ is obtained from $C$ by adjoining a (new) final object $Y_0$. We will refer to $C^\circ$ as the *right cone on $C$*, and to the object $Y_0 \in C^\circ$ as the *cone point*.

**Remark 5.6.2.10.** Let $C$ be a simplicial category. Then there is a canonical isomorphism of simplicial categories $(C^\circ)^{\text{op}} \simeq (C^{\text{op}})^{\circ}$.

**Remark 5.6.2.11.** For every simplicial category $C$, let $C^\circ$ denote the underlying ordinary category of $C$ (Example 2.4.1.4). Then we have canonical isomorphisms

\[ (C^\circ)^{\circ} \simeq (C^\circ)^{\circ} \quad (C^\circ)^{\circ} \simeq (C^\circ)^{\circ}, \]

where the left hand sides are defined using Notation 5.6.2.8 and Variant 5.6.2.9 and the right hand sides are defined in Example 4.3.2.5. In other words, the formation of cones is compatible with the forgetful functor from simplicial categories to ordinary categories.

**Remark 5.6.2.12.** Let $C$ be an ordinary category and let $\underline{C}$ denote the associated constant simplicial category (Example 2.4.2.4). Then the simplicial categories $\underline{C}^\circ$ and $\underline{C}^\circ$ of Notation 5.6.2.8 and Variant 5.6.2.9 are also constant, associated to the ordinary categories $C^\circ$ and $C^\circ$ of Example 4.3.2.5. In other words, the formation of cones is compatible with the operation of regarding an ordinary category as a (constant) simplicial category.

**Remark 5.6.2.13.** For every simplicial category $C$, let $hC$ denote its homotopy category. Then there are canonical isomorphism of categories

\[ h(C^\circ) \simeq (hC)^{\circ} \quad h(C^\circ) \simeq (hC)^{\circ}. \]

In other words, the formation of cones is compatible with the passage from a simplicial category to its homotopy category.

**Remark 5.6.2.14.** For every simplicial category $C$, let $N^{hc}_{\bullet}(C)$ denote the homotopy coherent nerve of $C$. Then there are canonical isomorphisms of simplicial sets

\[ N^{hc}_{\bullet}(C^\circ) \simeq N^{hc}_{\bullet}(C)^{\circ} \quad N^{hc}_{\bullet}(C^\circ) \simeq N^{hc}_{\bullet}(C)^{\circ}, \]

which are uniquely determined by the requirements that they restrict to the identity on $N^{hc}_{\bullet}(C)$ and preserve the cone points. In other words, the formation of cones is compatible with the homotopy coherent nerve.
Construction 5.6.2.15. Let $\mathcal{C}$ be a simplicial category and let $Y$ be an object of $\mathcal{C}$. We define a simplicial functor $V : (\mathcal{C}/Y)^{op} \to \mathcal{C}$ as follows:

- The functor $V$ carries each object $(C, f) \in \mathcal{C}/Y$ to the object $C \in \mathcal{C}$, and carries the cone point $Y_0 \in (\mathcal{C}/Y)^{op}$ to the object $Y \in \mathcal{C}$.
- If $(C, f)$ and $(D, g)$ are objects of $\mathcal{C}/Y$, then the induced map of simplicial sets
  \[ \text{Hom}_{\mathcal{C}/Y}((C, f), (D, g)) \to \text{Hom}_{\mathcal{C}}(V(C, f), V(D, g)) \]
  is equal to the inclusion map $\text{Hom}_{\mathcal{C}/Y}((C, f), (D, g)) \hookrightarrow \text{Hom}_{\mathcal{C}}(C, D)$.
- If $(C, f)$ is an object of $\mathcal{C}/Y$, then the induced map
  \[ \Delta^0 = \text{Hom}_{\mathcal{C}/Y}((C, f), Y_0) \to \text{Hom}_{\mathcal{C}}(V(C, f), V(Y_0)) = \text{Hom}_{\mathcal{C}}(C, Y) \]
  is equal to the vertex $f$.

We will refer to $V$ as the right cone contraction functor. Similarly, to every object $X \in \mathcal{C}$ we can associate a simplicial functor $V' : (\mathcal{C}_X)^{op} \to \mathcal{C}$ carrying the cone point of $(\mathcal{C}_X)^{op}$ to the object $X$, which we will refer to as the left cone contraction functor.

Proposition 5.6.2.16. Let $\mathcal{C}$ and $\mathcal{D}$ be simplicial categories. Let $X_0$ and $Y_0$ denote the cone points of $\mathcal{D}^{op}$ and $\mathcal{D}$, respectively. Then:

- For every object $Y \in \mathcal{C}$, postcomposition with the right cone contraction functor $V : (\mathcal{C}/Y)^{op} \to \mathcal{C}$ of Construction 5.6.2.15 induces a bijection
  \[ \{ \text{Simplicial functors } F : \mathcal{D} \to \mathcal{C}/Y \} \]
  \[ \sim \]
  \[ \{ \text{Simplicial functors } G : \mathcal{D}^{op} \to \mathcal{C} \text{ with } G(Y_0) = Y \} \]

- For every object $X \in \mathcal{C}$, postcomposition with the left cone contraction functor $V' : (\mathcal{C}_X)^{op} \to \mathcal{C}$ of Construction 5.6.2.15 induces a bijection
  \[ \{ \text{Simplicial functors } F : \mathcal{D} \to \mathcal{C}_X \} \]
  \[ \sim \]
  \[ \{ \text{Simplicial functors } G : \mathcal{D} \to \mathcal{C} \text{ with } G(X_0) = X \} \]
5.6. THE $\infty$-CATEGORIES $\mathcal{S}$ AND $\mathcal{QC}$

Proof. We will prove the first assertion; the proof of the second is similar. Fix a simplicial functor $G : \mathcal{D}^\circ \to \mathcal{C}$ and set $Y = G(Y_0)$. We wish to show that there is a unique simplicial functor $F : \mathcal{D} \to \mathcal{C}/Y$ for which the composition

$$
\mathcal{D}^\circ \xrightarrow{F^\circ} (\mathcal{C}/Y)^\circ \xrightarrow{Y} \mathcal{C}
$$

is equal to $G$. For each object $D \in \mathcal{D}$, the simplicial functor $G$ induces a morphism of simplicial sets

$$
\Delta^0 = \text{Hom}_{\mathcal{D}^\circ}(D, Y_0)_\bullet \xrightarrow{G} \text{Hom}_\mathcal{C}(G(D), G(Y_0))_\bullet,
$$

which we can identify with a vertex $f$ of the simplicial set $\text{Hom}_\mathcal{C}(G(D), Y)_\bullet$. The simplicial functor $F$ is then given on objects by the formula

$$
F(D) = (G(D), f),
$$

and is determined on morphisms by the requirement that the composition

$$
\text{Hom}_{\mathcal{D}^\circ}(D, E)_\bullet \xrightarrow{F} \text{Hom}_{\mathcal{C}/Y}(F(D), F(E))_\bullet \subseteq \text{Hom}_\mathcal{C}(G(D), G(E))_\bullet
$$

coincides with the map of simplicial sets determined by the simplicial functor $G$. 

Construction 5.6.2.17. Let $\mathcal{C}$ be a simplicial category, let $X$ be an object of $\mathcal{C}$, and let $V : (\mathcal{C}/X)^\circ \to \mathcal{C}$ be the right cone contraction functor of Construction 5.6.2.15. Passing to homotopy coherent nerves (and invoking Remark 5.6.2.14), we obtain a map

$$
N_{\text{hc}}(\mathcal{C}/X)^\circ \simeq N_{\text{hc}}((\mathcal{C}/X)^\circ) \to N_{\text{hc}}(\mathcal{C})
$$

carrying the cone point to the vertex $X$, which we can further identify with a morphism of simplicial sets $c : N_{\text{hc}}(\mathcal{C}/X) \to N_{\text{hc}}(\mathcal{C})_{/X}$. We will refer to $c$ as the slice comparison morphism. Similarly, the left cone contraction functor $V' : (\mathcal{C}/X)^{\text{op}} \to \mathcal{C}$ induces a morphism of simplicial sets $c' : N_{\text{hc}}(\mathcal{C}/X) \to N_{\text{hc}}(\mathcal{C})_{X/}$, which we will refer to as the coslice comparison morphism.

Example 5.6.2.18. Let $\mathcal{C}$ be an ordinary category, which we identify with the associated constant simplicial category $\mathcal{C}$ of Example 2.4.2.4. For every object $X \in \mathcal{C}$, the slice and coslice comparison morphisms

$$
c : N_{\bullet}(\mathcal{C}/X) \to N_{\bullet}(\mathcal{C})_{/X} \quad \quad c' : N_{\bullet}(\mathcal{C}/X) \to N_{\bullet}(\mathcal{C})_{X/}
$$

of Construction 5.6.2.17 can be identified with the isomorphisms $N_*(\mathcal{C}/X) \simeq N_*(\mathcal{C})_{/X}$ and $N_*(\mathcal{C}/X') \simeq N_*(\mathcal{C})_{X/}$ described in Example 4.3.5.8.

Warning 5.6.2.19. Let $\mathcal{C}$ be a simplicial category containing an object $X$. Then the slice and coslice comparison morphisms

$$
c : N_{\bullet}(\mathcal{C}/X) \to N_{\bullet}(\mathcal{C})_{/X} \quad \quad c' : N_{\bullet}(\mathcal{C}/X) \to N_{\bullet}(\mathcal{C})_{X/}
$$

of Construction 5.6.2.17 are always bijective at the level of vertices (on the left side, vertices of either of the simplicial sets $N^{hc}_\bullet(C/X)$ and $N^{hc}_\bullet(C)$ can be identified with pairs $(C,f)$, where $C$ is an object of $C$ and $f$ is a morphism from $C$ to $X$). Beware that $c$ and $c'$ are generally not bijective on simplices of dimension $\geq 1$. Unwinding the definitions, we see that edges of the simplicial set $N^{hc}_\bullet(C/X)$ can be identified with diagrams

$$
\begin{array}{ccc}
C & \xrightarrow{h} & D \\
\downarrow f & & \downarrow g \\
X & \xrightarrow{\mu} & X
\end{array}
$$

in the category $C$ which are strictly commutative, while edges of $N^{hc}_\bullet(C)$ can be identified with diagrams which commute up to a specified homotopy $\mu : g \circ h \to f$ in $\text{Hom}_C(C,X)_\bullet$.

**Exercise 5.6.2.20.** Let $C$ be a simplicial category and let $X$ be an object of $C$. Show that the slice and coslice comparison morphisms

$$
c : N^{hc}_\bullet(C/X) \to N^{hc}_\bullet(C) \\
c' : N^{hc}_\bullet(C)_X \to N^{hc}_\bullet(C)_X
$$

are monomorphisms of simplicial sets.

We are now ready to state the main result of this section. For the sake of brevity, we will formulate the statement only for coslice categories (one can deduce a dual statement for slice categories by replacing $C$ by its opposite).

**Theorem 5.6.2.21.** Let $C$ be a locally Kan simplicial category and let $X$ be an object of $C$ with the following property:

(*) For every morphism $f : X \to Y$ and every object $Z \in C$, the morphism of simplicial sets $\text{Hom}_C(Y,Z)_\bullet \xrightarrow{\circ f} \text{Hom}_C(X,Z)_\bullet$ is a Kan fibration.

Then the coslice comparison morphism $c' : N^{hc}_\bullet(C)_X \to N^{hc}_\bullet(C)$ of Construction 5.6.2.17 is an equivalence of $\infty$-categories.

For many applications, hypothesis (*) of Theorem 5.6.2.21 is too strong: it is often satisfied only for morphisms $f : X \to Y$ which are sufficiently well-behaved. We therefore consider a somewhat more general situation:

**Proposition 5.6.2.22.** Let $C$ be a locally Kan simplicial category, let $X$ be an object of $C$, and let $E$ be a full simplicial subcategory of $C_X$ with the following property:

(*') For every pair of objects $(Y,f)$ and $(Z,g)$ of the simplicial category $E \subseteq C_X$, the morphism of simplicial sets $\text{Hom}_C(Y,Z)_\bullet \xrightarrow{\circ f} \text{Hom}_C(X,Z)_\bullet$ is a Kan fibration.
Then the homotopy coherent nerve $N^\text{hc}(\mathcal{E})$ is an $\infty$-category, and the coslice comparison morphism $c' : N^\text{hc}(\mathcal{C}_X) \to N^\text{hc}(\mathcal{C})_{X/}$ of Construction 5.6.2.17 restricts to a fully faithful functor of $\infty$-categories $N^\text{hc}(\mathcal{E}) \to N^\text{hc}(\mathcal{C})_{X/}$.

**Proof of Theorem 5.6.2.21 from Proposition 5.6.2.22.** Let $\mathcal{C}$ be a locally Kan simplicial category and let $X$ be an object of $\mathcal{C}$ which satisfies hypothesis $(\ast)$ of Theorem 5.6.2.21. Applying Proposition 5.6.2.22 in the case $\mathcal{E} = \mathcal{C}_{X/}$, we conclude that the homotopy coherent nerve $N^\text{hc}(\mathcal{C})_{X/}$ is fully faithful. Since $c'$ is bijective on vertices, it is also essentially surjective, and is therefore an equivalence of $\infty$-categories by virtue of Theorem 4.6.2.17.

**Proof of Proposition 5.6.2.22.** Let $\mathcal{C}$ be a locally Kan simplicial category containing an object $X$, and let $\mathcal{E} \subseteq \mathcal{C}_{X/}$ be a full simplicial subcategory satisfying hypothesis $(\ast)$ of Proposition 5.6.2.22. For every pair of objects $(Y, f), (Z, g) \in \mathcal{E}$, the simplicial set $\text{Hom}_\mathcal{E}((Y, f), (Z, g))_\bullet$ is the fiber of the Kan fibration

$$\text{Hom}_\mathcal{C}(Y, Z)_\bullet \xrightarrow{\partial_f} \text{Hom}_\mathcal{C}(X, Z)_\bullet$$

over the vertex $g$, and is therefore a Kan complex (Remark 3.1.1.9). Applying Theorem 2.4.5.1, we conclude that the homotopy coherent nerve $N^\text{hc}(\mathcal{E})$ is an $\infty$-category. We wish to show that, for every pair of objects $(Y, f), (Z, g) \in \mathcal{E}$ as above, the coslice comparison morphism $c'$ induces a homotopy equivalence of morphism spaces

$$\text{Hom}_{N^\text{hc}(\mathcal{E})}((Y, f), (Z, g)) \to \text{Hom}_{N^\text{hc}(\mathcal{C})_{X/}}((Y, f), (Z, g)).$$

By virtue of Proposition 4.6.5.9, this is equivalent to the requirement that $c'$ induces a homotopy equivalence $\rho : \text{Hom}_{N^\text{hc}(\mathcal{E})}((Y, f), (Z, g)) \to \text{Hom}_{N^\text{hc}(\mathcal{C})_{X/}}((Y, f), (Z, g))$ of left-pinched morphism spaces.

Construction 4.6.7.3 supplies comparison maps

$$\theta : \text{Hom}_\mathcal{C}((Y, f), (Z, g))_\bullet \to \text{Hom}_{N^\text{hc}(\mathcal{E})}((Y, f), (Z, g))$$

$$\theta_{Y,Z} : \text{Hom}_\mathcal{C}(Y, Z)_\bullet \to \text{Hom}_{N^\text{hc}(\mathcal{C})}(Y, Z)$$

$$\theta_{X,Z} : \text{Hom}_\mathcal{C}(X, Z)_\bullet \to \text{Hom}_{N^\text{hc}(\mathcal{C})}(X, Z),$$

which are homotopy equivalences of Kan complexes by virtue of Theorem 4.6.7.3. Let us regard $f : X \to Y$ as an edge of the simplicial set $N^\text{hc}(\mathcal{C})$, and let $Q$ denote the fiber $N^\text{hc}(\mathcal{C})_{f/} \times_{N^\text{hc}(\mathcal{C})} \{Z\}$. Since the inclusion $\{1\} \hookrightarrow \Delta^1$ is right anodyne, the restriction map $N^\text{hc}(\mathcal{C})_{f/} \to N^\text{hc}(\mathcal{C})_{Y/}$ is a trivial Kan fibration (Proposition 4.3.6.12), and therefore restricts to a trivial Kan fibration

$$\pi : Q \to N^\text{hc}(\mathcal{C})_{Y/} \times_{N^\text{hc}(\mathcal{C})} \{Z\} = \text{Hom}_{N^\text{hc}(\mathcal{C})}(Y, Z).$$

In particular, $Q$ is a Kan complex and $\pi$ is a homotopy equivalence. Let $\pi'$ denote the restriction map

$$Q \to N^\text{hc}(\mathcal{C})_{X/} \times_{N^\text{hc}(\mathcal{C})} \{Z\} = \text{Hom}_{N^\text{hc}(\mathcal{C})}(X, Z).$$
Note that $\pi'$ is a pullback of the left fibration $N^\text{hc}_{\mathcal{C}}f/ \to N^\text{hc}_{\mathcal{C}}X/ \to N^\text{hc}_{\mathcal{C}}X/ \to N^\text{hc}_{\mathcal{C}}(\mathcal{C})/X$ (Corollary 4.3.6.11), and is therefore also a left fibration (Remark 4.2.1.8). Since the left-pinched morphism space $\text{Hom}^L_{N^\text{hc}_{\mathcal{C}}}(\mathcal{C})/X, Z)$ is a Kan complex (Proposition 4.6.5.4), the morphism $\pi'$ is a Kan fibration (Corollary 4.4.3.8). We will construct an auxiliary map of Kan complexes $\lambda : \text{Hom}_C(Y, Z)_\bullet \to Q$ with the following properties:

(a) The composition $\text{Hom}_{C}(Y, Z)_\bullet \xrightarrow{\lambda} Q \xrightarrow{\pi'} \text{Hom}^L_{N^\text{hc}_{\mathcal{C}}}(\mathcal{C})/X, Z)$ is equal to $\theta_{Y, Z}$.

(b) The cubical diagram of Kan complexes

\[
\begin{array}{ccc}
\text{Hom}_{C}((Y, f), (Z, g))_\bullet & \xrightarrow{\rho \circ \theta} & \text{Hom}_{C}(Y, Z)_\bullet \\
\downarrow & & \downarrow \lambda \\
\text{Hom}^L_{N^\text{hc}_{\mathcal{C}}}(\mathcal{C})/X, Z) & \xrightarrow{\rho \circ \theta} & Q \\
\downarrow & & \downarrow \pi' \\
\{g\} & \xrightarrow{\theta_{X, Z}} & \text{Hom}_{C}(X, Z)_\bullet \\
\downarrow & & \downarrow \\
\{g\} & \xrightarrow{\rho \circ \theta} & \text{Hom}^L_{N^\text{hc}_{\mathcal{C}}}(\mathcal{C})/X, Z)
\end{array}
\]

is commutative.

Suppose that such a map has been constructed. It follows from (a) that $\lambda$ is a homotopy equivalence. Moreover, the front and back faces of the diagram (5.29) are pullback squares of simplicial sets. Since the vertical maps

$$\text{Hom}_{C}(Y, Z)_\bullet \to \text{Hom}_{C}(X, Z)_\bullet \quad \pi' : Q \to \text{Hom}^L_{N^\text{hc}_{\mathcal{C}}}(\mathcal{C})/X, Z)$$

are Kan fibrations, these faces are also homotopy pullback squares (Example 3.4.1.3). Since $\lambda$, $\theta_{X, Z}$, and the identity map $\text{id} : \{g\} \to \{g\}$ are homotopy equivalences of Kan complexes, it follows from Corollary 3.4.1.12 that the map $\rho \circ \theta$ is also a homotopy equivalence of Kan complexes. Since $\theta$ is a homotopy equivalence, we conclude that $\rho$ is a homotopy equivalence as desired.

We now complete the proof by constructing the morphism $\lambda : \text{Hom}_{C}(Y, Z)_\bullet \to Q$. Let $\sigma$ be an $n$-simplex of the simplicial set $\text{Hom}_{C}(Y, Z)_\bullet$, so that $\theta_{Y, Z}(\sigma)$ is an $n$-simplex of the left-pinched morphism space $\text{Hom}^L_{N^\text{hc}_{\mathcal{C}}}(\mathcal{C})/X, Z)$ which we can identify with a simplicial functor $F_\sigma : \text{Path}([y] \star [n])_\bullet \to \mathcal{C}$ such that $F_\sigma(y) = Y$ and $F_\sigma|_{\text{Path}[n]}_\bullet$ is the constant
functor taking the value $Z$ (see Construction 4.6.7.3). We extend $F_\sigma$ to a simplicial functor $F_\sigma^+: \text{Path}\{x\} \star \{y\} \star [n] \to \mathcal{C}$ as follows:

- The functor $F_\sigma^+$ carries $x$ to the object $X \in \mathcal{C}$.
- For every element $i \in \{y\} \star [n]$, the induced map of simplicial sets $\text{Hom}_{\text{Path}\{x\} \star \{y\} \star [n]}(x, i) \to \text{Hom}_{\mathcal{C}}(X, F_\sigma(i))$ is given by the composition

$$
\text{Hom}_{\text{Path}\{x\} \star \{y\} \star [n]}(x, i) \xrightarrow{u} \text{Hom}_{\text{Path}\{y\} \star [n]}(y, i) \xrightarrow{F_\sigma} \text{Hom}_{\mathcal{C}}(Y, F_\sigma(i)) \xrightarrow{f} \text{Hom}_{\mathcal{C}}(X, F_\sigma(i)),
$$

where $u$ is induced by the map of partially ordered sets $\{x\} \star \{y\} \star [n] \to \{y\} \star [n]$ which is the identity on $\{y\} \star [n]$ and carries $x$ to $y$.

Then $F_\sigma^+$ determines a morphism of simplicial sets $\{x\} \star \{y\} \star \Delta^n \to N^\text{hc}\mathcal{C}$ carrying $\{x\}$ to $\Delta^n$ to the vertex $Z$, which we can identify with an $n$-simplex $\lambda(\sigma)$ of the Kan complex $Q$. The construction $\sigma \mapsto \lambda(\sigma)$ depends functorially on $[n] \in \Delta$, and therefore induces a morphism of simplicial sets $\lambda : \text{Hom}_{\mathcal{C}}(Y, Z) \to Q$ which is easily verified to satisfy conditions $(a)$ and $(b)$. 

\section{5.6.3 The $\infty$-Category of Pointed Spaces}

We now study a variant of Construction 5.6.1.1.

\textbf{Construction 5.6.3.1} (The $\infty$-Category of Pointed Spaces). Let $\mathcal{S} = N^\text{hc}\mathcal{S}$ denote the $\infty$-category of spaces, and regard the Kan complex $\Delta^0$ as an object of $\mathcal{S}$. We let $\mathcal{S}_*$ denote the coslice $\infty$-category $\mathcal{S}_{\Delta^0}/$. We will refer to $\mathcal{S}_*$ as the $\infty$-category of pointed spaces.

\textbf{Proposition 5.6.3.2.} The simplicial set $\mathcal{S}_*$ is an $\infty$-category, and the projection map $\mathcal{S}_* \to \mathcal{S}$ is a left fibration of $\infty$-categories.

\textbf{Proof.} By virtue of Proposition 5.6.1.2, the simplicial set $\mathcal{S}$ is an $\infty$-category. It follows that for every object $X \in \mathcal{S}$, the projection map $\mathcal{S}_{\Delta^0} \to \mathcal{S}$ is a left fibration (Corollary 4.3.6.11). Taking $X = \Delta^0$, we conclude that the projection map $\mathcal{S}_* \to \mathcal{S}$ is a left fibration, so that $\mathcal{S}_*$ is an $\infty$-category (Remark 4.2.1.4). 

\textbf{Example 5.6.3.3} (Objects of $\mathcal{S}_*$). By definition, an object of the $\infty$-category $\mathcal{S}_*$ is an edge $e : \Delta^0 \to X$ of the simplicial set $\mathcal{S} = N^\text{hc}\mathcal{S}$ whose source is the Kan complex $\Delta^0$. By virtue of Remark 5.6.1.3, this is the same data as a morphism $e : \Delta^0 \to X$ in the ordinary category of Kan complexes: that is, the data of a pointed Kan complex $(X, x)$ (Definition 3.2.1.1).
Example 5.6.3.4 (Morphisms of $S_*$). Let $(X, x)$ and $(Y, y)$ be pointed Kan complexes, regarded as objects of the $\infty$-category $S_*$. By definition, a morphism from $(X, x)$ to $(Y, y)$ in the $\infty$-category $S_*$ can be identified with a 2-simplex $\sigma$ of the simplicial set $S = N^\mathbf{hc}(\text{Kan})$, which we can identify with a diagram of simplicial sets

\[
\begin{array}{ccc}
\Delta^0 & \xrightarrow{f} & Y \\
\downarrow h & & \downarrow \\
X & \xrightarrow{x} & Y
\end{array}
\]

which commutes up to a specified homotopy $h$. In other words, a morphism from $(X, x)$ to $(Y, y)$ in the $\infty$-category $S_*$ can be identified with a pair $(f, h)$, where $f : X \to Y$ is a morphism of Kan complexes and $h : f(x) \to y$ is an edge of the simplicial set $Y$.

Remark 5.6.3.5. Let $X$ be a Kan complex, which we regard as an object of the $\infty$-category $S$. Then Theorem 4.6.7.5 supplies a homotopy equivalence

$$
\theta_X : X = \text{Hom}_{\text{Kan}}(\Delta^0, X) \to \text{Hom}_{S}^L(\Delta^0, X) = \{X\} \times_S S_* .
$$

Beware that $\theta_X$ is generally not an isomorphism of simplicial sets.

Proposition 5.6.3.6. Let $U : S_* \to S$ be the left fibration of Proposition 5.6.3.2 and let $h \text{Tr}_{S_*/S} : hS \to h\text{Kan}$ be the enriched homotopy transport representation of Variant 5.2.8.11. Then $h \text{Tr}_{S_*/S}$ is homotopy inverse (as an $h\text{Kan}$-enriched functor) to the isomorphism $h\text{Kan} \simeq hS$ of Remark 5.6.1.6. In particular, $h \text{Tr}_{S_*/S}$ is an equivalence of $h\text{Kan}$-enriched categories.

Proof. Apply Theorem 5.5.9.2 to the simplicial category $\text{Kan}_\bullet$.

Remark 5.6.3.7. The statement of Proposition 5.6.3.6 can be made more precise: Theorem 5.5.9.2 supplies an explicit $h\text{Kan}$-enriched isomorphism from the identity functor $id_{h\text{Kan}}$ to the composition

$$
h\text{Kan} \sim \to hS \xrightarrow{h \text{Tr}_{S_*/S}} h\text{Kan},
$$

which carries each Kan complex $X$ to the homotopy equivalence $\theta_X : X \to \{X\} \times_S S_* = h \text{Tr}_{S_*/S}(X)$ of Remark 5.6.3.5.

Let $\text{Kan}_*$ denote the category of pointed Kan complexes (Definition 3.2.1.1). For every pair of pointed Kan complexes $(X, x)$ and $(Y, y)$, we let

$$
\text{Hom}_{\text{Kan}_*}((X, x), (Y, y))_\bullet = \text{Fun}(X, Y) \times_{\text{Fun}(\{x\}, Y)} \{y\}
$$
be the simplicial set parametrizing pointed morphisms from \(X\) to \(Y\). If \((Z, z)\) is another pointed Kan complex, we have an evident composition law

\[\circ : \text{Hom}_{\text{Kan}}((Y, y), (Z, z)) \times \text{Hom}_{\text{Kan}}((X, x), (Y, y)) \to \text{Hom}_{\text{Kan}}((X, x), (Z, z)),\]

which endows \(\text{Kan}_*\) with the structure of a simplicial category. Note that this construction is a special case of Variant 5.6.2.3, since \(\text{Kan}_*\) can be identified with the coslice category \(\text{Kan}_{\Delta^0}/\). Applying Construction 5.6.2.17, we obtain a coslice comparison functor

\[\text{N}^{hc}_{\bullet}(\text{Kan}_*) = \text{N}^{hc}_{\bullet}(\text{Kan}_{\Delta^0}) \to \text{N}^{hc}_{\bullet}(\text{Kan})_{\Delta^0} = S_* .\]

**Proposition 5.6.3.8.** The coslice comparison functor \(\text{N}^{hc}_{\bullet}(\text{Kan}_*) \to S_*\) is an equivalence of \(\infty\)-categories.

**Proof.** Note that, for every pair of pointed Kan complexes \((X, x)\) and \((Y, y)\), the evaluation map \(\text{Fun}(X, Y) \to \text{Fun}(\{x\}, Y)\) is a Kan fibration (Corollary 3.1.3.3). Proposition 5.6.3.8 is therefore a special case of Theorem 5.6.2.21. \(\square\)

**Warning 5.6.3.9.** The coslice comparison functor \(F : \text{N}^{hc}_{\bullet}(\text{Kan}_*) \to S_*\) of Proposition 5.6.3.8 is bijective on vertices: objects of either \(\text{N}^{hc}_{\bullet}(\text{Kan}_*)\) and \(S_*\) can be identified with pointed Kan complexes \((X, x)\). However, it is not bijective on edges (and is therefore not an isomorphism of simplicial sets). If \((X, x)\) and \((Y, y)\) are pointed Kan complexes, then a morphism from \((X, x)\) to \((Y, y)\) in the \(\infty\)-category \(S_*\) can be identified with a pair \((f, h)\), where \(f : X \to Y\) is a morphism of Kan complexes and \(h : f(x) \to y\) is an edge of the Kan complex \(Y\). The pair \((f, h)\) belongs to the image of \(F\) if and only if the edge \(h\) is degenerate (which guarantees in particular that \(f(x) = y\), so that \(f\) is a morphism of pointed Kan complexes).

**Corollary 5.6.3.10.** The coslice comparison functor \(\Phi : \text{N}^{hc}_{\bullet}(\text{Kan}_*) \to S_*\) induces an isomorphism of homotopy categories \(\text{h}\Phi : \text{hKan}_* \xrightarrow{\sim} \text{hS}_*\), where \(\text{hKan}_*\) denotes the homotopy category of pointed Kan complexes (Construction 3.2.1.10).

**Proof.** It follows from Propositions 2.4.6.9 and 5.6.3.8 that the functor \(\text{h}\Phi\) is an equivalence of categories. Since it is bijective on objects, it is an isomorphism of categories. \(\square\)

Note that the coslice comparison functor \(\text{N}^{hc}_{\bullet}(\text{Kan}_*) \to S_*\) is a monomorphism of simplicial sets (Exercise 5.6.2.20). Heuristically, we can think of \(S_*\) as an enlargement of the homotopy coherent nerve \(\text{N}^{hc}_{\bullet}(\text{Kan}_*)\) which is obtained by allowing morphisms between pointed Kan complexes which preserve base points only up to (specified) homotopy. By virtue of Proposition 5.6.3.8 this enlargement gives rise to an equivalent \(\infty\)-category. However, the \(\infty\)-category \(S_*\) is in some respects more convenient to work with, because the forgetful functor \(S_* \to S\) is a left fibration of \(\infty\)-categories. The composite functor \(\text{N}^{hc}_{\bullet}(\text{Kan}_*) \to S_* \to S\) does not share this property:
Warning 5.6.3.11. There is an evident simplicial functor from the category Kan_* of pointed Kan complexes to the category Kan of Kan complexes, given on objects by the construction $(X, x) \mapsto X$. Passing to homotopy coherent nerves, we obtain a functor of $\infty$-categories $U : N^\text{hc}_\bullet(\text{Kan}_*) \to N^\text{hc}_\bullet(\text{Kan}) = S$. Beware that the functor $U$ is not a left fibration of simplicial sets. For example, suppose we are given a 2-simplex $\sigma$ of $S$, corresponding to a diagram of Kan complexes

$$\begin{array}{ccc}
Y & \xrightarrow{f} & Z \\
\downarrow^\mu & & \downarrow^h \\
X & \xrightarrow{g} & Z
\end{array}$$

which commutes up to a homotopy $\mu : (g \circ f) \to h$ (see Remark 5.6.1.3). Pick a vertex $x \in X$ and set $y = f(x)$ and $z = h(x)$, so that we have morphisms of pointed Kan complexes $f : (X, x) \to (Y, y)$ and $h : (X, x) \to (Z, z)$. This data determines a lifting problem

$$\Lambda^2_0 \xrightarrow{(\bullet, h, f)} N^\text{hc}_\bullet(\text{Kan}_*)$$

which admits a solution if and only if $\mu(x) : g(y) \to z$ is a degenerate edge of the Kan complex $Z$ (in which case $g(y) = z$, so that $g : (Y, y) \to (Z, z)$ is also a morphism of pointed Kan complexes).

Example 5.6.3.12 (Pointed Sets as Pointed Spaces). Let Set_* denote the category of pointed sets (see Example 4.2.3.3). Every pointed set $(X, x)$ can be regarded as a pointed Kan complex by identifying $X$ with the corresponding constant simplicial set. This construction determines a fully faithful embedding $\text{Set}_* \hookrightarrow \text{Kan}_*$. Composing with the equivalence of Proposition 5.6.3.8, we obtain a functor of $\infty$-categories

$N_\bullet(\text{Set}_*) \hookrightarrow N_\bullet(\text{Kan}_*) \hookrightarrow N^\text{hc}_\bullet(\text{Kan}_*) \hookrightarrow S_*$. 

It follows from Remark 5.6.1.7 that this functor is fully faithful: in fact, it is an isomorphism from $N_\bullet(\text{Set}_*)$ to the full subcategory of $S_*$ spanned by those pointed Kan complexes $(X, x)$ where the simplicial set $X$ is constant.

For every group $G$, let $B_* G$ denote the Milnor construction on $G$ (Example 1.2.4.3), which we regard as a Kan complex (Proposition 1.1.9.9) having a unique vertex. The construction
5.6. THE ∞-CATEGORIES $S$ AND QC

$G \mapsto B \bullet G$ determines a functor from the category $\text{Group}$ of groups to the category $\text{Kan}_*$ of pointed Kan complexes. Passing to nerves, we obtain a functor of $\infty$-categories

$$N_\bullet(\text{Group}) \to N_\bullet(\text{Kan}_*) \to N_{\text{hc}}(\text{Kan}_*) \to S_*.$$  

**Proposition 5.6.3.13.** The functor

$$N_\bullet(\text{Group}) \to S_* \quad G \mapsto B \bullet G$$

is fully faithful.

**Proof.** By virtue of Proposition 5.6.3.8 and Corollary 4.6.7.8, it will suffice to show that the construction $G \mapsto B \bullet G$ determines a weakly fully faithful functor from $\text{Group}$ (regarded as a constant simplicial category) to the simplicial category $\text{Kan}_*$. In other words, we must show that for every pair of groups $G$ and $H$, the canonical map

$$\theta: \{\text{Group homomorphisms from } G \text{ to } H\} \to \text{Hom}_{\text{Kan}_*}(B \bullet G, B \bullet H)_\bullet$$

is a homotopy equivalence of Kan complexes. In fact, we claim that $\theta$ is an isomorphism of simplicial sets. Let $BG$ denote the category having a single object $X$ with automorphism group $G$, and let $BH$ denote the category having a single object $Y$ with automorphism group $H$. Proposition 1.4.3.3 then supplies an isomorphism

$$\text{Hom}_{\text{Kan}_*}(B \bullet G, B \bullet H)_\bullet \cong N_\bullet(\text{Fun}(BG, BH) \times BH \{Y\}).$$

Note that if $F, F': BG \to BH$ are functors and $\alpha: F \to F'$ is a natural transformation with the property that $\alpha_X: F(X) \to F'(X)$ is the identity morphism $\text{id}_Y$, then the functors $F$ and $F'$ are equal and $\alpha$ is the identity transformation (since $X$ is the only object of the category $BG$). It follows that the fiber product category $\text{Fun}(BG, BH) \times BH \{Y\}$ is discrete: that is, it has only identity morphisms. We conclude by observing that the set of objects of the category $\text{Fun}(BG, BH) \times BH \{Y\}$ can be identified with the set of group homomorphisms from $G$ to $H$.

**Remark 5.6.3.14 (Comparison with Pointed Topological Spaces).** Let $\text{Top}_*$ denote the category whose objects are pointed topological spaces $(X, x)$ and whose morphisms $f: (X, x) \to (Y, y)$ are continuous functions $f: X \to Y$ satisfying $f(x) = y$. We regard $\text{Top}_*$ as a simplicial category, where the $n$-simplices of $\text{Hom}_{\text{Top}_*}((X, x), (Y, y))_\bullet$ are continuous maps $f: |\Delta^n| \times X \to Y$ satisfying $f(t, x) = y$ for every point $t \in |\Delta^n|$.

The construction $(X, x) \mapsto (|X|, x)$ determines a simplicial functor from the category $\text{Kan}_*$ of pointed Kan complexes to the category $\text{Top}_*$ of pointed topological spaces. Moreover,
if \((X, x)\) and \((Y, y)\) are pointed Kan complexes, then we have a commutative diagram of Kan complexes

\[
\begin{array}{ccc}
\text{Hom}_{\text{Kan}}(X, Y) \bullet & \longrightarrow & \text{Hom}_{\text{Top}}(|X|, |Y|) \bullet \\
\downarrow & & \downarrow \\
Y & \longrightarrow & \text{Sing}_\bullet(|Y|),
\end{array}
\]

where the vertical maps are Kan fibrations given by evaluation at \(x\) and the horizontal maps are homotopy equivalences (Proposition 3.5.5.2). Passing to the fiber over the vertex \(y \in Y\), we deduce that the induced map

\[
\text{Hom}_{\text{Kan}}((X, x), (Y, y)) \bullet \to \text{Hom}_{\text{Top}}_\bullet((|X|, x), (|Y|, y)) \bullet
\]

is also a homotopy equivalence of Kan complexes. Allowing \((X, x)\) and \((Y, y)\) to vary, we deduce that geometric realization \(|\bullet| : \text{Kan}_\bullet \to \text{Top}_\bullet\) is a weakly fully faithful functor of simplicial categories (Definition 4.6.7.7), and therefore induces a fully faithful functor of \(\infty\)-categories \(N_{\text{hc}}\bullet(\text{Kan}_\bullet) \to N_{\text{hc}}\bullet(\text{Top}_\bullet)\) (Corollary 4.6.7.8). Composing this functor with a homotopy inverse to the equivalence \(N_{\text{hc}}\bullet(\text{Kan}_\bullet) \to \mathcal{S}_\bullet\) of Proposition 5.6.3.8, we obtain a fully faithful functor \(\mathcal{S}_\bullet \to N_{\text{hc}}\bullet(\text{Top}_\bullet)\).

**Exercise 5.6.3.15.** Let \((X, x)\) be a pointed topological space. Show that \((X, x)\) belongs to the essential image of the functor \(\mathcal{S}_\bullet \to N_{\text{hc}}\bullet(\text{Top}_\bullet)\) if and only if the topological space \(X\) has the homotopy type of a CW complex and the inclusion map \(\{x\} \hookrightarrow X\) is a Hurewicz fibration (that is, the union \((\{0\} \times X) \cup ([0, 1] \times \{x\})\) is a retract of the product space \([0, 1] \times X\)).

### 5.6.4 The \(\infty\)-Category of \(\infty\)-Categories

Let \(\mathcal{HQC}\) denote the homotopy category of (small) \(\infty\)-categories (Construction 4.5.1.1). Recall that the objects of \(\mathcal{HQC}\) are (small) \(\infty\)-categories, and a morphism from \(\mathcal{C}\) to \(\mathcal{D}\) in \(\mathcal{HQC}\) is an isomorphism class of functors from \(\mathcal{C}\) to \(\mathcal{D}\). In this section, we show that \(\mathcal{HQC}\) can be realized as the homotopy category of an \(\infty\)-category \(\mathcal{QC}\), which we will refer to as the \(\infty\)-category of \(\infty\)-categories. Proceeding as in §5.6.1, we will realize \(\mathcal{QC}\) as the homotopy coherent nerve of a simplicial category.

**Construction 5.6.4.1 (The \(\infty\)-Category of \(\infty\)-Categories).** We define a simplicial category \(\mathcal{QC}\) as follows:

- The objects of \(\mathcal{QC}\) are (small) \(\infty\)-categories.
• If $\mathcal{C}$ and $\mathcal{D}$ are $\infty$-categories, then the simplicial set $\operatorname{Hom}_{\mathcal{QC}}(\mathcal{C}, \mathcal{D})$ is the core $\operatorname{Fun}(\mathcal{C}, \mathcal{D}) \simeq$ of the functor $\infty$-category $\operatorname{Fun}(\mathcal{C}, \mathcal{D})$.

• If $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$ are $\infty$-categories, then the composition law

$$\circ : \operatorname{Hom}_{\mathcal{QC}}(\mathcal{D}, \mathcal{E}) \times \operatorname{Hom}_{\mathcal{QC}}(\mathcal{C}, \mathcal{D}) \to \operatorname{Hom}_{\mathcal{QC}}(\mathcal{C}, \mathcal{E})$$

is induced by the composition map $\operatorname{Fun}(\mathcal{D}, \mathcal{E}) \times \operatorname{Fun}(\mathcal{C}, \mathcal{D}) \to \operatorname{Fun}(\mathcal{C}, \mathcal{E})$.

We let $\mathcal{QC}$ denote the homotopy coherent nerve $\mathcal{N}^{hc}(\mathcal{QC})$. We will refer to $\mathcal{QC}$ as the $\infty$-category of $\infty$-categories.

**Remark 5.6.4.2.** Many authors use the term *quasicategory* for what we refer to as an $\infty$-category (see Remark [1.3.0.2]); the notations of Construction 5.6.4.1 reflect this alternative terminology.

**Proposition 5.6.4.3.** The simplicial set $\mathcal{QC}$ is an $\infty$-category.

*Proof.* For every pair of $\infty$-categories $\mathcal{C}$ and $\mathcal{D}$, the core $\operatorname{Fun}(\mathcal{C}, \mathcal{D}) \simeq$ is a Kan complex (Corollary [4.4.3.11]). It follows that the simplicial category $\mathcal{QC}$ of Construction 5.6.4.1 is locally Kan, so its homotopy coherent nerve $\mathcal{QC} = \mathcal{N}^{hc}(\mathcal{QC})$ is an $\infty$-category by virtue of Theorem 2.4.5.1. □

**Remark 5.6.4.4.** The low-dimensional simplices of $\mathcal{QC}$ are simple to describe:

• An object of $\mathcal{QC}$ is a (small) $\infty$-category $\mathcal{C}$.

• If $\mathcal{C}$ and $\mathcal{D}$ are objects of $\mathcal{QC}$, then a morphism from $\mathcal{C}$ to $\mathcal{D}$ in $\mathcal{QC}$ is a functor $F : \mathcal{C} \to \mathcal{D}$.

• A 2-simplex of $\mathcal{QC}$ can be identified with a diagram

$$\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{D} \\
\downarrow{H} & \searrow{\sim} {\mu} & \\
\mathcal{E} & \xleftarrow{\cong} & \mathcal{D}
\end{array}$$

where $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$ are (small) $\infty$-categories, $F$, $G$, and $H$ are functors, and $\mu : G \circ F \to H$ is an isomorphism in the $\infty$-category $\operatorname{Fun}(\mathcal{C}, \mathcal{E})$.

**Remark 5.6.4.5.** Let $\mathcal{C}$ and $\mathcal{D}$ be $\infty$-categories. Then Remark [1.6.7.6] supplies a homotopy equivalence of Kan complexes $\phi : \operatorname{Fun}(\mathcal{C}, \mathcal{D}) \simeq \to \operatorname{Hom}_{\mathcal{QC}}(\mathcal{C}, \mathcal{D})$. Beware that this homotopy equivalence is generally not an isomorphism.
Remark 5.6.4.6. Let hQCat denote the homotopy category of ∞-categories (Construction 4.5.1.1), which we view as an hKan-enriched category (see Remark 3.1.5.12). Applying Proposition 2.4.6.9 and Corollary 4.6.8.20, we obtain a canonical isomorphism of hKan-enriched categories \( \Phi : hQCat \cong hQC \), which is given on objects by the construction \( \Phi(C) = C \) and on morphism spaces by the homotopy equivalences
\[
\text{Hom}_{QCat}(C, D) \cong \text{Fun}(C, D) \cong \text{Hom}_{QC}(C, D)
\]
of Remark 5.6.4.5.

Remark 5.6.4.7. Let \( F : C \to D \) be a functor between ∞-categories. Then \( F \) is an equivalence of ∞-categories (in the sense of Definition 4.5.1.10) if and only if it is an isomorphism in the ∞-category QC.

Remark 5.6.4.8 (Comparison with Kan Complexes). Every Kan complex is an ∞-category (Example 1.3.0.3). Moreover, if \( X \) and \( Y \) are Kan complexes, then the simplicial set \( \text{Fun}(X, Y) \) is also a Kan complex (Corollary 3.1.3.4), and therefore coincides with its core \( \text{Fun}(X, Y)^\simeq \). It follows that we can regard the simplicial category Kan of Construction 5.6.1.1 as a full simplicial subcategory of QCat. Passing to homotopy coherent nerves, we deduce that the ∞-category \( S = N^hc(Kan) \) is the full subcategory of \( QC = N^hc(QCat) \) spanned by the Kan complexes.

Remark 5.6.4.9 (Comparison with Categories). Let \( \text{Cat} \) denote the strict 2-category of small categories (Example 2.2.0.4), let \( \text{Pith}(\text{Cat}) \) denote its pith (Construction 2.2.8.9), and let us abuse notation by identifying \( \text{Pith}(\text{Cat}) \) with the simplicial category described in Example 2.4.2.8. Concretely, this simplicial category can be described as follows:

- The objects of \( \text{Pith}(\text{Cat}) \) are small categories.

- If \( C \) and \( D \) are objects of \( \text{Pith}(\text{Cat}) \), then the simplicial set \( \text{Hom}_{\text{Pith}(\text{Cat})}(C, D) \) is the nerve of the groupoid \( \text{Fun}(C, D)^\simeq \) whose objects are functors from \( C \) to \( D \) and whose morphisms are natural isomorphisms.

By virtue of Proposition 1.4.3.3, the construction \( C \mapsto N_*(C) \) determines a fully faithful embedding of simplicial categories \( \text{Pith}(\text{Cat}) \to \text{QCat} \). Passing to homotopy coherent nerves (and invoking Example 2.4.3.11), we obtain a functor of ∞-categories \( N^D_*(\text{Pith}(\text{Cat})) \to \text{QCat} \). Unwinding the definitions, we see that this functor induces an isomorphism from the Duskin nerve \( N^D_*(\text{Pith}(\text{Cat})) \) to the full subcategory of \( \text{QC} \) spanned by those ∞-categories of the form \( N_*(\mathcal{C}) \), where \( \mathcal{C} \) is an ordinary category.

Variant 5.6.4.10. Let \( \kappa \) be an uncountable cardinal. We let \( \text{QC}^{<\kappa} \) denote the full subcategory of \( \text{QC} \) spanned by the ∞-categories which are \( \kappa \)-small. We will refer to \( \text{QC}^{<\kappa} \) as the ∞-category of essentially \( \kappa \)-small ∞-categories.
Remark 5.6.4.11 (Set-Theoretic Conventions). By definition, the objects of the $\infty$-category $\mathcal{QC} = N^h_{\infty}(\mathcal{Q}\mathcal{C})$ are small $\infty$-categories. According to the convention of Remark 5.4.0.5 this means that we restrict our attention to essentially $\lambda$-small Kan complexes, where $\lambda$ is some fixed uncountable strongly inaccessible cardinal. In this case, the definitions given in Variant 5.6.4.10 are appropriate only for uncountable cardinals $\kappa < \lambda$. More generally, if $\kappa$ is an arbitrary uncountable cardinal, we can define $\mathcal{QC}^{\leq \kappa}$ to be the homotopy coherent nerve $N^h_{\infty}(\mathcal{Q}\mathcal{C}^{\leq \kappa})$, where $\mathcal{Q}\mathcal{C}^{\leq \kappa}$ denotes the (simplicially enriched) category of $\kappa$-small $\infty$-categories. We then have three cases:

(a) If $\kappa < \lambda$, then $\mathcal{QC}^{\leq \kappa}$ is a full subcategory of $\mathcal{QC}$.

(b) If $\kappa = \lambda$, then $\mathcal{QC}^{\leq \kappa}$ coincides with $\mathcal{QC}$.

(c) If $\kappa > \lambda$, then $\mathcal{QC}$ is a full subcategory of $\mathcal{QC}^{\leq \kappa}$.

To simplify the exposition, we will often implicitly assume that we are in case (a), as suggested in Variant 5.6.4.10. However, it will be convenient to also allow case (c) when working with $\infty$-categories which are not necessarily small (such as $\mathcal{QC}$ itself).

Variant 5.6.4.12. Let $\kappa$ be an uncountable cardinal. We let $\mathcal{S}^{\leq \kappa}$ denote the full subcategory of $\mathcal{S}$ spanned by the $\kappa$-small Kan complexes, which we also regard as a full subcategory of $\mathcal{QC}^{\leq \kappa}$. Similarly, we let $\mathcal{S}^{\leq \kappa}_{\ast}$ denote the full subcategory of $\mathcal{S}_{\ast}$ spanned by those pointed Kan complexes $(X, x)$ where $X$ is $\kappa$-small.

Remark 5.6.4.13. Let $\kappa$ and $\lambda$ be regular cardinals and suppose that $\kappa$ is less than or equal to the exponential cofinality $\text{ecf}(\lambda)$ (see Definition 5.4.3.16). Then the $\infty$-category $\mathcal{QC}^{\leq \kappa}$ is locally $\lambda$-small. This follows by combining Remarks 5.6.4.5 and 5.4.5.10. It follows that the full subcategory $\mathcal{S}^{\leq \kappa} \subseteq \mathcal{QC}^{\leq \kappa}$ is also locally $\lambda$-small.

5.6.5 The $(\infty, 2)$-Category of $\infty$-Categories

For some applications, it will be convenient to work with a variant of Construction 5.6.4.1 which retains information about non-invertible natural transformations of functors.

Construction 5.6.5.1 (The $(\infty, 2)$-Category of $\infty$-Categories). Let $\text{Set}_{\Delta}$ denote the category of simplicial sets, endowed with the simplicial enrichment of Example 2.4.2.1. We let $\mathcal{Q}\mathcal{C}$ denote the full simplicial subcategory of $\text{Set}_{\Delta}$ spanned by the (small) $\infty$-categories, which we can describe concretely as follows:

- The objects of $\mathcal{Q}\mathcal{C}$ are (small) $\infty$-categories.
- If $\mathcal{C}$ and $\mathcal{D}$ are $\infty$-categories, then the simplicial set $\text{Hom}_{\mathcal{Q}\mathcal{C}}(\mathcal{C}, \mathcal{D})_{\bullet}$ is the $\infty$-category of functors $\text{Fun}(\mathcal{C}, \mathcal{D})$. 
We let $\mathcal{QC}$ denote the homotopy coherent nerve $N_{hc}^\bullet(Q\text{Cat})$. We will refer to $\mathcal{QC}$ as the $(\infty,2)$-category of $\infty$-categories.

**Proposition 5.6.5.2.** The simplicial set $\mathcal{QC}$ is an $(\infty,2)$-category.

**Proof.** For every pair of $\infty$-categories $\mathcal{C}$ and $\mathcal{D}$, Theorem 1.4.3.7 guarantees that the simplicial set $\text{Hom}_{Q\text{Cat}}(\mathcal{C},\mathcal{D})_\bullet = \text{Fun}(\mathcal{C},\mathcal{D})$ is an $\infty$-category. The desired result is now a special case of Theorem 5.5.8.1. $\square$

**Remark 5.6.5.3.** The low-dimensional simplices of $\mathcal{QC}$ are simple to describe:

- An object of $\mathcal{QC}$ is a (small) $\infty$-category $\mathcal{C}$.
- If $\mathcal{C}$ and $\mathcal{D}$ are objects of $\mathcal{QC}$, then a morphism from $\mathcal{C}$ to $\mathcal{D}$ in $\mathcal{QC}$ is a functor $F : \mathcal{C} \to \mathcal{D}$.
- A 2-simplex $\sigma$ of $\mathcal{QC}$ can be identified with a diagram

$$
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{D} \\
\downarrow H & & \downarrow \mu \\
\mathcal{E} & \xleftarrow{G} & \mathcal{D}
\end{array}
$$

where $\mathcal{C}$, $\mathcal{D}$, and $\mathcal{E}$ are (small) $\infty$-categories, $F$, $G$, and $H$ are functors, and $\mu : G \circ F \to H$ is a morphism in the $\infty$-category $\text{Fun}(\mathcal{C},\mathcal{E})$. Moreover, $\sigma$ is thin if and only if only if $\mu$ is an isomorphism of functors (Proposition 5.5.8.7).

**Remark 5.6.5.4 (Comparison with $Q\mathcal{C}$).** Let $Q\text{Cat}$ and $Q\text{Cat}$ be the simplicial categories defined in Constructions 5.6.4.1 and 5.6.5.1, respectively. There is an evident comparison map $Q\text{Cat} \hookrightarrow Q\text{Cat}$ which is the identity at the level of objects, and which is given on morphism spaces by the inclusion maps

$$
\text{Hom}_{Q\text{Cat}}(\mathcal{C},\mathcal{D})_\bullet = \text{Fun}(\mathcal{C},\mathcal{D}) \hookrightarrow \text{Fun}(\mathcal{C},\mathcal{D}) = \text{Hom}_{Q\text{Cat}}(\mathcal{C},\mathcal{D}).
$$

Passing to the homotopy coherent nerve, we obtain a functor of $(\infty,2)$-categories $Q\mathcal{C} \hookrightarrow \mathcal{QC}$ which restricts to an isomorphism of $\infty$-categories $Q\mathcal{C} \simeq \text{Pith}(\mathcal{QC})$ (Corollary 5.5.8.8).

**Remark 5.6.5.5.** Let $\mathcal{C}$ and $\mathcal{D}$ be $\infty$-categories. Then Theorem 4.6.7.5 supplies an equivalence of $\infty$-categories $\text{Fun}(\mathcal{C},\mathcal{D}) \to \text{Hom}_{Q\mathcal{C}}(\mathcal{C},\mathcal{D})$. Beware that this equivalence is generally not an isomorphism at the level of simplicial sets.
Remark 5.6.5.6 (Comparison with Kan Complexes). Since every Kan complex is an ∞-category (Example 1.3.0.3), we can identify the simplicial category Kan of Construction 5.6.1.1 with a full simplicial subcategory of QCat. Passing to homotopy coherent nerves, we can identify ∞-category of spaces $S = N^\text{hc}_\bullet(\text{Kan})$ with the full subcategory of $QC = N^\text{hc}_\bullet(\text{QCat})$ spanned by the Kan complexes.

Remark 5.6.5.7 (Comparison with Categories). Let $\text{Cat}$ denote the strict 2-category of small categories (Example 2.2.0.4). By virtue of Proposition 1.4.3.3, the construction $C \mapsto N^\bullet(\text{Cat})$ induces an isomorphism from the Duskin nerve $N^\text{D}_\bullet(\text{Cat})$ to the full subcategory of $QC$ spanned by those ∞-categories of the form $N^\bullet_\bullet(\text{C})$, where $C$ is an ordinary category.

Remark 5.6.5.8 (Passage to the Homotopy Category). Let $\text{Cat}^\bullet$ denote the simplicial category associated to the strict 2-category $\text{Cat}$ (see Example 2.4.2.8). For every pair of ∞-categories $C$ and $D$, Corollary 1.4.3.5 supplies a comparison map

$\text{Fun}(C, D) \to \text{Fun}(C, N^\bullet_\bullet(\text{h}D)) \simeq N^\bullet_\bullet(\text{Fun}(\text{h}C, \text{h}D))$.

This construction is compatible with composition, and therefore determines a functor of simplicial categories

$\text{QCat} \to \text{Cat}^\bullet \quad C \mapsto \text{h}C$.

Passing to homotopy coherent nerves (and invoking Example 2.4.3.11), we obtain a functor of (∞, 2)-categories

$QC = N^\text{hc}_\bullet(\text{QCat}) \to N^\text{hc}_\bullet(\text{Cat}^\bullet) \simeq N^\text{D}_\bullet(\text{Cat})$.

Stated more informally, the construction $C \mapsto \text{h}C$ determines a functor from the (∞, 2)-category $QC$ to the ordinary 2-category $\text{Cat}$.

Variant 5.6.5.9. Let $\kappa$ be an uncountable cardinal. We let $QC^{<\kappa}$ denote the full simplicial subset of $QC$ spanned by those ∞-categories $C$ which are $\kappa$-small. Then $QC^{<\kappa}$ is an (∞, 2)-category, which we will refer to as the (∞, 2)-category of essentially $\kappa$-small ∞-categories.

5.6.6 ∞-Categories with a Distinguished Object

In this section, we study pairs $(C, C)$, where $C$ is a (small) ∞-category and $C \in C$ is a distinguished object. Our goal is to organize the collection of such pairs into an ∞-category. We consider several variants of this construction which are related by inclusion maps

$N^\text{hc}_\bullet(\text{QCat}^\bullet) \hookrightarrow QC^\bullet \hookrightarrow QC_{\text{Obj}} \hookrightarrow QC_{\text{Obj}}$;

their interrelationships can be described informally as follows:
• Morphisms from \((C, C)\) to \((D, D)\) in the \(\infty\)-category \(N^\text{hc}_\bullet(\text{QCat}_\ast)\) are given by functors \(F : C \to D\) which satisfy \(F(C) = D\) (that is, \(F\) is strictly compatible with the choice of distinguished objects).

• Morphisms from \((C, C)\) to \((D, D)\) in the \(\infty\)-category \(\text{QC}_\ast\) are given by pairs \((F, \alpha)\), where \(F : C \to D\) is a functor and \(\alpha : F(C) \to D\) is an isomorphism in the \(\infty\)-category \(\mathcal{D}\) (that is, \(F\) is compatible with the choice of distinguished objects up to isomorphism). The inclusion \(N^\text{hc}_\bullet(\text{QCat}_\ast) \hookrightarrow \text{QC}_\ast\) is an equivalence of \(\infty\)-categories (Proposition 5.6.6.6).

• Morphisms from \((C, C)\) to \((D, D)\) in the \(\infty\)-category \(\text{QC}_{\text{Obj}}\) are given by pairs \((F, \alpha)\), where \(F : C \to D\) is a functor and \(\alpha : F(C) \to D\) is a morphism in the \(\infty\)-category \(\mathcal{D}\) which is not required to be an isomorphism; this \(\infty\)-category contains \(\text{QC}_\ast\) as a (non-full) subcategory (Remark 5.6.6.16).

• The simplicial set \(\mathcal{QC}_{\text{Obj}}\) is an \((\infty, 2)\)-category having the same objects and morphisms as \(\text{QC}_{\text{Obj}}\), but which also contains information about non-invertible natural transformations between functors (see Example 5.6.6.17).

Construction 5.6.6.1. Let \(\mathcal{QC}\) denote the \(\infty\)-category of \(\infty\)-categories (Construction 5.6.4.1), and regard the Kan complex \(\Delta^0\) as an object of \(\mathcal{QC}\). We let \(\mathcal{QC}_\ast\) denote the coslice simplicial set \(\mathcal{QC}_{\Delta^0/}\).

Proposition 5.6.6.2. The simplicial set \(\mathcal{QC}_\ast\) is an \(\infty\)-category, and the projection map \(\mathcal{QC}_\ast \to \mathcal{QC}\) is a left fibration of \(\infty\)-categories.

Proof. By virtue of Proposition 5.6.4.3, the simplicial set \(\mathcal{QC}\) is an \(\infty\)-category. It follows that for every object \(C \in \mathcal{QC}\), the projection map \(\mathcal{QC}_C/ \to \mathcal{QC}\) is a left fibration (Corollary 4.3.6.11). Taking \(C = \Delta^0\), we conclude that the projection map \(\mathcal{QC}_\ast \to \mathcal{QC}\) is a left fibration, so that \(\mathcal{QC}_\ast\) is an \(\infty\)-category (Remark 4.2.1.4). \(\square\)

Example 5.6.6.3 (Objects and Morphisms of \(\mathcal{QC}_\ast\)). The low-dimensional simplices of the \(\infty\)-category \(\mathcal{QC}_\ast\) are easy to describe:

• The objects of \(\mathcal{QC}_\ast\) can be identified with pairs \((\mathcal{C}, C)\), where \(\mathcal{C}\) is a (small) \(\infty\)-category and \(C \in \mathcal{C}\) is an object (which we identify with the morphism \(\Delta^0 \to \mathcal{C}\) taking the value \(C\)).

• Let \((\mathcal{C}, C)\) and \((\mathcal{D}, D)\) be objects of \(\mathcal{QC}_\ast\). A morphism from \((\mathcal{C}, C)\) to \((\mathcal{D}, D)\) in the \(\infty\)-category \(\mathcal{QC}_\ast\) can be identified with a pair \((F, \alpha)\), where \(F : \mathcal{C} \to \mathcal{D}\) is a functor of \(\infty\)-categories and \(\alpha : F(C) \to D\) is an isomorphism in the \(\infty\)-category \(\mathcal{D}\).
5.6. THE $\infty$-CATEGORIES $S$ AND $QC$

**Warning 5.6.6.4.** By analogy with Definition 3.2.1.1, it would be natural to refer to the objects $(C, C)$ of $QC_*$ as pointed $\infty$-categories. We will avoid using this terminology, since it conflicts with another (related but distinct) notion of pointed $\infty$-category that we will consider later (Definition [?]).

**Remark 5.6.6.5** (Comparison with Pointed Spaces). Let us regard the $\infty$-category of spaces $S$ as a full subcategory of the $\infty$-category $QC$ (Remark 5.6.4.8). The inclusion $S \hookrightarrow QC$ determines a functor of coslice $\infty$-category $S_* \rightarrow QC_*$. This functor restricts to an isomorphism from $S_*$ with the full subcategory of $QC_*$ spanned by those pairs $(C, C)$, where $C$ is a Kan complex.

Let $QC$ denote the ordinary category whose objects are (small) $\infty$-categories and whose morphisms are functors, and let $QC_*^\Delta$ denote the coslice category $QC^\Delta_{\Delta^0}$. The simplicial enrichment of $QC$ (described in Construction 5.6.4.1) determines a simplicial enrichment of the coslice category $QC_*^\Delta$ (see Variant 5.6.2.3), and Construction 5.6.2.17 yields a coslice comparison functor

$$N^{hc}_*(QC) = N^{hc}_*(QC^\Delta_{\Delta^0}) \rightarrow N^{hc}_*(QC^\Delta_{\Delta^0}) = QC_*^\Delta.$$ 

**Proposition 5.6.6.6.** The coslice comparison functor $N^{hc}_*(QC) \rightarrow QC_*^\Delta$ is an equivalence of $\infty$-categories.

**Proof.** By virtue of Theorem 5.6.2.21 it will suffice to show that for every pair of objects $(C, C), (D, D) \in QC_*$, the restriction map

$$\text{Fun}(C, D) \rightarrow \text{Hom}_{QC}(C, D) \rightarrow \text{Hom}_{QC_*^\Delta}(\{C\}, D) = \text{Fun}(\{C\}, D)$$

is a Kan fibration. This follows from Proposition 4.4.3.7 since the restriction functor $\text{Fun}(C, D) \rightarrow \text{Fun}(\{C\}, D)$ is an isofibration of $\infty$-categories (Corollary 4.4.5.3). □

**Warning 5.6.6.7.** The coslice comparison functor $U : N^{hc}_*(QC) \rightarrow QC_*^\Delta$ of Proposition 5.6.6.6 is bijective on vertices: objects of either $N^{hc}_*(QC)$ and $QC_*$ can be identified with pairs $(C, C)$, where $C$ is an $\infty$-category and $C$ is an object of $C$. However, it is not bijective on edges (and is therefore not an isomorphism of simplicial sets). If $(C, C)$ and $(D, D)$ are objects of $QC_*$, then a morphism from $(C, C)$ to $(D, D)$ in the $\infty$-category $QC_*$ can be identified with a pair $(F, \alpha)$, where $F : C \rightarrow D$ is a functor of $\infty$-categories and $\alpha : F(C) \rightarrow D$ is an isomorphism in the $\infty$-category $D$. The pair $(F, \alpha)$ belongs to the image of $U$ if and only if the isomorphism $\alpha$ is a degenerate edge of $D$ (which guarantees in particular that $F(C) = D$).

We now introduce an enlargement of the $\infty$-category $QC_*$. 

Construction 5.6.6.8. Let $\mathcal{QC}$ denote the $(\infty, 2)$-category of $\infty$-categories (Construction 5.6.5.1), and regard the Kan complex $\Delta^0$ as an object of $\mathcal{QC}$. We let $\mathcal{QC}_{\text{Obj}}$ denote the coslice simplicial set $\mathcal{QC}_{\Delta^0/}$.

Proposition 5.6.6.9. The simplicial set $\mathcal{QC}_{\text{Obj}}$ is an $(\infty, 2)$-category. Moreover, the projection map $\mathcal{QC}_{\text{Obj}} \to \mathcal{QC}$ is an interior fibration of $(\infty, 2)$-categories.

Proof. It follows from Proposition 5.6.5.2 that $\mathcal{QC}$ is an $(\infty, 2)$-category. The desired conclusion now follows from Corollary 5.5.3.4 and Proposition 5.5.3.1.

Definition 5.6.6.10. Let $\mathcal{QC}_{\text{Obj}}$ denote the pith of the $(\infty, 2)$-category $\mathcal{QC}_{\text{Obj}}$ (see Construction 5.5.5.1).

Proposition 5.6.6.11.

1. The simplicial set $\mathcal{QC}_{\text{Obj}}$ is an $\infty$-category.
2. The projection map $\bar{V} : \mathcal{QC}_{\ast} = \mathcal{QC}_{\Delta^0} \to \mathcal{QC}$ restricts to a functor $V : \mathcal{QC}_{\text{Obj}} = \text{Pith}(\mathcal{QC}_{\text{Obj}}) \to \text{Pith}(\mathcal{QC}) = \mathcal{QC}$.
3. The diagram

$$
\begin{array}{ccc}
\mathcal{QC}_{\text{Obj}} & \longrightarrow & \mathcal{QC}_{\text{Obj}} \\
\downarrow V & & \downarrow \bar{V} \\
\mathcal{QC} & \longrightarrow & \mathcal{QC}
\end{array}
$$

is a pullback square of simplicial sets.
4. The functor $V$ is a cocartesian fibration of $\infty$-categories.

Proof. Assertion (1) follows from Proposition 5.5.5.6. Since $\bar{V}$ is an interior fibration (Proposition 5.6.6.9), assertions (2) and (3) follow from Proposition 5.5.7.9. Assertion (4) is a special case of Corollary 5.5.7.10.

Example 5.6.6.12 (Objects and Morphisms of $\mathcal{QC}_{\text{Obj}}$). The inclusion of simplicial sets $\mathcal{QC} \hookrightarrow \mathcal{QC}$ induces a functor of $\infty$-categories $\iota : \mathcal{QC}_{\ast} \hookrightarrow \mathcal{QC}_{\text{Obj}}$. The functor $\iota$ is bijective on vertices. In particular, we can identify the objects of $\mathcal{QC}_{\text{Obj}}$ with pairs $(C, C)$, where $C$ is a (small) $\infty$-category and $C \in C$ is an object. However, it is not bijective on edges. Unwinding the definitions, we see that a morphism $\bar{F}$ from $(C, C)$ to $(D, D)$ in the $\infty$-category $\mathcal{QC}_{\text{Obj}}$ can be identified with a pair $(F, \alpha)$, where $F : C \to D$ is a functor of $\infty$-categories and $\alpha : F(C) \to D$ is a morphism in the $\infty$-category $D$. For every such pair $(F, \alpha)$, the following conditions are equivalent:
5.6. THE ∞-CATEGORIES S AND QC

- The morphism $\tilde{F} = (F, \alpha)$ belongs to the image of the inclusion map $\iota : QC_s \hookrightarrow QC_{\text{Obj}}$.
- The morphism $\alpha : F(C) \to D$ is an isomorphism in the ∞-category $D$.
- The morphism $\tilde{F}$ is $V$-cocartesian, where $V : QC_{\text{Obj}} \to QC$ is the cocartesian fibration of Proposition 5.6.6.11.

**Remark 5.6.6.13** (Fibers of $V$). Let $C$ be a small ∞-category, which we regard as an object of the ∞-category $QC$. Then Construction 4.6.7.3 supplies a comparison map

$$\theta_C : \text{Hom}_{QC}(\Delta^0, C) \to \text{Hom}_{QC}(\Delta^0, C)$$

which is an equivalence of ∞-categories (Theorem 4.6.7.9). Beware that $\theta_C$ is generally not an isomorphism of simplicial sets (though it is bijective on $n$-simplices for $n \leq 1$; see Example 5.6.6.12).

We have the following generalization of Proposition 5.6.3.6:

**Proposition 5.6.6.14.** Let $V : QC_{\text{Obj}} \to QC$ be the cocartesian fibration of Proposition 5.6.6.11 and let

$$h\text{Tr}_{QC_{\text{Obj}}/QC} : hQC \to hQC$$

denote the enriched homotopy transport representation of Construction 5.2.8.9. Then $h\text{Tr}_{QC_{\text{Obj}}/QC}$ is homotopy inverse (as an hKan-enriched functor) to the isomorphism $hQC \simeq hQC$ supplied by Remark 5.6.4.6. In particular, $h\text{Tr}_{QC_{\text{Obj}}/QC}$ is an equivalence of hKan-enriched categories.

**Proof.** Apply Theorem 5.5.9.2 to the simplicial category $QC$.

**Remark 5.6.6.15.** The statement of Proposition 5.6.6.14 can be made more precise: Theorem 5.5.9.2 supplies an explicit hKan-enriched isomorphism from the identity functor $id_{hQC}$ to the composition

$$hQC \overset{\sim}{\to} hQC \xrightarrow{h\text{Tr}_{QC_{\text{Obj}}/QC}} hQC$$

which carries each small ∞-category $C$ to the equivalence

$$\theta_C : C \to \{C\} \times QC_{\text{Obj}} = h\text{Tr}_{QC_{\text{Obj}}/QC}(C)$$

described in Remark 5.6.6.13.
Remark 5.6.6.16. The inclusion map \( \iota : \mathcal{QC}_* \hookrightarrow \mathcal{QC}_{\text{Obj}} \) is an isomorphism from \( \mathcal{QC}_* \) to the (non-full) subcategory of \( \mathcal{QC}_{\text{Obj}} \) spanned by those morphisms which satisfy the conditions of Example 5.6.6.12. In other words, the projection map \( \mathcal{QC}_* \to \mathcal{QC} \) is the underlying left fibration of the cocartesian fibration \( \mathcal{QC}_{\text{Obj}} \to \mathcal{QC} \) (see Corollary 5.5.7.11).

Note that the inclusion map \( \mathcal{QC}_{\text{Obj}} = \text{Pith}(\mathcal{QC}_{\text{Obj}}) \hookrightarrow \mathcal{QC}_{\text{Obj}} \) is bijective on simplices of dimension \( \leq 1 \) (Remark 5.5.5.2). However, it is not bijective at the level of 2-simplices.

Example 5.6.6.17 (2-Simplices of \( \mathcal{QC}_{\text{Obj}} \)). By virtue of Example 5.6.6.12, a morphism of simplicial sets \( \sigma_0 : \partial \Delta^2 \to \mathcal{QC}_{\text{Obj}} \) can be identified with the following data:

- A collection of \( \infty \)-categories \( \mathcal{C}, \mathcal{D}, \) and \( \mathcal{E} \) equipped with distinguished objects \( C \in \mathcal{C}, \) \( D \in \mathcal{D}, \) and \( E \in \mathcal{E}. \)

- A collection of functors \( F : \mathcal{C} \to \mathcal{D}, \) \( G : \mathcal{D} \to \mathcal{E}, \) and \( H : \mathcal{C} \to \mathcal{E}. \)

- A collection of morphisms \( \alpha : F(C) \to D, \) \( \beta : G(D) \to E, \) and \( \gamma : H(C) \to E \) in the \( \infty \)-categories \( \mathcal{D} \) and \( \mathcal{E}. \)

Unwinding the definitions, we see that extending \( \sigma_0 \) to a 2-simplex \( \sigma \) of \( \mathcal{QC}_{\text{Obj}} \) is equivalent to choosing a natural transformation of functors \( \mu : (G \circ F) \to H \) and a morphism of simplicial sets \( \theta : \square^2 \to \mathcal{E} \) whose restriction to the boundary \( \partial \square^2 \) is indicated in the diagram

\[
\begin{array}{ccc}
(G \circ F)(C) & \xrightarrow{\mu(C)} & H(C) \\
\downarrow G(\alpha) & & \downarrow \gamma \\
G(D) & \xrightarrow{\beta} & E.
\end{array}
\]

Moreover:

- The 2-simplex \( \sigma \) belongs to the image of \( \mathcal{QC}_{\text{Obj}} \hookrightarrow \mathcal{QC}_{\text{Obj}} \) if and only if \( \mu : G \circ F \to H \) is an isomorphism in the functor \( \infty \)-category \( \text{Fun}(C, \mathcal{E}). \)

- The 2-simplex \( \sigma \) belongs to the image of \( \mathcal{QC}_* \hookrightarrow \mathcal{QC}_{\text{Obj}} \) if and only \( \mu, \alpha, \beta, \) and \( \gamma \) are all isomorphisms.

- The 2-simplex \( \sigma \) belongs to the image of \( \text{N}^h_*(\text{QCat}_*) \hookrightarrow \mathcal{QC}_{\text{Obj}} \) if and only if \( \mu, \alpha, \beta, \) and \( \gamma \) are identity morphisms (so that \( H = G \circ F, \) \( D = F(C), \) and \( E = G(D) \)) and the morphism \( \theta : \square^2 \to \mathcal{E} \) is constant.

Variant 5.6.6.18. Let \( \kappa \) be an uncountable cardinal. We let \( \mathcal{QC}_{\text{Obj}}^{<\kappa} \) denote the full simplicial subset of \( \mathcal{QC}_{\text{Obj}} \) spanned by those pairs \( (C, C) \) where the \( \infty \)-category \( \mathcal{C} \) is \( \kappa \)-small, and we define \( \mathcal{QC}_{\text{Obj}}^{<\kappa} = \text{Pith}(\mathcal{QC}_{\text{Obj}}^{<\kappa}) \) similarly. The projection map \( \mathcal{QC}_{\text{Obj}}^{<\kappa} \to \mathcal{QC}^{<\kappa} \) is then cocartesian fibration of \( \infty \)-categories, whose fibers are \( \kappa \)-small.
5.7 Classification of Cocartesian Fibrations

Our goal in this section is to address the following:

**Question 5.7.0.1.** Let $U : E \to C$ be a cocartesian fibration of $\infty$-categories. To what extent can $U$ be recovered from the collection of $\infty$-categories $\{E_C\}_{C \in C}$?

In §5.2.7, we gave an answer to Question 5.7.0.1 under the assumption that $U$ is a left covering map. In this case, the construction $C \mapsto E_C$ determines a functor $h\text{Tr}_{E/C} : hC \to \text{Set}$. Moreover, the $\infty$-category $E$ can be recovered (up to isomorphism) as the fiber product $C \times_{N_\bullet(hC)} h\text{Tr}_{E/C}(hC)$ (Proposition 5.2.7.2), where the second factor denotes the category of elements of the set-valued functor $h\text{Tr}_{E/C}$ (Construction 5.2.6.1).

In the setting of classical category theory, Grothendieck gave a complete answer to Question 5.7.0.1. Let $C$ be an ordinary category, and let $\text{Cat}$ denote the (strict) 2-category of small categories (Example 2.2.0.4), and let $F : C \to \text{Cat}$ be a functor of 2-categories. In §5.7.1, we introduce a category $\int C F$ whose objects are pairs $(C, X)$ where $C$ is an object of $C$ and $X$ is an object of the category $F(C)$. We will refer to $\int C F$ as the category of elements of the functor $F$ (Definition 5.7.1.1). The category $\int C F$ is equipped with a cocartesian fibration $U : \int C F \to C$, given on objects by the construction $(C, X) \mapsto C$. In [20], Grothendieck showed that, up to isomorphism, every cocartesian fibration between (small) categories can be obtained in this way (Corollary 5.7.5.19).

In §5.7.2, we introduce an $\infty$-categorical counterpart of the preceding construction. Let $QC_{\text{Obj}}$ denote the $\infty$-category of Construction 5.6.6.10 whose objects are pairs $(A, X)$ where $A$ is a (small) $\infty$-category and $X$ is an object of $A$. For every morphism of simplicial sets $F : C \to QC$, we let $\int_C F$ denote the fiber product $C \times_{QC} QC_{\text{Obj}}$. By construction, vertices of $\int_C F$ can be identified with pairs $(C, X)$, where $C$ is a vertex of $C$ and $X$ is an object of the $\infty$-category $F(C)$. Projection onto the first factor determines a cocartesian fibration of simplicial sets $U : \int_C F \to C$, given on objects by the construction $(C, X) \mapsto C$ (Proposition 5.7.2.2). In particular, if $C$ is an $\infty$-category, then the simplicial set $\int_C F$ is also an $\infty$-category, which we refer to as the $\infty$-category of elements of $F$ (Definition 5.7.2.4). This construction has the following features:

- Let $C$ be an ordinary category and let $F : C \to \text{Cat}$ be a functor of 2-categories, so that the construction $C \mapsto N_\bullet(F(C))$ determines a functor of $\infty$-categories $N_\bullet(F) : N_\bullet(C) \to QC$. In §5.7.3, we construct a canonical isomorphism of simplicial sets

$$\int_{N_\bullet(C)} N_\bullet(F) \simeq N_\bullet(\int_C F)$$

where the left hand side is the $\infty$-category of elements of the functor $N_\bullet(F)$ and the right hand side is the nerve of the ordinary category of elements of the functor.
(Proposition 5.7.3.4). Consequently, we can view the ∞-category of elements construction as a generalization of the classical category of elements construction.

• Let C be an ordinary category and let \( \mathcal{F} : C \to \text{QCat} \) be a functor of ordinary categories. Passing to the homotopy coherent nerve, we obtain a functor of ∞-categories \( N_{\text{hc}}^\bullet(\mathcal{F}) : N_{\bullet}(C) \to \text{QC} \). In §5.7.4.8 we construct a comparison map

\[
\theta : N_{\bullet}(C) \to \int_{N_{\bullet}(C)} N_{\text{hc}}^\bullet(\mathcal{F})
\]

and show that it is an equivalence of ∞-categories (Proposition 5.7.4.8). In other words, we can think of the ∞-category of elements as a variant of the weighted nerve construction, which can be applied to homotopy coherent diagrams which are not strictly commutative. Beware that \( \theta \) is usually not an isomorphism of simplicial sets.

It is not difficult to show that if diagrams \( \mathcal{F}, \mathcal{F}' : C \to \text{QC} \) are isomorphic (as objects of the ∞-category \( \text{Fun}(C, \text{QC}) \)), then the cocartesian fibrations

\[
\int_{C} \mathcal{F} \to C \quad \int_{C} \mathcal{F}' \to C
\]

are equivalent (see Proposition 5.7.2.19). It follows that the construction \( \mathcal{F} \mapsto \int_{C} \mathcal{F} \) determines a function from the collection of isomorphism classes in the ∞-category \( \text{Fun}(C, \text{QC}) \) to the collection of equivalence classes of cocartesian fibrations over \( C \). We will show that, modulo set-theoretic technicalities, this function is a bijection.

**Theorem 5.7.0.2** (Universality Theorem). Let \( C \) be a simplicial set. Then the construction

\[
(\mathcal{F} : C \to \text{QC}) \mapsto (\int_{C} \mathcal{F} \to C)
\]

induces a bijection from \( \pi_0(\text{Fun}(C, \text{QC})^\sim) \) to the set of equivalence classes of cocartesian fibrations \( U : \mathcal{E} \to C \) having the following property: for every object \( C \in C \), the ∞-category \( \mathcal{E}_C = \{C\} \times_C \mathcal{E} \) is essentially small.

**Warning 5.7.0.3.** In the statement of Theorem 5.7.0.2, the essential smallness assumption cannot be omitted: if the cocartesian fibration \( U : \mathcal{E} \to C \) is equivalent to \( \int_{C} \mathcal{F} \) for some diagram \( \mathcal{F} : C \to \text{QC} \), then each fiber \( \mathcal{E}_C = \{C\} \times_C \mathcal{E} \) is equivalent to the small ∞-category \( \mathcal{F}(C) \) (see Example 5.7.2.18).

**Remark 5.7.0.4.** We can summarize Theorem 5.7.0.2 more informally by saying that the projection map \( V : \text{QCat}_{\text{Obj}} \to \text{QC} \) is universal among cocartesian fibrations having essentially small fibers. Note that this property characterizes the ∞-category \( \text{QC} \) (and the cocartesian fibration \( V \)) up to equivalence.
5.7. CLASSIFICATION OF COCARTESIAN FIBRATIONS

Remark 5.7.0.5. We will later show that the bijection of Theorem 5.7.0.2 can be upgraded to an equivalence of ∞-categories; see Theorem [?].

Corollary 5.7.0.6. Let C be a simplicial set. Then the construction

\[(\mathcal{F} : \mathcal{C} \to \mathcal{S}) \mapsto (\int_{\mathcal{C}} \mathcal{F} \to \mathcal{C})\]

induces a bijection from \(\pi_0(\text{Fun}(\mathcal{C}, \mathcal{S}))\) to the set of equivalence classes of left fibrations \(U : \mathcal{E} \to \mathcal{C}\) having the following property: for every object \(C \in \mathcal{C}\), the Kan complex \(\mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E}\) is essentially small.

Example 5.7.0.7. Let \(\mathcal{C}\) be a small \(\infty\)-category and let \(X\) be an object of \(\mathcal{C}\). It follows from Corollary 5.7.0.6 that there is an essentially unique functor \(h^X : \mathcal{C} \to \mathcal{S}\) for \(\int_{\mathcal{C}} h^X\) is equivalent to \(\mathcal{C}_{X/}\) as left fibrations over \(\mathcal{C}\). We will refer to \(h^X : \mathcal{C} \to \mathcal{S}\) as the functor corepresented by \(X\). For every object \(Y \in \mathcal{C}\), we have isomorphisms

\[h^X(Y) \simeq \{Y\} \times_{\mathcal{C}} h^X \simeq \{Y\} \times_{\mathcal{C}} \mathcal{C}_{X/} = \text{Hom}_{\mathcal{C}}^L(X, Y) \simeq \text{Hom}_{\mathcal{C}}(X, Y)\]

in the homotopy category \(h\text{Kan}\), depending functorially on \(Y\). In §5.7.6, we will show that this property characterizes the functor \(h^X\) up to isomorphism (Theorem 5.7.6.13).

Let \(U : \mathcal{E} \to \mathcal{C}\) be a cocartesian fibration of simplicial sets. We will say that a diagram \(\mathcal{F} : \mathcal{C} \to \mathcal{QC}\) is a covariant transport representation for \(U\) if there exists an equivalence \(\alpha : \mathcal{E} \to \int_{\mathcal{C}} \mathcal{F}\) of cocartesian fibrations over \(\mathcal{C}\) (Definition 5.7.5.1). Theorem 5.7.0.2 asserts that if the cocartesian fibration \(U\) has essentially small fibers, then there exists a covariant transport representation for \(U\), which is uniquely determined up to isomorphism (as an object of the \(\infty\)-category \(\text{Fun}(\mathcal{C}, \mathcal{QC})\)). In fact, we will prove something stronger: the covariant transport representation of \(U\) is unique up to a contractible space of choices. In §5.7.8, we formulate this statement more precisely by introducing a Kan complex \(\text{TW}(\mathcal{E}/\mathcal{C})\) whose vertices are pairs \((\mathcal{F}, \alpha)\) as above (see Notation 5.7.8.1). We prove the contractibility of \(\text{TW}(\mathcal{E}/\mathcal{C})\) in §5.7.9; as we will see, it is a formal consequence of the fact that the homotopy transport representation of the cocartesian fibration \(V : \mathcal{QC}_{\text{Obj}} \to \mathcal{QC}\) determines an equivalence of \(h\text{Kan}\)-enriched categories \(h\text{Tr}_{\mathcal{QC}_{\text{Obj}}/\mathcal{QC}} : h\mathcal{QC} \to h\text{QCat}\) (Proposition 5.6.6.14).

Remark 5.7.0.8. Let \(U : \mathcal{E} \to \mathcal{C}\) be a cocartesian fibration between (small) simplicial sets. We will denote the covariant transport representation of \(U\) by \(\text{Tr}_{\mathcal{E}/\mathcal{C}}\); it can be regarded as a homotopy coherent refinement of the homotopy transport representation \(h\text{Tr}_{\mathcal{E}/\mathcal{C}}\) introduced in Construction 5.2.5.2 (see Remark 5.7.5.8 for a precise statement). We can summarize the situation with the following informal answer to Question 5.7.0.1:
• For every cocartesian fibration between (small) ∞-categories \( U : \mathcal{E} \to \mathcal{C} \), the construction \( C \mapsto \mathcal{E}_C \) determines a functor of ∞-categories \( \text{Tr}_{\mathcal{E}/\mathcal{C}} : \mathcal{C} \to \mathcal{QC} \). Moreover, we can recover \( \mathcal{E} \) (up to equivalence) as the ∞-category of elements \( \int^{\mathcal{C}} \text{Tr}_{\mathcal{E}/\mathcal{C}} \).

Remark 5.7.0.9. In the statement of Theorem 5.7.0.2, it is not necessary to assume that the simplicial set \( \mathcal{C} \) is an ∞-category. This additional generality will play an essential role in our proof (which will require us to analyze the restriction of the cocartesian fibration \( U : \mathcal{E} \to \mathcal{C} \) to simplicial subsets of \( \mathcal{C} \)). Moreover, it has a number of pleasant consequences: since \( \mathcal{QC} \) is an ∞-category, it guarantees that every cocartesian fibration of simplicial sets is equivalent to the pullback of a cocartesian fibration between ∞-categories. In §5.7.7, we use this to prove a sharper statement: every cocartesian fibration of simplicial sets is isomorphic to the pullback of a cocartesian fibration between ∞-categories (Corollary 5.7.7.3). From this, we deduce that every cocartesian fibration of simplicial sets is an isofibration (Corollary 5.7.7.5), and that the collection of categorical equivalences of simplicial sets is stable under the formation of pullback by cocartesian fibrations (Corollary 5.7.7.6).

5.7.1 Elements of Category-Valued Functors

Let \( \mathcal{C} \) be a category and let \( \mathcal{F} : \mathcal{C} \to \text{Set} \) be a functor. In §5.2.6 we introduced the category of elements \( \int_{\mathcal{C}} \mathcal{F} \), whose objects are pairs \((C,x)\) where \( C \) is an object of \( \mathcal{C} \) and \( x \) is an element of the set \( \mathcal{F}(C) \) (Construction 5.2.6.1). In this section, we study a generalization of this construction, where we allow \( \mathcal{F} \) to be a diagram of categories indexed by \( \mathcal{C} \). In this section, we introduce a generalization of this construction, where we allow \( \mathcal{F} \) to be a \( \mathcal{C} \)-indexed diagram of categories (rather than a \( \mathcal{C} \)-indexed diagram of sets). In what follows, we let \( \text{Cat} \) denote the (strict) 2-category of small categories (Example 2.2.0.4).

Definition 5.7.1.1 (The Category of Elements: Covariant Version). Let \( \mathcal{C} \) be a category and let \( \mathcal{F} : \mathcal{C} \to \text{Cat} \) be a functor of 2-categories. We define a category \( \int_{\mathcal{C}} \mathcal{F} \) as follows:

- The objects of \( \int_{\mathcal{C}} \mathcal{F} \) are pairs \((C,X)\), where \( C \) is an object of \( \mathcal{C} \) and \( X \) is an object of the category \( \mathcal{F}(C) \).
- Let \((C,X)\) and \((D,Y)\) be objects of \( \int_{\mathcal{C}} \mathcal{F} \). Then a morphism from \((C,X)\) to \((D,Y)\) in the category \( \int_{\mathcal{C}} \mathcal{F} \) is a pair \((f,u)\), where \( f : C \to D \) is a morphism in the category \( \mathcal{C} \) and \( u : \mathcal{F}(f)(X) \to Y \) is a morphism in the category \( \mathcal{F}(D) \).
- Let \((f,u) : (C,X) \to (D,Y)\) and \((g,v) : (D,Y) \to (E,Z)\) be morphisms in the category \( \int_{\mathcal{C}} \mathcal{F} \). Then the composition \((g,v) \circ (f,u)\) is the pair \((g \circ f,w)\), where \( w : \mathcal{F}(g \circ f)(X) \to Z \) is the morphism of \( \mathcal{F}(E) \) given by the composition

\[
\mathcal{F}(g \circ f)(X) \xrightarrow{\mu_{g,f}^{-1}(X)} (\mathcal{F}(g) \circ \mathcal{F}(f))(X) \xrightarrow{\mathcal{F}(g)(u)} \mathcal{F}(D)(Y) \xrightarrow{v} Z,
\]
where \( \mu_{g,f} : \mathcal{F}(g) \circ \mathcal{F}(f) \simeq \mathcal{F}(g \circ f) \) denotes the composition constraint for the functor \( \mathcal{F} \).

We will refer to \( \int_{\mathcal{C}} \mathcal{F} \) as the category of elements of \( \mathcal{F} \).

**Remark 5.7.1.2.** The category of elements \( \int_{\mathcal{C}} \mathcal{F} \) was originally introduced by Grothendieck in \cite{26}. For this reason, many authors refer to the category \( \int_{\mathcal{C}} \mathcal{F} \) as the Grothendieck construction on the functor \( \mathcal{F} \).

**Proposition 5.7.1.3.** Let \( \mathcal{C} \) be a category and let \( \mathcal{F} : \mathcal{C} \to \text{Cat} \) be a functor of 2-categories. Then the category of elements \( \int_{\mathcal{C}} \mathcal{F} \) is well-defined: that is, the composition law described in Definition 5.7.1.1 is unital and associative.

**Proof.** Let \( (D,Y) \) be an object of \( \int_{\mathcal{C}} \mathcal{F} \). We let \( \text{id}_{(D,Y)} \) denote the morphism from \( (D,Y) \) to itself given by the pair \( (\text{id}_D, \epsilon^{-1}_D(Y)) \), where \( \epsilon_D : \text{id}_{\mathcal{F}(D)} \xrightarrow{\sim} \mathcal{F}(\text{id}_D) \) is the identity constraint for the functor \( \mathcal{F} \). We first show that \( \text{id}_{(D,Y)} \) is a (two-sided) unit for the composition law on \( \int_{\mathcal{C}} \mathcal{F} \). We consider two cases:

- Let \( (C,X) \) be another object of \( \int_{\mathcal{C}} \mathcal{F} \) and let \( (f,u) : (C,X) \to (D,Y) \) be a morphism in \( \int_{\mathcal{C}} \mathcal{F} \). We wish to show that the composition \( \text{id}_{(D,Y)} \circ (f,u) \) is equal to \( (f,u) \) as a morphism from \( (C,X) \) to \( (D,Y) \). Unwinding the definitions, this is equivalent to the assertion that the morphism \( u : \mathcal{F}(f)(X) \to Y \) is equal to the composition

\[
\mathcal{F}(f)(X) \xrightarrow{\mu^{-1}_{\text{id}_D,f}(X)} (\mathcal{F}(\text{id}_D) \circ \mathcal{F}(f))(X) \xrightarrow{\mathcal{F}(\text{id}_D)(u)} \mathcal{F}(\text{id}_D)(Y) \xrightarrow{\epsilon^{-1}_D(Y)} Y.
\]

Using the commutativity of the diagram

\[
\begin{array}{ccc}
\mathcal{F}(f)(X) & \xrightarrow{\epsilon_D(\mathcal{F}(f)(X))} & (\mathcal{F}(\text{id}_D) \circ \mathcal{F}(f))(X) \\
\downarrow \quad \text{u} & & \downarrow \quad \mathcal{F}(\text{id}_D)(u) \\
Y & \xrightarrow{\epsilon_D(Y)} & \mathcal{F}(\text{id}_D)(Y),
\end{array}
\]

we are reduced to showing that the composition

\[
\mathcal{F}(f)(X) \xrightarrow{\mu^{-1}_{\text{id}_D,f}(X)} (\mathcal{F}(\text{id}_D) \circ \mathcal{F}(f))(X) \xrightarrow{\epsilon^{-1}_D(\mathcal{F}(f)(X))} \mathcal{F}(f)(X)
\]

is equal to the identity, which follows from axiom \((a)\) of Definition \[2.2.4.5.\]

- Let \( (E,Z) \) be another object of \( \int_{\mathcal{C}} \mathcal{F} \), and let \( (g,v) : (D,Y) \to (E,Z) \) be a morphism in \( \int_{\mathcal{C}} \mathcal{F} \). We wish to show that the composition \( (g,v) \circ \text{id}_{(D,Y)} \) is equal to \( (g,v) \) (as a
morphism from \((D, Y)\) to \((E, Z)\)). Unwinding the definitions, this is equivalent to the assertion that the morphism \(v : \mathcal{F}(g)(Z) \to Y\) is equal to the composition

\[
\mathcal{F}(g)(Y) \xrightarrow{\mu^{-1}_{g, \text{id}_D}(Y)} \mathcal{F}(g) \circ \mathcal{F}(\text{id}_D))\((Y) \xrightarrow{\mathcal{F}(g)(\epsilon^{-1}_D(Y))} \mathcal{F}(g)(Y) \xrightarrow{v} Z,
\]

which follows from axiom \((b)\) of Definition 2.2.4.5.

We now show that composition of morphisms in \(\int_c \mathcal{F}\) is associative. Suppose we are given a composable sequence

\[
(B, W) \xrightarrow{(e, t)} (C, X) \xrightarrow{(f, u)} (D, Y) \xrightarrow{(g, v)} (E, Z)
\]

of morphisms of \(\int_c \mathcal{F}\). Unwinding the definitions, we obtain equalities

\[
(g, v) \circ ((f, u) \circ (e, t)) = (g \circ f \circ e, v \circ \mathcal{F}(g)(u) \circ w)
\]

\[
((g, v) \circ (f, u)) \circ (e, t) = (g \circ f \circ e, v \circ \mathcal{F}(g)(u) \circ w')
\]

where \(w, w' : \mathcal{F}(g \circ f \circ e)(W) \to (\mathcal{F}(e) \circ \mathcal{F}(f))(X)\) are the morphisms in the category \(\mathcal{F}(E)\) given by clockwise and counterclockwise composition in the diagram

\[
\begin{array}{ccc}
\mathcal{F}(g \circ f \circ e)(W) & \xrightarrow{\mu^{-1}_{g, f, e}(W)} & \mathcal{F}(g) \circ \mathcal{F}(f \circ e))\((W) \\
\sim \downarrow \mu^{-1}_{g, f, e}(W) & & \sim \downarrow \mathcal{F}(g)(\mu^{-1}_{f, e}(W)) \\
\mathcal{F}(g \circ f)(e) \circ \mathcal{F}(e)\((W) & \xrightarrow{\mu^{-1}_{g, f, e}(\mathcal{F}(e)(W))} & \mathcal{F}(g) \circ \mathcal{F}(f \circ e))\((W) \\
\mathcal{F}(g \circ f)(t) & \sim \downarrow & (\mathcal{F}(g) \circ \mathcal{F}(f))(t) \\
\mathcal{F}(g \circ f)(X) & \xrightarrow{\mu^{-1}_{g, f}(X)} & (\mathcal{F}(g) \circ \mathcal{F}(f))(X).
\end{array}
\]

It will therefore suffice to show that this diagram commutes. For the upper square, this follows from axiom \((c)\) of Definition 2.2.4.5. For the lower square, it follows from the naturality of the composition constraint \(\mu_{g, f}\). ☐

Definition 5.7.1.1 has a counterpart for contravariant functors:

**Definition 5.7.1.4 (The Category of Elements: Contravariant Version).** Let \(C\) be a category and let \(\mathcal{F} : C^{\text{op}} \to \text{Cat}\) be a functor of 2-categories (Definition 2.2.4.5). We define a category \(\int^C \mathcal{F}\) as follows:
5.7. CLASSIFICATION OF COCARTESIAN FIBRATIONS

- The objects of \( \int^{C} F \) are pairs \((C, X)\), where \( C \) is an object of \( C \) and \( X \) is an object of the category \( F(C) \).

- Let \((C, X)\) and \((D, Y)\) be objects of \( \int^{C} F \). Then a morphism from \((C, X)\) to \((D, Y)\) in the category \( \int^{C} F \) is a pair \((f, u)\), where \( f : C \to D \) is a morphism in the category \( C \) and \( u : X \to F(f)(Y) \) is a morphism in the category \( F(C) \).

- Let \((f, u) : (C, X) \to (D, Y)\) and \((g, v) : (D, Y) \to (E, Z)\) be morphisms in the category \( \int^{C} F \). Then the composition \((g, v) \circ (f, u)\) is the pair \((g \circ f, w)\), where \( w : X \to F(g \circ f)(Z) \) is the morphism of \( F(C) \) given by the composition

\[
X \xrightarrow{u} F(f)(Y) \xrightarrow{F(f)(v)} (F(g \circ f))(Z) \xrightarrow{\mu_{f,g}(Z)} F(g \circ f)(Z),
\]

where \( \mu_{f,g} : F(f) \circ F(g) \simeq F(g \circ f) \) denotes the composition constraint for the lax functor \( F \).

We will refer to \( \int^{C} F \) as the category of elements of the functor \( F \).

Remark 5.7.1.5. The category of elements \( \int^{C} F \) can be defined more generally when \( F : C^{\text{op}} \to \text{Cat} \) is a lax functor of 2-categories. We will return to this point in §[?] (see Definition [?]).

Remark 5.7.1.6. Let \( C \) be a category and let \( F : C \to \text{Cat} \) be a functor of 2-categories. Then the construction \((C \in C) \mapsto F(C)^{\text{op}}\) determines a functor of 2-categories \( F^{\text{op}} : C = (C^{\text{op}})^{\text{op}} \to \text{Cat} \). In this case, we have a canonical isomorphism of categories

\[
\int^{C^{\text{op}}} F^{\text{op}} \simeq (\int_{C} F)^{\text{op}},
\]

where the left hand side is given by Definition 5.7.1.4 and the right hand side is given by Definition 5.7.1.1.

Example 5.7.1.7 (Set-Valued Functors). Let \( C \) be a category and let \( F : C \to \text{Set} \) be a functor from \( C \) to the category of sets. Then we can also regard \( F \) as a functor from \( C \) to the 2-category \( \text{Cat} \) (by composing with the fully faithful embedding \( \text{Set} \hookrightarrow \text{Cat} \), carrying each set \( S \) to the associated discrete category). In this case, the category \( \int_{C} F \) of Definition 5.7.1.1 agrees with the category of elements of \( F \) defined in Construction 5.2.6.1. Similarly, for every functor \( F : C^{\text{op}} \to \text{Set} \), the category \( \int^{C} F \) can be identified with the category of elements of \( F \) defined in Variant 5.2.6.2.

Example 5.7.1.8. Let \( \text{Cat} \) denote the category whose objects are (small) categories and whose morphisms are functors, and let \( F : C \to \text{Cat} \) be a functor of ordinary categories. Composing with the nerve functor \( N_{\bullet} : \text{Cat} \to \text{Set}_{\Delta} \), we obtain a functor \( F' : C \to \text{Set}_{\Delta} \).
There is a canonical isomorphism of simplicial sets $N_ullet^{\mathcal{F}'}(C) \simeq N_ullet(\int_C \mathcal{F})$, where the left hand side denotes the weighted nerve of Definition 5.3.3.1 and $\int_C \mathcal{F}$ denotes the category of elements introduced in Definition 5.7.1.1.

Example 5.7.1.9. Let $\mathcal{I}$ denote the inclusion from the ordinary category $\text{Cat}$ (regarded as a 2-category having only identity 2-morphisms) to the 2-category $\text{Cat}$, and let $\text{Cat}_{\text{lax}}$ denote the category of elements $\int_{\text{Cat}} \mathcal{I}$. The category $\text{Cat}_{\text{lax}}$ can be described concretely as follows:

- The objects of $\text{Cat}_{\text{lax}}$ are pairs $(C, X)$, where $C$ is a category and $X$ is an object of $C$.
- A morphism from $(C, X)$ to $(D, Y)$ is a pair $(F, u)$, where $F : C \to D$ is a functor and $u : F(X) \to Y$ is a morphism in the category $D$.
- If $(F, u) : (C, X) \to (D, Y)$ and $(G, v) : (D, Y) \to (E, Z)$ are morphisms in $\text{Cat}_{\text{lax}}$, then their composition is the pair $(G \circ F, w)$, where $w$ is the morphism of $E$ given by the composition

  $$(G \circ F)(X) \xrightarrow{G(u)} G(Y) \xrightarrow{v} Z.$$  

Example 5.7.1.10. Let $C$ be a category and let $\mathcal{F} : C \to \text{Cat}$ denote the (strict) functor given on objects by the formula $\mathcal{F}(C) = C/C$. Then the category of elements $\int_C \mathcal{F}$ can be identified with the arrow category $\text{Fun}([1], C)$.

Notation 5.7.1.11. Let $C$ be a category and let $\mathcal{F} : C \to \text{Cat}$ be a functor of 2-categories. Then the category of elements $\int_C \mathcal{F}$ is equipped with a forgetful functor $U : \int_C \mathcal{F} \to C$, given on objects by the construction $(C, X) \mapsto C$ and on morphisms by the construction $(f, u) \mapsto f$. Similarly, for every functor of 2-categories $\mathcal{F} : C^{\text{op}} \to \text{Cat}$, the category of $\int^C \mathcal{F}$ of Definition 5.7.1.4 is equipped with a forgetful functor $U : \int^C \mathcal{F} \to C$.

Remark 5.7.1.12 (Fibers of the Forgetful Functor). Let $C$ be a category and let $\mathcal{F} : C \to \text{Cat}$ be a functor of 2-categories. For every object $C \in C$, there is a canonical isomorphism of categories

$$\mathcal{F}(C) \simeq \{C\} \times_C \int_C \mathcal{F},$$  

which carries each object $X \in \mathcal{F}(C)$ to the object $(C, X) \in \int_C \mathcal{F}$ and each morphism $u : X \to Y$ in $\mathcal{F}$ to the morphism $(\text{id}_C, u \circ \epsilon_C(X)) : (C, X) \to (C, Y)$ of $\int_C \mathcal{F}$ (here $\epsilon_C : \mathcal{F}(\text{id}_C) \simeq \text{id}_{\mathcal{F}(C)}$ denotes the identity constraint on the functor $\mathcal{F}$). Similarly, for each functor $\mathcal{F} : C^{\text{op}} \to \text{Cat}$, we have a canonical isomorphism

$$\mathcal{F}(C) \simeq \{C\} \times^C \int^C \mathcal{F}.$$
Remark 5.7.1.13. Let \( V : D \to C \) be a functor between categories. If \( \mathcal{F} : C \to \text{Cat} \) is a functor of 2-categories, then the composition \( (\mathcal{F} \circ V) : D \to \text{Cat} \) is also a functor of 2-categories, and we have a pullback diagram of categories

\[
\begin{array}{ccc}
\int^D (\mathcal{F} \circ V) & \to & f^C \mathcal{F} \\
\downarrow & & \downarrow \\
D & \to & C
\end{array}
\]

where the vertical maps are the forgetful functors of Notation 5.7.1.11. Similarly, for every functor of 2-categories \( \mathcal{F} : C^{\text{op}} \to \text{Cat} \), we have a pullback diagram

\[
\begin{array}{ccc}
\int^D (\mathcal{F} \circ V^{\text{op}}) & \to & f^C \mathcal{F} \\
\downarrow & & \downarrow \\
D & \to & C.
\end{array}
\]

Example 5.7.1.14. Let \( C \) be a category and let \( \mathcal{F} : C \to \text{Cat} \) be a functor between ordinary categories, which we can identify with a strict functor from \( C \) to the 2-category \( \text{Cat} \). Applying Remark 5.7.1.13, we deduce that the category of elements \( \int^C \mathcal{F} \) fits into a pullback diagram

\[
\begin{array}{ccc}
\int_C \mathcal{F} & \to & \text{Cat}^{\text{lax}} \\
\downarrow & & \downarrow \\
C & \to & \text{Cat}.
\end{array}
\]

Proposition 5.7.1.15. Let \( C \) be a category, let \( \mathcal{F} : C \to \text{Cat} \) be a functor of 2-categories, and let \( U : \int^C \mathcal{F} \to C \) denote the forgetful functor. Then a morphism \( (f,u) : (C,X) \to (D,Y) \) of \( \int^C \mathcal{F} \) is \( U \)-cocartesian if and only if \( u : \mathcal{F}(f)(X) \to Y \) is an isomorphism in the category \( \mathcal{F}(D) \).

Proof. Assume first that \( u \) is an isomorphism; we wish to show that \( (f,u) \) is a \( U \)-cocartesian morphism of the category \( \int_C \mathcal{F} \). Fix a morphism \( q : D \to E \) of \( C \) and an object \( Z \in \mathcal{F}(E) \); we wish to show that every morphism \( (g \circ f,v) : (C,X) \to (E,Z) \) in the category \( \int^C \mathcal{F} \) can be written uniquely as a composition \( (g,v) \circ (f,u) \) for some morphism \( (g,v) : (D,Y) \to (E,Z) \). Unwinding the definitions, we wish to show that there is a unique morphism \( v : \mathcal{F}(g)(Y) \to Z \)
in the category $\mathcal{F}(E)$ for which the composition
\[ \mathcal{F}(g \circ f)(X) \xrightarrow{\mu_{g,f}^{-1}(X)} (\mathcal{F}(g) \circ \mathcal{F}(f))(X) \xrightarrow{\mathcal{F}(g)(u)} \mathcal{F}(g)(Y) \xrightarrow{v} Z \]
is equal to $w$. This is clear, since $\mu_{g,f}^{-1}(X)$ and $\mathcal{F}(g)(u)$ are isomorphisms.

Now suppose that $(f,u)$ is a $U$-cocartesian morphism of the category $\int_C \mathcal{F}$; we wish to show that $u$ is an isomorphism. Let $\iota : \mathcal{F}(D) \to \{D\} \times_C \int_C \mathcal{F}$ be the isomorphism of Remark 5.7.1.12. Then the morphism $(f,u)$ factors as a composition
\[ (C,X) \xrightarrow{(f,\text{id})} (D,\mathcal{F}(f)(X)) \xrightarrow{\iota(u)} (D,Y). \]
The first half of the argument shows that the morphism $(f,\text{id})$ is also $U$-cocartesian, so that $\iota(u)$ is an isomorphism in the fiber $\{D\} \times_C \int_C \mathcal{F}$. Since $\iota$ is an isomorphism of categories, it follows that $u$ is an isomorphism in the category $\mathcal{F}(D)$.

**Corollary 5.7.1.16.** Let $\mathcal{C}$ be a category. If $\mathcal{F} : \mathcal{C} \to \text{Cat}$ is a functor of 2-categories, then the forgetful functor $U : \int_C \mathcal{F} \to \mathcal{C}$ is a cocartesian fibration of categories. If $\mathcal{F} : \mathcal{C}^{\text{op}} \to \text{Cat}$ is a functor of 2-categories, then the forgetful functor $\int^C \mathcal{F} \to \mathcal{C}$ is a cartesian fibration of categories.

**Proof.** We will prove the first assertion; the second follows by a similar argument. Let $(C,X)$ be an object of the category $\int_C \mathcal{F}$ and let $f : C \to D$ be a morphism in $\mathcal{C}$; we wish to show that $f$ can be lifted to a $U$-cocartesian morphism $(f,u) : (C,X) \to (D,Y)$ of $\int_C \mathcal{F}$. This follows immediately from the criterion of Proposition 5.7.1.15 for example, we can take $Y = \mathcal{F}(f)(X)$ and $u$ to be the identity morphism.

**Remark 5.7.1.17.** In §5.7 we will prove a converse to Corollary 5.7.1.16: for every cocartesian fibration of categories $U : \mathcal{E} \to \mathcal{C}$, there exists a functor of 2-categories $\mathcal{F} : \mathcal{C} \to \text{Cat}$ and an isomorphism of categories $\int_C \mathcal{F} \simeq \mathcal{E}$ whose composition with $U$ is the forgetful functor of Notation 5.7.1.11. See Corollary 5.7.5.19.

**Remark 5.7.1.18** (Covariant Transport). Let $\mathcal{C}$ be a category, let $\mathcal{F} : \mathcal{C} \to \text{Cat}$ be a functor of 2-categories, and let $U : \int_C \mathcal{F} \to \mathcal{C}$ be the forgetful functor of Notation 5.7.1.11. For each object $C \in \mathcal{C}$, let
\[ \iota_C : \mathcal{F}(C) \simeq \{C\} \times_C \int_C \mathcal{F} \subseteq \int_C \mathcal{F} \]
be the isomorphism of Remark 5.7.1.12. Note that every morphism $f : C \to D$ in $\mathcal{C}$ determines a natural transformation of functors $\tilde{f} : \iota_C \to \iota_D \circ \mathcal{F}(f)$, which carries an object $X \in \mathcal{F}(C)$ to the $U$-cocartesian morphism $(f,\text{id}) : (C,X) \to (D,\mathcal{F}(f)(X))$. It follows that $\tilde{f}$ identifies $\mathcal{F}(f)$ with the covariant transport functor $f_!$ of Notation 5.2.2.2.
5.7. Elements of QC-Valued Functors

Let QCat denote the ordinary category whose objects are ∞-categories and whose morphisms are functors (Construction 5.6.4.1). To every functor \( \mathcal{F} : \mathcal{C} \to \text{QCat} \), the weighted nerve construction of Definition 5.3.3.1 supplies a cocartesian fibration of ∞-categories \( U : N^\bullet_\mathcal{F}(\mathcal{C}) \to N^\bullet_{\mathcal{C}}(\mathcal{C}) \) (Proposition 5.3.3.15), whose fiber over an object \( C \in \mathcal{C} \) is isomorphic to the ∞-category \( \mathcal{F}(C) \) (Example 5.3.3.8). The utility of this construction is limited by the fact that it applies only to strictly commutative diagrams in QCat: that is, Definition 5.3.3.1 requires \( \mathcal{C} \) to be an ordinary category and \( \mathcal{F} \) to be a functor of ordinary categories. Our goal in this section is to introduce a homotopy coherent variant of the weighted nerve which is associated to any functor of ∞-categories \( \mathcal{F} : \mathcal{C} \to \text{QC} \); here \( \text{QC} \) denotes the ∞-category of ∞-categories introduced in Construction 5.6.4.1.

Definition 5.7.2.1. Let \( \mathcal{C} \) be a simplicial set and let \( \mathcal{F} : \mathcal{C} \to N^\text{hc}\bullet(\text{Set}_\Delta) \) be a morphism of simplicial sets. We let \( \int_\mathcal{C} \mathcal{F} \) denote the fiber product \( \mathcal{C} \times_{N^\text{hc}\bullet(\text{Set}_\Delta)} N^\text{hc}\bullet(\text{Set}_\Delta)_{\Delta^0/} \), so that we have a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
\int_\mathcal{C} \mathcal{F} & \longrightarrow & N^\text{hc}\bullet(\text{Set}_\Delta)_{\Delta^0/} \\
\downarrow U & & \downarrow \\
\mathcal{C} & \underset{\mathcal{F}}{\longrightarrow} & N^\text{hc}\bullet(\text{Set}_\Delta).
\end{array}
\]

We will refer to \( U : \int_\mathcal{C} \mathcal{F} \to \mathcal{C} \) as the projection map.

The simplicial set \( \int_\mathcal{C} \mathcal{F} \) of Definition 5.7.2.1 is defined for an arbitrary morphism \( \mathcal{F} : \mathcal{C} \to N^\bullet_{\text{Set}_\Delta} \). However, we will be primarily interested in the case where \( \mathcal{F} \) takes values in the simplicial subset \( \text{QC} \subseteq N^\text{hc}\bullet(\text{Set}_\Delta) \) introduced in Construction 5.6.4.1.

Proposition 5.7.2.2. Let \( \mathcal{F} : \mathcal{C} \to \text{QC} \) be a morphism of simplicial sets. Then the projection map \( U : \int_\mathcal{C} \mathcal{F} \to \mathcal{C} \) is a cocartesian fibration of simplicial sets.

Proof. By construction, the morphism \( U \) fits into a pullback diagram

\[
\begin{array}{ccc}
\int_\mathcal{C} \mathcal{F} & \longrightarrow & \text{QC}_{\text{Obj}} \\
\downarrow U & & \downarrow \\
\mathcal{C} & \underset{\mathcal{F}}{\longrightarrow} & \text{QC},
\end{array}
\]

where

\( \text{QC}_{\text{Obj}} = \text{QC} \times_{N^\text{hc}\bullet(\text{Set}_\Delta)} N^\text{hc}\bullet(\text{Set}_\Delta)_{\Delta^0/} \).
is the ∞-category introduced in Construction 5.6.6.10. It will therefore suffice to show that the projection map \( QC_{\text{Obj}} \to QC \) is a cocartesian fibration of simplicial sets, which follows from Proposition 5.6.6.11.

**Corollary 5.7.2.3.** Let \( \mathcal{F} : C \to QC \) be a functor of ∞-categories. Then the simplicial set \( \int_C \mathcal{F} \) of Definition 5.7.2.1 is an ∞-category.

**Definition 5.7.2.4.** Let \( \mathcal{F} : C \to QC \) be a functor of ∞-categories. We will refer to \( \int_C \mathcal{F} \) as the ∞-category of elements of \( \mathcal{F} \).

**Remark 5.7.2.5.** Let \( C \) be an ordinary category equipped with a strictly unitary functor of 2-categories \( \mathcal{F} : C \to \text{Cat} \). Then the construction \( C \mapsto N_\bullet(\mathcal{F}(C)) \) determines a functor of ∞-categories \( N_\bullet(\mathcal{F}) : N_\bullet(C) \to QC \) (see Remark 5.6.4.9). In §5.7.3, we will construct a canonical isomorphism

\[
\int_{N_\bullet(C)} N_\bullet(\mathcal{F}) \simeq N_\bullet(\int_C \mathcal{F}),
\]

where the simplicial set on the left hand side is given by Definition 5.7.2.1 and \( \int_C \mathcal{F} \) is the category of elements introduced in Definition 5.7.1.1 (see Proposition 5.7.3.4). Stated more informally, we can regard the ∞-category of elements construction (Definition 5.7.2.4) as a generalization of the classical category of elements construction (Definition 5.7.1.1).

**Warning 5.7.2.6.** In §5.7.1, we introduced a variant of the category of elements construction for contravariant \( \text{Cat} \)-valued functors \( \mathcal{F} : C^{\text{op}} \to \text{Cat} \) (see Definition 5.7.1.4), which is characterized by the formula

\[
\int^C \mathcal{F} = (\int^C \mathcal{F}^{\text{op}})^{\text{op}}.
\]

In the ∞-categorical setting, the situation is more subtle: the involution \( \mathcal{E} \mapsto \mathcal{E}^{\text{op}} \) does not preserve the simplicial structure on the category QC and therefore does not induce an involution on the simplicial set \( QC = N_{\text{hc}}(\text{QC}) \). We will return to this point in §[?].

**Warning 5.7.2.7.** Let \( \mathcal{F} : C \to QC \) be a functor of ordinary categories. Passing to the homotopy coherent nerve, we obtain a functor of ∞-categories \( N_{\text{hc}}(\mathcal{F}) : N_\bullet(C) \to QC \). Beware that the simplicial set \( \int_{N_\bullet(C)} N_{\text{hc}}(\mathcal{F}) \) is usually not isomorphic to the weighted nerve \( N_\bullet(\mathcal{F}) \) of Definition 5.3.3.1 even in the special case \( C = \Delta^0 \). However, in §5.7.4 we will construct a comparison map

\[
N_\bullet(\mathcal{F}) \to \int_{N_\bullet(C)} N_{\text{hc}}(\mathcal{F})
\]

which is an equivalence of ∞-categories (Proposition 5.7.4.8).

**Example 5.7.2.8 (Set-Valued Functors).** Let Set denote the category of sets, and let us regard the nerve \( N_\bullet(\text{Set}) \) as a simplicial subset of the homotopy coherent nerve \( N_{\text{hc}}(\text{Set}_\Delta) \).
Let $F : C \to N\bullet(\text{Set})$ be a morphism of simplicial sets, which we can identify with a functor of categories $hF : hC \to \text{Set}$. Using Example 5.6.3.12 and Remark 5.2.6.6 we obtain a canonical isomorphism of simplicial sets

$$\int^C F \simeq C \times_{N\bullet(hC)} N\bullet(\int hC hF),$$

where $\int^C F$ is the simplicial set of Definition 5.7.2.1 and $\int hC hF$ is the category of elements introduced in Construction 5.2.6.1. In particular, the projection map $f_C F \to C$ is a left covering map.

**Example 5.7.2.9** ($\mathcal{S}$-Valued Functors). Let $\mathcal{S}$ denote the $\infty$-category of spaces (Construction 5.6.1.1), which we view as a full simplicial subset of $N^\bullet_{hc}(\text{Set}_\Delta)$, and let $F : C \to \mathcal{S}$ be a morphism of simplicial sets. Then the simplicial set $f_C F$ fits into pullback diagram

$$f_C F \hookrightarrow \mathcal{S}_* \quad \xrightarrow{\pi} \quad C \xrightarrow{F} \mathcal{S},$$

where $\mathcal{S}_*$ is the $\infty$-category of pointed spaces (Construction 5.6.3.1). In this case, Proposition 5.6.3.2 guarantees that the projection map $\pi : f_C F \to C$ is a left fibration of simplicial sets.

**Example 5.7.2.10** ($\mathcal{QC}$-Valued Functors). Let $\mathcal{QC}$ denote the $(\infty,2)$-category of $\infty$-categories (Construction 5.6.5.1), which we view as a full simplicial subset of $N^\bullet_{hc}(\text{Set}_\Delta)$, and let $F : C \to \mathcal{QC}$ be a morphism of simplicial sets. We then have a pullback diagram of simplicial sets

$$f_C F \hookrightarrow \mathcal{QC}_{\text{Obj}} \quad \xrightarrow{\pi} \quad C \xrightarrow{F} \mathcal{QC},$$

where $\mathcal{QC}_{\text{Obj}}$ is the $(\infty,2)$-category of Construction 5.6.6.10 (Construction 5.6.6.8). If $F : C \to \mathcal{QC}$ is a functor of $(\infty,2)$-categories, then Proposition 5.6.6.9 and Remark 5.5.2.4 guarantee that $\pi : f_C F$ is an interior fibration; in particular, $f_C F$ is also an $(\infty,2)$-category.

**Warning 5.7.2.11.** Let $C$ be an $(\infty,2)$-category and let $F : C \to \mathcal{QC}$ be a morphism of simplicial sets. If $F$ is not a functor, then $f_C F$ need not be an $(\infty,2)$-category (this phenomenon arises already in the case $C = \Delta^2$).
Example 5.7.2.12 (Objects of the ∞-Category of Elements). Let \( \mathcal{F} : \mathcal{C} \to \mathrm{N}^\infty_{\bullet}(\Delta) \) be a morphism of simplicial sets. Then vertices of the simplicial set \( \int_{\mathcal{C}} \mathcal{F} \) can be identified with pairs (\( C, X \)), where \( C \) is a vertex of \( \mathcal{C} \) and \( X \) is a vertex of the simplicial set \( \mathcal{F}(C) \) (see Example 5.6.6.12). Moreover, the projection map \( U : \int_{\mathcal{C}} \mathcal{F} \to \mathcal{C} \) is given on vertices by the construction \( U(C, X) = C \).

Example 5.7.2.13 (Morphisms of the ∞-Category of Elements). Let \( \mathcal{F} : \mathcal{C} \to \mathrm{N}^\infty_{\bullet}(\Delta) \) be a morphism of simplicial sets. Let (\( C, X \)) and (\( D, Y \)) be vertices of the simplicial set \( \int_{\mathcal{C}} \mathcal{F} \). Edges of \( \int_{\mathcal{C}} \mathcal{F} \) from (\( C, X \)) to (\( D, Y \)) can be identified with pairs (\( f, u \)), where \( f : C \to D \) is an edge of the simplicial set \( \mathcal{C} \) and \( u : \mathcal{F}(f)(X) \to Y \) is an edge of the simplicial set \( \mathcal{F}(D) \) (see Example 5.6.6.12). Moreover, the projection map \( U : \int_{\mathcal{C}} \mathcal{F} \to \mathcal{C} \) is given on edges by the construction \( U(f, u) = f \).

Remark 5.7.2.14 (Cocartesian Morphisms of the ∞-Category of Elements). Let \( \mathcal{F} : \mathcal{C} \to \mathrm{Q} \) be a morphism of simplicial sets, so that the projection map \( U : \int_{\mathcal{C}} \mathcal{F} \to \mathcal{C} \) is a cocartesian fibration of simplicial sets (Proposition 5.7.2.2). Then an edge (\( f, u \)) : (\( C, X \)) \to (\( D, Y \)) of \( \int_{\mathcal{C}} \mathcal{F} \) is \( U \)-cocartesian if and only if \( u : \mathcal{F}(f)(X) \to Y \) is an isomorphism in the ∞-category \( \mathcal{F}(D) \) (see Example 5.6.6.12).

Example 5.7.2.15 (2-Simplices of the ∞-Category of Elements). Let \( \mathcal{F} : \mathcal{C} \to \mathrm{N}^\infty_{\bullet}(\Delta) \) be a morphism of simplicial sets and let \( \sigma_0 : \partial \Delta^2 \to \int_{\mathcal{C}} \mathcal{F} \) be a morphism of simplicial sets, which we depict informally as a diagram

\[
\begin{array}{ccc}
(D, Y) & \xrightarrow{(f, u)} & (E, Z) \\
\downarrow{(g, v)} & & \downarrow{(h, w)} \\
(C, X) & \xrightarrow{(h, w)} & (E, Z).
\end{array}
\]

Extensions of \( \sigma_0 \) to a 2-simplex of \( \int_{\mathcal{C}} \mathcal{F} \) can be identified with pairs (\( \mu, \theta \)), where \( \mu : \mathcal{F}(g) \circ \mathcal{F}(f) \to \mathcal{F}(h) \) is an edge of the simplicial set \( \mathrm{Fun}(\mathcal{F}(C), \mathcal{F}(E)) \), and \( \theta : \partial \Delta^2 \to \mathcal{F}(E) \) is a morphism of simplicial sets whose restriction to the boundary \( \partial \Delta^2 \) is indicated in the diagram

\[
\begin{array}{ccc}
(\mathcal{F}(g) \circ \mathcal{F}(f))(X) & \xrightarrow{\mu(X)} & \mathcal{F}(h)(X) \\
\downarrow{\mathcal{F}(g)(u)} & & \downarrow{w} \\
\mathcal{F}(g)(Y) & \xrightarrow{v} & Z
\end{array}
\]

(see Example 5.6.6.17). Moreover, the projection map \( U : \int_{\mathcal{C}} \mathcal{F} \to \mathcal{C} \) is given on 2-simplices by the construction \( U(\mu, \theta) = \mu \).
Example 5.7.2.16. Let $\mathcal{E}$ be a simplicial set, which we identify with the morphism of simplicial sets $\Delta^0 \to N_\bullet^{hc}(\text{Set}_\Delta)$ taking the value $\mathcal{E}$. Then the simplicial set $\int_{\Delta^0} \mathcal{E}$ can be identified with the left-pinched morphism space $\text{Hom}_{N_\bullet^{hc}(\text{Set}_\Delta)}^L(\Delta^0, \mathcal{E})$. In particular, Construction 4.6.7.3 supplies a comparison morphism

$$\theta_{\mathcal{E}} : \mathcal{E} = \text{Hom}_{\text{Set}_\Delta}(\Delta^0, \mathcal{E}) \to \text{Hom}_{N_\bullet^{hc}(\text{Set}_\Delta)}^L(\Delta^0, \mathcal{E}) = \int_{\Delta^0} \mathcal{E}.$$ 

If $\mathcal{E}$ is an $\infty$-category, then $\text{Hom}_{N_\bullet^{hc}(\text{Set}_\Delta)}^L(\Delta^0, \mathcal{E})$ is also an $\infty$-category, and the comparison morphism $\rho$ is an equivalence of $\infty$-categories (Theorem 4.6.7.9). Beware that $\theta_{\mathcal{E}}$ is generally not an isomorphism (though it is always a monomorphism which is bijective on simplices of dimension $\leq 1$). For example, Example 5.7.2.15 implies that 2-simplices of $\int_{\Delta^0} \mathcal{E}$ can be identified with morphisms of simplicial sets $\rho : \Delta^1 \times \Delta^1 \to \mathcal{E}$ for which the restriction $\rho|_{\Delta^1 \times \{0\}}$ is a degenerate edge of $\mathcal{E}$, as indicated in the diagram

\[
\begin{array}{ccc}
X & \xrightarrow{id_X} & X \\
\downarrow \sigma & & \downarrow \sigma \\
Y & \underset{\tau}{\xrightarrow{}} & Z.
\end{array}
\]

The corresponding 2-simplex of $\int_{\Delta^0} \mathcal{E}$ belongs to the image of $\theta_{\mathcal{E}}$ if and only if $\sigma$ is a left-degenerate 2-simplex of $\mathcal{E}$ (in which case it is given by $\theta_{\mathcal{E}}(\tau)$).

Remark 5.7.2.17. Let $U : C' \to C$ and $\mathcal{F} : C \to N_\bullet^{hc}(\text{Set}_\Delta)$ be morphisms of simplicial sets, and let $\mathcal{F}'$ denote the composition $(\mathcal{F}' \circ U) : C' \to N_\bullet^{hc}(\text{Set}_\Delta)$. Then the simplicial set $\int_C \mathcal{F}'$ can be identified with the fiber product $C' \times_C \int_C \mathcal{F}$.

Example 5.7.2.18 (Fibers of the $\infty$-Category of Elements). Let $\mathcal{F} : C \to QC$ be a morphism of simplicial sets. For each vertex $C \in C$, Remark 5.7.2.17 and Example 5.7.2.16 supply a canonical isomorphism

$${\{C\}} \times_C \int_C \mathcal{F} \simeq \text{Hom}_{QC}^L(\Delta^0, \mathcal{F}(C)).$$

In particular, Construction 4.6.7.3 supplies a comparison functor $\theta_C : \mathcal{F}(C) \to {\{C\}} \times_C \int_C \mathcal{F}$ which is an equivalence of $\infty$-categories (Theorem 4.6.7.9), but generally not an isomorphism of simplicial sets.

Proposition 5.7.2.19. Let $C$ be a simplicial set, let $\mathcal{F}, \mathcal{F}' : C \to QC$ be diagrams, and let $U : \int_C \mathcal{F} \to C$ and $U' : \int_C \mathcal{F}' \to C$ be the projection maps. If $\mathcal{F}$ and $\mathcal{F}'$ are isomorphic as objects of the diagram $\infty$-category $\text{Fun}(C, QC)$, then $U$ and $U'$ are equivalent as cocartesian fibrations over $C$ (in the sense of Definition 5.1.6.1).
Proof. Apply Proposition 5.1.6.10 to the cocartesian fibration $\mathcal{QC}_{\text{Obj}} \to \mathcal{QC}$ of Proposition 5.6.6.11. □

**Proposition 5.7.2.20.** Let $\mathcal{F} : \mathcal{C} \to \mathcal{QC}$ be a functor of ∞-categories, let $\mathcal{E} = \int_{\mathcal{C}} \mathcal{F}$ denote the ∞-category of elements of $\mathcal{F}$, and let

$$h\text{Tr}_{\mathcal{E}/\mathcal{C}} : h\mathcal{C} \to h\mathcal{QC}$$

denote the enriched homotopy transport representation associated to the cocartesian fibration $U : \mathcal{E} \to \mathcal{C}$ (see Construction 5.2.8.9). Then there is a canonical isomorphism of hKan-enriched functors $\theta : h\mathcal{F} \to h\text{Tr}_{\mathcal{E}/\mathcal{C}}$, which carries each object $C \in \mathcal{C}$ to the comparison map

$$\theta_C : \mathcal{F}(C) \to h\text{Tr}_{\mathcal{E}/\mathcal{C}}(C) = \{C\} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathcal{F}$$

of Example 5.7.2.18.

Proof. By virtue of Remarks 5.2.8.10 and 5.7.2.17 we may assume without loss of generality that $\mathcal{C} = \mathcal{QC}$ and that $\mathcal{F}$ is the identity functor. In this case, the desired result is a restatement of Proposition 5.6.6.14. □

**Corollary 5.7.2.21.** Let $\mathcal{F} : \mathcal{C} \to \mathcal{QC}$ be a morphism of simplicial sets, let $U : \int_{\mathcal{C}} \mathcal{F} \to \mathcal{C}$ be the cocartesian fibration of Proposition 5.7.2.2, and let

$$f! : \{C\} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathcal{F} \to \{D\} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathcal{F}$$

be a functor which is given by covariant transport along an edge $f : C \to D$ of $\mathcal{C}$ (Definition 5.2.2.4). Then the diagram

$$\begin{array}{ccc}
\mathcal{F}(C) & \xrightarrow{\sim} & \{C\} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathcal{F} \\
|\mathcal{F}(f)| & \downarrow & |f| \\
\mathcal{F}(D) & \xrightarrow{\sim} & \{D\} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathcal{F}
\end{array}$$

commutes in the homotopy category $h\mathcal{QC}$ (where the horizontal maps are the equivalences described in Example 5.7.2.18).

Proof. Without loss of generality, we may assume that $\mathcal{C} = \Delta^1$, in which case the desired result reduces to Proposition 5.7.2.20. □
5.7. CLASSIFICATION OF COCARTESIAN FIBRATIONS

Corollary 5.7.2.22. Let $\mathcal{F} : \mathcal{C} \to \mathcal{QC}$ be a functor of $\infty$-categories and set $\mathcal{E} = \int_{\mathcal{C}} \mathcal{F}$. Then there is a canonical isomorphism $h_{\mathcal{E}} \cong h_{\operatorname{Tr}} /\mathcal{C}$ in the functor category $\operatorname{Fun}(h\mathcal{C}, h\mathcal{QC})$, which carries each vertex $C \in \mathcal{C}$ to the comparison map

$$\theta_C : \mathcal{F}(C) \to h_{\operatorname{Tr}} /\mathcal{C}(C) = \{C\} \times_{\int_{\mathcal{C}}} \mathcal{F}$$

of Example 5.7.2.18.

5.7.3 Comparison with the Category of Elements

Let $\mathsf{Cat}$ denote the 2-category of small categories (Example 2.2.0.4) and let $\mathcal{QC}$ denote the $(\infty,2)$-category of small $\infty$-categories (Construction 5.6.5.1). Suppose we are given a category $\mathcal{C}$ equipped with a functor $\mathcal{F} : N_{\bullet}(\mathcal{C}) \to \mathcal{QC}$. Composing with the functor $\mathcal{QC} \to N_{\bullet}(\mathsf{Cat})$ of Remark 5.6.5.8 and invoking Corollary 2.3.4.5, we obtain a (strictly unitary) functor of 2-categories $h\mathcal{F} : \mathcal{C} \to \mathsf{Cat}$, which carries each object $C \in \mathcal{C}$ to the homotopy category of the $\infty$-category $\mathcal{F}(C)$. Our goal in this section is to compare the $\infty$-category $\int_{N_{\bullet}(\mathcal{C})} \mathcal{F}$ of Definition 5.7.2.1 with the ordinary category $\int_{\mathcal{C}} h\mathcal{F}$ of Definition 5.7.1.1. We begin with two simple observations:

- Objects of the $\infty$-category $\int_{N_{\bullet}(\mathcal{C})} \mathcal{F}$ can be identified with pairs $(C, X)$, where $C$ is an object of $\mathcal{C}$ and $X$ is an object of the $\infty$-category $\mathcal{F}(C)$ (Example 5.7.2.12). Since the $\infty$-category $\mathcal{F}(C)$ and its homotopy category $h\mathcal{F}(C)$ have the same objects, we can also identify such pairs with objects of the ordinary category $\int_{\mathcal{C}} h\mathcal{F}$.

- Let $(C, X)$ and $(D, Y)$ be objects of the $\infty$-category $\int_{N_{\bullet}(\mathcal{C})} \mathcal{F}$. By definition, morphisms from $(C, X)$ to $(D, Y)$ in the $\infty$-category $\int_{N_{\bullet}(\mathcal{C})} \mathcal{F}$ can be identified with pairs $(f, u)$, where $f : C \to D$ is a morphism in the category $\mathcal{C}$ and $u : \mathcal{F}(f)(X) \to Y$ is a morphism in the $\infty$-category $\mathcal{F}(D)$ (Example 5.7.2.13). Every such pair determines a morphism $(f, [u])$ in the ordinary category $\int_{\mathcal{C}} h\mathcal{F}$, where $[u]$ denotes the homotopy class of $u$ (regarded as a morphism in the homotopy category $h\mathcal{F}(D)$).

Proposition 5.7.3.1. Let $\mathcal{C}$ be a category and let $\mathcal{F} : N_{\bullet}(\mathcal{C}) \to \mathcal{QC}$ be a functor of $\infty$-categories. Then there is a unique functor of $\infty$-categories

$$T : \int_{N_{\bullet}(\mathcal{C})} \mathcal{F} \to N_{\bullet}(\int_{\mathcal{C}} h\mathcal{F})$$

which is the identity on objects and which carries each morphism $(f, u)$ of $\int_{N_{\bullet}(\mathcal{C})} \mathcal{F}$ to the pair $(f, [u])$, regarded as a morphism in the ordinary category $\int_{\mathcal{C}} h\mathcal{F}$. Moreover, the functor $T$ exhibits the classical category of elements $\int_{\mathcal{C}} h\mathcal{F}$ as the homotopy category of the $\infty$-category of elements $\int_{N_{\bullet}(\mathcal{C})} \mathcal{F}$. 
Stated more informally, Proposition 5.7.3.1 asserts that there is a canonical isomorphism of categories

\[ h \int_{N^\bullet(C)} F \cong \int_C hF. \]

In other words, passage to the homotopy category intertwines the classical category of elements construction (Definition 5.7.1.1) with the \(\infty\)-category of elements construction introduced in §5.7.2.

**Proof of Proposition 5.7.3.1.** We first prove the existence of the functor \(T\) appearing in the statement of Proposition 5.7.3.1 (the uniqueness is immediate). Since the induced functor of 2-categories \(hF : C \to \text{Cat}\) is strictly unitary, the construction \((f, u) \mapsto (f, [u])\) carries degenerate edges of the \(\infty\)-category \(\int_{N^\bullet(C)} F\) to identity morphisms in the category \(\int_C hF\). It will therefore suffice to show that, for every 2-simplex \(\sigma\) of the simplicial set \(\int N^\bullet(C) F\) whose boundary is indicated in the diagram

\[
\begin{array}{ccc}
(D, Y) & \rightarrow & (E, Z) \\
\downarrow^{(f, u)} & & \downarrow^{(f, [u])} \\
(C, X) & \rightarrow & (E, Z), \quad \downarrow^{(h, w)} \\
\end{array}
\]

we have an identity \((h, [w]) = (g, [v]) \circ (f, [u])\) in the category \(\int_C F\). Note that the functor \(F\) determines a natural isomorphism \(\mu : F(g) \circ F(f) \cong F(h)\) in the \(\infty\)-category \(\text{Fun}(F(C), F(E))\). Unwinding the definitions, we see that the composition \((g, [v]) \circ (f, [u])\) is equal to \((h, [v] \circ [F(f)(u)] \circ [\mu(X)]^{-1})\). We are therefore reduced to proving the commutativity of the diagram

\[
\begin{array}{ccc}
(F(g) \circ F(f))(X) & \rightarrow & (F(h)(X) \\
\downarrow^{[F(u)]} & & \downarrow^{[\mu(X)]} \\
F(g)(Y) & \rightarrow & Z \\
\downarrow^{[v]} & & \downarrow^{[v]} \\
F(g)(Y) & \rightarrow & Z \\
\end{array}
\]

in the homotopy category \(hF(Z)\). This commutativity is witnessed by the existence of a diagram

\[
\begin{array}{ccc}
(F(g) \circ F(f))(X) & \rightarrow & (F(h)(X) \\
\downarrow^{F(u)} & & \downarrow^{w} \\
F(g)(Y) & \rightarrow & Z \\
\end{array}
\]
5.7. CLASSIFICATION OF COCARTESIAN FIBRATIONS

in the ∞-category \( \mathcal{F}(Z) \) itself, which is supplied by the datum of the 2-simplex \( \sigma \) (see Example 5.7.2.15). This completes the construction of the functor \( T \).

It follows immediately from the definitions that the functor \( T \) is bijective at the level of objects and that, for every pair of objects \((C, X)\) and \((D, Y)\), the induced map

\[
\theta : \pi_0(\text{Hom}_{\int \Delta \mathcal{F}}((C, X), (D, Y))) \to \text{Hom}_{\int \Delta \mathcal{F}}((C, X), (D, Y))
\]

is surjective. To complete the proof, we must show that \( \theta \) is also injective. Fix a pair of morphisms \((f, u) : (C, X) \to (D, Y)\) and \((f', u') : (C, X) \to (D, Y)\) in the ∞-category \( \int \Delta \mathcal{F} \) having the same image under \( T \), so that \( f = f' \) as elements of \( \text{Hom}_C(C, D) \) and the morphisms \( u, u' : \mathcal{F}(f)(X) \to Y \) are homotopic in the ∞-category \( \mathcal{F}(D) \). By virtue of Corollary 1.3.3.7, there exists a morphism of simplicial sets \( \theta : \square^2 \to \mathcal{F}(D) \) whose restriction to the boundary \( \partial \square^2 \) is indicated in the diagram

\[
\begin{array}{ccc}
\mathcal{F}(f)(X) & \xrightarrow{id} & \mathcal{F}(f)(X) \\
\downarrow u & & \downarrow u' \\
Y & \xrightarrow{id} & Y.
\end{array}
\]

By virtue of Example 5.7.2.15, \( \theta \) determines a 2-simplex of the ∞-category \( \int \Delta \mathcal{F} \) whose boundary is indicated in the diagram

\[
\begin{array}{ccc}
(D, Y) & \xleftarrow{(f, u)} & (C, X) \\
\downarrow (f', u') & & \downarrow (\text{id}_D, \text{id}_Y) \\
(D, Y), & &
\end{array}
\]

which we can regard as a homotopy from \((f, u)\) to \((f', u')\).

In the statement of Proposition 5.7.3.1, it is essential that the source of the functor \( \mathcal{F} \) is (the nerve of) an ordinary category. For a more general functor of ∞-categories \( \mathcal{F} : \mathcal{C} \to \mathcal{Q}\mathcal{C} \), one cannot expect to obtain the homotopy category of \( \int \Delta \mathcal{F} \) from the construction of Definition 5.7.1.1, because the forgetful functor \( h\int \Delta \mathcal{F} \to h\mathcal{C} \) need not be a cocartesian fibration. However, this difficulty does not arise in the case where \( \mathcal{F} \) is a set-valued functor:

**Proposition 5.7.3.2.** Let \( \mathcal{C} \) be a simplicial set equipped with a morphism \( \mathcal{F} : \mathcal{C} \to \Delta^\bullet \text{Set} \), which we can identify with a functor \( h\mathcal{F} : h\mathcal{C} \to \text{Set} \). Then the isomorphism of simplicial sets

\[
\int \mathcal{F} \simeq \mathcal{C} \times_{\Delta^\bullet \text{Set}} \Delta^\bullet (\int h\mathcal{F})
\]

0275
of Example 5.7.2.8 induces an isomorphism of categories

\[ h \int_c \mathcal{F} \to \int_{hC} h\mathcal{F}. \]

**Proof.** Using Proposition 4.1.3.2, we can factor the unit map \( C \to \mathbb{N}_\bullet(hC) \) as a composition

\[ C \xrightarrow{F} C' \xrightarrow{G} \mathbb{N}_\bullet(hC) \]

where \( F \) is inner anodyne and \( G \) is an inner fibration of simplicial sets (so that \( C' \) is an \( \infty \)-category). It follows that \( \mathcal{F} \) extends uniquely to a morphism \( \mathcal{F}' : C' \to \mathbb{N}_\bullet(\text{Set}) \). Using Remark 5.7.2.17, we obtain a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
\int_c \mathcal{F} & \xrightarrow{\widetilde{F}} & \int_{C'} \mathcal{F}' \\
\downarrow U & & \downarrow \\
C & \xrightarrow{F} & C',
\end{array}
\]

where the vertical maps are cocartesian fibrations (Proposition 5.7.2.2). Since \( F \) is inner anodyne, the map \( \widetilde{F} \) is a categorical equivalence of simplicial sets (Proposition 5.3.6.1). Moreover, since \( F \) is bijective at the level of vertices, \( \widetilde{F} \) is also bijective at the level of vertices. It follows that \( F \) and \( \widetilde{F} \) induce isomorphisms of homotopy categories

\[ hF : hC \to hC' \quad h\widetilde{F} : h\int_c \mathcal{F} \to h\int_{C'} \mathcal{F}'. \]

Replacing \( C \) by \( C' \), we are reduced to proving Proposition 5.7.3.2 in the special case where \( C \) is an \( \infty \)-category.

Let \( D \) be the category of elements \( \int_{hC} h\mathcal{F} \), so that Example 5.7.2.8 supplies a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
\int_c \mathcal{F} & \xrightarrow{G} & \mathbb{N}_\bullet(D) \\
\downarrow U & & \downarrow \\
C & \xrightarrow{\mathcal{G}} & \mathbb{N}_\bullet(hC).
\end{array}
\]

We wish to show that \( G \) exhibits \( D \) as a homotopy category of the \( \infty \)-category \( \int_c \mathcal{F} \). Note that, since \( \mathcal{G} \) is bijective at the level of vertices, the functor \( G \) has the same property. It will therefore suffice to show that, for every pair of objects \( X, Y \in \int_c \mathcal{F} \), the induced map

\[ \theta_{X,Y} : \text{Hom}_{\int_c \mathcal{F}}(X, Y) \to \text{Hom}_D(G(X), G(Y)) \]
exhibits \( \text{Hom}_D(G(X), G(Y)) \) as the set of connected components of the Kan complex \( \text{Hom}_{\mathcal{C}}(X, Y) \). Equivalently, we wish to show that each fiber of the map \( \theta_{X,Y} \) is a connected (and therefore nonempty) Kan complex. This is clear, since \( \theta_{X,Y} \) is a pullback of the map

\[
\bar{\theta}_{X,Y} : \text{Hom}_C(U(X), U(Y)) \to \pi_0(\text{Hom}_C(U(X), U(Y))) = \text{Hom}_{hC}(U(X), U(Y)),
\]
whose fibers are the connected components of \( \text{Hom}_C(U(X), U(Y)) \).

\[\textbf{Corollary 5.7.3.3.} \text{ Let } U : \mathcal{E} \to \mathcal{C} \text{ be a morphism of simplicial sets. Then } U \text{ is a left covering map (in the sense of Definition 4.2.3.8) if and only if the following pair of conditions is satisfied: }
\]

1. The induced map \( hU : h\mathcal{E} \to h\mathcal{C} \) is a left covering functor (in the sense of Definition 4.2.3.1).

2. The diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{U} & h\mathcal{E} \\
\downarrow & & \downarrow
\\
\mathcal{C} & \xrightarrow{hU} & h\mathcal{C}
\end{array}
\]

is a pullback square.

\[\text{Proof.} \text{ The sufficiency of conditions (1) and (2) follows from Proposition 4.2.3.16 and Remark 4.2.3.15. To prove the converse, assume that } U \text{ is a left covering map. By virtue of Corollary 5.2.7.4, we may assume that } \mathcal{E} = \int_{\mathcal{C}} \mathcal{F} \text{ for some morphism of simplicial sets } \mathcal{F} : \mathcal{C} \to \mathcal{N}(\text{Set}). \text{ Let us abuse notation by identifying } \mathcal{F} \text{ with a functor from the homotopy category } h\mathcal{C} \text{ to the category of sets. Using Proposition 5.7.3.2, we can identify } h\mathcal{E} \text{ with the category of elements } \int_{h\mathcal{C}} \mathcal{F} \text{ of Construction 5.2.6.1. Condition (1) now follows from Remark 5.2.6.9 and condition (2) by combining Example 5.7.2.8 with Remark 5.7.2.17.} \]

We now consider a variant of the situation described in Proposition 5.7.3.1. Let \( \mathcal{C} \) be an ordinary category and suppose we are given a strictly unitary functor of 2-categories \( \mathcal{F} : \mathcal{C} \to \textbf{Cat} \). Passing to the Duskin nerve (and using Remark 5.6.5.7 to identify \( \mathcal{N}^D(\text{Cat}) \) with a full subcategory of \( \mathcal{QC} \)), we obtain a functor of \( \infty \)-categories \( \mathcal{N}^D(\mathcal{F}) : \mathcal{N}(\mathcal{C}) \to \mathcal{QC} \). Identifying \( h\mathcal{N}^D(\mathcal{F}) \) with the original functor \( \mathcal{F} \), Proposition 5.7.3.1 yields a comparison functor

\[ T : \int_{\mathcal{N}(\mathcal{C})} \mathcal{N}^D(\mathcal{F}) \to \mathcal{N}\left( \int_{\mathcal{C}} \mathcal{F} \right). \]
Proposition 5.7.3.4. Let $C$ be a category and let $\mathcal{F} : C \to \text{Cat}$ be a strictly unitary functor of 2-categories. Then the comparison map

$$T : \int_{N_\bullet(C)} N^D_\bullet(\mathcal{F}) \to N_\bullet(\int_C \mathcal{F})$$

is an isomorphism of simplicial sets.

Stated more informally, Proposition 5.7.3.4 asserts that we can regard the classical category of elements construction (Definition 5.7.1.1) as a special case of Definition 5.7.2.4.

Proof of Proposition 5.7.3.4. By virtue of Proposition 5.7.3.1, it will suffice to show that the simplicial set $\int_{N_\bullet(C)} N^D_\bullet(\mathcal{F})$ is isomorphic to the nerve of a category. We will prove this by verifying the criterion of Proposition 1.2.3.1. Fix $0 < i < n$; we wish to show that every morphism of simplicial sets $\sigma_0 : \Lambda_i^n \to \int_{N_\bullet(C)} N^D_\bullet(\mathcal{F})$ can be extended uniquely to an $n$-simplex $\sigma$ of $\int_{N_\bullet(C)} N^D_\bullet(\mathcal{F})$. Let $\sigma_0$ denote the composition of $\sigma_0$ with the projection map $\int_{N_\bullet(C)} N^D_\bullet(\mathcal{F}) \to N_\bullet(C)$. Proposition 1.2.3.1 then guarantees that $\sigma_0$ extends uniquely to a morphism of simplicial sets $\sigma : \Delta^n \to N_\bullet(C)$. It will therefore suffice to show that the lifting problem

$$\begin{array}{ccc}
\Lambda_i^n & \xrightarrow{\sigma_0} & \int_{N_\bullet(C)} N^D_\bullet(\mathcal{F}) \\
\downarrow & & \downarrow \pi \\
\Delta^n & \xrightarrow{\sigma} & N_\bullet(C)
\end{array}$$

has a unique solution.

We begin by treating the special case $n = 2$ (so that $i = 1$). In this case, we can identify $\sigma_0$ with a pair of composable morphisms

$$(C, X) \xrightarrow{(f,u)} (D, Y) \xrightarrow{(g,v)} (E, Z)$$

in the $\infty$-category $\int_{N_\bullet(C)} N^D_\bullet(\mathcal{F})$. Set $h = g \circ f \in \text{Hom}_C(C, E)$, so that the composition constraint of $\mathcal{F}$ determines an isomorphism of functors $\mu : \mathcal{F}(g) \circ \mathcal{F}(f) \simeq \mathcal{F}(h)$. Unwinding the definitions (using Example 5.7.2.15), we are reduced to proving that there is a unique morphism $w : \mathcal{F}(h)(X) \to Z$ in the category $\mathcal{F}(E)$ for which the diagram

$$\begin{array}{ccc}
(\mathcal{F}(g) \circ \mathcal{F}(f))(X) & \xrightarrow{\mu(X)} & \mathcal{F}(h)(X) \\
\downarrow \mathcal{F}(u) & & \downarrow \mathcal{F}(v) \\
\mathcal{F}(g)(Y) & \xrightarrow{w} & Z
\end{array}$$

commutes.
commutes. This is clear, since $\mu(X)$ is an isomorphism in the category $\mathcal{F}(E)$.

We now treat the case $n \geq 3$. Note that the existence of a solution to the lifting problem (5.30) is automatic (since the projection map $\pi$ is a cocartesian fibration; see Proposition 5.7.2.2). It will therefore suffice to show that $\sigma$ is unique. Using Lemma 4.3.6.14 and Remark 5.6.5.7 we can rewrite (5.30) as a lifting problem

The uniqueness of its solution is now an immediate consequence of Proposition 2.3.1.9 since the horn $\Lambda^{n+1}_{i+1}$ contains the 2-skeleton of $\Delta^n$.

Corollary 5.7.3.5. Let $\mathcal{F} : \mathcal{C} \to \mathcal{Q}\mathcal{C}$ be a morphism of simplicial sets which factors through the full subcategory $N^\bullet_c(\text{Pith}(\mathcal{C})) \subset \mathcal{Q}\mathcal{C}$ of Remark 5.6.4.9. Then the projection map $\int_{\mathcal{C}} \mathcal{F} \to \mathcal{C}$ is an inner covering map of simplicial sets.

Proof. By virtue of Corollary 4.1.5.11 we may assume without loss of generality that $\mathcal{C} = \Delta^n$ is a standard simplex. In this case, we wish to show that the simplicial set $\int_{\mathcal{C}} \mathcal{F}$ is isomorphic to the nerve of an ordinary category (see Proposition 4.1.5.10), which is a special case of Proposition 5.7.4 Comparison with the Weighted Nerve

Let $\mathcal{C}$ be a category which is equipped with a functor $\mathcal{F} : \mathcal{C} \to \mathcal{Q}\mathcal{C}$. In §5.3.3 and §5.7.3 we introduced two different cocartesian fibrations associated to $\mathcal{F}$:

- The projection map $U : N^\bullet_{\mathcal{F}}(\mathcal{C}) \to N^\bullet(\mathcal{C})$, where $N^\bullet_{\mathcal{F}}(\mathcal{C})$ denotes the $\mathcal{F}$-weighted nerve of $\mathcal{C}$ (Definition 5.3.3.1). For each object $C \in \mathcal{C}$, the fiber $U^{-1}\{C\}$ is isomorphic (as a simplicial set) to the $\infty$-category $\mathcal{F}(C)$ (Example 5.3.3.8).

- The projection map $U' : \int_{N^\bullet(\mathcal{C})} N^\bullethc(\mathcal{F}) \to N^\bullet(\mathcal{C})$, where $\int_{N^\bullet(\mathcal{C})} N^\bullethc(\mathcal{F})$ denotes the $\infty$-category of elements of the functor $N^\bullethc(\mathcal{F}) : N^\bullet(\mathcal{C}) \to N^\bullethc(\mathcal{Q}\mathcal{C}) = \mathcal{Q}\mathcal{C}$. For each object $C \in \mathcal{C}$, the fiber $U'^{-1}\{C\}$ is equivalent (but not necessarily isomorphic) to the $\infty$-category $\mathcal{F}(C)$ (Example 5.7.2.18).

Our goal in this section is to show that these constructions are equivalent (though not necessarily isomorphic).
Construction 5.7.4.1 (The Comparison Map). Let $\mathcal{C}$ be a category and let $\overrightarrow{\Delta}$ be an $n$-simplex of the nerve $N_\bullet(\mathcal{C})$, given by a diagram

$$C_0 \to C_1 \to C_2 \to \cdots \to C_{n-1} \to C_n$$

in the category $\mathcal{C}$. Let $\mathcal{F}$ be a functor from $\mathcal{C}$ to the category of simplicial sets and suppose that we are given a collection of simplices $\overrightarrow{\sigma} = \{\sigma_j : \Delta^j \to \mathcal{F}(C_j)\}_{0 \leq j \leq n}$ which fit into a commutative diagram

$$\begin{array}{ccccccccc}
\Delta^0 & \to & \Delta^1 & \to & \Delta^2 & \to & \cdots & \to & \Delta^n \\
\sigma_0 & \downarrow & \sigma_1 & \downarrow & \sigma_2 & \downarrow & \cdots & \downarrow & \sigma_n \\
\mathcal{F}(C_0) & \to & \mathcal{F}(C_1) & \to & \mathcal{F}(C_2) & \to & \cdots & \to & \mathcal{F}(C_n).
\end{array}$$

To this data, we can associate a commutative diagram of simplicial sets

$$\begin{array}{ccc}
\Delta^n & \to & N_{\Delta}^h(S_{\Delta})_{\overrightarrow{\sigma}}/ \\
\overrightarrow{\sigma} & \downarrow & \\
N_\bullet(\mathcal{C}) & \to & N_{\Delta}^h(\mathcal{F})
\end{array} \tag{5.31}$$

where the upper horizontal map is given by the simplicial functor

$$F : \operatorname{Path}[\{x\} \ast [n]]_{\bullet} \to \Delta_{\Delta}$$

described as follows:

- The functor $F$ carries $x$ to the simplicial set $\Delta^0$ (so that $F$ can be identified with an $n$-simplex of the coslice simplicial set $N_{\Delta}^h(S_{\Delta})_{\overrightarrow{\sigma}}$).
- The restriction of $F$ to the simplicial path category $\operatorname{Path}[n]_{\bullet}$ is given by the composition

$$\begin{array}{ccc}
\operatorname{Path}[n]_{\bullet} & \to & [n] & \overset{\overrightarrow{\sigma}}{\to} & \mathcal{C} & \overset{\mathcal{F}}{\to} & \Delta_{\Delta}
\end{array}$$

(as required by the commutativity of the diagram (5.31)).
- For $0 \leq m \leq n$, the induced map of simplicial sets

$$\operatorname{Hom}_{\operatorname{Path}[\{x\} \ast [n]]}(x, m)_{\bullet} \to \operatorname{Hom}_{\Delta_{\Delta}}(F(x), F(m))_{\bullet} = \mathcal{F}(C_m)$$

is given by the composition $\operatorname{Hom}_{\operatorname{Path}[\{x\} \ast [n]]}(x, m)_{\bullet} \overset{\rho}{\to} \Delta^m \overset{\sigma_m}{\to} \mathcal{F}(C_m)$, where $\rho$ is induced by the morphism of partially ordered sets

$$\operatorname{Hom}_{\operatorname{Path}[\{x\} \ast [n]]}(x, m) \to [m] \quad (S \subseteq \{x\} \ast [n]) \mapsto \min(S \setminus \{x\}).$$
5.7. CLASSIFICATION OF COCARTESIAN FIBRATIONS

Note that we can identify the diagram \([5.3.1]\) with an \(n\)-simplex \(\theta(\vec{C}, \vec{\sigma})\) of the simplicial set \(\int_{N_n(C)} \mathbb{N}^\text{hc}(\mathcal{F})\). The construction \((\vec{C}, \vec{\sigma}) \mapsto \theta(\vec{C}, \vec{\sigma})\) then determines a morphism of simplicial sets \(\theta : N^\mathbb{F}(C) \rightarrow \int_{N_n(C)} \mathbb{N}^\text{hc}(\mathcal{F})\), which we will refer to as the **comparison map**.

**Example 5.7.4.2** (The Comparison Map on Vertices). Let \(C\) be a category and let \(\mathcal{F}\) be a functor from \(C\) to the category of simplicial sets. Let us identify vertices of the weighted nerve \(N^\mathbb{F}(C)\) with pairs \((C, X)\), where \(C\) is an object of \(C\) and \(X\) is a vertex of the simplicial set \(\mathcal{F}(C)\) (Remark \([5.3.3.3]\)). Under this identification, the comparison map \(\theta : N^\mathbb{F}(C) \rightarrow \int_{N_n(C)} \mathbb{N}^\text{hc}(\mathcal{F})\) of Construction \([5.7.4.1]\) is given on vertices by the construction \((C, X) \mapsto (\theta(C, X))\), where we identify \((C, X)\) with a vertex of \(\int_{N_n(C)} \mathbb{N}^\text{hc}(\mathcal{F})\) using Example \([5.7.2.12]\). In particular, the morphism \(\theta\) is bijective at the level of vertices.

**Example 5.7.4.3** (The Comparison Map on Edges). Let \(C\) be a category and let \(\mathcal{F}\) be a functor from \(C\) to the category of simplicial sets. Let \((C, X)\) and \((D, Y)\) be vertices of the weighted nerve \(N^\mathbb{F}(C)\). Using Remark \([5.3.3.4]\) we can identify edges of \(N^\mathbb{F}(C)\) having source \((C, X)\) and target \((D, Y)\) with pairs \((f, u)\), where \(f : C \rightarrow D\) is a morphism in the category \(C\) and \(u : \mathcal{F}(f)(X) \rightarrow Y\) is an edge of the simplicial set \(\mathcal{F}(D)\). Under this identification, the comparison map \(\theta : N^\mathbb{F}(C) \rightarrow \int_{N_n(C)} \mathbb{N}^\text{hc}(\mathcal{F})\) of Construction \([5.7.4.1]\) is given on edges by the construction \((f, u) \mapsto (\theta(f, u))\), where we identify \((f, u)\) with an edge of the simplicial set \(\int_{N_n(C)} \mathbb{N}^\text{hc}(\mathcal{F})\) using Example \([5.7.2.13]\). In particular, the morphism \(\theta\) is bijective at the level of edges.

**Warning 5.7.4.4.** Let \(C\) be a category and let \(\mathcal{F}\) be a functor from \(C\) to the category of simplicial sets. The comparison map \(\theta : N^\mathbb{F}(C) \rightarrow \int_{N_n(C)} \mathbb{N}^\text{hc}(\mathcal{F})\) of Construction \([5.7.4.1]\) is generally not bijective on \(n\)-simplices for \(n \geq 2\) (even in the special case \(C = [0]\)).

**Exercise 5.7.4.5.** Let \(C\) be a category and let \(\mathcal{F}\) be a functor from \(C\) to the category of simplicial sets. Show that the comparison map \(\theta : N^\mathbb{F}(C) \rightarrow \int_{N_n(C)} \mathbb{N}^\text{hc}(\mathcal{F})\) of Construction \([5.7.4.1]\) is a monomorphism of simplicial sets.

**Remark 5.7.4.6.** Let \(C\) be a category and let \(\mathcal{F}\) be a functor from \(C\) to the category of simplicial sets. Then the diagram of simplicial sets

\[
\begin{array}{ccc}
N^\mathbb{F}(C) & \xrightarrow{\theta} & \int_{N_n(C)} \mathbb{N}^\text{hc}(\mathcal{F}) \\
\downarrow \quad & & \downarrow \\
N_n(C) & & 
\end{array}
\]
is commutative, where the vertical morphisms are the projection maps of Definitions \[5.3.3.1\] and \[5.7.2.1\] and \(\theta\) is the comparison morphism of Construction \[5.7.4.1\].

**Example 5.7.4.7.** Let \(\mathcal{C}\) be a category and let \(\mathcal{F}\) be a functor from \(\mathcal{C}\) to the category of simplicial sets. For every object \(C \in \mathcal{C}\), the comparison morphism \(\theta : N_\bullet^\mathcal{F}(C) \to \int_{N_\bullet(C)}^{hc} (\mathcal{F})\) of Construction \[5.7.4.1\] induces a morphism of simplicial sets

\[
\theta_C : \{C\} \times_{N_\bullet(C)} N_\bullet^\mathcal{F}(C) \to \{C\} \times_{N_\bullet(C)} \int_{N_\bullet(C)}^{hc} (\mathcal{F}).
\]

Under the isomorphisms

\[
\mathcal{F}(C) \simeq \{C\} \times_{N_\bullet(C)} N_\bullet^\mathcal{F}(C) \quad \text{Hom}_{N_\bullet(\Delta\text{Set})}^L(\Delta^0, \mathcal{F}(C)) \simeq \{C\} \times_{N_\bullet(C)} \int_{N_\bullet(C)}^{hc} (\mathcal{F})
\]

supplied by Examples \[5.3.3.8\] and \[5.7.2.18\] we can identify \(\theta_C\) with the comparison map \(\mathcal{F}(C) \to \text{Hom}_{N_\bullet(\Delta\text{Set})}^L(\Delta^0, \mathcal{F}(C))\) of Construction \[4.6.7.3\].

**Proposition 5.7.4.8.** Let \(\mathcal{C}\) be a category equipped with a functor \(\mathcal{F} : \mathcal{C} \to \text{QCat}\), and let

\[
\begin{array}{ccc}
N_\bullet^\mathcal{F}(C) & \xrightarrow{\theta} & \int_{N_\bullet(C)}^{hc} (\mathcal{F}) \\
\downarrow U & & \downarrow U' \\
N_\bullet(C) & &
\end{array}
\]

be the commutative diagram of Remark \[5.7.4.6\]. Then:

1. For each object \(C \in \mathcal{C}\), the morphism \(\theta\) induces an equivalence of \(\infty\)-categories

\[
\theta_C : \{C\} \times_{N_\bullet(C)} N_\bullet^\mathcal{F}(C) \to \{C\} \times_{N_\bullet(C)} \int_{N_\bullet(C)}^{hc} (\mathcal{F}).
\]

2. A morphism \(f\) of the weighted nerve \(N_\bullet^\mathcal{F}(C)\) is \(U\)-cocartesian if and only if \(\theta(f)\) is a \(U'\)-cocartesian morphism of the \(\infty\)-category \(\int_{N_\bullet(C)}^{hc} (\mathcal{F})\).

3. The functor \(\theta\) is an equivalence of \(\infty\)-categories.

**Proof.** Assertion (1) follows from Example \[5.7.4.7\] and Theorem \[4.6.7.9\]. Assertion (2) follows from Example \[5.7.4.3\] together with the descriptions of \(U\)-cocartesian and \(U'\)-cocartesian morphisms supplied by Proposition \[5.3.3.15\] and Remark \[5.7.2.14\]. Assertion (3) follows by combining (1) and (2) with Theorem \[5.1.5.1\] (since \(U\) and \(U'\) are cocartesian fibrations, by virtue of Propositions \[5.3.3.15\] and \[5.7.2.2\]).
5.7. CLASSIFICATION OF COCARTESIAN FIBRATIONS

5.7.5 The Universality Theorem

Throughout this section, we let $\mathcal{QC}_{\text{Obj}}$ denote the $\infty$-category of pairs $(\mathcal{C}, C)$, where $\mathcal{C}$ is a small $\infty$-category and $C$ is an object of $\mathcal{C}$ (Definition 5.6.6.10), and we let $V : \mathcal{QC}_{\text{Obj}} \to \mathcal{QC}$ denote the forgetful functor (given on objects by the formula $V(C, C) = C$).

**Definition 5.7.5.1.** Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets. We will say that a commutative diagram of simplicial sets

$$
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{\mathcal{F}} & \mathcal{QC}_{\text{Obj}} \\
U & & V \\
\mathcal{C} & \xrightarrow{\mathcal{F}} & \mathcal{QC}
\end{array}
$$

witnesses $\mathcal{F}$ as a covariant transport representation of $U$ if the induced map

$$\mathcal{E} \to \mathcal{C} \times_{\mathcal{QC}} \mathcal{QC}_{\text{Obj}} = \int_{\mathcal{C}} \mathcal{F}$$

is an equivalence of cocartesian fibrations over $\mathcal{C}$, in the sense of Definition 5.1.6.1. We say that $\mathcal{F} : \mathcal{C} \to \mathcal{QC}$ is a covariant transport representation of $U$ if there exists a diagram which witnesses $\mathcal{F}$ as a covariant transport representation of $U$.

**Remark 5.7.5.2.** Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of $\infty$-categories and let $\mathcal{F} : \mathcal{C} \to \mathcal{QC}$ be a functor. By virtue of Proposition 5.1.6.5, a diagram

$$
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{\mathcal{F}} & \mathcal{QC}_{\text{Obj}} \\
U & & V \\
\mathcal{C} & \xrightarrow{\mathcal{F}} & \mathcal{QC}
\end{array}
$$

witnesses $\mathcal{F}$ as a covariant transport representation for $U$ if and only if the induced map $\mathcal{E} \to \int_{\mathcal{C}} \mathcal{F}$ is an equivalence of $\infty$-categories. We will later extend this observation to the case where $\mathcal{C}$ is a general simplicial set (Corollary 5.7.7.7).

**Remark 5.7.5.3.** Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets. A commutative diagram

$$
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{\mathcal{F}} & \mathcal{QC}_{\text{Obj}} \\
U & & V \\
\mathcal{C} & \xrightarrow{\mathcal{F}} & \mathcal{QC}
\end{array}
$$

...
witnesses $\mathcal{F}$ as a covariant transport representation of $U$ if and only if it satisfies the following pair of conditions:

(a) For every vertex $C \in \mathcal{C}$, the map of fibers

$$\widetilde{\mathcal{F}}_C : \mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E} \to \{C\} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathcal{F}$$

is an equivalence of $\infty$-categories.

(b) The morphism $\widetilde{\mathcal{F}}$ carries $U$-cocartesian edges of $\mathcal{E}$ to $V$-cocartesian edges of $\mathcal{Q}_C\text{Obj}$.

See Proposition 5.1.6.14. Moreover, we can replace (b) by the following \textit{a priori} weaker condition (see Remark 5.1.5.8):

\[(b') \text{ For every vertex } X \in \mathcal{E} \text{ and every edge } e : U(X) \to Y \text{ in } \mathcal{C}, \text{ there exists a } U \text{-cocartesian edge } e : X \to Y \text{ of } \mathcal{E} \text{ for which } U(e) = \tau \text{ and and } \widetilde{\mathcal{F}}(e) \text{ is a } V \text{-cocartesian edge of } \mathcal{Q}_C\text{Obj}.
\]

\section*{Example 5.7.5.4 (Left Covering Maps).} Let $U : \mathcal{E} \to \mathcal{C}$ be a left covering map of simplicial sets and let $h\text{Tr}_{\mathcal{E}/\mathcal{C}} : h\mathcal{C} \to \text{Set}$ be the homotopy transport representation of $U$ (Example 5.2.5.3), so that $h\text{Tr}_{\mathcal{E}/\mathcal{C}}$ can be identified with a morphism of simplicial sets $\text{Tr}_{\mathcal{E}/\mathcal{C}} : \mathcal{C} \to N_{\bullet}(\text{Set})$. Combining Proposition 5.2.7.2 with Example 5.7.2.8 we obtain a canonical isomorphism of simplicial sets $\mathcal{E} \simeq \int_{\mathcal{C}} \text{Tr}_{\mathcal{E}/\mathcal{C}}$, which exhibits $\text{Tr}_{\mathcal{E}/\mathcal{C}}$ as a covariant transport representation of $U$ (in the sense of Definition 5.7.5.1).

\section*{Example 5.7.5.5 (Fibrations over a Point).} Let $\mathcal{E}$ be a small $\infty$-category, which we identify with a morphism $\mathcal{F} : \Delta^0 \to \mathcal{Q}_C\text{Obj}$. Then $\mathcal{F}$ is a covariant transport representation of the projection map $U : \mathcal{E} \to \Delta^0$. More precisely, Example 5.7.2.16 supplies an equivalence of $\infty$-categories $\mathcal{E} \simeq \int_{\Delta^0} \mathcal{F}$ which witnesses $\mathcal{F}$ as a covariant transport representation of $U$. More generally, a functor $\Delta^0 \to \mathcal{Q}_C\text{Obj}$ is a covariant transport representation of $U$ if and only if corresponds to an $\infty$-category which is equivalent to $\mathcal{E}$.

\section*{Example 5.7.5.6 (Weighted Nerves).} Let $\mathcal{C}$ be an ordinary category, let $U : \mathcal{E} \to \mathcal{C} \to \text{QCat}$ be a cocartesian fibration of $\infty$-categories, and let $s\text{Tr}_{\mathcal{E}/\mathcal{C}} : \mathcal{C} \to \text{QCat}$ be the strict transport representation of $U$ (Construction 5.3.1.5). Then the functor $N^{hc}\text{Tr}_{\mathcal{E}/\mathcal{C}} : N_{\bullet}(\mathcal{C}) \to N^{hc}_\bullet(\mathcal{Q}_C\text{Obj}) = \mathcal{Q}_C$
is a covariant transport representation for $U$ (in the sense of Definition 5.7.5.1). In other words, $U$ is equivalent to the cocartesian fibration $U' : \underline{\mathcal{E}}_{\mathcal{C}} \to \mathcal{C}$. To see this, we observe that both $U$ and $U'$ are equivalent to the cocartesian fibration $\mathcal{N}_{\mathcal{C}}(\mathcal{E}) \to \mathcal{C}$: this follows from Theorem 5.3.5.6 and Proposition 5.7.4.8.

**Remark 5.7.5.8.** Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets, and let $h\operatorname{Tr}_{\mathcal{E}}/\mathcal{C}$ be the homotopy transport representation of $U$ (Construction 5.2.5.2). Let $\mathcal{F} : \mathcal{C} \to \mathcal{Q}\mathcal{C}$ be a morphism of simplicial sets and let $h\mathcal{F} : h\mathcal{C} \to h\mathcal{Q}\mathcal{C}$ be the induced functor between homotopy categories. Let $\alpha : \mathcal{E} \to \underline{\mathcal{E}}_{\mathcal{C}}$ be an equivalence of cocartesian fibrations over $\mathcal{C}$. By virtue of Corollary 5.7.2.22, $\alpha$ induces an isomorphism from $h\operatorname{Tr}_{\mathcal{E}}/\mathcal{C}$ to $h\mathcal{F}$ in the functor category $\operatorname{Fun}(h\mathcal{C}, h\mathcal{Q}\mathcal{C})$. Stated more informally, any covariant transport representation of $U$ provides a lifting of the homotopy transport representation $h\operatorname{Tr}_{\mathcal{E}}/\mathcal{C}$ from the ordinary category $\operatorname{Fun}(h\mathcal{C}, h\mathcal{Q}\mathcal{C})$ to the $\infty$-category $\operatorname{Fun}(\mathcal{C}, \mathcal{Q}\mathcal{C})$. Moreover, if the simplicial set $\mathcal{C}$ is an $\infty$-category, then the identification $h\operatorname{Tr}_{\mathcal{E}}/\mathcal{C} \simeq h\mathcal{F}$ is an isomorphism of $h\operatorname{Kan}$-enriched functors (Proposition 5.7.2.20).

**Remark 5.7.5.9.** Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets and let $\mathcal{F}, \mathcal{F}' : \mathcal{C} \to \mathcal{Q}\mathcal{C}$ be morphisms which are isomorphic as objects of the diagram $\infty$-category $\operatorname{Fun}(\mathcal{C}, \mathcal{Q}\mathcal{C})$. Then $\mathcal{F}$ is a covariant transport representation of $U$ if and only if $\mathcal{F}'$ is a covariant transport representation of $U$. This follows immediately from Proposition 5.7.2.19.

We now formulate a stronger version of Theorem 5.7.0.2:

**Theorem 5.7.5.10** (Relative Universality Theorem). Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets having essentially small fibers, let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a simplicial subset having inverse image $\mathcal{E}_0 = \mathcal{C}_0 \times \mathcal{C} \subseteq \mathcal{E}$, and let $U_0 : \mathcal{E}_0 \to \mathcal{C}_0$ be the restriction $U|_{\mathcal{E}_0}$. Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{E}_0 & \xrightarrow{\mathcal{F}_0} & \mathcal{Q}\mathcal{C}_{\text{Obj}} \\
\downarrow U_0 & & \downarrow V \\
\mathcal{C}_0 & \xrightarrow{\mathcal{F}_0} & \mathcal{Q}\mathcal{C}
\end{array}
\]

which witnesses $\mathcal{F}_0$ as a covariant transport representation of $U_0$. Then there exists a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{\mathcal{F}} & \mathcal{Q}\mathcal{C}_{\text{Obj}} \\
\downarrow U & & \downarrow V \\
\mathcal{C} & \xrightarrow{\mathcal{F}} & \mathcal{Q}\mathcal{C}
\end{array}
\]
which witnesses \( \mathcal{F} \) as a covariant transport representation of \( U \), where \( \mathcal{F}_0 = \mathcal{F}|_{C_0} \) and \( \mathcal{F}_0 = \tilde{\mathcal{F}}|_{E_0} \).

We will give a reformulation of Theorem \[5.7.5.10\] in §5.7.8 (see Theorem \[5.7.8.3\]), which we prove in §5.7.9.

**Corollary 5.7.5.11.** Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets having essentially small fibers, let \( C' \subseteq \mathcal{C} \) be a simplicial subset, and let \( \mathcal{F}' : C' \to \mathcal{Q}\mathcal{C} \) be a covariant transport representation for the projection map \( C' \times_\mathcal{C} \mathcal{E} \to C' \). Then there exists a morphism \( \mathcal{F} : \mathcal{C} \to \mathcal{Q}\mathcal{C} \) satisfying \( \mathcal{F}' = \mathcal{F}|_{C'} \) which is a covariant transport representation of \( U \).

**Corollary 5.7.5.12.** Let \( Q \) be a full subcategory of \( \mathcal{Q}\mathcal{C} \) and let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets having the property that, for each vertex \( C \in \mathcal{C} \), the fiber \( \mathcal{E}_C = \{ C \} \times_\mathcal{C} \mathcal{E} \) is equivalent to an \( \infty \)-category which belongs to \( Q \). Then there exists a morphism \( \mathcal{F} : \mathcal{C} \to \mathcal{Q} \subseteq \mathcal{Q}\mathcal{C} \) which is a covariant transport representation of \( U \).

**Proof.** For each vertex \( C \in \mathcal{C} \), choose an \( \infty \)-category \( \mathcal{F}'(C) \in Q \) which is equivalent to the fiber \( \mathcal{E}_C = \{ C \} \times_\mathcal{C} \mathcal{E} \). The construction \( C \mapsto \mathcal{F}'(C) \) determines a morphism of simplicial sets \( \mathcal{F}' : C' \to Q \), where \( C' = \text{sk}_0(\mathcal{C}) \) is the 0-skeleton of \( \mathcal{C} \), which is a covariant transport representation of the projection map \( C' \times_\mathcal{C} \mathcal{E} \to C' \) (see Example \[5.7.5.5\]). Applying Corollary \[5.7.5.11\], we can extend \( \mathcal{F}' \) to a morphism \( \mathcal{F} : \mathcal{C} \to \mathcal{Q} \subseteq \mathcal{Q}\mathcal{C} \) which is a covariant transport representation of \( U \). By construction, the morphism \( \mathcal{F} \) takes values in the full subcategory \( Q \subseteq \mathcal{Q}\mathcal{C} \).

**Corollary 5.7.5.13.** Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets and let \( \mathcal{F}_0, \mathcal{F}_1 : \mathcal{C} \to \mathcal{Q}\mathcal{C} \) be covariant transport representations for \( U \). Then \( \mathcal{F}_0 \) and \( \mathcal{F}_1 \) are isomorphic as objects of the \( \infty \)-category \( \text{Fun}(\mathcal{C}, \mathcal{Q}\mathcal{C}) \).

**Proof.** Let \( U_{\Delta^1} : \Delta^1 \times \mathcal{E} \to \Delta^1 \times \mathcal{C} \) be the product of \( U \) with the identity map \( \text{id}_{\Delta^1} \), and define \( U_{\partial \Delta^1} : \partial \Delta^1 \times \mathcal{E} \to \partial \Delta^1 \times \mathcal{C} \) similarly. Note that the map \(( \mathcal{F}_0, \mathcal{F}_1 ) : \partial \Delta^1 \times \mathcal{C} \to \mathcal{Q}\mathcal{C} \) is a covariant transport representation of \( U_{\partial \Delta^1} \). Applying Corollary \[5.7.5.11\], we deduce that \( U_{\Delta^1} \) admits a covariant transport representation \( \mathcal{F} : \Delta^1 \times \mathcal{C} \to \mathcal{Q}\mathcal{C} \) which satisfies \( \mathcal{F}|_{\{ 0 \} \times S} = \mathcal{F}_0 \) and \( \mathcal{F}|_{\{ 1 \} \times S} = \mathcal{F}_1 \). Let us identify \( \mathcal{F} \) with a morphism \( u : \mathcal{F}_0 \to \mathcal{F}_1 \) in the \( \infty \)-category \( \text{Fun}(\mathcal{C}, \mathcal{Q}\mathcal{C}) \). We will complete the proof by showing that \( u \) is an isomorphism. By virtue of Theorem \[4.4.4.4\], it will suffice to show that for each vertex \( C \in \mathcal{C} \), the induced map \( u_C : \mathcal{F}_0(C) \to \mathcal{F}_1(C) \) is an isomorphism in \( \mathcal{Q}\mathcal{C} \). Using Remark \[5.7.5.8\] (and Remark \[5.2.8.5\]), we see that the homotopy class \([ u_C ]\) is isomorphic (as an object of the arrow category \( \text{Fun}([1], \mathcal{Q}\mathcal{C}) \)) to the homotopy class of the functor \( \mathcal{E}_C \to \mathcal{E}_C \) given by covariant transport along the degenerate edge \( \text{id}_C \) of \( \mathcal{C} \): that is, the homotopy class of the identity functor \( \text{id}_{\mathcal{E}_C} \).
5.7. CLASSIFICATION OF COCARTESIAN FIBRATIONS

Proof of Theorem 5.7.0.2. Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibrations of simplicial sets and suppose that, for each vertex \( C \in \mathcal{C} \), the fiber \( \mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E} \) is essentially small. We wish to show that \( U \) admits a covariant transport representation \( \mathcal{F} : \mathcal{C} \to \mathcal{QC} \), which is uniquely determined up to isomorphism (as an object of the functor \( \infty \)-category \( \text{Fun}(\mathcal{C}, \mathcal{QC}) \)). The existence statement follows by applying Theorem 5.7.5.10 in the special case \( \mathcal{C}_0 = \emptyset \), and the uniqueness follows from Corollary 5.7.5.13.

Notation 5.7.5.14 (The Covariant Transport Representation). Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets having essentially small fibers. We let \( \text{Tr}_{\mathcal{E}/\mathcal{C}} \) denote a covariant transport representation of \( U \), regarded as an object of the \( \infty \)-category \( \text{Fun}(\mathcal{C}, \mathcal{QC}) \) (which exists by virtue of Corollary 5.7.5.12). We write \([ \text{Tr}_{\mathcal{E}/\mathcal{C}} ]\) for the isomorphism class of the diagram \( \text{Tr}_{\mathcal{E}/\mathcal{C}} \), regarded as an object of the set \( \pi_0(\text{Fun}(\mathcal{C}, \mathcal{QC})) \). By virtue of Corollary 5.7.5.13, the isomorphism class \([ \text{Tr}_{\mathcal{E}/\mathcal{C}} ]\) is well-defined: that is, it depends only on the cocartesian fibration \( U : \mathcal{E} \to \mathcal{C} \). Beware that \( \text{Tr}_{\mathcal{E}/\mathcal{C}} \) is not unique determined: in fact, any diagram isomorphic to \( \text{Tr}_{\mathcal{E}/\mathcal{C}} \) is also a covariant transport representation of \( U \) (Remark 5.7.5.9). Nevertheless, it will be convenient to abuse terminology and refer to \( \text{Tr}_{\mathcal{E}/\mathcal{C}} \) as the covariant transport representation of \( U \), with the caveat that it is well-defined only up to isomorphism.

Remark 5.7.5.15. Let \( \mathcal{C} \) be a simplicial set equipped with a functor \( \mathcal{F} : h\mathcal{C} \to h\mathcal{QCat} \). It follows from Corollary 5.7.5.12 that the functor \( \mathcal{F} \) is isomorphic to the homotopy transport representation of a cocartesian fibration \( U : \mathcal{E} \to \mathcal{C} \) if and only if it can be promoted to a diagram \( \mathcal{F} : \mathcal{C} \to \mathcal{QC} \).

Corollary 5.7.5.16. Let \( \mathcal{C} \) be a small category. Then passage to the homotopy coherent nerve induces a bijection

\[
\{\text{Functors of ordinary categories } \mathcal{C} \to \mathcal{QC}\}/\text{Levelwise equivalence}
\downarrow
\{\text{Functors of } \infty\text{-categories } N_{\bullet}(\mathcal{C}) \to \mathcal{QC}\}/\text{Isomorphism}.
\]

Proof. Combine Example 5.7.5.7, Theorem 5.3.5.6, and Theorem 5.7.0.2.

Remark 5.7.5.17 (Rectification). Corollary 5.7.5.16 is a prototypical example of a rectification result. If \( \mathcal{C} \) is an ordinary category, then a functor of \( \infty \)-categories \( \mathcal{F} : N_{\bullet}(\mathcal{C}) \to \mathcal{QC} \) can be viewed as a homotopy coherent diagram in the simplicial category \( \mathcal{QCat} \):

- To every object \( X \) of the category \( \mathcal{C} \), the functor \( \mathcal{F} \) associates an \( \infty \)-category \( \mathcal{F}(X) \).
- To every morphism \( u : X \to Y \) of the category \( \mathcal{C} \), the functor \( \mathcal{F} \) associates a functor of \( \infty \)-categories \( \mathcal{F}(u) : \mathcal{F}(X) \to \mathcal{F}(Y) \).
CHAPTER 5. FIBRATIONS OF $\infty$-CATEGORIES

To every pair of composable morphisms $u : X \to Y$ and $v : Y \to Z$ in the category $\mathcal{C}$, the functor $\mathcal{F}$ associates an isomorphism of functors $\alpha_{u,v} : \mathcal{F}(v) \circ \mathcal{F}(u) \to \mathcal{F}(v \circ u)$.

When applied to higher-dimensional simplices of $\mathcal{N}_\bullet(\mathcal{C})$, the functor $\mathcal{F}$ provides additional data which encode coherence laws satisfied by the isomorphisms $\alpha_{u,v}$.

Corollary 5.7.5.16 asserts that we can always find a strictly commutative diagram $\mathcal{G} : \mathcal{C} \to \mathcal{QC}$ which is isomorphic to $\mathcal{F}$ in the $\infty$-category $\text{Fun}(\mathcal{N}_\bullet(\mathcal{C}), \mathcal{QC})$. In particular, the diagram $\mathcal{G}$ carries each object $X \in \mathcal{C}$ to an $\infty$-category $\mathcal{G}(X)$ which is equivalent to $\mathcal{F}(X)$ (beware that we generally cannot arrange that $\mathcal{G}(X)$ is isomorphic to $\mathcal{F}(X)$ as a simplicial set).

In §[?], we will prove a more refined version of this result, which allows us to describe the entire $\infty$-category $\text{Fun}(\mathcal{N}_\bullet(\mathcal{C}), \mathcal{QC})$ in terms of strictly commutative diagrams indexed by $\mathcal{C}$ (Proposition [?]).

Using Theorem 5.7.5.10, we obtain the following converse of Corollary 5.7.3.5

**Proposition 5.7.5.18.** Let $U : \mathcal{E} \to \mathcal{C}$ be a morphism of simplicial sets. The following conditions are equivalent:

1. The morphism $U$ an inner covering map (Definition 4.1.5.1), a cocartesian fibration, and each fiber of $U$ is small.

2. There exists morphism of simplicial sets $\mathcal{F} : \mathcal{C} \to \mathcal{N}_\bullet(\text{Pith}(\mathcal{Cat})) \subseteq \mathcal{QC}$ and an isomorphism $G : \mathcal{E} \simeq \int_{\mathcal{C}} \mathcal{F}$ in the category $(\text{Set}_\Delta)/\mathcal{C}$.

**Proof.** The implication (2) $\Rightarrow$ (1) follows from Corollary 5.7.3.5 and Proposition 5.7.2.2. For each vertex $C \in \mathcal{C}$, our assumption that $U$ is an inner covering map guarantees that the fiber $\{C\} \times_{\mathcal{C}} \mathcal{E}$ is isomorphic to the nerve of a (small) category $\mathcal{F}_0(C)$ (Example 4.1.5.3). Let $\mathcal{C}_0$ be the 0-skeleton of $\mathcal{C}$, so that the construction $C \mapsto \mathcal{F}_0(C)$ determines a morphism of simplicial sets $\mathcal{F}_0 : \mathcal{C}_0 \to \mathcal{N}_\bullet(\text{Pith}(\mathcal{Cat}))$. Let $\mathcal{E}_0$ denote the inverse image $\mathcal{C}_0 \times_{\mathcal{C}} \mathcal{E}$, so that Proposition 5.7.3.4 supplies an isomorphism of simplicial sets $G_0 : \mathcal{E}_0 \simeq \int_{\mathcal{C}_0} \mathcal{F}_0$. In particular, $G_0$ is an equivalence of cocartesian fibrations over $\mathcal{C}_0$. Invoking Theorem 5.7.5.10 we can extend $\mathcal{F}_0$ to a diagram $\mathcal{F} : \mathcal{C} \to \mathcal{N}_\bullet(\text{Pith}(\mathcal{Cat}))$ and $G_0$ to a morphism of simplicial sets $G : \mathcal{E} \to \int_{\mathcal{C}} \mathcal{F}$ which is an equivalence of cocartesian fibrations over $\mathcal{C}$. We will complete the proof by showing that $G$ is an isomorphism of simplicial sets. To prove this, it will suffice to show that for every simplex $G_\sigma : \Delta^n \to \mathcal{C}$, the induced map

$$G_\sigma : \Delta^n \times_{\mathcal{C}} \mathcal{E} \to \Delta^n \times_{\mathcal{C}} \int_{\mathcal{C}} \mathcal{F}$$

is an isomorphism of simplicial sets. Replacing $U$ by the projection map $\Delta^n \times_{\mathcal{C}} \mathcal{E} \to \Delta^n$, we are reduced to proving that $G$ is an isomorphism under the additional assumption
that $C = \Delta^n$ is a standard simplex. Since $U$ and the projection map $\int_C \mathcal{F} \to C$ are inner covering maps, the simplicial sets $\mathcal{E}$ and $\int_C \mathcal{F}$ are isomorphic to the nerves of their homotopy categories $h\mathcal{E}$ and $h\int_C \mathcal{F}$, respectively; it will therefore suffice to show that the functor of ordinary categories $hG : h\mathcal{E} \to h\int_C \mathcal{F}$ is an isomorphism. Our assumption that $G$ is an equivalence of cocartesian fibrations over $C = \Delta^n$ guarantees that it is an equivalence of $\infty$-categories (Corollary 5.1.6.8), so that $hG$ is an equivalence of ordinary categories. It will therefore suffice to show that the functor $hG$ is bijective on objects: that is, that the morphism $G_0 = G|_{\mathcal{E}_0}$ is an isomorphism.

![01SU Corollary 5.7.5.19 (Grothendieck).](image)

Let $U : \mathcal{E} \to \mathcal{C}$ be a functor between categories. The following conditions are equivalent:

1. The functor $U$ is a cocartesian fibration and each fiber of $U$ is a small category.

2. There exists a functor of $2$-categories $\mathcal{F} : \mathcal{C} \to \text{Cat}$ and an isomorphism $\int_C \mathcal{F} \to \mathcal{E}$ whose composition with $U$ coincides with the forgetful functor $\int_C \mathcal{F} \to \mathcal{C}$.

Proof. We will show that (1) $\Rightarrow$ (2); the reverse implication follows from Corollary 5.7.1.16.

Note that the map $N_\bullet(U) : N_\bullet(\mathcal{E}) \to N_\bullet(\mathcal{C})$ is a cocartesian fibration of simplicial sets (Example 5.1.4.2) and an inner covering map (Proposition 4.1.5.10). By virtue of Proposition 5.7.5.18, there exists a morphism of simplicial sets $F' : N_\bullet(\mathcal{C}) \to N_\bullet(\text{Pith}(\text{Cat}))$ and an isomorphism of simplicial sets $V : \int_{N_\bullet(\mathcal{C})} \mathcal{F} \simeq N_\bullet(\mathcal{E})$ which is compatible with $N_\bullet(U)$. By virtue of Theorem 2.3.4.1 (and Corollary 2.3.4.5), we have $\mathcal{F}' = N_\bullet(\mathcal{F})$ for a unique functor of $2$-categories $\mathcal{F}' : \mathcal{C} \to \text{Cat}$. In this case, we can use Proposition 5.7.3.4 to identify $\int_{N_\bullet(\mathcal{C})} \mathcal{F}'$ with the nerve of the ordinary category of elements $\int_C \mathcal{F}$. Under this identification, $V$ corresponds to the nerve of an isomorphism $\int_C \mathcal{F}' \simeq \mathcal{E}$ which is compatible with $U$. 

Let $\text{Gpd} \subseteq \text{Cat}$ denote the full subcategory spanned by the groupoids.

![01SZ Corollary 5.7.5.20.](image)

Let $U : \mathcal{E} \to \mathcal{C}$ be a functor between categories. The following conditions are equivalent:

- The functor $U$ is an opfibration in groupoids (Variant 4.2.2.4) and each fiber of $U$ is a small groupoid.

- There exists a functor of $2$-categories $\mathcal{F} : \mathcal{C} \to \text{Gpd}$ and an isomorphism of categories $\int_C \mathcal{F} \to \mathcal{E}$ which carries $U$ to the forgetful functor $\int_C \mathcal{F} \to \mathcal{C}$.

Proof. Combine Corollary 5.7.5.19 with Exercise 5.0.0.6.
5.7.6 Application: Corepresentable Functors

Let \( C \) be a category. Every object \( X \in C \) determines a functor
\[
h_X : C \to \text{Set} \quad Y \mapsto \text{Hom}_C(X,Y),
\]
which we refer to as the \textit{functor corepresented by} \( X \). We say that a functor from \( C \) to \text{Set} is \textit{corepresentable} if it is isomorphic to \( h_X \) for some object \( X \in C \). Our goal in this section is to develop an \( \infty \)-categorical counterpart of the notion of corepresentable functor (and the dual notion of representable functor), where we replace the ordinary category \text{Set} by the \( \infty \)-category \( S \) of Construction 5.6.1.1.

We begin with an elementary observation. Let \( F : C \to \text{Set} \) be a functor between ordinary categories. For each object \( X \in C \), Yoneda’s lemma supplies a bijection
\[
F(X) \cong \text{Hom}_{\text{Fun}(C,\text{Set})}(h_X, F).
\]
Concretely, this bijection carries each element \( x \in F(X) \) to a natural transformation \( \alpha_x : h_X \to F \), characterized by the requirement that it carries each \( Y \in C \) to the composite map
\[
h_X(Y) = \text{Hom}_C(X,Y) \xrightarrow{\alpha_x} \text{Hom}_{\text{Set}}(F(X), F(Y)) \xrightarrow{ev_x} F(Y).
\]
The functor \( F \) is corepresentable if it is possible to choose the object \( X \in C \) and the element \( x \in F(X) \) so that the map (5.32) is bijective, for each \( Y \in C \). This motivates the following:

\textbf{Definition 5.7.6.1 (Corepresentable Functors).} Let \( C \) be an \( \infty \)-category containing an object \( X \), let \( F : C \to S \) be a functor, and let \( x \) be a vertex of the Kan complex \( F(X) \). We will say that \( x \) \textit{exhibits} \( F \) \textit{as corepresented by} \( X \) if, for every object \( Y \in C \), the composite map
\[
\text{Hom}_C(X,Y) \xrightarrow{\alpha_x} \text{Hom}_S(F(X), F(Y)) \cong \text{Fun}(F(X), F(Y)) \xrightarrow{ev_x} F(Y)
\]
is an isomorphism in the homotopy category \( \text{hKan} \); here the second map is the inverse of the homotopy equivalence \( \text{Fun}(F(X), F(Y)) \to \text{Hom}_S(X,Y) \) supplied by Remark 5.6.1.5.

We say that the functor \( F : C \to S \) is \textit{corepresentable by} \( X \) if there exists a vertex \( x \in F(X) \) which exhibits \( F \) as corepresented by \( X \). We say that the functor \( F \) is \textit{corepresentable} if it is corepresentable by \( X \), for some object \( X \in C \).

\textbf{Variant 5.7.6.2 (Representable Functors).} Let \( C \) be an \( \infty \)-category, let \( X \) be an object of \( C \), and write \( X^{\text{op}} \) for the corresponding object of the opposite \( \infty \)-category \( C^{\text{op}} \). Given a functor \( F : C^{\text{op}} \to S \), we say that a vertex \( x \in F(X^{\text{op}}) \) \textit{exhibits} \( F \) \textit{as represented by} \( X \) if it
exhibits $\mathcal{F}$ as corepresented by the object $X^{\text{op}}$, in the sense of Definition 5.7.6.1. We say that a functor $\mathcal{F} : \mathcal{C}^{\text{op}} \to \mathcal{S}$ is \textit{representable} by $X$ if it is corepresentable by $X^{\text{op}}$, and that $\mathcal{F}$ is \textit{representable} if it is representable by $X$ for some object $X \in \mathcal{C}$.

\textbf{Remark 5.7.6.3.} Let $\mathcal{F} : \mathcal{C} \to \mathcal{S}$ be a functor of $\infty$-categories and let $X \in \mathcal{C}$ be an object, and let $x \in \mathcal{F}(X)$ be a vertex. The condition that $x$ exhibits $\mathcal{F}$ as corepresented by $X$ depends only on the connected component $[x] \in \pi_0(\mathcal{F}(X))$.

\textbf{Remark 5.7.6.4.} Let $\mathcal{C}$ be an $\infty$-category containing an object $X$, let $\alpha : \mathcal{F} \to \mathcal{G}$ be a morphism in the $\infty$-category $\text{Fun}(\mathcal{C}, \mathcal{S})$, and let $x$ be a vertex of the Kan complex $\mathcal{F}(X)$. Then any two of the following conditions imply the third:

- The vertex $x \in \mathcal{F}(X)$ exhibits the functor $\mathcal{F}$ as corepresented by $X$.
- The vertex $\alpha(x) \in \mathcal{G}(X)$ exhibits the functor $\mathcal{G}$ as corepresented by $X$.
- The natural transformation $\alpha$ is an isomorphism.

In particular, if $\mathcal{F}$ and $\mathcal{G}$ are isomorphic objects of $\text{Fun}(\mathcal{C}, \mathcal{S})$, then $\mathcal{F}$ is corepresentable by $X$ if and only if $\mathcal{G}$ is corepresentable by $X$.

\textbf{Remark 5.7.6.5.} Let $\mathcal{F} : \mathcal{C} \to \mathcal{S}$ and $U : \mathcal{D} \to \mathcal{C}$ be functors of $\infty$-categories. Suppose we are given an object $Y \in \mathcal{D}$ and a vertex $\eta \in \mathcal{F}(U(Y))$. Then:

- If $U$ is fully faithful and $\eta$ exhibits the functor $\mathcal{F}$ as corepresented by $U(Y)$, then it also exhibits the functor $\mathcal{F} \circ U$ as corepresented by $\eta$.
- If $U$ is an equivalence of $\infty$-categories and $\eta$ exhibits the functor $\mathcal{F} \circ U$ as corepresented by $\eta$, then it also exhibits $\mathcal{F}$ as corepresented by $U(Y)$.
- If $U$ is an equivalence of $\infty$-categories, then the functor $\mathcal{F}$ is corepresentable if and only if $\mathcal{F} \circ U$ is corepresentable.

\textbf{Remark 5.7.6.6.} Let $\mathcal{F} : \mathcal{C} \to \mathcal{S}$ be a functor of $\infty$-categories, let $u : X \to Y$ be a morphism in $\mathcal{C}$, and let $x \in \mathcal{F}(X)$ be a vertex having image $y = \mathcal{F}(u)(x) \in \mathcal{F}(Y)$. Then any two of the following conditions imply the third:

- The vertex $x$ exhibits the functor $\mathcal{F}$ as corepresented by $X$.
- The vertex $y$ exhibits the functor $\mathcal{F}$ as corepresented by $Y$.
- The morphism $u$ is an isomorphism.
Remark 5.7.6.7 (Uniqueness of the Corepresenting Object). Let \( F : \mathcal{C} \to \mathcal{S} \) be a functor of \( \infty \)-categories which is corepresentable by an object \( X \in \mathcal{C} \). Let \( Y \) be another object of \( \mathcal{C} \). Then \( F \) is corepresentable by \( Y \) if and only if \( Y \) is isomorphic to \( X \). The “if” direction follows immediately from Remark 5.7.6.6. Conversely, suppose that \( F \) is corepresented by \( Y \). Choose vertices \( x \in F(X) \) and \( y \in F(Y) \) which exhibit \( F \) as corepresented by \( x \) and \( y \), respectively. Since evaluation at \( x \) induces a homotopy equivalence \( \text{Hom}_C(X,Y) \to F(Y) \), we can choose a morphism \( u : X \to Y \) such that \( F(u)(x) \) and \( y \) belong to the same connected component of \( F(Y) \). Then \( F(u)(x) \) also exhibits \( F \) as corepresented by \( Y \) (Remark 5.7.6.3), so that \( u \) is an isomorphism in \( \mathcal{C} \) by virtue of Remark 5.7.6.6.

Remark 5.7.6.8. Let \( F : \mathcal{C} \to \mathcal{S} \) be a functor of \( \infty \)-categories. Then the construction \( Y \mapsto \pi_0(F(Y)) \) determines a functor from the homotopy category \( h\mathcal{C} \) to the category of sets, which we will denote by \( \pi_0(F) \). Suppose that \( X \) is an object of \( \mathcal{C} \) and \( x \in F(X) \) exhibits \( F \) as corepresented by \( X \). Then, for every object \( Y \in \mathcal{C} \), evaluation on the connected component \( [x] \in \pi_0(F(X)) \) induces a bijection

\[
\text{Hom}_{h\mathcal{C}}(X,Y) = \pi_0(\text{Hom}_C(X,Y)) \to \pi_0(F(Y)).
\]

It follows that the functor \( \pi_0(F) : h\mathcal{C} \to \text{Set} \) is corepresentable by \( X \), in the sense of classical category theory.

Warning 5.7.6.9. The converse of Remark 5.7.6.8 is false in general. For example, let \( \mathcal{C} \) be an \( \infty \)-category containing an object \( X \), and let \( F : \mathcal{C} \to \text{Set} \subset \mathcal{S} \) be the functor given on objects by the formula \( F(Y) = \pi_0(\text{Hom}_C(X,Y)) \). Then \( \pi_0(F) \) is corepresentable by the object \( X \) (when regarded as a functor from \( h\mathcal{C} \) to the category of sets), but the functor \( F \) is usually not corepresentable.

In spite of Warning 5.7.6.9, the corepresentability of a functor \( F : \mathcal{C} \to \mathcal{S} \) can be tested at the level of the homotopy category \( h\mathcal{C} \). The caveat is that we must equip \( h\mathcal{C} \) with the enrichment described in Construction 4.6.8.13.

Definition 5.7.6.10. Let \( h\text{Kan} \) denote the homotopy category of Kan complexes (Construction 3.1.5.10) and let \( \mathcal{C} \) be an \( h\text{Kan} \)-enriched category containing an object \( X \). We will say that an \( h\text{Kan} \)-enriched functor \( F : \mathcal{C} \to h\text{Kan} \) is corepresentable by \( X \) if there exists a vertex \( x \in F(X) \) such that, for every object \( Y \in \mathcal{C} \), the induced map

\[
\text{Hom}_C(X,Y) \times \{x\} \to \text{Hom}_C(X,Y) \times F(X) \to F(Y)
\]

is an isomorphism in the homotopy category \( h\text{Kan} \). In this case, we also say that \( x \) exhibits \( F \) as corepresented by the object \( X \). We say that the functor \( F \) is corepresentable if it is corepresentable by \( X \) for some object \( X \in \mathcal{C} \).
5.7. CLASSIFICATION OF COCARTESIAN FIBRATIONS

We say that an hKan-enriched functor $\mathcal{F} : C^{\text{op}} \to \text{hKan}$ is \textit{representable by $X$} if it is corepresentable by the object $X^{\text{op}} \in C^{\text{op}}$, and that $\mathcal{F}$ is \textit{representable} if it is representable by some object of $C$.

\textbf{Remark 5.7.6.11.} Let $\mathcal{F} : C \to S$ be a functor of $\infty$-categories, and let $h\mathcal{F} : hC \to hS = \text{hKan}$ be the induced functor of hKan-enriched homotopy categories (see Construction 4.6.8.13). Then:

- A vertex $x \in \mathcal{F}(X)$ exhibits $\mathcal{F}$ as corepresented by an object $X \in C$ (in the sense of Definition 5.7.6.1) if and only if it exhibits $h\mathcal{F}$ as corepresented by the object $X \in hC$ (in the sense of Definition 5.7.6.10).
- The functor $\mathcal{F}$ is corepresentable by an object $X \in C$ if and only if $h\mathcal{F}$ is corepresentable by $X \in hC$.
- The functor $\mathcal{F}$ is corepresentable if and only if $h\mathcal{F}$ is corepresentable as an hKan-enriched functor.

\textbf{Remark 5.7.6.12.} Let $C$ be an hKan-enriched category. Then an hKan-enriched functor $\mathcal{F} : C \to \text{hKan}$ is corepresentable by an object $X \in C$ if and only if it is isomorphic (as an hKan-enriched functor) to the functor

$$C \to \text{hKan} \quad Y \mapsto \text{Hom}_C(X, Y).$$

Let $C$ be an $\infty$-category. It follows from Remarks 5.7.6.4 and 5.7.6.7 that there is a unique function

$$\{\text{Isomorphism classes of corepresentable functors } C \to S\} \to \{\text{Isomorphism classes of objects of } C\},$$

which carries (the isomorphism class of) a corepresentable functor $\mathcal{F}$ to (the isomorphic class of) an object $X \in C$ which corepresents $\mathcal{F}$. Our main goal in this section is to show that, modulo set-theoretic considerations, this map is bijective.

\textbf{Theorem 5.7.6.13.} Let $C$ be a locally small $\infty$-category. Then, for every object $X \in C$, there exists a functor $\mathcal{F} : C \to S$ which is corepresentable by $X$. Moreover, the functor $\mathcal{F}$ is uniquely determined up to isomorphism.
**Notation 5.7.6.14 (Corepresentable Functors).** Let \( \mathcal{C} \) be a locally small \( \infty \)-category. For every object \( X \in \mathcal{C} \), Theorem 5.7.6.13 asserts that there exists a functor \( \mathcal{F} : \mathcal{C} \to \mathcal{S} \) which is corepresented by \( X \), which is uniquely determined up to isomorphism. To emphasize this uniqueness, we will typically denote the functor \( \mathcal{F} \) by \( h^X \) and refer to it as the functor corepresented by \( X \). For every object \( Y \in \mathcal{C} \), we can apply the same argument to the opposite \( \infty \)-category \( \mathcal{C}^{\text{op}} \) to obtain a functor represented by \( Y \), which we will typically denote by \( h_Y : \mathcal{C}^{\text{op}} \to \mathcal{S} \) and refer to as the functor represented by \( Y \). Note that Remark 5.7.6.12 supplies isomorphisms \( h_X(Y) \cong \text{Hom}_C(X,Y) \cong h_Y(X) \) in the homotopy category \( h\text{Kan} \), depending functorially on the pair \((X,Y) \in h\text{C}^{\text{op}} \times h\text{C} \).

**Remark 5.7.6.15.** Let \( \mathcal{C} \) be an \( \infty \)-category. Then every object \( X \in \mathcal{C} \) determines an \( h\text{Kan} \)-enriched functor \( \text{Hom}_C(X,\bullet) : h\text{C} \to h\text{Kan} \). Theorem 5.7.6.13 asserts \( \text{Hom}_C(X,\bullet) \) can be promoted, in an essentially unique way, to a functor of \( \infty \)-categories \( h^X : \mathcal{C} \to \mathcal{S} \) (see Remark 5.7.6.12). Beware that this is a special feature of corepresentable functors. In general, an \( h\text{Kan} \)-enriched functor \( \mathcal{F} : h\text{C} \to h\text{Kan} \) cannot be promoted to a functor of \( \infty \)-categories. Moreover, when such a promotion exists, it need not be unique.

**Remark 5.7.6.16 (Functoriality).** Let \( \mathcal{C} \) be a locally small \( \infty \)-category. We will see later that the corepresentable functor \( h^X : \mathcal{C} \to \mathcal{S} \) and the representable functor \( h_Y : \mathcal{C}^{\text{op}} \to \mathcal{S} \) of Notation 5.7.6.14 depend functorially on the objects \( X \) and \( Y \), respectively. More precisely, the construction
\[
\text{Hom}_C(\bullet,\bullet) : h\text{C}^{\text{op}} \times h\text{C} \to h\text{Kan} \quad (X,Y) \mapsto \text{Hom}_C(X,Y)
\]
can be promoted to a functor of \( \infty \)-categories \( H : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S} \) with the following properties:

- For each object \( X \in \mathcal{C} \), the restriction \( H|_{\{X\} \times \mathcal{C}} \) is corepresentable by \( X \).
- For each object \( Y \in \mathcal{C} \), the restriction \( H|_{\mathcal{C}^{\text{op}} \times \{Y\}} \) is representable by \( Y \).

See Proposition [?].

Unlike its classical counterpart, Theorem 5.7.6.13 is nontrivial: given an object \( X \) of an \( \infty \)-category \( \mathcal{C} \), there is no immediately obvious candidate for a functor \( h^X : \mathcal{C} \to \mathcal{S} \) which is corepresented by \( X \). However, the situation is better when \( \mathcal{C} \) arises from a simplicially enriched category.

**Proposition 5.7.6.17.** Let \( \mathcal{C} \) be a locally Kan simplicial category, let \( X \) be an object of \( \mathcal{C} \), and let
\[
\mathcal{F} : N^\text{hc}_\bullet(\mathcal{C}) \to N^\text{hc}_\bullet(\text{Kan}) = \mathcal{S}.
\]
5.7. CLASSIFICATION OF COCARTESIAN FIBRATIONS

\[ \text{denote the homotopy coherent nerve of the simplicial functor } Y \mapsto \text{Hom}_C(X,Y)_\bullet. \] Then the identity morphism \( \text{id}_X \in \text{Hom}_C(X,X)_\bullet = \mathcal{F}(X) \) exhibits the functor \( \mathcal{F} \) as corepresented by \( X \), in the sense of Definition 5.7.6.1.

**Proof.** Fix an object \( Y \in \mathcal{C} \). We then have a commutative diagram of Kan complexes

\[
\begin{array}{ccc}
\text{Hom}_C(X,Y)_\bullet & \xrightarrow{U} & \text{Hom}_{\text{Kan}}(\mathcal{F}(X),\mathcal{F}(Y))_\bullet \\
\sim \downarrow & & \sim \downarrow \\
\text{Hom}_{\text{N}^{hc}}(\mathcal{C})(X,Y) & \xrightarrow{V} & \text{Hom}_S(\mathcal{F}(X),\mathcal{F}(Y)),
\end{array}
\]

where the vertical maps are supplied by Construction 4.6.7.3 (applied in the simplicial categories \( \mathcal{C} \) and Kan, respectively) and \( \text{ev} \) is given by evaluation at the vertex \( \text{id}_X \in \mathcal{F}(X) \).

Let \( \theta^{-1} \) denote a homotopy inverse to \( \theta' \) (which exists by virtue of Theorem 4.6.7.5). Proposition 5.7.6.17 asserts that the composition \( \text{ev} \circ \theta^{-1} \circ V \) is a homotopy equivalence. Since \( \theta \) is also a homotopy equivalence (Theorem 4.6.7.5), this is equivalent to the assertion that \( \text{ev} \circ U \) is a homotopy equivalence. This is clear: the composition \( \text{ev} \circ U \) is the identity map from the Kan complex \( \mathcal{F}(Y) = \text{Hom}_C(X,Y)_\bullet \) to itself. \( \square \)

**Remark 5.7.6.18.** Let \( \mathcal{C} \) be a locally Kan simplicial category. The preceding proof shows that if \( \mathcal{C} \) satisfies the conclusion of Proposition 5.7.6.17 then it also satisfies the conclusion of Theorem 4.6.7.5, that is, the comparison map \( \theta : \text{Hom}_C(X,Y)_\bullet \to \text{Hom}_{\text{N}^{hc}}(\mathcal{C})(X,Y) \) is a homotopy equivalence for every pair of objects \( X,Y \in \mathcal{C} \). Note however that we have already used Theorem 4.6.7.5 (applied to the simplicial category Kan) implicitly to give the definition of a corepresentable functor in the \( \infty \)-categorical setting.

The rest of this section is devoted to the proof of Theorem 5.7.6.13. Fix a locally small \( \infty \)-category \( \mathcal{C} \) and an object \( X \in \mathcal{C} \). We can then use the dictionary of Corollary 5.7.0.6 to identify functors \( \mathcal{F} : \mathcal{C} \to \mathcal{S} \) with left fibrations \( U : \mathcal{E} \to \mathcal{C} \) having essentially small fibers. We will show that \( \mathcal{F} \) is corepresentable by an object \( X \in \mathcal{C} \) if and only if the \( \infty \)-category \( \mathcal{E} \) has an initial object \( \tilde{X} \) satisfying \( U(\tilde{X}) = X \) (Proposition 5.7.6.21). We will then show that this condition guarantees that \( U \) is equivalent to the left fibration \( U_0 : \mathcal{C}_{X/} \to \mathcal{C} \) (Proposition 5.7.6.21). Combining these assertions, we see that a functor \( \mathcal{F} : \mathcal{C} \to \mathcal{S} \) is corepresentable by \( X \) if and only if it is a covariant transport representation for \( U_0 \), so that the existence and uniqueness assertions of Theorem 5.7.6.13 follow from Theorem 5.7.0.2.

**Proposition 5.7.6.19.** Let \( U : \mathcal{D} \to \mathcal{C} \) be a left fibration of \( \infty \)-categories and let \( \tilde{X} \in \mathcal{D} \) be an object having image \( X = U(\tilde{X}) \). The following conditions are equivalent:

1. There exists an equivalence \( F : \mathcal{C}_{X/} \to \mathcal{D} \) of left fibrations over \( \mathcal{C} \) satisfying \( F(\text{id}_X) = \tilde{X} \).
(2) The object \( \tilde{X} \in \mathcal{D} \) is initial (Definition 4.6.6.1).

(3) For every left fibration \( V : \mathcal{E} \to \mathcal{C} \), evaluation on the object \( \tilde{X} \) induces a trivial Kan fibration \( \text{Fun}_{/\mathcal{C}}(\mathcal{D}, \mathcal{E}) \to \{X\} \times_{\mathcal{C}} \mathcal{E} \).

(4) For every left fibration \( V : \mathcal{E} \to \mathcal{C} \), evaluation on the object \( \tilde{X} \) induces a bijection

\[
\pi_0(\text{Fun}_{/\mathcal{C}}(\mathcal{D}, \mathcal{E})) \to \pi_0(\{X\} \times_{\mathcal{C}} \mathcal{E}).
\]

Proof. If \( F : \mathcal{C}_{X/} \to \mathcal{D} \) is an equivalence of left fibrations over \( \mathcal{C} \), then it is an equivalence of \( \infty \)-categories (Proposition 5.1.6.5). Since \( \text{id}_X : X \to X \) is initial when regarded as an object of the \( \infty \)-category \( \mathcal{C}_{X/} \) (Proposition 4.6.6.23), Corollary 4.6.6.21 guarantees that \( \tilde{X} \) is an initial object of \( \mathcal{D} \). This proves the implication (1) \( \Rightarrow \) (2). The implication (2) \( \Rightarrow \) (3) follows by combining Corollary 4.6.6.25 with Proposition 4.2.5.4 and the implication (3) \( \Rightarrow \) (4) is immediate.

We will complete the proof by showing that (4) implies (1). Note that the object \( \text{id}_X \in \mathcal{C}_{X/} \) satisfies condition (1) and therefore also satisfies condition (3). It follows that there exists a commutative diagram

\[
\begin{array}{ccc}
\mathcal{C}_{X/} & \xrightarrow{F} & \mathcal{D} \\
\downarrow & & \downarrow U \\
\mathcal{C} & \xleftarrow{\mathcal{C}} & \mathcal{C}
\end{array}
\]

satisfying \( F(\text{id}_X) = \tilde{X} \). To complete the proof, it will suffice to show that if condition (4) is satisfied, then \( F \) is an equivalence of left fibrations over \( \mathcal{C} \). For every left fibration \( V : \mathcal{E} \to \mathcal{C} \), we have a commutative diagram of sets

\[
\begin{array}{ccc}
\pi_0(\text{Fun}_{/\mathcal{C}}(\mathcal{D}, \mathcal{E})) & \xrightarrow{\circ F} & \pi_0(\text{Fun}_{/\mathcal{C}}(\mathcal{C}_{X/}, \mathcal{E})) \\
\downarrow & & \downarrow \\
\pi_0(\{X\} \times_{\mathcal{C}} \mathcal{E}) & \xleftarrow{} & \pi_0(\{X\} \times_{\mathcal{C}} \mathcal{E})
\end{array}
\]

where the vertical maps are given by evaluation on the objects \( \tilde{X} \in \mathcal{D} \) and \( \text{id}_X \in \mathcal{C}_{X/} \), and are therefore bijective. It follows that the horizontal map is also bijective.  \( \square \)
Corollary 5.7.6.20. Suppose we are given a commutative diagram of $\infty$-categories

$$
\begin{array}{ccc}
\mathcal{D} & \xrightarrow{F} & \mathcal{E} \\
\downarrow U & & \downarrow V \\
\mathcal{C} & \xleftarrow{\sim} & \\
\end{array}
$$

where $U$ and $V$ are left fibrations. Let $\bar{X} \in \mathcal{D}$ be an initial object. Then $F$ is an equivalence of $\infty$-categories if and only if $F(\bar{X})$ is an initial object of $\mathcal{E}$.

Proof. If $F$ is an equivalence of $\infty$-categories, then it carries initial objects to initial objects by virtue of Corollary 4.6.6.21. Conversely, suppose that $F(\bar{X})$ is an initial object of $\mathcal{E}$; we wish to show that $F$ is an equivalence of $\infty$-categories. Set $X = U(\bar{X})$. Applying Proposition 5.7.6.19 we deduce that there is a functor $G \in \text{Fun}_{/\mathcal{C}}(\mathcal{E}, \mathcal{D})$ such that $(G \circ F)(\bar{X})$ is isomorphic to $\bar{X}$ as an object of the $\infty$-category $\mathcal{D}_X = \{X\} \times_{\mathcal{C}} \mathcal{D}$. Applying Proposition 5.7.6.19 again, we deduce that $G \circ F$ is isomorphic to $\text{id}_\mathcal{D}$ as an object of the $\infty$-category $\text{Fun}_{/\mathcal{C}}(\mathcal{D}, \mathcal{D})$; in particular, $F$ is a right homotopy inverse to $G$. Since $G$ carries $F(\bar{X})$ to an initial object of $\mathcal{D}$, we can apply the same argument (with the roles of $\mathcal{D}$ and $\mathcal{E}$ reversed) to show that $G$ has a left homotopy inverse. It follows that $G$ is an equivalence of $\infty$-categories, so that $F$ is also an equivalence of $\infty$-categories. \qed

Proposition 5.7.6.21. Let $U : \mathcal{D} \to \mathcal{C}$ be a left fibration of $\infty$-categories having essentially small fibers, and let $X \in \mathcal{C}$ be an object. Then:

1. Let $\bar{X} \in \mathcal{D}$ be an object satisfying $U(\bar{X}) = X$. Then $\bar{X}$ is an initial object of $\mathcal{D}$ if and only if, for every object $Y \in \mathcal{C}$, the composition

   $$
   \text{Hom}_\mathcal{C}(X,Y) \xrightarrow{\theta} \text{Fun}(\mathcal{D}_X, \mathcal{D}_Y) \xrightarrow{\text{ev}_{\bar{X}}} \mathcal{D}_Y
   $$

   is a homotopy equivalence, where $\theta$ is given by parametrized covariant transport (see Definition 5.2.8.1).

2. Let $h\text{Tr}_{\mathcal{D}/\mathcal{C}} : h\mathcal{C} \to h\text{Kan}$ be the homotopy transport representation of $U$, which we regard as an $h\text{Kan}$-enriched functor (Variant 5.2.8.12). Then $\bar{X}$ is an initial object of $\mathcal{D}$ if and only if it exhibits $h\text{Tr}_{\mathcal{D}/\mathcal{C}}$ as corepresented by $X$, in the sense of Definition 5.7.6.10.

3. The homotopy transport representation $h\text{Tr}_{\mathcal{D}/\mathcal{C}}$ is corepresentable by the object $X$ if and only if there exists an initial object $\bar{X} \in \mathcal{D}$ satisfying $U(\bar{X}) = X$.

4. Let $\text{Tr}_{\mathcal{D}/\mathcal{C}} : \mathcal{C} \to \mathcal{S}$ be a covariant transport representation for $U$. Then $\text{Tr}_{\mathcal{D}/\mathcal{C}}$ is corepresentable by the object $X$ if and only if there exists an initial object $\bar{X} \in \mathcal{D}$ satisfying $U(\bar{X}) = X$. 

Proof. Let \( \{X\} \times_C C \) be the oriented fiber product of Definition 4.6.4.1 and let us regard \( \text{id}_X \) as an initial object of \( \{X\} \times_C C \) (Proposition 4.6.6.23). Using Proposition 5.7.6.19 we can choose a functor of \( \infty \)-categories \( F : \{X\} \times_C C \to D \) satisfying \( F(\text{id}_X) = X \) which fits into a commutative diagram

\[
\begin{array}{ccc}
\{X\} \times_C C & \xrightarrow{F} & D \\
\downarrow{U} & & \downarrow{\text{id}_\mathcal{C}} \\
\mathcal{C} & & \\
\end{array}
\]

Using Proposition 5.7.6.19 we see that \( \tilde{X} \) is an initial object of \( D \) if and only if \( F \) is an equivalence of left fibrations over \( \mathcal{C} \). By virtue of Corollary 5.1.6.15 this is equivalent to the requirement that for each object \( Y \in \mathcal{C} \), the functor \( F \) restricts to a homotopy equivalence of Kan complexes

\[ F_Y : \text{Hom}_\mathcal{C}(X,Y) = \{X\} \times_C \{Y\} \to D_Y \]

Assertion (1) follows from the observation that \( F_Y \) is homotopic to the composition of the parametrized covariant transport morphism \( \theta : \text{Hom}_\mathcal{C}(X,Y) \to \text{Fun}(\mathcal{D}_X, \mathcal{D}_Y) \) with the evaluation map \( \text{ev}_{\tilde{X}} : \text{Fun}(\mathcal{D}_X, \mathcal{D}_Y) \to \mathcal{D}_Y \) (see Remark 5.2.8.5 and Proposition 5.2.8.7). The implication (1) \( \Rightarrow \) (2) follows from Remark 5.7.5.8, the implication (2) \( \Rightarrow \) (3) is immediate, and the implication (3) \( \Rightarrow \) (4) follows from Remark 5.7.6.11.

Proof of Theorem 5.7.6.13. Let \( \mathcal{C} \) be a locally small \( \infty \)-category and let \( X \) be an object of \( \mathcal{C} \). We wish to show that there exists a functor \( \mathcal{F} : \mathcal{C} \to \mathcal{S} \) which is co-representable by \( X \), and that \( \mathcal{F} \) is uniquely determined up to isomorphism (as an object of the \( \infty \)-category \( \text{Fun}(\mathcal{C}, \mathcal{S}) \)). By virtue of Proposition 5.7.6.21 and Corollary 5.7.0.6, this is equivalent to the assertion that there exists a left fibration \( U : \mathcal{D} \to \mathcal{C} \) together with an initial object \( \tilde{X} \in \mathcal{D} \) satisfying \( U(\tilde{X}) = X \), and that the left fibration \( U \) is uniquely determined up to equivalence (in the sense of Definition 5.1.6.1). To prove existence, we can take \( \mathcal{D} = \mathcal{C}_{/X} \) and \( \tilde{X} \) to be the identity morphism \( \text{id}_X \) (Proposition 4.6.6.23). The uniqueness assertion follows from Proposition 5.7.6.19.

5.7.7 Application: Extending Cocartesian Fibrations

In §3.3.8 we showed that every Kan fibration of simplicial sets \( f : X \to S \) can be obtained as the pullback of a Kan fibration between Kan complexes. Our goal in this section is to prove an analogous result for cocartesian fibrations of simplicial sets (Corollary 5.7.7.3). Our starting point is the following:
Lemma 5.7.7.1. Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{E}_0 & \xrightarrow{G_0} & \mathcal{E}' \\
V_0 & \downarrow & V \\
\mathcal{C}_0 & \xrightarrow{\mathcal{C}} & \mathcal{C}
\end{array}
\]

(5.33)

where the vertical maps are inner fibrations, the bottom horizontal map exhibits \( \mathcal{C}_0 \) as a simplicial subset of \( \mathcal{C} \), and \( G_0 \) induces an equivalence \( \mathcal{E}_0 \to \mathcal{C}_0 \times_{\mathcal{C}} \mathcal{E}' \) of inner fibrations over \( \mathcal{C}_0 \). Then (5.33) can be extended to a commutative diagram

\[
\begin{array}{ccc}
\mathcal{E}_0 & \xrightarrow{G} & \mathcal{E}' \\
U_0 & \downarrow & U \\
\mathcal{C}_0 & \xrightarrow{\mathcal{C}} & \mathcal{C}_0
\end{array}
\]

where \( U \) is an inner fibration, \( G \) is an equivalence of inner fibrations over \( \mathcal{C} \), and the square on the left induces an isomorphism of simplicial sets \( \mathcal{E}_0 \simeq \mathcal{C}_0 \times_{\mathcal{C}} \mathcal{E}' \).

Proof. Choose a monomorphism of simplicial sets \( \mathcal{E}_0 \xhookrightarrow{} Q \), where \( Q \) is a contractible Kan complex (see Exercise 3.1.7.10). Replacing \( \mathcal{E}' \) with the product \( \mathcal{E}' \times Q \), we can reduce to the case where \( G_0 \) is a monomorphism of simplicial sets. Let \( \mathcal{E} \) denote the simplicial subset of \( \mathcal{E}' \) consisting of those simplices \( \sigma : \Delta^m \to \mathcal{E}' \) for which the induced map \( \mathcal{C}_0 \times_{\mathcal{C}} \Delta^m \to \mathcal{C}_0 \times_{\mathcal{C}} \mathcal{E}' \) factors through \( G_0 \). To complete the proof, it will suffice to verify the following:

(a) The morphism \( U = V|_{\mathcal{E}} \) is an inner fibration from \( \mathcal{E} \) to \( \mathcal{C} \).

(b) The inclusion \( \mathcal{E} \hookrightarrow \mathcal{E}' \) is an equivalence of inner fibrations over \( \mathcal{C} \).

By virtue of Remark 4.1.1.13 and Proposition 5.1.6.9, it suffices to prove (a) and (b) in the special case where \( \mathcal{C} = \Delta^n \) is a standard simplex. In this case, the morphism \( V : \mathcal{E}' \to \mathcal{C} \) is an isofibration (Example 4.4.1.6).

Let \( \mathcal{E}_0' \) denote the fiber product \( \mathcal{C}_0 \times_{\mathcal{C}} \mathcal{E}' \). Applying Lemma 5.1.6.12 to the morphism \( G_0 : \mathcal{E}_0 \to \mathcal{E}_0' \) (which is an equivalence of inner fibrations over \( \mathcal{C}_0 \)), we deduce that there exists a morphism \( R_0 : \mathcal{E}_0' \to \mathcal{E}_0 \) in the category \( \text{Set}_{\Delta}/\mathcal{C}_0 \) such that \( R_0 \circ G_0 = \text{id}_{\mathcal{E}_0} \), and an isomorphism \( \alpha_0 : \text{id}_{\mathcal{E}_0'} \to G_0 \circ R_0 \) in the \( \infty \)-category \( \text{Fun}_{/\mathcal{C}_0}(\mathcal{E}_0, \mathcal{E}_0') \) whose image in \( \text{Fun}_{/\mathcal{C}_0}(\mathcal{E}_0, \mathcal{E}_0') \) is degenerate. Applying Proposition 4.4.5.8 (and the criterion of Proposition 4.4.4.9), we can choose a morphism \( R : \mathcal{E}' \to \mathcal{E}' \) in \( \text{Set}_{\Delta}/\mathcal{C} \) such that \( R|_{\mathcal{E}_0'} = G_0 \circ R_0 \) and an
isomorphism \( \alpha : \text{id}_{\mathcal{E}'} \to R \) in the \( \infty \)-category \( \text{Fun}_{/C}(\mathcal{E}', \mathcal{E}') \) whose image in \( \text{Fun}_{/C_0}(\mathcal{E}'_0, \mathcal{E}'_0) \) is equal to \( \alpha_0 \).

We now prove (a). Suppose we are given a lifting problem

\[
\begin{array}{ccc}
A & \xrightarrow{f_0} & \mathcal{E} \\
\downarrow & \searrow & \downarrow U \\
B & \xleftarrow{f} & C,
\end{array}
\]

where the left vertical map is inner anodyne. Since \( V : \mathcal{E}' \to C \) is an inner fibration, we can extend \( f_0 \) to a morphism \( f' : B \to \mathcal{E} \) satisfying \( V \circ f' = \mathcal{F} \). Set \( B_0 = C_0 \times_C B \) and \( A_0 = C_0 \times_C A \), and define

\[
f_1 : (A \coprod_{A_0} B_0) \to \mathcal{E}
\]

by the formula \( f_1|_A = f_0 \) and \( f_1|_{B_0} = R \circ f'|_{B_0} \). Note that there is an isomorphism

\[
\beta : f'|_{A \coprod_{A_0} B_0} \to f_1
\]

in the \( \infty \)-category \( \text{Fun}_{/C}(A \coprod_{A_0} B_0, \mathcal{E}') \), whose image in \( \text{Fun}_{/C}(A, \mathcal{E}') \) is degenerate and whose image in \( \text{Fun}_{/C}(B_0, \mathcal{E}') \) is the restriction of \( \alpha \). Applying Proposition 4.4.5.8, we deduce that \( f_1 \) admits an extension \( f : B \to C \) satisfying \( U \circ f = \mathcal{F} \).

To prove (b), we observe that the morphism \( R : \mathcal{E}' \to \mathcal{E} \) is a homotopy inverse of the inclusion \( \iota : \mathcal{E} \hookrightarrow \mathcal{E}' \) relative to \( C \). By construction, \( \alpha \) determines an isomorphism from \( \text{id}_{\mathcal{E}'} \) to the composition \( \iota \circ R \) in the \( \infty \)-category \( \text{Fun}_{/C}(\mathcal{E}, \mathcal{E}') \), and the restriction of \( \alpha \) determines an isomorphism from \( \text{id}_{\mathcal{E}} \) to \( R \circ \iota \) in the \( \infty \)-category \( \text{Fun}_{/C}(\mathcal{E}, \mathcal{E}) \).

\[\square\]

**Proposition 5.7.7.2** (Extending Cocartesian Fibrations). Let \( \mathcal{C} \) be a simplicial set, let \( \mathcal{C}_0 \subseteq \mathcal{C} \) be a simplicial subset, and let \( U_0 : \mathcal{E}_0 \to \mathcal{C}_0 \) be a cocartesian fibration of simplicial sets. Suppose that the inclusion \( \mathcal{C}_0 \hookrightarrow \mathcal{C} \) is a categorical equivalence of simplicial sets. Then there exists a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{E}_0 & \xrightarrow{U_0} & \mathcal{E} \\
\downarrow & \searrow & \downarrow U \\
\mathcal{C}_0 & \xrightarrow{} & \mathcal{C},
\end{array}
\]

where \( U \) is a cocartesian fibration.
5.7. CLASSIFICATION OF COCARTESIAN FIBRATIONS

Proof. By virtue of Theorem 5.7.0.2, there exists a morphism of simplicial sets $\mathcal{F}_0 : C_0 \to QC$ and an equivalence $G_0 : \mathcal{E}_0 \to \int_{C_0} \mathcal{F}_0$ of cocartesian fibrations over $C_0$. Since $QC$ is an $\infty$-category (Proposition 5.6.4.3), our assumption that the inclusion $C_0 \hookrightarrow C$ is a categorical equivalence guarantees that we can extend $\mathcal{F}_0$ to a morphism of simplicial sets $\mathcal{F} : C \to QC$. We can then identify $G_0$ with an equivalence $E_0 \to C_0 \times_C \int_C \mathcal{F}$ of cocartesian fibrations over $C_0$. Applying Lemma 5.7.7.1, we can write $U_0$ as the pullback of an inner fibration $U : \mathcal{E} \to C$ which is equivalent to the projection map $V : \int_C \mathcal{F} \to C$ as an inner fibration over $C$. Since $V$ is a cocartesian fibration (Proposition 5.7.2.2), it follows that $U$ is also a cocartesian fibration (Proposition 5.1.6.13).

029F Corollary 5.7.7.3. Let $U_0 : \mathcal{E}_0 \to C_0$ be a cocartesian fibration of simplicial sets. Then there exists a pullback diagram

$$
\begin{array}{ccc}
\mathcal{E}_0 & \to & \mathcal{E} \\
\downarrow U_0 & & \downarrow U \\
C_0 & \underset{F}{\to} & C,
\end{array}
$$

where $U$ is a cocartesian fibration of $\infty$-categories and $F$ is inner anodyne.

Proof. Using Corollary 4.1.3.3 we can choose an inner anodyne map $F : C_0 \hookrightarrow C$, where $C$ is an $\infty$-category. Since $F$ is a categorical equivalence of simplicial sets (Corollary 4.5.3.14, Proposition 5.7.7.2) guarantees that $U_0$ is the pullback of a cocartesian fibration $U : \mathcal{E} \to C$. □

02LR Remark 5.7.7.4. In the situation of Corollary 5.7.7.3, if $U_0$ is a left fibration, then $U$ is also a left fibration. To see this, it suffices to show that the fibers of $U$ are Kan complexes (Proposition 5.1.4.14). This is clear, since every fiber of $U$ is also a fiber of $U_0$ (note that the inner anodyne morphism $F : C_0 \to C$ is bijective at the level of vertices; see Exercise 1.4.6.6).

029G Corollary 5.7.7.5. Let $U : \mathcal{E} \to C$ be a cocartesian fibration of simplicial sets. Then $U$ is an isofibration.

Proof. By virtue of Corollary 5.7.7.3, we may assume without loss of generality that $U$ is a cocartesian fibration of $\infty$-categories, in which case the desired result follows from Proposition 5.1.4.8. □
Corollary 5.7.7.6. Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets. Then $U$ is exponentiable (Definition \[4.5.9.10\]). In particular, for any pullback diagram of simplicial sets

$$
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{F} & \mathcal{E} \\
\downarrow U' & & \downarrow U \\
\mathcal{C}' & \xrightarrow{\mathcal{F}} & \mathcal{C},
\end{array}
$$

(5.34)

if $\mathcal{F}$ is a categorical equivalence, then $F$ is also a categorical equivalence.

Proof. By virtue of Corollary 5.7.7.3 and Remark \[4.5.9.13\] we may assume that $U$ is a cocartesian fibration of $\infty$-categories, in which case the desired result follows from Proposition 5.3.6.1.

Corollary 5.7.7.7. Suppose we are given a commutative diagram of simplicial sets

$$
\begin{array}{ccc}
\mathcal{D} & \xrightarrow{F} & \mathcal{E} \\
\downarrow U & & \downarrow V \\
\mathcal{C}' & \xrightarrow{\mathcal{F}} & \mathcal{C},
\end{array}
$$

where $U$ and $V$ are cocartesian fibrations. Then $F$ is an equivalence of cocartesian fibrations over $\mathcal{C}$ (Definition \[5.1.6.1\]) if and only if it is a categorical equivalence of simplicial sets.

Proof. Combine Proposition 5.1.6.5 with Corollary 5.7.7.5.

5.7.8 Transport Witnesses

Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of $\infty$-categories, and assume that for every object $X \in \mathcal{C}$ the fiber $\mathcal{E}_X = \{X\} \times_\mathcal{C} \mathcal{E}$ is essentially small. Theorem \[5.7.0.2\] asserts that there exists a commutative diagram

$$
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{\widetilde{\mathcal{F}}} & \mathcal{QC}_{\text{Obj}} \\
\downarrow U & & \downarrow V \\
\mathcal{C} & \xrightarrow{\mathcal{F}} & \mathcal{QC}
\end{array}
$$
which witnesses \( \mathcal{F} \) as a covariant transport representation for \( U \); here \( V : \mathcal{QC}_{\text{Obj}} \to \mathcal{QC} \) is the cocartesian fibration of Proposition 5.6.6.11. In this section, we formulate a stronger statement, which asserts that the collection of all such diagrams is parametrized by a contractible Kan complex (Theorem 5.7.8.3).

**Notation 5.7.8.1.** Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets. We let \( TW(\mathcal{E} / \mathcal{C}) \) denote the simplicial subset of the fiber product
\[
\text{Fun}(\mathcal{C}, \mathcal{QC}) \times_{\text{Fun}(\mathcal{E}, \mathcal{QC})} \text{Fun}(\mathcal{E}, \mathcal{QC}_{\text{Obj}})
\]
whose \( n \)-simplices are diagrams
\[
\begin{tikzcd}
\Delta^n \times \mathcal{E} 
& \mathcal{QC}_{\text{Obj}} \\
\Delta^n \times \mathcal{C} 
& \mathcal{QC}
\end{tikzcd}
\]
which witness \( \mathcal{F} \) as a covariant transport representation for the cocartesian fibration \( (\text{id}_{\Delta^n} \times U) : \Delta^n \times \mathcal{E} \to \Delta^n \times \mathcal{C} \).

**Example 5.7.8.2.** Let \( \mathcal{E} \) be an \( \infty \)-category and let \( U : \mathcal{E} \to \Delta^0 \) denote the projection map. Note that projection onto the first factor determines a morphism of simplicial sets
\[
TW(\mathcal{E} / \Delta^0) \to \text{Fun}(\Delta^0, \mathcal{QC}) = \mathcal{QC}.
\]
Unwinding the definitions, we see that the fiber of this morphism over a small \( \infty \)-category \( \mathcal{E}' \) can be identified with the full subcategory
\[
\text{Equiv}(\mathcal{E}, \{\mathcal{E}'\} \times _{\mathcal{QC}} \mathcal{QC}_{\text{Obj}}) \subseteq \text{Fun}(\mathcal{E}, \{\mathcal{E}'\} \times _{\mathcal{QC}} \mathcal{QC}_{\text{Obj}})^\sim
\]
spanned by the equivalences of \( \infty \)-categories \( \mathcal{E} \to \{\mathcal{E}'\} \times _{\mathcal{QC}} \mathcal{QC}_{\text{Obj}}. \)

We will prove the following result in §5.7.9

**Theorem 5.7.8.3.** Let \( \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets. Suppose that, for every vertex \( \mathcal{C} \in \mathcal{C} \), the \( \infty \)-category \( \mathcal{E}_{\mathcal{C}} = \{\mathcal{C}\} \times _{\mathcal{C}} \mathcal{E} \) is essentially small. Then the simplicial set \( TW(\mathcal{E} / \mathcal{C}) \) is a contractible Kan complex.

**Remark 5.7.8.4.** Theorem 5.7.8.3 is an immediate consequence of Theorem 5.7.5.10. We will see at the end of this section that the converse is also true.

The remainder of this section is devoted to establishing some formal properties of the simplicial sets \( TW(\mathcal{E} / \mathcal{C}) \) which will be useful for the proof of Theorem 5.7.8.3.
Lemma 5.7.8.5. Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{\tilde{F}} & \mathcal{QC}_{\text{Obj}} \\
\downarrow \scriptstyle{U} & & \downarrow \scriptstyle{V} \\
\mathcal{C} & \xrightarrow{\mathcal{F}} & \mathcal{QC}
\end{array}
\]

where \(U\) is a cocartesian fibration. Let \(j : \mathcal{C}_0 \hookrightarrow \mathcal{C}\) be an inner anodyne morphism of simplicial sets, let \(\mathcal{E}_0\) denote the fiber product \(\mathcal{C}_0 \times_{\mathcal{C}} \mathcal{E}\), and let \(U_0 : \mathcal{E}_0 \to \mathcal{C}_0\) denote the projection map. If \(\tilde{F}|_{\mathcal{E}_0}\) witnesses \(\mathcal{F}|_{\mathcal{C}_0}\) as a covariant transport representation for \(U_0\), then \(\hat{F}\) witnesses \(\mathcal{F}\) as a covariant transport representation for \(U\).

Proof. Let \(S\) denote the collection of all morphisms of simplicial sets \(i : A \to B\) with the following property: for every morphism of simplicial sets \(B \to \mathcal{C}\), if the restriction \(\tilde{F}|_{A \times_{\mathcal{C}} \mathcal{E}}\) witnesses \(\mathcal{F}|_{A}\) as a covariant transport representation for the projection map \(A \times_{\mathcal{C}} \mathcal{E} \to A\), then \(\tilde{F}|_{B \times_{\mathcal{C}} \mathcal{E}}\) witnesses \(\mathcal{F}|_{B}\) as a covariant transport representation for the projection map \(B \times_{\mathcal{C}} \mathcal{E} \to B\). To prove Lemma 5.7.8.5, it will suffice to show that every inner anodyne morphism of simplicial sets belongs to \(S\). It is not difficult to see that the collection of morphisms \(S\) is weakly saturated, in the sense of Definition 1.4.4.15. It will therefore suffice to show that, for every pair of integers \(0 < i < n\), the inner horn inclusion \(\Lambda^n_i \hookrightarrow \Delta^n\) belongs to \(S\). We may therefore assume without loss of generality that \(\mathcal{C} = \Delta^n\) and \(\mathcal{C}_0 = \Lambda^n_i\) is an inner horn.

Since every vertex of \(\Delta^n\) is contained in \(\Lambda^n_i\), it follows immediately that the pair \((\mathcal{F}, \tilde{F})\) satisfies condition (a) of Remark 5.7.5.3. To verify (b), let \(e : X \to Z\) be an \(U\)-cocartesian edge of \(\mathcal{E}\) having image \(\overline{e} = U(e) \in \Delta^n\); we wish to show that \(\tilde{F}(e)\) is a \(V\)-cocartesian edge of \(\mathcal{E}'\). If \(\overline{e}\) belongs to the horn \(\Lambda^n_i\), then this follows from our assumption on \(\tilde{F}|_{\mathcal{E}_0}\). We may therefore assume without loss of generality that \(\mathcal{C} = \Delta^2\) and that \(\overline{e} : 0 \to 2\) is the “long” edge of the simplex \(\Delta^2\). Since \(U\) is a cocartesian fibration, there exists a \(U\)-cocartesian edge \(e' : X \to Y\) of \(\mathcal{E}\), where \(U(Y) = 1\). Our assumption that \(e'\) is \(U\)-cocartesian guarantees the existence of a 2-simplex

\[
\begin{array}{ccc}
X & \xrightarrow{e} & Z \\
\uparrow \scriptstyle{e'} & & \uparrow \scriptstyle{e''} \\
Y & & 
\end{array}
\]

of \(\mathcal{E}\), and Proposition 5.1.4.12 implies that \(e''\) is also \(U\)-cocartesian. Since \(\tilde{F}|_{\mathcal{C}_0}\) carries \(U_0\)-cocartesian morphisms of \(\mathcal{E}_0\) to \(V\)-cocartesian morphisms of \(\mathcal{QC}_{\text{Obj}}\), it follows that \(\tilde{F}(e')\)
and $\tilde{F}(e'')$ are $V$-cocartesian edges of $E'$. Applying Proposition 5.1.4.12 again, we deduce that $\tilde{F}(e)$ is also $V$-cocartesian.

Lemma 5.7.8.6. Let $U : E \to C$ be a cocartesian fibration of simplicial sets. Then:

1. The fiber product $\mathcal{M} = \text{Fun}(C, QC) \times_{\text{Fun}(E, QC)} \text{Fun}(E, QC_{\text{Obj}})$ is an $\infty$-category.

2. The simplicial set $\text{TW}(E / C)$ is a replete subcategory of $\mathcal{M}$ (see Example 4.4.1.11).

In particular, the simplicial set $\text{TW}(E / C)$ is an $\infty$-category.

Proof. Since $V$ is an inner fibration, the induced map $V' : \text{Fun}(E, QC_{\text{Obj}}) \to \text{Fun}(E, QC)$ is also an inner fibration (Corollary 4.1.4.3). The projection map $\mathcal{M} \to \text{Fun}(C, QC)$ is a pullback of $V'$, and is therefore also an inner fibration. Since $\text{Fun}(C, QC)$ is an $\infty$-category (Theorem 1.4.3.7), assertion (1) follows from Remark 4.1.1.9.

We now prove (2). We first show that $\text{TW}(E / C)$ is a subcategory of $\mathcal{M}$: that is, that the inclusion map $\text{TW}(E / C) \hookrightarrow \mathcal{M}$ is an inner fibration. Fix integers $0 < i < n$ and let $\sigma$ be an $n$-simplex of $\mathcal{M}$ for which the restriction $\sigma|_{\Lambda^n_i}$ belongs to $\text{TW}(E / C)$; we wish to show that $\sigma$ is an $n$-simplex of $\text{TW}(E / C)$. Unwinding the definitions, we can identify $\sigma$ with a commutative diagram

$$
\begin{array}{ccc}
\Delta^n \times E & \xrightarrow{\tilde{F}} & QC_{\text{Obj}} \\
\downarrow \text{id}_{\Delta^n \times U} & & \downarrow V \\
\Delta^n \times C & \xrightarrow{\mathcal{F}} & QC;
\end{array}
$$

we wish to show that $\tilde{F}$ witnesses $\mathcal{F}$ as a covariant transport representation for the cocartesian fibration $\text{id}_{\Delta^n \times U}$. This follows from Lemma 5.7.8.5, since the inclusion $\Lambda^n_i \times C \hookrightarrow \Delta^n \times C$ is inner anodyne (Lemma 1.4.7.5).

We now complete the proof by showing that the subcategory $\text{TW}(E / C) \subseteq \mathcal{M}$ is replete. Let $u$ be an isomorphism in the $\infty$-category $\mathcal{M}$, which we identify with a commutative diagram

$$
\begin{array}{ccc}
\Delta^1 \times E & \xrightarrow{\tilde{F}} & QC_{\text{Obj}} \\
\downarrow \text{id}_{\Delta^1 \times U} & & \downarrow V \\
\Delta^1 \times C & \xrightarrow{\mathcal{F}} & QC.
\end{array}
$$

Set $\mathcal{F}_0 = \mathcal{F}|_{\{0\} \times C}$ and $\tilde{\mathcal{F}}_0 = \tilde{F}|_{\{0\} \times E}$, and suppose that the pair $(\mathcal{F}_0, \tilde{\mathcal{F}}_0)$ is an object of the $\infty$-category $\text{TW}(E / C)$ (that is, $\tilde{\mathcal{F}}_0$ witnesses $\mathcal{F}_0$ as a covariant transport representation
for \( U \). We wish to show that \( \tilde{F} \) witnesses \( F \) as a covariant transport representation for \( (\text{id}_{\Delta^1} \times U) : \Delta^1 \times \mathcal{E} \to \Delta^1 \times \mathcal{C} \).

We first verify condition (b) of Remark 5.7.5.3. Let \( e \) be an \( (\text{id}_{\Delta^1} \times U) \)-cocartesian edge of the simplicial set \( \Delta^1 \times \mathcal{E} \); we wish to show that \( \tilde{F}(e) \) is a \( V \)-cocartesian morphism of \( \mathcal{QC}_{\text{Obj}} \).

Write \( e = (\varphi_{ij}, \tau) \), where \( \varphi_{ij} : i \to j \) is an edge of \( \Delta^1 \) and \( \tau : X \to Y \) is a \( U \)-cocartesian edge of \( \mathcal{E} \). We consider three cases:

1. Suppose that \( i = j = 0 \). Then \( \tilde{F}(e) = \tilde{F}_0(e) \) is \( V \)-cocartesian by virtue of our assumption that \( \tilde{F}_0 \) witnesses \( F_0 \) as a covariant transport representation for \( U \).

2. Suppose that \( i = 0 \) and \( j = 1 \). In this case, there exists a 2-simplex of \( \Delta^1 \times \mathcal{E} \) whose boundary is indicated in the diagram

\[
\begin{array}{ccc}
(0, Y) & \xrightarrow{(\varphi_{01}, \tau)} & (\varphi_{01}, \text{id}_Y) \\
(0, X) & \xleftarrow{(\varphi_{01}, \tau)} & (1, Y).
\end{array}
\]

Our assumption that \( u \) is an isomorphism in the \( \infty \)-category \( \mathcal{M} \) guarantees that \( \tilde{F}(\varphi_{01}, \text{id}_Y) \) is an isomorphism in the \( \infty \)-category \( \mathcal{QC}_{\text{Obj}} \), and is therefore \( V \)-cocartesian (Proposition 5.1.1.8). It follows from case (1) that \( \tilde{F}(\varphi_{00}, \tau) \) is also a \( V \)-cocartesian morphism of \( \mathcal{QC}_{\text{Obj}} \). Since the collection of \( V \)-cocartesian morphisms of \( \mathcal{QC}_{\text{Obj}} \) is closed under composition (Corollary 5.1.2.4), we conclude that \( \tilde{F}(\varphi_{01}, \tau) \) is also \( V \)-cocartesian.

3. Suppose that \( i = j = 1 \). In this case, there exists a 2-simplex of \( \Delta^1 \times \mathcal{E} \) whose boundary is indicated in the diagram

\[
\begin{array}{ccc}
(1, X) & \xrightarrow{(\varphi_{01}, \text{id}_X)} & (\varphi_{11}, \tau) \\
(0, X) & \xleftarrow{(\varphi_{01}, \tau)} & (1, Y).
\end{array}
\]

Our assumption that \( u \) is an isomorphism in the \( \infty \)-category \( \mathcal{M} \) guarantees that \( \tilde{F}(\varphi_{01}, \text{id}_X) \) is an isomorphism in the \( \infty \)-category \( \mathcal{QC}_{\text{Obj}} \), and is therefore \( V \)-cocartesian (Proposition 5.1.1.8). It follows from case (2) that \( \tilde{F}(\varphi_{01}, \tau) \) is also a \( V \)-cocartesian morphism of \( \mathcal{QC}_{\text{Obj}} \), so that \( \tilde{F}(\varphi_{11}, \tau) \) is \( V \)-cocartesian by virtue of Corollary 5.1.2.4.

We now complete the proof by showing that the pair \( (\tilde{F}, F) \) satisfies condition (a) of Remark 5.7.5.3. Let \( (i, C) \) be a vertex of the product \( \Delta^1 \times \mathcal{C} \), so that \( \tilde{F} \) restricts to a functor
5.7. CLASSIFICATION OF COCARTESIAN FIBRATIONS

of ∞-categories

\[ \tilde{\mathcal{F}}_{(i,C)} : \{i\} \times \mathcal{E} \rightarrow \{\mathcal{F}(i,C)\} \times \mathcal{QC}_{\text{Obj}}. \]

We wish to show that the functor \( \tilde{\mathcal{F}}_{(i,C)} \) is an equivalence of ∞-categories. If \( i = 0 \), this follows from our assumption that \( \tilde{\mathcal{F}}_0 \) witnesses \( \mathcal{F}_0 \) as a covariant transport representation for \( U \). We may therefore assume without loss of generality that \( i = 1 \). Set \( v = \mathcal{F}(\varphi_{01}, \text{id}_C) \) and let

\[ v_! : \{\mathcal{F}(0,C)\} \times \mathcal{QC}_{\text{Obj}} \rightarrow \{\mathcal{F}(1,C)\} \times \mathcal{QC}_{\text{Obj}} \]

be the functor given by covariant transport along \( v \). Since \( u \) is an isomorphism in the ∞-category \( \mathcal{M} \), \( v \) is an isomorphism in the ∞-category \( \mathcal{QC} \) so that \( v_! \) is an equivalence of ∞-categories (Remark 5.2.5.5). Combining the first part of the proof with Remark 5.2.8.5, we deduce that the diagram of ∞-categories

\[ \begin{array}{ccc}
\{0\} \times \mathcal{E} & \xrightarrow{\tilde{\mathcal{F}}_{(0,C)}} & \{\mathcal{F}(0,C)\} \times \mathcal{QC}_{\text{Obj}} \\
\downarrow \sim & & \downarrow v_! \\
\{1\} \times \mathcal{E} & \xrightarrow{\tilde{\mathcal{F}}_{(1,C)}} & \{\mathcal{F}(1,C)\} \times \mathcal{QC}_{\text{Obj}}
\end{array} \]

commutes up to isomorphism (that is, it determines a commutative diagram in the homotopy category \( h\mathcal{QC} \)). Since \( v_! \) and \( \tilde{\mathcal{F}}_{(0,C)} \) are equivalences of ∞-categories, it follows that \( \tilde{\mathcal{F}}_{(1,C)} \) is also an equivalence of ∞-categories.

\[ \square \]

\textbf{Lemma 5.7.8.7.} Let \( U : \mathcal{E} \rightarrow \mathcal{C} \) be a cocartesian fibration of simplicial sets. Then the simplicial set \( \text{TW}(\mathcal{E}/\mathcal{C}) \) is a Kan complex.

\textbf{Proof.} Since \( \text{TW}(\mathcal{E}/\mathcal{C}) \) is an ∞-category (Lemma 5.7.8.6), it will suffice to show that every morphism \( u \) of \( \text{TW}(\mathcal{E}/\mathcal{C}) \) is an isomorphism (Proposition 4.4.2.1). Let us identify \( u \) with a commutative diagram of simplicial sets

\[ \begin{array}{ccc}
\Delta^1 \times \mathcal{E} & \xrightarrow{\tilde{\mathcal{F}}} & \mathcal{QC}_{\text{Obj}} \\
\downarrow \text{id}_{\Delta^1} \times U & & \downarrow V \\
\Delta^1 \times \mathcal{C} & \xrightarrow{\mathcal{F}} & \mathcal{QC}
\end{array} \]

satisfying conditions (a) and (b) of Remark 5.7.5.3.

Passing to homotopy categories, we see that \( \tilde{\mathcal{F}} \) induces a functor \( h\mathcal{F} : [1] \times h\mathcal{C} \rightarrow h\mathcal{QC} \sim h\mathcal{QCat} \). Applying Remark 5.7.5.8, we see that \( h\mathcal{F} \) is isomorphic to the composite functor.
[1] × hC → hC \overset{hTr_{\mathcal{E}/\mathcal{C}}}{\longrightarrow} h\mathcal{QC}, where hTr_{\mathcal{E}/\mathcal{C}} denotes the homotopy transport representation of Construction 5.2.5.2. It follows that, for every vertex \( C \in \mathcal{C} \), the morphism \( F \) carries the edge \( \Delta^1 \times \{C\} \) to an isomorphism \( \tilde{\tau} \) in \( \mathcal{QC} \). If \( X \) is an object of \( \mathcal{E} \) satisfying \( U(X) = C \), then \( \tilde{\mathcal{F}} \) carries \( \Delta^1 \times \{X\} \) to a \( V \)-cocartesian morphism \( e \) of \( \mathcal{QC}_{\mathcal{Obj}} \) satisfying \( V(e) = \tilde{\tau} \), which is then also an isomorphism by virtue of Corollary 5.1.1.10. Allowing \( C \) and \( X \) to vary and applying Theorem 4.4.4.4, we deduce that \( F \) and \( \tilde{F} \) are isomorphisms when regarded as morphisms in the \( \infty \)-categories \( \text{Fun}(\mathcal{C}, \mathcal{QC}) \) and \( \text{Fun}(\mathcal{E}, \mathcal{QC}_{\mathcal{Obj}}) \), respectively.

Set \( \mathcal{M} = \text{Fun}(\mathcal{C}, \mathcal{QC}) \times_{\text{Fun}(\mathcal{E}, \mathcal{QC})} \text{Fun}(\mathcal{E}, \mathcal{QC}_{\mathcal{Obj}}) \). Applying Corollary 4.4.3.18 to the pullback diagram

\[
\begin{array}{ccc}
\mathcal{M} & \longrightarrow & \text{Fun}(\mathcal{E}, \mathcal{QC}_{\mathcal{Obj}}) \\
\downarrow & & \downarrow \\
\text{Fun}(\mathcal{C}, \mathcal{QC}) & \longrightarrow & \text{Fun}(\mathcal{E}, \mathcal{QC}),
\end{array}
\]

we deduce that \( u \) is an isomorphism when regarded as a morphism of the \( \infty \)-category \( \mathcal{M} \). Since \( \text{TW}(\mathcal{E}/\mathcal{C}) \) is replete subcategory of \( \mathcal{M} \) (Lemma 5.7.8.6), it follows that \( u \) is also an isomorphism when regarded as a morphism of \( \text{TW}(\mathcal{E}/\mathcal{C}) \) (Example 4.4.2.9).

Remark 5.7.8.8. Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets. It follows from Lemmas 5.7.8.6 and 5.7.8.7 that \( \text{TW}(\mathcal{E}/\mathcal{C}) \) can be identified with the full subcategory of the Kan complex

\[
\text{Fun}(\mathcal{C}, \mathcal{QC}) \cong \times_{\text{Fun}(\mathcal{E}, \mathcal{QC})} \text{Fun}(\mathcal{E}, \mathcal{QC}_{\mathcal{Obj}}) \cong
\]

spanned by those pairs \((\mathcal{F}, \tilde{\mathcal{F}})\) which witness \( \mathcal{F} \) as a covariant transport representation for \( U \).

Notation 5.7.8.9 (Functoriality). Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets. Suppose we are given an arbitrary morphism of simplicial sets \( f : \mathcal{C}_0 \to \mathcal{C} \), and set \( \mathcal{E}_0 = \mathcal{C}_0 \times_{\mathcal{C}} \mathcal{E} \). Precomposition with \( f \) and with the projection map \( \mathcal{E}_0 \to \mathcal{E} \) determines a morphism of simplicial sets

\[
f^* : \text{TW}(\mathcal{E}/\mathcal{C}) \to \text{TW}(\mathcal{E}_0/\mathcal{C}_0),
\]

which we will refer to as the restriction map. Note that the construction \( \mathcal{C}_0 \mapsto \text{TW}(\mathcal{E}_0/\mathcal{C}_0) \) carries colimits in the category \((\text{Set}_{\Delta})/\mathcal{C}\) to limits in the category of simplicial sets.

Lemma 5.7.8.10. Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets. Let \( \mathcal{C}_0 \) be a simplicial subset of \( \mathcal{C} \) and set \( \mathcal{E}_0 = \mathcal{C}_0 \times_{\mathcal{C}} \mathcal{E} \). Then:

1. The restriction map \( \theta : \text{TW}(\mathcal{E}/\mathcal{C}) \to \text{TW}(\mathcal{E}_0/\mathcal{C}_0) \) of Notation 5.7.8.9 is a Kan fibration between Kan complexes.
5.7. CLASSIFICATION OF COCARTESIAN FIBRATIONS

(2) If the inclusion $C_0 \hookrightarrow C$ is inner anodyne, then $\theta$ is a trivial Kan fibration.

Proof. We first prove (1). Since the simplicial set $TW(E_0/C_0)$ is a Kan complex (Lemma 5.7.8.7), it will suffice to show that $\theta$ is an isofibration. Define fiber products

$$M = \text{Fun}(C, QC) \times_{\text{Fun}(E, QC)} \text{Fun}(E, QC_{\text{Obj}})$$

$$M_0 = \text{Fun}(C_0, QC) \times_{\text{Fun}(E_0, QC)} \text{Fun}(E_0, QC_{\text{Obj}}),$$

so that we have a commutative diagram

$$\begin{align*}
TW(E/C) & \longrightarrow M \\
\downarrow \theta & \quad \downarrow \theta' \\
TW(E_0/C_0) & \longrightarrow M_0.
\end{align*}$$

(5.35)

It follows from Lemma 5.7.8.6 that $TW(E/C)$ is a replete subcategory of $M$, and therefore also a replete subcategory of the fiber product $TW(E_0/C_0) \times_{M_0} M$. It will therefore suffice to show that the projection map $TW(E_0/C_0) \times_{M_0} M \to TW(E_0/C_0)$ is an isofibration of $\infty$-categories. Since the collection of isofibrations is stable under pullback, we are reduced to showing that the map $\theta : M \to M_0$ is an isofibration. We now observe that $\theta$ factors as a composition

$$M = \text{Fun}(C, QC) \times_{\text{Fun}(E, QC)} \text{Fun}(E, QC_{\text{Obj}})$$

$$\rightarrow \text{Fun}(C, QC) \times_{\text{Fun}(E_0, QC)} \text{Fun}(E_0, QC_{\text{Obj}})$$

$$\rightarrow \text{Fun}(C_0, QC) \times_{\text{Fun}(E_0, QC)} \text{Fun}(E_0, QC_{\text{Obj}})$$

$$= M_0,$$

where $\theta''$ is a pullback of the restriction map

$$\psi'' : \text{Fun}(E, QC_{\text{Obj}}) \to \text{Fun}(E_0, QC_{\text{Obj}}) \times_{\text{Fun}(E_0, QC)} \text{Fun}(E, QC).$$

Since the forgetful functor $V : QC_{\text{Obj}} \to QC$ is an isofibration, $\psi''$ is also an isofibration (Propositions 4.4.5.1). Similarly, $\theta'$ is a pullback of the restriction map $\psi' : \text{Fun}(C, QC) \to \text{Fun}(C_0, QC)$, which is an isofibration by virtue of Corollary 4.4.5.3. It follows that $\theta = \theta'' \circ \theta'$ is also an isofibration. This completes the proof of (1).

We now prove (2). Suppose that the inclusion map $C_0 \hookrightarrow C$ is inner anodyne; we wish to show that $\theta$ is a trivial Kan fibration. Applying Proposition 1.4.7.6 we deduce that $\psi'$ is a trivial Kan fibration of simplicial sets. Since $U$ is a cocartesian fibration, the inclusion
map $\mathcal{E}_0 \rightarrow \mathcal{E}$ is a categorical equivalence (Lemma 5.3.6.5). Applying Proposition 4.5.5.18 we deduce that $\psi''$ is a trivial Kan fibration. It follows that the morphisms $\overline{\theta}$ and $\overline{\theta}'$ are also trivial Kan fibrations, so that $\overline{\theta} = \overline{\theta}'' \circ \overline{\theta}'$ is a trivial Kan fibration. Applying Lemma 5.7.8.5 we see that the diagram (5.35) is a pullback square, so that $\theta$ is also a trivial Kan fibration.

Proof of Theorem 5.7.5.10 from Theorem 5.7.8.3. Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a cocartesian fibration of simplicial sets having the property that, for every vertex $C \in \mathcal{C}$, the $\infty$-category $\mathcal{E}_C = \{C\} \times_\mathcal{C} \mathcal{E}$ is essentially small. Let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a simplicial subset and set $\mathcal{E}_0 = \mathcal{C}_0 \times_\mathcal{C} \mathcal{E}$. Applying Theorem 5.7.8.3 we see that the simplicial sets $\operatorname{TW}(\mathcal{E} / \mathcal{C})$ and $\operatorname{TW}(\mathcal{E}_0 / \mathcal{C}_0)$ are contractible Kan complexes. It follows that the restriction map $\theta : \operatorname{TW}(\mathcal{E} / \mathcal{C}) \rightarrow \operatorname{TW}(\mathcal{E}_0 / \mathcal{C}_0)$ is a homotopy equivalence. Since $\theta$ is also Kan fibration (Lemma 5.7.8.10), it is a trivial Kan fibration (Corollary 3.2.7.4). In particular, $\theta$ is surjective on vertices, which is a restatement of Theorem 5.7.5.10.

5.7.9 Proof of the Universality Theorem

Let $U : \mathcal{E} \rightarrow \mathcal{C}$ be a cocartesian fibration of simplicial sets, and suppose that the fiber $\mathcal{E}_C = \{C\} \times_\mathcal{C} \mathcal{E}$ is essentially small for each vertex $C \in \mathcal{C}$. Our goal in this section is to prove Theorem 5.7.8.3, which that the space of transport witnesses $\operatorname{TW}(\mathcal{E} / \mathcal{C})$ of Notation 5.7.8.1 is a contractible Kan complex. The main step is to establish the following:

Lemma 5.7.9.1. Let $U : \mathcal{E} \rightarrow \Delta^1$ be a cocartesian fibration having fibers $\mathcal{E}_0 = \{0\} \times_{\Delta^1} \mathcal{E}$ and $\mathcal{E}_1 = \{1\} \times_{\Delta^1} \mathcal{E}$. Then the restriction map

$$\theta : \operatorname{TW}(\mathcal{E} / \Delta^1) \rightarrow \operatorname{TW}(\mathcal{E}_0 \amalg \mathcal{E}_1 / \partial \Delta^1)$$

is a trivial Kan fibration of simplicial sets.

Proof. It follows from Lemma 5.7.8.10 that $\theta$ is a Kan fibration; we wish to show that it is a trivial Kan fibration. Fix a pair of small $\infty$-categories $\mathcal{D}_0$ and $\mathcal{D}_1$. Set $\mathcal{E}_0' = \{\mathcal{D}_0\} \times_{\mathcal{Q}\mathcal{C}} \mathcal{Q}\mathcal{C}_{\text{Obj}}$ and $\mathcal{E}_1' = \{\mathcal{D}_1\} \times_{\mathcal{Q}\mathcal{C}} \mathcal{Q}\mathcal{C}_{\text{Obj}}$, and let $\operatorname{Equiv}(\mathcal{E}_0, \mathcal{E}_0')$ and $\operatorname{Equiv}(\mathcal{E}_1, \mathcal{E}_1')$ be the Kan complexes introduced in Example 5.7.8.2 so that the fiber

$$\{(\mathcal{D}_0, \mathcal{D}_1)\} \times_{\operatorname{Fun}(\partial \Delta^1, \mathcal{Q}\mathcal{C})} \operatorname{TW}(\mathcal{E}_0 \amalg \mathcal{E}_1 / \partial \Delta^1)$$

can be identified with the product $\operatorname{Equiv}(\mathcal{E}_0, \mathcal{E}_0') \times \operatorname{Equiv}(\mathcal{E}_1, \mathcal{E}_1')$. Let $\operatorname{TW}(\mathcal{E} / \Delta^1)_{\mathcal{D}_0, \mathcal{D}_1}$ denote the fiber product $\{(\mathcal{D}_0, \mathcal{D}_1)\} \times_{\operatorname{Fun}(\partial \Delta^1, \mathcal{Q}\mathcal{C})} \operatorname{TW}(\mathcal{E} / \Delta^1)$, so that $\theta$ restricts to a Kan fibration

$$\theta_{\mathcal{D}_0, \mathcal{D}_1} : \operatorname{TW}(\mathcal{E} / \Delta^1)_{\mathcal{D}_0, \mathcal{D}_1} \rightarrow \operatorname{Equiv}(\mathcal{E}_0, \mathcal{E}_0') \times \operatorname{Equiv}(\mathcal{E}_1, \mathcal{E}_1').$$

Note that every fiber of $\theta$ can also be viewed as a fiber of $\theta_{\mathcal{D}_0, \mathcal{D}_1}$ for suitably chosen $\infty$-categories $\mathcal{D}_0$ and $\mathcal{D}_1$. Consequently, to show that $\theta$ is a trivial Kan fibration, it will suffice
to show that each of the morphisms \( \theta_{D_0, D_1} \) is a trivial Kan fibration (Proposition 3.2.6.15), or equivalently that it is a homotopy equivalence (Corollary 3.2.7.4).

For the remainder of the proof, we will regard the \( \infty \)-categories \( D_0 \) and \( D_1 \) as fixed. Let \( B^+ \) denote the fiber product

\[
\text{Hom}_{\mathcal{QC}}(D_0, D_1) \times_{\text{Fun}(\Delta^1 \times E_0, \mathcal{QC})^\sim} \text{Fun}(\Delta^1 \times E_0, \mathcal{QC}_{\text{Obj}})^\sim.
\]

Let \( \pi^+ : B^+ \to \text{Hom}_{\mathcal{QC}}(D_0, D_1) \) be given by projection onto the first factor, and let

\[
r_0^+ : B^+ \to \text{Fun}(E_0, E'_0)^\sim \quad r_1^+ : B^+ \to \text{Fun}(E_0, E'_1)^\sim
\]

be given by restriction to the simplicial subsets \( \{0\} \times E_0 \) and \( \{1\} \times E_0 \), respectively. Combining Propositions 4.4.5.1 and 4.4.3.7 we deduce that the map

\[
(r_0^+, r_1^+, \pi^+) : B^+ \to \text{Fun}(E_0, E'_0)^\sim \times \text{Fun}(E_0, E'_1)^\sim \times \text{Hom}_{\mathcal{QC}}(D_0, D_1)
\]

is a Kan fibration. In particular, the simplicial set \( B^+ \) is a Kan complex.

Let \( B \) denote the summand \( B^+ \) spanned by those pairs \((e, \tilde{e})\), where \( e : D_0 \to D_1 \) is a functor and \( \tilde{e} : \Delta^1 \times E_0 \to \mathcal{QC}_{\text{Obj}} \) is a morphism fitting into a commutative diagram

\[
\begin{array}{ccc}
\Delta^1 \times E_0 & \xrightarrow{\tilde{e}} & \mathcal{QC}_{\text{Obj}} \\
\downarrow & \ & \downarrow V \\
\Delta^1 & \xrightarrow{e} & \mathcal{QC}
\end{array}
\]

which satisfies the following pair of conditions:

(i) The restriction \( \tilde{e}|_{\{0\} \times E_0} : E_0 \to E'_0 \) is an equivalence of \( \infty \)-categories.

(ii) For each object \( Z \in E_0 \), the composite map

\[
\Delta^1 \times \{Z\} \hookrightarrow \Delta^1 \times E_0 \xrightarrow{\tilde{e}} \mathcal{QC}_{\text{Obj}}
\]

is a \( V \)-cocartesian morphism of \( \mathcal{QC}_{\text{Obj}} \).

Condition (i) ensures that \( r_0^+ \) restricts to a morphism of Kan complexes \( r_0 : B \to \text{Equiv}(E_0, E'_0) \). Moreover, \( \pi^+ \) and \( r_1^+ \) restrict to morphisms \( \pi : B \to \text{Hom}_{\mathcal{QC}}(D_0, D_1) \) and \( r_1 : B \to \text{Fun}(E_0, E'_1)^\sim \), respectively. Since \( B \) is a summand of \( B^+ \), the map

\[
(r_0, r_1, \pi) : B \to \text{Equiv}(E_0, E'_0) \times \text{Fun}(E_0, E'_1)^\sim \times \text{Hom}_{\mathcal{QC}}(D_0, D_1)
\]

is also a Kan fibration.
It follows from Theorem 5.2.1.1 that composition with \( V \) induces a cocartesian fibration \( V' : \text{Fun}(\mathcal{E}_0, \mathcal{QC}_{\text{Obj}}) \to \text{Fun}(\mathcal{E}_0, \mathcal{QC}) \). Moreover, a morphism of the \( \infty \)-category \( \text{Fun}(\mathcal{E}_0, \mathcal{QC}_{\text{Obj}}) \) is \( V' \)-cocartesian if and only if it corresponds to a morphism of simplicial sets \( \tilde{e} : \Delta^1 \times \mathcal{E}_0 \to \mathcal{QC}_{\text{Obj}} \) satisfying condition (ii). Let \( \text{Fun}'(\Delta^1 \times \mathcal{E}_0, \mathcal{QC}_{\text{Obj}}) \) denote the full subcategory of \( \text{Fun}(\Delta^1 \times \mathcal{E}_0, \mathcal{QC}_{\text{Obj}}) \) spanned by morphisms which satisfy this condition. Unwinding the definitions, we have a pullback square

\[
\begin{array}{ccc}
\mathcal{B} & \xrightarrow{(r_0, \pi)} & \text{Equiv}(\mathcal{E}_0, \mathcal{E}'_0) \times \text{Hom}_{\mathcal{QC}}(\mathcal{D}_0, \mathcal{D}_1) \\
\downarrow & & \downarrow \\
\text{Fun}(\{0\} \times \mathcal{E}_0, \mathcal{QC}_{\text{Obj}}) \times_{\text{Fun}(\mathcal{E}_0, \mathcal{QC})} \text{Fun}(\Delta^1 \times \mathcal{E}_0, \mathcal{QC}) & \xrightarrow{(r_0, r_1)} & \text{Fun}'(\Delta^1 \times \mathcal{E}_0, \mathcal{QC}_{\text{Obj}})
\end{array}
\]

where the bottom right map is a trivial Kan fibration (Proposition 5.2.1.3). It follows that the map \((r_0, \pi) : \mathcal{B} \to \text{Equiv}(\mathcal{E}_0, \mathcal{E}'_0) \times \text{Hom}_{\mathcal{QC}}(\mathcal{D}_0, \mathcal{D}_1)\) is a trivial Kan fibration of simplicial sets.

Let \( s : \text{Equiv}(\mathcal{E}_0, \mathcal{E}'_0) \times \text{Hom}_{\mathcal{QC}}(\mathcal{D}_0, \mathcal{D}_1) \to \mathcal{B} \) be a section of the trivial Kan fibration \((r_0, \pi)\), and let \( T \) denote the composite map

\[
\text{Equiv}(\mathcal{E}_0, \mathcal{E}'_0) \times \text{Hom}_{\mathcal{QC}}(\mathcal{D}_0, \mathcal{D}_1) \xrightarrow{s} \mathcal{B} \xrightarrow{(r_0, r_1)} \text{Equiv}(\mathcal{E}_0, \mathcal{E}'_0) \times \text{Fun}(\mathcal{E}_0, \mathcal{E}'_1)^\simeq.
\]

For every equivalence of \( \infty \)-categories \( F : \mathcal{E}_0 \to \mathcal{E}'_0 \), we can regard \( T|_{\{F\} \times \text{Hom}_{\mathcal{QC}}(\mathcal{D}_0, \mathcal{D}_1)} \) as a morphism of Kan complexes \( T_F : \text{Hom}_{\mathcal{QC}}(\mathcal{D}_0, \mathcal{D}_1) \to \text{Fun}(\mathcal{E}_0, \mathcal{E}'_1)^\simeq \). Unwinding the definitions, we can identify \( T_F \) with the composition

\[
\text{Hom}_{\mathcal{QC}}(\mathcal{D}_0, \mathcal{D}_1) \xrightarrow{T'} \text{Fun}(\mathcal{E}'_0, \mathcal{E}'_1)^\simeq \xrightarrow{\circ F} \text{Fun}(\mathcal{E}_0, \mathcal{E}'_1)^\simeq,
\]

where \( T' \) is given by parametrized covariant transport for the cocartesian fibration \( \mathcal{V} : \mathcal{QC}_{\text{Obj}} \to \mathcal{QC} \) (Definition 5.2.8.1). It follows from Proposition 5.6.6.14 that \( T' \) is a homotopy equivalence. Our assumption that \( F \) is an equivalence of \( \infty \)-categories then guarantees that \( T_F \) is also a homotopy equivalence. Allowing \( F \in \text{Equiv}(\mathcal{E}_0, \mathcal{E}'_0) \) to vary and applying Proposition 3.2.8.1, we conclude that \( T \) is a homotopy equivalence. Since \( s \) is homotopy inverse to the trivial Kan fibration \((r_0, \pi)\), it is also a homotopy equivalence. Applying the two-out-of-three property (Remark 3.1.6.7), we conclude that the map

\[
(r_0, r_1) : \mathcal{B} \to \text{Equiv}(\mathcal{E}_0, \mathcal{E}'_0) \times \text{Fun}(\mathcal{E}_0, \mathcal{E}'_1)^\simeq
\]
is also a homotopy equivalence. Since \((r_0, r_1)\) is also a Kan fibration, it is a trivial Kan fibration (Proposition 3.3.7.4).

Using Proposition 5.2.2.8, we can choose a functor \(\lambda : E_0 \to E_1\) and a natural transformation \(h : \Delta^1 \times E_0 \to E\) which witnesses \(\lambda\) as given by covariant transport along the nondegenerate edge of \(\Delta^1\) (in the sense of Definition 5.2.2.4). Form a pullback diagram

\[
\begin{array}{ccc}
\tilde{B} & \longrightarrow & B \\
\downarrow (\tilde{r}_0, \tilde{r}_1) & & \downarrow (r_0, r_1) \\
\text{Equiv}(E_0, E_0') \times \text{Equiv}(E_1, E_1') & \overset{\circ \lambda}{\longrightarrow} & \text{Equiv}(E_0, E_0') \times \text{Fun}(E_0, E_1) \simeq.
\end{array}
\]

Let \(M\) denote the pushout \((\Delta^1 \times E_0) \amalg \{(1) \times E_0\} E_1\), so that we can identify \(\tilde{B}\) with a summand of the Kan complex

\[
\text{Hom}_{\mathcal{QC}}(D_0, D_1) \times_{\text{Fun}(M, \mathcal{QC})} \simeq \text{Fun}(M, \mathcal{QC}_{\text{Obj}}) \simeq.
\]

Note that \(h\) induces a categorical equivalence of simplicial sets \(h^+ : M \to E\) (Corollary 5.2.4.2). We have a commutative diagram of Kan complexes

\[
\begin{array}{ccc}
\text{Hom}_{\mathcal{QC}}(D_0, D_1) \times_{\text{Fun}(E, \mathcal{QC})} \simeq & \longrightarrow & \text{Hom}_{\mathcal{QC}}(D_0, D_1) \\
\downarrow & & \downarrow \\
\text{Fun}(E, \mathcal{QC}_{\text{Obj}}) \simeq & \overset{V\circ}{\longrightarrow} & \text{Fun}(E, \mathcal{QC}) \simeq \\
\downarrow \circ h^+ & & \downarrow \circ h^+ \\
\text{Fun}(M, \mathcal{QC}_{\text{Obj}}) \simeq & \overset{V\circ}{\longrightarrow} & \text{Fun}(M, \mathcal{QC}) \simeq,
\end{array}
\]

where the upper vertical are homotopy equivalences (since \(h^+\) is a categorical equivalence) and the horizontal maps are Kan fibrations (Corollary 4.4.5.7). Note that the top and bottom squares of (5.37) are homotopy pullback squares (Example 3.4.1.3 and Corollary 3.4.1.5). It follows that the outer rectangle is also a homotopy pullback square (Proposition
3.4.1.11): that is, precomposition with $h^+$ induces a homotopy equivalence of Kan complexes

$$\hom_{\mathcal{QC}}(D_0, D_1) \times_{\fun(M, \mathcal{QC})} \fun(\mathcal{E}, \mathcal{QC}_{\obj}) \simeq \hom_{\mathcal{QC}}(D_0, D_1) \times_{\fun(M, \mathcal{QC})} \fun(M, \mathcal{QC}_{\obj}) \simeq \phi \downarrow \downarrow \hom_{\mathcal{QC}}(D_0, D_1) \times_{\fun(M, \mathcal{QC})} \fun(\mathcal{E}, \mathcal{QC}_{\obj}) \simeq \fun(\mathcal{E}, \mathcal{QC}_{\obj}) \simeq \phi.$$ 

Applying Remark 5.7.5.3, we see that $\tw_{\mathcal{E}}(\partial \Delta^1_{D_0, D_1})$ can be identified with the inverse image of $\tilde{B}$ under the homotopy equivalence $\phi$. In particular, $\phi$ restricts to a homotopy equivalence $\phi_0 : \tw_{\mathcal{E}}(\partial \Delta^1_{D_0, D_1}) \to \tilde{B}$. Unwinding the definitions, we see that the morphism

$$\theta_{D_0, D_1} : \tw_{\mathcal{E}}(\Delta^1_{D_0, D_1}) \to \equiv_{\mathcal{E}_0} \times \equiv_{\mathcal{E}_1}$$

coincides with the composition $(\tilde{r}_0, \tilde{r}_1) \circ \varphi_0$. Since $(\tilde{r}_0, \tilde{r}_1)$ is a pullback of the trivial Kan fibration $(r_0, r_1) : \mathcal{B} \to \equiv_{\mathcal{E}_0} \times \fun(\mathcal{E}_0, \mathcal{E}_1') \simeq$, it is also a trivial Kan fibration. In particular, $(\tilde{r}_0, \tilde{r}_1)$ is a homotopy equivalence, so that the composite map $\theta_{D_0, D_1} = (\tilde{r}_0, \tilde{r}_1) \circ \varphi_0$ is also a homotopy equivalence, as desired.

**Lemma 5.7.9.2.** Let $\mathcal{E}$ be an essentially small $\infty$-category. Then the simplicial set $\tw_{\mathcal{E}}(\Delta^0)$ is a contractible Kan complex.

**Proof.** It follows from Lemma 5.7.8.7 that the simplicial set $\tw_{\mathcal{E}}(\Delta^0)$ is a Kan complex. Since $\mathcal{E}$ is essentially small, the Kan complex $\tw_{\mathcal{E}}(\Delta^0)$ is nonempty. It will therefore suffice to show that the diagonal map

$$\delta : \tw_{\mathcal{E}}(\Delta^0) \to \tw_{\mathcal{E}}(\Delta^0) \times \tw_{\mathcal{E}}(\Delta^0)$$

is a homotopy equivalence (Corollary 3.2.6.6). Unwinding the definitions, we see that $\delta$ factors as a composition

$$\tw_{\mathcal{E}}(\Delta^0) \xrightarrow{\delta'} \fun(\Delta^1, \tw_{\mathcal{E}}(\Delta^0)) \simeq \tw(\Delta^1 \times \mathcal{E} / \Delta^1) \xrightarrow{\delta''} \tw(\partial \Delta^1 \times \mathcal{E} / \partial \Delta^1) \simeq \tw_{\mathcal{E}}(\Delta^0) \times \tw_{\mathcal{E}}(\Delta^0).$$

Since the 1-simplex $\Delta^1$ is contractible (Example 3.2.6.3), the morphism $\delta'$ is a homotopy equivalence. It will therefore suffice to show that the restriction map $\delta''$ is a homotopy equivalence, which follows from Lemma 5.7.9.1. □
5.7. CLASSIFICATION OF COCARTESIAN FIBRATIONS

Proof of Theorem 5.7.8.3. Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets. Assume that, for each vertex \( C \in \mathcal{C} \), the \( \infty \)-category \( \mathcal{E}_C = \{ C \} \times_{\mathcal{C}} \mathcal{E} \) is essentially small. We wish to show that the simplicial set \( TW(\mathcal{E} / \mathcal{C}) \) is a contractible Kan complex.

For every simplicial set \( \mathcal{C}_0 \) equipped with a morphism \( \mathcal{C}_0 \to \mathcal{C} \), let \( X(\mathcal{C}_0) \) denote the simplicial set \( TW(\mathcal{E}_0 / \mathcal{C}_0) \), where \( \mathcal{E}_0 \) is the fiber product \( \mathcal{C}_0 \times_{\mathcal{C}} \mathcal{E} \). Note that the simplicial set \( X(\mathcal{C}) = TW(\mathcal{E} / \mathcal{C}) \) can be realized as the inverse limit of the tower

\[
\cdots \to X(\text{sk}_2(\mathcal{C})) \to X(\text{sk}_1(\mathcal{C})) \to X(\text{sk}_0(\mathcal{C})),
\]

where each of the transition maps is a Kan fibration (Lemma 5.7.8.10). Consequently, to show that \( X(\mathcal{C}) \) is a contractible Kan complex, it will suffice to show that each of the simplicial sets \( X(\text{sk}_k(\mathcal{C})) \) is a contractible Kan complex. Replacing \( \mathcal{C} \) by \( \text{sk}_k(\mathcal{C}) \), we can assume that the simplicial set \( \mathcal{C} \) has dimension \( \leq k \), for some integer \( k \geq -1 \).

We now proceed by induction on \( k \). In the case \( k = -1 \), the simplicial set \( \mathcal{C} \) is empty and \( TW(\mathcal{E} / \mathcal{C}) \) is isomorphic to \( \Delta^0 \). We may therefore assume without loss of generality that \( k \geq 0 \). Let \( S \) be the collection of nondegenerate \( k \)-simplices of \( \mathcal{C} \), so that Proposition 1.1.3.13 supplies a pushout diagram of simplicial sets

\[
\begin{array}{ccc}
\coprod_{\sigma \in S} \partial \Delta^k & \to & \coprod_{\sigma \in S} \Delta^k \\
\downarrow & & \downarrow \\
\mathcal{C}_0 & \to & \mathcal{C},
\end{array}
\]

where \( \mathcal{C}_0 = \text{sk}_{k-1}(\mathcal{C}) \) is the \((k-1)\)-skeleton of \( \mathcal{C} \). It follows from our inductive hypothesis that the simplicial set \( X(\mathcal{C}_0) \) is a contractible Kan complex. Consequently, to show that \( X(\mathcal{C}) \) is a contractible Kan complex, it will suffice to show that the restriction map \( \theta : X(\mathcal{C}) \to X(\mathcal{C}_0) \) is a trivial Kan fibration. Note that \( \theta \) is a pullback of the restriction map

\[
\theta_0 : X(\coprod_{\sigma \in S} \Delta^k) \to X(\coprod_{\sigma \in S} \partial \Delta^k).
\]

We will complete the proof by showing that \( \theta_0 \) is a trivial Kan fibration. Since \( \theta_0 \) is a Kan fibration (Lemma 5.7.8.10), this is equivalent to the assertion that \( \theta_0 \) is a homotopy equivalence (Corollary 3.2.7.4). Our inductive hypothesis guarantees that the Kan complex \( X(\coprod_{\sigma \in S} \partial \Delta^k) \) is contractible. We are therefore reduced to showing that the Kan complex \( X(\coprod_{\sigma \in S} \Delta^k) \) is also contractible. Since the collection of contractible Kan complexes is closed under products, we are reduced to verifying the contractibility of the simplicial set \( X(\mathcal{C}_0) \) in the special case where \( \mathcal{C}_0 = \Delta^k \) is a standard simplex of dimension \( k \). We now consider several cases:
• In the case $k = 0$, the desired result follows from Lemma 5.7.9.2.

• In the case $k = 1$, Lemma 5.7.9.1 supplies a trivial Kan fibration $X(\Delta^1) \to X(\partial \Delta^1)$. Our inductive hypothesis guarantees that the Kan complex $X(\partial \Delta^1)$ is contractible, so that $X(\Delta^1)$ is also contractible.

• In the case $k \geq 2$, we can choose an integer $0 < i < k$. In this case, the inclusion $\Lambda^k_i \hookrightarrow \Delta^k$ is inner anodyne, so the restriction map $X(\Delta^k) \to X(\Lambda^k_i)$ is a trivial Kan fibration (Lemma 5.7.8.10). Our inductive hypothesis guarantees that the Kan complex $X(\Lambda^k_i)$ is contractible, so that $X(\Delta^k)$ is also contractible.

\qed
Part II

Higher Category Theory
Chapter 6

Adjoint Functors

6.1 Adjunctions in 2-Categories

We begin by reviewing the theory of adjoint functors in the setting of classical category theory, originally introduced in [33].

Definition 6.1.0.1 (Kan). Let $\mathcal{C}$ and $\mathcal{D}$ be categories, and let $F : \mathcal{C} \to \mathcal{D}$ and $G : \mathcal{D} \to \mathcal{C}$ be functors. A Hom-adjunction between $F$ and $G$ is a collection of bijections

$$\rho_{C,D} : \Hom_{\mathcal{D}}(F(C), D) \simeq \Hom_{\mathcal{C}}(C, G(D))$$

which depend functorially on $C \in \mathcal{C}$ and $D \in \mathcal{D}$ (that is, the construction $(C, D) \mapsto \rho_{C,D}$ is an isomorphism in the functor category $\Fun(\mathcal{C}^{\text{op}} \times \mathcal{D}, \Set)$). In this case, we say that the construction $(C, D) \mapsto \rho_{C,D}$ exhibits $F$ as a left adjoint to $G$ and $G$ as a right adjoint to $F$.

In the situation of Definition 6.1.0.1, functoriality imposes strong constraints on the construction $(C, D) \mapsto \rho_{C,D}$. For each object $C \in \mathcal{C}$, let $\eta_C : C \to (G \circ F)(C)$ be the morphism of $\mathcal{C}$ given by the image of the identity morphism $\id_{F(C)}$ under the bijection

$$\rho_{C,F(C)} : \Hom_{\mathcal{D}}(F(C), F(C)) \simeq \Hom_{\mathcal{D}}(C, (G \circ F)(C)).$$

For every morphism $f : F(C) \to D$ in $\mathcal{D}$, the commutativity of the diagram

$$\begin{array}{ccc}
\Hom_{\mathcal{D}}(F(C), F(C)) & \xrightarrow{\rho_{C,F(C)}} & \Hom_{\mathcal{D}}(C, (G \circ F)(C)) \\
\downarrow{f \circ} & & \downarrow{G(f) \circ} \\
\Hom_{\mathcal{D}}(F(C), D) & \xrightarrow{\rho_{C,D}} & \Hom_{\mathcal{C}}(C, G(D))
\end{array}$$
supplies an equality
\[ \rho_{C,D}(f) = \rho_{C,D}(f \circ \text{id}_{F(C)}) = G(f) \circ \rho_{C,F(C)}(\text{id}_{F(C)}) = G(f) \circ \eta_C. \]

In particular, the bijection \( \rho_{C,D} \) is completely determined by the morphism \( \eta_C \). Moreover, the functoriality of \( \rho_{\bullet, \bullet} \) in the first variable guarantees that the construction \( C \mapsto \eta_C \) is a natural transformation from the identity functor \( \text{id}_\mathcal{C} \) to the composition \( G \circ F \). Similarly, the inverse bijections \( \rho^{-1}_{C,D} : \text{Hom}_\mathcal{C}(C,G(D)) \cong \text{Hom}_\mathcal{D}(F(C),D) \) can be recovered from the collection of morphisms \( \{ \epsilon_D = \rho^{-1}_{G(D),D}(\text{id}_{G(D)}) \}_{D \in \mathcal{D}} \), which comprise a natural transformation of functors \( \epsilon : (F \circ G) \to \text{id}_\mathcal{D} \). This leads to a reformulation of Definition 6.1.0.1.

**Definition 6.1.0.2.** Let \( F : \mathcal{C} \to \mathcal{D} \) and \( G : \mathcal{D} \to \mathcal{C} \) be functors between categories. An adjunction between \( F \) and \( G \) is a pair \( (\eta, \epsilon) \), where \( \eta : \text{id}_\mathcal{C} \to G \circ F \) and \( \epsilon : F \circ G \to \text{id}_\mathcal{D} \) are natural transformations satisfying the following compatibility conditions:

(Z1) For each object \( C \in \mathcal{C} \), the composite morphism
\[ F(C) \xrightarrow{F(\eta_C)} (F \circ G \circ F)(C) \xrightarrow{\epsilon_{F(C)}} F(C) \]
is equal to the identity \( \text{id}_{F(C)} \).

(Z2) For each object \( D \in \mathcal{D} \), the composite morphism
\[ G(D) \xrightarrow{\eta_{G(D)}} (G \circ F \circ G)(D) \xrightarrow{G(\epsilon_D)} G(D) \]
is equal to the identity \( \text{id}_{G(D)} \).

If these conditions are satisfied, then we will refer to \( \eta \) as the *unit* of the adjunction \( (\eta, \epsilon) \) and to \( \epsilon \) as the *counit* of the adjunction \( (\eta, \epsilon) \). In this case, we will say that \( (\eta, \epsilon) \) *exhibits* \( F \) as a left adjoint to \( G \) and also that \( it \) *exhibits* \( G \) as a right adjoint to \( F \).

**Example 6.1.0.3.** Let \( F : \mathcal{C} \to \mathcal{D} \) and \( G : \mathcal{D} \to \mathcal{C} \) be functors between categories, and let \( \{ \rho_{C,D} \}_{C \in \mathcal{C}, \ D \in \mathcal{D}} \) be a Hom-adjunction between \( F \) and \( G \) (in the sense of Definition 6.1.0.1). Let \( \eta : \text{id}_\mathcal{C} \to G \circ F \) and \( \epsilon : F \circ G \to \text{id}_\mathcal{D} \) be the natural transformations given by the formulae
\[ \eta_C = \rho^{-1}_{C,F(C)}(\text{id}_{F(C)}) \in \text{Hom}_\mathcal{C}(C,(G \circ F)(C)) \]
\[ \epsilon_D = \rho^{-1}_{G(D),F(C)}(\text{id}_{G(D)}) \in \text{Hom}_\mathcal{D}((F \circ G)(D),D). \]

Then the pair \( (\eta, \epsilon) \) is an adjunction between \( F \) and \( G \) (in the sense of Definition 6.1.0.2).

Condition (Z1) follows from the observation that for each object \( C \in \mathcal{C} \), we have
\[
\text{id}_{F(C)} = \rho^{-1}_{C,F(C)}(\rho_{C,F(C)}(\text{id}_{F(C)})) = \rho^{-1}_{C,F(C)}(\eta_C) = \rho^{-1}_{C,F(C)}(\text{id}_{(G \circ F)(C)} \circ \eta_C) = \rho^{-1}_{(G \circ F)(C),F(C)}(\text{id}_{(G \circ F)(C)}) \circ F(\eta_C) = \epsilon_{F(C)} : F(\eta_C).
\]
The verification of (Z2) is similar.

**Exercise 6.1.0.4.** Let \( F : \mathcal{C} \to \mathcal{D} \) and \( G : \mathcal{D} \to \mathcal{C} \) be functors between categories. Show that every adjunction \((\eta, \epsilon)\) between \( F \) and \( G \) can be obtained by applying the construction of Example 6.1.0.3 to a unique Hom-adjunction \( \{p_{C,D}\}_{C \in \mathcal{C}, D \in \mathcal{D}} \) between \( F \) and \( G \) (see Example 6.1.2.7).

It follows from Exercise 6.1.0.4 that Definitions 6.1.0.1 and 6.1.0.2 are essentially equivalent to one another. However, an advantage of Definition 6.1.0.2 is that it can be formulated entirely in the language of functors and natural transformations: that is, it uses only the structure of the 2-category \( \text{Cat} \) of Example 2.2.0.4. In §6.1.1, we exploit this observation to generalize the notion of adjunction to an arbitrary 2-category. Given a 2-category \( \mathcal{C} \) containing 1-morphisms \( f : \mathcal{C} \to \mathcal{D} \) and \( g : \mathcal{D} \to \mathcal{C} \), we define an adjunction between \( f \) and \( g \) to be a pair of 2-morphisms
\[
\eta : \text{id}_{\mathcal{C}} \Rightarrow g \circ f \quad \epsilon : f \circ g \Rightarrow \text{id}_{\mathcal{D}}
\]
satisfying analogues of the compatibility conditions (Z1) and (Z2) above (Definition 6.1.1.1).

Our first goal is to adapt Exercise 6.1.0.4 to the setting of a general 2-category \( \mathcal{C} \). Suppose we are given 1-morphisms \( f : \mathcal{C} \to \mathcal{D} \), \( g : \mathcal{D} \to \mathcal{C} \), \( c : T \to \mathcal{C} \), and \( d : T \to \mathcal{D} \) in \( \mathcal{C} \). In §6.1.2, we show that every adjunction \((\eta, \epsilon)\) between \( f \) and \( g \) determines a bijection
\[
\text{Hom}_{\text{Hom}_{\mathcal{C}}(T, \mathcal{D})}(f \circ c, d) \simeq \text{Hom}_{\text{Hom}_{\mathcal{C}}(T, \mathcal{C})}(c, g \circ d),
\]
depending functorially on \( c \) and \( d \) (see Corollary 6.1.2.6 and Remark 6.1.2.4). Here the map from right to left is constructed using the unit map \( \eta : \text{id}_{\mathcal{C}} \Rightarrow g \circ f \), and from left to right using the counit \( \epsilon : f \circ g \Rightarrow \text{id}_{\mathcal{D}} \). As an application, we show that an adjunction \((\eta, \epsilon)\) is completely determined by the unit \( \eta \) (or the counit \( \epsilon \)), and give a criterion which can be used to test if an arbitrary 2-morphism \( \eta : \text{id}_{\mathcal{C}} \Rightarrow g \circ f \) is the unit of an adjunction (see Proposition 6.1.2.9, Variant 6.1.2.12, and Proposition 6.1.2.13).

Let \( \mathcal{C} \) be a 2-category and let \( f : \mathcal{C} \to \mathcal{D} \) be a 1-morphism in \( \mathcal{C} \). In §6.1.3, we show that if \( f \) admits a right adjoint \( g \), then \( g \) is uniquely determined up to (canonical) isomorphism (Corollary 6.1.3.3). Moreover, the formation of right adjoints can be regarded as a (partially defined) functor from \( \text{Hom}_{\mathcal{C}}(C, D)_{\text{op}} \) to \( \text{Hom}_{\mathcal{C}}(C, D) \) (Notation 6.1.3.5), with a (partially defined) inverse given by the formation of left adjoints (Notation 6.1.3.8). In §6.1.4, we consider the special case where \( f : \mathcal{C} \to \mathcal{D} \) is an isomorphism in \( \mathcal{C} \); in this case, \( f \) automatically admits a right adjoint (and a left adjoint), which can be identified with a homotopy inverse isomorphism \( D \to \mathcal{C} \) (Proposition 6.1.4.1).

In §6.1.5, we show that the formation of adjoints is compatible with composition. More precisely, if \( f : \mathcal{C} \to \mathcal{D} \) and \( f' : \mathcal{D} \to \mathcal{E} \) are 1-morphisms in a 2-category \( \mathcal{C} \) which admit right adjoints \( g : \mathcal{D} \to \mathcal{C} \) and \( g' : \mathcal{E} \to \mathcal{D} \), respectively, then the composition \((f' \circ f) : \mathcal{C} \to \mathcal{E} \) also
admits a right adjoint, which is canonically isomorphic to the composition \((g \circ g') : E \to C\) (Corollary 6.1.5.5).

The theory of adjunctions can be usefully applied to many 2-categories \(C\) other than \(\text{Cat}\) (for example, we will use it in §6.2 to generalize the theory of adjoint functors to the setting of \(\infty\)-categories). In §6.1.6 we consider the case \(C\) has a single object \(X\), and can therefore be identified with the monoidal category \(E = \text{End}_C(X)\) (see Example 2.2.2.5). Specializing the theory of adjunctions to this situation, we recover the classical notion of a duality datum in \(E\) (Definition 6.1.6.1).

6.1.1 Adjunctions

Our goal in this section is to generalize the notion of an adjunction to an arbitrary 2-category \(C\). Here Definition 6.1.0.2 adapts without essential change; the only additional complications are the fact that the associativity and unit constraints of \(C\) need not be strict.

Definition 6.1.1.1. Let \(C\) be a 2-category, let \(C\) and \(D\) be objects of \(C\), and let \(f : C \to D\) and \(g : D \to C\) be 1-morphisms in \(C\). An adjunction between \(f\) and \(g\) is a pair of 2-morphisms \((\eta, \epsilon)\), where \(\eta : \text{id}_C \Rightarrow g \circ f\) is a morphism in the category \(\text{Hom}_C(C, C)\) and \(\epsilon : f \circ g \Rightarrow \text{id}_D\) is a morphism in the category \(\text{Hom}_C(D, D)\), which satisfy the following compatibility conditions:

\[(Z1)\] The composition
\[
f \xrightarrow{\rho_f^{-1}} f \circ \text{id}_C \xrightarrow{\text{id}_C \circ \eta} (g \circ f) \xrightarrow{\alpha_{g,f}} (f \circ g) \xrightarrow{\epsilon \circ \text{id}_f} \text{id}_D \circ f \xrightarrow{\lambda_f^{-1}} f
\]
is the identity 2-morphism from \(f\) to itself. Here \(\lambda_f\) and \(\rho_f\) are the left and right unit constraints of the 2-category \(C\) (Construction 2.2.1.11) and \(\alpha_{f,g,f}\) is the associativity constraint for the 2-category \(C\).

\[(Z2)\] The composition
\[
g \xrightarrow{\lambda_g^{-1}} \text{id}_C \circ g \xrightarrow{\text{id}_C \circ \epsilon} (g \circ f) \circ g \xrightarrow{\alpha_{g,f}^{-1}} (f \circ g) \circ g \xrightarrow{\rho_g} \text{id}_D \circ g \xrightarrow{\lambda_g} g
\]
is the identity 2-morphism from \(g\) to itself.

If these conditions are satisfied, then we will refer to \(\eta\) as the unit of the adjunction \((\eta, \epsilon)\) and to \(\epsilon\) as the counit of the adjunction \((\eta, \epsilon)\). In this case, we say that \((\eta, \epsilon)\) exhibits \(f\) as a left adjoint of \(g\), and also that it exhibits \(g\) as a right adjoint of \(f\).

Example 6.1.1.2. Let \(F : C \to D\) and \(G : D \to C\) be functors between categories, which we regard as 1-morphisms in the strict 2-category \(\text{Cat}\) of Example 2.2.0.4. An adjunction between \(F\) and \(G\) in the 2-category \(\text{Cat}\) is an adjunction between \(F\) and \(G\) in the usual category-theoretic sense: that is, a pair of natural transformations \(\eta : \text{id}_C \to G \circ F\) and \(\epsilon : F \circ G \to \text{id}_D\) which satisfy the requirements of Definition 6.1.0.2.
Remark 6.1.1.3. Let \( \mathcal{C} \) be a 2-category, let \( f : C \to D \) and \( g : D \to C \) be 1-morphisms of \( \mathcal{C} \), and let \( \eta : \text{id}_C \Rightarrow g \circ f \) and \( \epsilon : f \circ g \Rightarrow \text{id}_D \) be 2-morphisms of \( \mathcal{C} \). Then the pair \((\eta, \epsilon)\) is an adjunction between \( f \) and \( g \) in the 2-category \( \mathcal{C} \) if and only if the pair \((\eta^{\text{op}}, \epsilon^{\text{op}})\) it is an adjunction between \( g^{\text{op}} \) and \( f^{\text{op}} \) in the opposite 2-category \( \mathcal{C}^{\text{op}} \) (Construction 2.2.3.1). Note that in this case, \( g^{\text{op}} \) is the left adjoint, while \( f^{\text{op}} \) is the right adjoint.

Remark 6.1.1.4. Let \( \mathcal{C} \) be a 2-category, let \( f : C \to D \) and \( g : D \to C \) be 1-morphisms of \( \mathcal{C} \), and let \( \eta : \text{id}_C \Rightarrow g \circ f \) and \( \epsilon : f \circ g \Rightarrow \text{id}_D \) be 2-morphisms of \( \mathcal{C} \). Then the pair \((\eta, \epsilon)\) is an adjunction between \( f \) and \( g \) in the 2-category \( \mathcal{C} \) if and only if the pair \((\epsilon^{\text{c}}, \eta^{\text{c}})\) is an adjunction between \( g^{\text{c}} \) and \( f^{\text{c}} \) in the conjugate 2-category \( \mathcal{C}^{\text{c}} \) (Construction 2.2.3.4). Note that in this case, \( \epsilon^{\text{c}} \) is the unit of the adjunction and \( \eta^{\text{c}} \) is the counit. Similarly, \( g^{\text{c}} \) is the left adjoint and \( f^{\text{c}} \) is the right adjoint.

Remark 6.1.1.5 (Isomorphism Invariance). Let \( \mathcal{C} \) be a 2-category, let \( f, f' : C \to D \) and \( g, g' : D \to C \) be 1-morphisms in \( \mathcal{C} \), and let \((\eta, \epsilon)\) be an adjunction between \( f \) and \( g \). Suppose we are given invertible 2-morphisms \( \beta : g \Rightarrow g' \) and \( \gamma : f \Rightarrow f' \). Let \( \eta' \) denote the composition \( \text{id}_C \Rightarrow g \circ f \overset{\beta \circ \gamma}{\Rightarrow} g' \circ f' \) and let \( \epsilon' \) denote the composition \( f' \circ g' \overset{\gamma^{-1} \circ \beta^{-1}}{\Rightarrow} f \circ g \Rightarrow \text{id}_D \). Then the pair \((\eta', \epsilon')\) is an adjunction between \( f' \) and \( g' \).

Exercise 6.1.1.6 (Functoriality). Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of 2-categories. Suppose we are given 1-morphisms \( f : C \to D \) and \( g : D \to C \) in \( \mathcal{C} \). Let \((\eta, \epsilon)\) be an adjunction between \( f \) and \( g \) in the 2-category \( \mathcal{C} \), let \( \eta' \) denote the composition
\[
\text{id}_{F(C)} \Rightarrow F(\text{id}_C) \overset{F(\eta)}{\Rightarrow} F(g \circ f) \overset{\mu_{g,f}^{-1}}{\Rightarrow} F(g) \circ F(f),
\]
and let \( \epsilon' \) denote the composition
\[
F(f) \circ F(g) \overset{\mu_{f,g}^{-1}}{\Rightarrow} F(f \circ g) \overset{F(\epsilon)}{\Rightarrow} F(\text{id}_D) \Rightarrow \text{id}_{F(D)},
\]
where \( \mu_{f,g} \) and \( \mu_{g,f} \) are the composition constraints of the functor \( F \) and the unlabeled isomorphisms are the identity constraints of \( F \). Show that the pair \((\eta', \epsilon')\) is an adjunction between \( F(f) \) and \( F(g) \) in the 2-category \( \mathcal{D} \).

Example 6.1.1.7. Let \( \mathcal{C} \) be an ordinary category which admits fiber products, and let \( \text{Corr}(\mathcal{C}) \) denote the 2-category of correspondences in \( \mathcal{C} \) (Example 2.2.2.1). Every morphism \( f : X \to Y \) in \( \mathcal{C} \) determines diagrams

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow{\text{id}_X} & & \downarrow{\text{id}_Y} \\
X & \xrightarrow{f} & Y \\
\end{array}
\]
which we can regard as 1-morphisms \( f_! : X \rightarrow Y \) and \( f^! : Y \rightarrow X \) in the 2-category \( \text{Corr}(\mathcal{C}) \). Unwinding the definitions, we see that the compositions \( f^! \circ f_! \) and \( f_! \circ f^! \) are given (up to isomorphism) by the diagrams

\[
\begin{array}{ccc}
X \times_Y X & \xrightarrow{\pi_0} & X \\
\downarrow & & \downarrow \\
X & \xrightarrow{f} & Y
\end{array}
\quad
\begin{array}{ccc}
X & \xleftarrow{f} & Y \\
\downarrow & & \downarrow \\
X \times_Y X & \xleftarrow{\pi_1} & X
\end{array}
\]

where \( \pi_0, \pi_1 : X \times_Y X \rightarrow X \) are the projection maps. We can therefore regard the diagonal map \( \delta : X \rightarrow X \times_X X \) as a 2-morphism from \( \text{id}_X \) to \( f^! \circ f_! \) in \( \text{Corr}(\mathcal{C}) \), and the morphism \( f : X \rightarrow Y \) as a 2-morphism from \( f_! \circ f^! \) to \( \text{id}_Y \) in \( \text{Corr}(\mathcal{C}) \). The pair \((\delta, f)\) is an adjunction between \( f_! \) and \( f^! \).

### 6.1.2 Adjuncts

Let \( F : \mathcal{C} \rightarrow \mathcal{D} \) and \( G : \mathcal{D} \rightarrow \mathcal{C} \) be functors between categories. By virtue of Exercise 6.1.0.4, every adjunction \((\eta, \epsilon)\) between \( F \) and \( G \) determines a collection of bijections

\[
\rho_{C,D} : \text{Hom}_\mathcal{D}(F(C), D) \simeq \text{Hom}_\mathcal{C}(C, G(D)),
\]

depending functorially on \( C \in \mathcal{C} \) and \( D \in \mathcal{D} \). In this section, we establish an analogue of this statement for adjunctions in an arbitrary 2-category.

#### Construction 6.1.2.1

Let \( \mathcal{C} \) be a 2-category containing objects \( T, C, \) and \( D \), together with 1-morphisms \( f : C \rightarrow D, g : D \rightarrow C, c : T \rightarrow C, \) and \( d : T \rightarrow D \).

- Let \( \epsilon : f \circ g \Rightarrow \text{id}_D \) and \( \beta : c \Rightarrow g \circ d \) be 2-morphisms of \( \mathcal{C} \). We will refer to the composition

\[
f \circ c \xrightarrow{\text{id}_f \circ \beta} f \circ (g \circ d) \xrightarrow{\alpha_{f,g,d}} (f \circ g) \circ d \xrightarrow{\epsilon \circ \text{id}_d} \text{id}_D \circ d \xrightarrow{\lambda_d} d
\]

as the left adjunct of \( \beta \) with respect to \( \epsilon \), or more simply as the left adjunct of \( \beta \) if the 2-morphism \( \epsilon \) is clear from context. Here \( \lambda_d \) and \( \alpha_{f,g,d} \) are the left unit and associativity constraints for the 2-category \( \mathcal{C} \).

- Let \( \eta : \text{id}_C \Rightarrow g \circ f \) and \( \gamma : f \circ c \Rightarrow d \) be 2-morphisms of \( \mathcal{C} \). We will refer to the composition

\[
c \xrightarrow{\lambda_c^{-1}} \text{id}_C \circ c \Rightarrow (g \circ f) \circ c \xrightarrow{\alpha_{g,f,c}^{-1}} g \circ (f \circ c) \xrightarrow{\eta \circ \gamma} g \circ d
\]

as the right adjunct of \( \gamma \) with respect to \( \eta \), or more simply as the right adjunct of \( \gamma \) if the 2-morphism \( \eta \) is clear from context. Here again \( \lambda_c \) and \( \alpha_{g,f,c} \) are the left unit and associativity constraints for the 2-category \( \mathcal{C} \).
Example 6.1.2.2. Let $\mathcal{C}$ be a 2-category containing 1-morphisms $f : C \to D$ and $g : D \to C$. Then:

- Every 2-morphism $\eta : \text{id}_C \Rightarrow g \circ f$ is equal to the right adjunct of the right unit constraint $\rho_f : f \circ \text{id}_D \Rightarrow f$ (with respect to $\eta$).

- Every 2-morphism $\epsilon : f \circ g \Rightarrow \text{id}_D$ is equal to the left adjunct of $\rho_g^{-1} : g \Rightarrow g \circ \text{id}_D$ (with respect to $\epsilon$).

Example 6.1.2.3. Let $\mathcal{C}$ be a 2-category containing 1-morphisms $f : C \to D$ and $g : D \to C$, and suppose we are given 2-morphisms $\eta : \text{id}_C \Rightarrow g \circ f$ and $\epsilon : f \circ g \Rightarrow \text{id}_D$. Then $(\eta, \epsilon)$ is an adjunction between $f$ and $g$ if and only if the following conditions are satisfied:

$(Z1)$ The left adjunct of $\eta$ (with respect to $\epsilon$) is equal to the right unit constraint $\rho_f : f \circ \text{id}_C \Rightarrow f$.

$(Z2)$ The right adjunct of $\epsilon$ (with respect to $\eta$) is the inverse $\rho_g^{-1} : g \Rightarrow g \circ \text{id}_D$ of the right unit constraint.

Remark 6.1.2.4 (Functoriality). Let $\mathcal{C}$ be a 2-category containing objects $T, C,$ and $D$, together with 1-morphisms $f : C \to D, g : D \to C, c, c' : T \to C$, and $d, d' : T \to D$. Then:

- If $\eta : \text{id}_C \Rightarrow g \circ f$ and $\varphi : c \Rightarrow c'$ are 2-morphisms of $\mathcal{C}$, then the diagram of sets

$$
\begin{array}{ccc}
\text{Hom}_{\text{Hom}_\mathcal{C}(T,D)}(f \circ c', d) & \to & \text{Hom}_{\text{Hom}_\mathcal{C}(T,C)}(c', g \circ d) \\
\downarrow \text{id}_f \circ \varphi & & \downarrow \varphi \\
\text{Hom}_{\text{Hom}_\mathcal{C}(T,D)}(f \circ c, d) & \to & \text{Hom}_{\text{Hom}_\mathcal{C}(T,C)}(c, g \circ d)
\end{array}
$$

is commutative, where the horizontal maps are given by the formation of right adjuncts with respect to $\eta$.

- If $\epsilon : f \circ g \Rightarrow \text{id}_D$ and $\varphi : c \Rightarrow c'$ are 2-morphisms of $\mathcal{C}$, then the diagram of sets

$$
\begin{array}{ccc}
\text{Hom}_{\text{Hom}_\mathcal{C}(T,C)}(c', g \circ d) & \to & \text{Hom}_{\text{Hom}_\mathcal{C}(T,D)}(f \circ c', d) \\
\downarrow \varphi & & \downarrow \text{id}_f \circ \varphi \\
\text{Hom}_{\text{Hom}_\mathcal{C}(T,C)}(c, g \circ d) & \to & \text{Hom}_{\text{Hom}_\mathcal{C}(T,D)}(f \circ c, d),
\end{array}
$$

where the horizontal maps are given by the formation of left adjuncts with respect to $\epsilon$. 
If \( \eta : \text{id}_C \Rightarrow g \circ f \) and \( \psi : d \Rightarrow d' \) are 2-morphisms of \( C \), then the diagram of sets

\[
\begin{array}{ccc}
\text{Hom}_{\text{Hom}_e(T,D)}(f \circ c, d) & \rightarrow & \text{Hom}_{\text{Hom}_e(T,C)}(c, g \circ d) \\
\downarrow \psi & & \downarrow \text{id}_g \circ \psi \\
\text{Hom}_{\text{Hom}_e(T,D)}(f \circ c, d') & \rightarrow & \text{Hom}_{\text{Hom}_e(T,C)}(c, g \circ d')
\end{array}
\]

is commutative, where the horizontal maps are given by the formation of right adjuncts with respect to \( \eta \).

If \( \epsilon : f \circ g \Rightarrow \text{id}_D \) and \( \psi : d \Rightarrow d' \) are 2-morphisms of \( C \), then the diagram of sets

\[
\begin{array}{ccc}
\text{Hom}_{\text{Hom}_e(T,C)}(c, g \circ d) & \rightarrow & \text{Hom}_{\text{Hom}_e(T,D)}(f \circ c, d) \\
\downarrow \text{id}_g \circ \psi & & \downarrow \psi \\
\text{Hom}_{\text{Hom}_e(T,C)}(c, g \circ d') & \rightarrow & \text{Hom}_{\text{Hom}_e(T,D)}(f \circ c, d')
\end{array}
\]

is commutative, where the horizontal maps are given by the formation of left adjuncts with respect to \( \epsilon \).

Stated more informally, Construction \[6.1.2.1\] depends functorially on the 1-morphisms \( c : T \rightarrow C \) and \( d : T \rightarrow D \).

**Proposition 6.1.2.5.** Let \( C \) be a 2-category, let \( f : C \rightarrow D \) and \( g : D \rightarrow C \) be 1-morphisms of \( C \), and let \( \eta : \text{id}_C \Rightarrow g \circ f \) and \( \epsilon : f \circ g \Rightarrow \text{id}_D \) be 2-morphisms. Suppose we are given another object \( T \in C \) equipped with 1-morphisms \( c : T \rightarrow C \) and \( d : T \rightarrow D \), together with 2-morphisms \( \beta : c \Rightarrow g \circ d \) and \( \gamma : f \circ c \Rightarrow d \). Then:

1. If the pair \((\eta, \epsilon)\) satisfies condition \((Z1)\) of Definition \[6.1.1.1\] and \( \beta \) is the right adjunct of \( \gamma \), then \( \gamma \) is the left adjunct of \( \beta \).

2. If the pair \((\eta, \epsilon)\) satisfies condition \((Z2)\) of Definition \[6.1.1.1\] and \( \gamma \) is the left adjunct of \( \beta \), then \( \beta \) is the right adjunct of \( \gamma \).

**Proof.** We will prove (1); the proof of (2) follows by applying the same argument in the
Conjugate 2-category $C^c$. Consider the diagram

\[
\begin{array}{c}
f \circ c \xrightarrow{\lambda_f^{-1}} f \circ (\text{id}_C \circ c) \xrightarrow{\eta} f \circ ((g \circ f) \circ c) \xrightarrow{\sim} f \circ (g \circ (f \circ c)) \xrightarrow{\gamma} f \circ (g \circ d) \\
\rho_f \sim \\
(f \circ \text{id}_C) \circ c \xrightarrow{\eta} (f \circ (g \circ f) \circ c) \xrightarrow{\sim} ((f \circ g) \circ f) \circ c \xrightarrow{\sim} (f \circ g) \circ (f \circ c) \xrightarrow{\gamma} (f \circ g) \circ c \\
\epsilon \\
\end{array}
\]

\[
\begin{array}{c}
(id_D \circ f) \circ c \xrightarrow{\sim} id_D \circ (f \circ c) \xrightarrow{\gamma} id_D \circ d \\
\lambda_f \\
\lambda_{f \circ c} \\
\lambda_d \\
\end{array}
\]

in the category $\text{Hom}_{C}(T, D)$, where the unlabeled morphisms are given by the associativity constraints of $C$ (and their inverses). Our assumption that $\beta$ is the right adjunct of $\gamma$ guarantees that the composition along the top line coincides with $id_f \circ \beta$. Consequently, the left adjunct of $\beta$ is the 2-morphism of $C$ given by clockwise composition around the outside of the diagram. On the other hand, axiom (Z1) of Definition 6.1.1.1 guarantees counterclockwise composition around the outside of the diagram coincides with $\gamma$. To complete the proof, it will suffice to show that the diagram commutes. The commutativity of the triangular regions follows Propositions 2.2.1.14 and 2.2.1.16. The commutativity of the bottom right square follows from the naturality of left unit constraints (Remark 2.2.1.13) and the commutativity of the middle right square from the functoriality of composition. The remaining squares commute by the naturality of the associativity constraints of $C$, and the five-sided region commutes by virtue of the pentagon identity.

**Corollary 6.1.2.6.** Let $C$ be a 2-category, let $f : C \rightarrow D$ and $g : D \rightarrow C$ be 1-morphisms of $C$, and suppose we are given 2-morphisms $\eta : \text{id}_C \Rightarrow g \circ f$ and $\epsilon : f \circ g \Rightarrow \text{id}_D$. The following conditions are equivalent:

1. The pair $(\eta, \epsilon)$ is an adjunction between $f$ and $g$ (in the sense of Definition 6.1.1.1).
2. For every object $T \in C$ and every pair of 1-morphisms $c : T \rightarrow C$ and $d : T \rightarrow D$, the formation of left and right adjuncts (Construction 6.1.2.1) supplies mutually inverse bijections

\[
\text{Hom}_{\text{Hom}_{C}(T, D)}(f \circ c, d) \simeq \text{Hom}_{\text{Hom}_{C}(T, C)}(c, f \circ d).
\]

\[\square\]
Proof. The implication (1) ⇒ (2) follows from Proposition 6.1.2.5. For the converse, we first observe that \( \eta : \text{id}_C \Rightarrow g \circ f \) is equal to the right adjunct of the right unit constraint \( \rho_f : f \circ \text{id}_D \rightleftharpoons f \) with respect to \( \eta \) (Example 6.1.2.2). If assumption (2) is satisfied, then \( \rho_f \) is the left adjunct of \( \eta \) with respect to \( \epsilon \). Similarly, assumption (2) guarantees that \( \rho^{-1}_g : g \Rightarrow g \circ \text{id}_D \) is the right adjunct of \( \epsilon \) with respect to \( \eta \), so that the pair \((\eta, \epsilon)\) is an adjunction by virtue of Example 6.1.2.3.

Example 6.1.2.7. Let \( F : C \to D \) and \( G : D \to C \) be functors between categories, and let \((\eta, \epsilon)\) be an adjunction between \( F \) and \( G \). Suppose we are given objects \( C \in C \) and \( D \in D \), which we identify with functors \( C : \{\ast\} \to C \) and \( D : \{\ast\} \to D \), respectively. Applying Corollary 6.1.2.6 to the 2-category \( \text{Cat} \), we obtain a bijection

\[
\rho_{C,D} : \text{Hom}_D(F(C), D) \simeq \text{Hom}_D(C, G(D)).
\]

This bijection depends functorially on \( C \) and \( D \) (Remark 6.1.2.4), and can therefore be regarded as a Hom-adjunction between \( F \) and \( G \) in the sense of Definition 6.1.0.1. Note that, for every morphism \( f : F(C) \to D \) in \( C \), the image \( \rho_{C,D}(f) \in \text{Hom}_C(C, G(D)) \) is given explicitly by the composition \( C \xrightarrow{\eta_C} (G \circ F)(C) \xrightarrow{G(f)} G(D) \). In particular, the morphism \( \eta_C : C \to (G \circ F)(C) \) can be recovered by applying \( \rho_{C,F(C)} \) to the identity morphism \( \text{id}_{F(C)} \).

Similarly, for each object \( D \in D \), the morphism \( \epsilon_D : (F \circ G)(D) \to D \) can be recovered by applying \( \rho^{-1}_{G(D), D} \) to the identity morphism \( \text{id}_{G(D)} \). In other words, the adjunction \((\eta, \epsilon)\) is obtained by applying the construction of Example 6.1.0.3 to the Hom-adjunction \( \{\rho_{C,D}\}_{C \in C, D \in D} \).

Corollary 6.1.2.8. Let \( C \) be a 2-category, let \( f : C \to D \) and \( g : D \to C \) be 1-morphisms of \( C \), and suppose we are given 2-morphisms \( \eta : \text{id}_C \Rightarrow g \circ f \) and \( \epsilon : f \circ g \Rightarrow \text{id}_D \) satisfying condition (Z1) of Definition 6.1.1.1. Let \( \gamma : g \Rightarrow g \) denote the 2-morphism given by the composition

\[
g \xmapsto{\eta^{-1}} \text{id}_C \circ g \xmapsto{\eta \circ \text{id}_D} (g \circ f) \circ g \xmapsto{\alpha_{g,f,g}} g \circ (f \circ g) \xmapsto{\text{id}_g \circ \epsilon} g \circ \text{id}_D \xmapsto{\rho_g} g.
\]

Then \( \gamma \) is idempotent: that is, \( \gamma^2 = \gamma \) in the category \( \text{Hom}_C(D, C) \). In particular, if \( \gamma \) has either a left or a right inverse, then \( \gamma = \text{id}_g \) (so that \((\eta, \epsilon)\) is an adjunction between \( f \) and \( g \)).

Proof. Let \( \gamma' \) denote the composition \( g \xmapsto{\gamma} g \xmapsto{\rho^{-1}_g} g \circ \text{id}_D \). Then \( \gamma' \) is the right adjunct of \( \epsilon \) with respect to \( \eta \) (see Example 6.1.2.3). Invoking Remark 6.1.2.4, we deduce that the horizontal composition \( \gamma' \gamma \) is the right adjunct of \( \epsilon' \) with respect to \( \eta \), where \( \epsilon' \) denotes the composite map \( f \circ g \xmapsto{\eta \circ \text{id}_D} f \circ g \Rightarrow \text{id}_D \). Combining Example 6.1.2.2 with Remark 6.1.2.4, we see that \( \epsilon' \) is the left adjunct of \( \gamma' \) with respect to \( \epsilon \). Since the pair \((\eta, \epsilon)\) satisfies (Z1),
it follows that $\gamma'\gamma = \gamma'$, Composing with the right unit constraint $\rho_g$, we conclude that $\gamma\gamma = \gamma$.

**Proposition 6.1.2.9.** Let $\mathcal{C}$ be a 2-category, let $f : C \to D$ and $g : D \to C$ be 1-morphisms of $\mathcal{C}$, and let $\eta : \text{id}_C \Rightarrow g \circ f$ be a 2-morphism of $\mathcal{C}$. The following conditions are equivalent:

1. For every object $T \in \mathcal{C}$ and every pair of 1-morphisms $c : T \to C$ and $d : T \to D$, the formation of right adjuncts with respect to $\eta$ (Construction 6.1.2.1) induces a bijection $\text{Hom}_{\text{Hom}_*(T,D)}(f \circ c, d) \to \text{Hom}_{\text{Hom}_*(T,C)}(c, g \circ d)$.

2. There exists a 2-morphism $\epsilon : f \circ g \Rightarrow \text{id}_D$ for which $(\eta, \epsilon)$ is an adjunction between $f$ and $g$.

Moreover, if these conditions are satisfied, then the 2-morphism $\epsilon$ is uniquely determined.

**Proof.** The implication (2) $\Rightarrow$ (1) follows from Corollary 6.1.2.6. Conversely, suppose that condition (1) is satisfied. Applying (1) in the case $T = D$, $c = g$, and $d = \text{id}_D$, we conclude that there is a unique 2-morphism $\epsilon : f \circ g \Rightarrow \text{id}_D$ whose right adjunct is equal to the inverse $\rho_{g}^{-1} : g \Rightarrow g \circ \text{id}_D$ of the right unit constraint $\rho_g$, so that the pair $(\eta, \epsilon)$ satisfies condition (Z2) of Definition 6.1.1.1 (Example 6.1.2.3). We will complete the proof by showing that $(\eta, \epsilon)$ also satisfies condition (Z1). Let $\gamma : f \circ \text{id}_C \Rightarrow f$ be the left adjunct of $\eta$. It follows from Proposition 6.1.2.5 that the right adjunct of $\gamma$ is equal to $\eta$, which is also the right adjunct of the unit constraint $\rho_f : f \circ \text{id}_C \Rightarrow f$. Invoking assumption (1), we conclude that $\gamma = \rho_f$, which is a restatement of (Z1) (Example 6.1.2.3). 

**Definition 6.1.2.10.** Let $\mathcal{C}$ be a 2-category and let $f : C \to D$ and $g : D \to C$ be 1-morphisms of $\mathcal{C}$. We say that a 2-morphism $\eta : \text{id}_C \Rightarrow g \circ f$ is the unit of an adjunction if it satisfies the equivalent conditions of Proposition 6.1.2.9; that is, if there exists a 2-morphism $\epsilon : f \circ g \Rightarrow \text{id}_D$ for which the pair $(\eta, \epsilon)$ is an adjunction. If this condition is satisfied, we will say that $\eta$ exhibits $f$ as a left adjoint of $g$ and also that $\eta$ exhibits $g$ as a right adjoint of $f$.

In the 2-category $\text{Cat}$, we can formulate a sharper version of Proposition 6.1.2.9:

**Variant 6.1.2.11.** Let $F : \mathcal{C} \to \mathcal{D}$ and $G : \mathcal{D} \to \mathcal{C}$ be functors between categories and let $\eta : \text{id}_C \Rightarrow G \circ F$ be a natural transformation. The following conditions are equivalent:

1. For every pair of objects $C \in \mathcal{C}$ and $D \in \mathcal{D}$, the formation of right adjuncts with respect to $\eta$ induces a bijection $\text{Hom}_{\mathcal{D}}(F(C), D) \to \text{Hom}_{\mathcal{C}}(C, G(D))$.

2. There exists a natural transformation $\epsilon : F \circ G \Rightarrow \text{id}_D$ for which $(\eta, \epsilon)$ is an adjunction between $F$ and $G$. 
Moreover, if these conditions are satisfied, then the natural transformation \( \epsilon \) is uniquely determined.

**Proof.** We will prove that (1) \( \Rightarrow \) (2); the remaining assertions follow immediately from Proposition \ref{prop:6.1.2.9}. Fix an object \( D \in \mathcal{D} \). Applying assertion (1) in the case \( C = G(D) \), we deduce that there is a unique morphism \( \epsilon_D : (F \circ G)(D) \to D \) for which the composition

\[
G(D) \xrightarrow{\eta_{G(D)}} (G \circ F \circ G)(D) \xrightarrow{G(\epsilon_D)} G(D)
\]

is the identity morphism from \( G(D) \) to itself.

We first claim that the construction \( D \mapsto \epsilon_D \) is a natural transformation of functors from \( F \circ G \) to \( \text{id}_D \). Let \( h : D \to D' \) be a morphism in the category \( \mathcal{D} \); we wish to show that the diagram

\[
\begin{array}{ccc}
(F \circ G)(D) & \xrightarrow{\epsilon_D} & D \\
\downarrow{(F \circ G)(h)} & & \downarrow{h} \\
(F \circ G)(D') & \xrightarrow{\epsilon_{D'}} & D'
\end{array}
\]

commutes. Consider the diagram

\[
\begin{array}{ccc}
G(D) & \xrightarrow{\eta_{G(D)}} & (G \circ F \circ G)(D) \xrightarrow{G(\epsilon_D)} G(D) \\
\downarrow{G(h)} & & \downarrow{G(F(G(h)))} \\
G(D') & \xrightarrow{\eta_{G(D')}} & (G \circ F \circ G)(D') \xrightarrow{G(\epsilon_{D'})} G(D')
\end{array}
\]

in the category \( \mathcal{C} \). It follows from the definitions of \( \epsilon_D \) and \( \epsilon_{D'} \) that both horizontal compositions are equal to the identity, so the outer rectangle commutes. Since \( \eta \) is a natural transformation, the left square commutes. It follows that the compositions \( G(h) \circ G(\epsilon_D) \circ u_{G(D)} \) and \( G(\epsilon_{D'}) \circ G(F(G(h))) \circ \eta_{G(D)} \) are the same: that is, the morphisms

\[
h \circ \epsilon_D, \epsilon_{D'} \circ F(G(h)) \in \text{Hom}_\mathcal{D}((F \circ G)(D), D')
\]

have the same right adjunct. Invoking assumption (1), we deduce that \( h \circ \epsilon_D = \epsilon_{D'} \circ (F(G(h))) \), as desired.

It follows immediately from the construction that the pair of natural transformations \( (\eta, \epsilon) \) satisfies condition \((Z2)\) of Definition \ref{def:6.1.0.2}. To complete the proof, it will suffice to show that it also satisfies condition \((Z1)\). Let \( C \) be an object of \( \mathcal{C} \); we wish to show that the composite map

\[
F(C) \xrightarrow{F(G(C))} (F \circ G \circ F)(C) \xrightarrow{\epsilon_{F(C)}} F(C)
\]
is equal to the identity map $\text{id}_{F(C)}$. Note that the right adjunct of $\epsilon_{F(C)} \circ F(\eta_C)$ is the composite map

$$C \xrightarrow{\eta_C} (G \circ F)(C) \xrightarrow{(GoF)(\eta_C)} (G \circ F \circ G \circ F)(C) \xrightarrow{G(\epsilon_{F(C)})} (G \circ F)(C).$$

By virtue of the fact that $(\eta, \epsilon)$ satisfies $(Z2)$, this composition is equal to $\eta_C$, which is also the right adjunct of the identity map $\text{id}_{F(C)}$. Invoking assumption (1), we conclude that $\epsilon_{F(C)} \circ F(\eta_C) = \text{id}_{F(C)}$, as desired.

We can give another characterization of the units of adjunctions by applying Proposition 6.1.2.9 in the opposite 2-category $C^{\text{op}}$:

**Variant 6.1.2.12.** Let $C$ be a 2-category, let $f : C \to D$ and $g : C \to D$ be 1-morphisms of $C$, and let $\eta : \text{id}_C \Rightarrow g \circ f$ be a 2-morphism of $C$. Then $\eta$ is the unit of an adjunction if and only if the following condition is satisfied:

- For every object $T \in C$ and every pair of morphisms $c : C \to T$ and $d : D \to T$, the 2-morphism $\eta$ determines a bijection

$$\text{Hom}_{\text{Hom}_C(D,T)}(c \circ g, d) \to \text{Hom}_{\text{Hom}_C(C,T)}(c, d \circ f),$$

carrying each 2-morphism $\beta : c \circ g \Rightarrow d$ to the composition

$$c \xrightarrow{\beta} c \circ \text{id}_C \xrightarrow{id_c \circ \eta} c \circ (g \circ f) \xrightarrow{\alpha_{c,g,f}} (c \circ g) \circ f \xrightarrow{\beta \circ \text{id}_f} d \circ f.$$

For the reader’s convenience, let us also record a conjugate version of the preceding discussion:

**Proposition 6.1.2.13.** Let $C$ be a 2-category, let $f : C \to D$ and $g : D \to C$ be 1-morphisms of $C$, and let $\epsilon : f \circ g \Rightarrow \text{id}_D$ be a 2-morphism of $C$. The following conditions are equivalent:

1. For every object $T \in C$ and every pair of 1-morphisms $c : T \to C$ and $d : D \to T$, the formation of left adjuncts with respect to $\epsilon$ (Construction 6.1.2.1) induces a bijection

$$\text{Hom}_{\text{Hom}_C(T,C)}(c \circ g, d) \to \text{Hom}_{\text{Hom}_C(T,D)}(f \circ c, d)$$

2. For every object $T \in C$ and every pair of 1-morphisms $c : C \to T$ and $d : D \to T$, the 2-morphism $\epsilon$ determines a bijection

$$\text{Hom}_{\text{Hom}_C(T,C)}(c, d \circ f) \to \text{Hom}_{\text{Hom}_C(T,D)}(c \circ g, d)$$

carrying each 2-morphism $\gamma : c \Rightarrow d \circ f$ to the composition

$$c \circ g \xrightarrow{\gamma \circ \text{id}_g} (d \circ f) \circ g \xrightarrow{\alpha_{d,f,g}^{-1}} d \circ (f \circ g) \xrightarrow{\text{id}_d \circ \epsilon} d \circ \text{id}_D \xrightarrow{\beta_d} d.$$
(3) There exists a 2-morphism \( \eta : \text{id}_C \Rightarrow g \circ f \) for which \((\eta, \epsilon)\) is an adjunction between \( f \) and \( g \).

Moreover, if these conditions are satisfied, then the 2-morphism \( \eta \) is uniquely determined.

**Proof.** Apply Proposition 6.1.2.9 and Variant 6.1.2.12 to the conjugate 2-category \( C^c \).

**Definition 6.1.2.14.** Let \( C \) be a 2-category and let \( f : C \rightarrow D \) and \( g : D \rightarrow C \) be 1-morphisms of \( C \). We say that a 2-morphism \( \epsilon : f \circ g \Rightarrow \text{id}_D \) is the counit of an adjunction if it satisfies the equivalent conditions of Proposition 6.1.2.13: that is, there exists a 2-morphism \( \eta : \text{id}_C \Rightarrow g \circ f \) for which the pair \((\eta, \epsilon)\) is an adjunction. If this condition is satisfied, we will say that \( \epsilon \) exhibits \( f \) as a left adjoint of \( g \) and also that \( \epsilon \) exhibits \( g \) as a right adjoint of \( f \).

### 6.1.3 Uniqueness of Adjoints

Let \( C \) be a 2-category and let \( f : C \rightarrow D \) be a 1-morphism of \( C \). We will say that a 1-morphism \( g : D \rightarrow C \) is a right adjoint of \( f \) if there exists an adjunction \((\eta, \epsilon)\) between \( f \) and \( g \), in the sense of Definition 6.1.1.1. Beware that the right adjoint of \( f \) is usually not unique: if \( g \) is a right adjoint of \( f \), then any 1-morphism \( g' : D \rightarrow C \) which is isomorphic to \( g \) can also be regarded as a right adjoint to \( f \) (see Remark 6.1.1.5). However, we will show in this section that this is the only source of ambiguity: the right adjoint of a 1-morphism \( f \) (if it exists) is well-defined up to canonical isomorphism.

**Proposition 6.1.3.1.** Let \( C \) be a 2-category, let \( f : C \rightarrow D \) and \( g : D \rightarrow C \) be 1-morphisms of \( C \), and let \( \eta : \text{id}_C \Rightarrow g \circ f \) be the unit of an adjunction. Then:

1. For every 1-morphism \( f' : C \rightarrow D \), the function

\[
\text{Hom}_{\text{Hom}_c}(C,D)(f,f') \rightarrow \text{Hom}_{\text{Hom}_c}(C,C)(\text{id}_C, g \circ f') \quad \gamma \mapsto (\text{id}_g \circ \gamma) \eta
\]

is a bijection.

2. For every 1-morphism \( g' : D \rightarrow C \), the function

\[
\text{Hom}_{\text{Hom}_c}(D,C)(g,g') \rightarrow \text{Hom}_{\text{Hom}_c}(C,C)(\text{id}_C, g' \circ f) \quad \beta \mapsto (\beta \circ \text{id}_f) \eta
\]

is a bijection.

**Proof.** Let \( \rho_f : f \circ \text{id}_C \Rightarrow f \) be the right unit constraint. To prove (1), we observe that the composition

\[
\text{Hom}_{\text{Hom}_c}(C,D)(f \circ \text{id}_C, f') \xrightarrow{\rho_f} \text{Hom}_{\text{Hom}_c}(C,D)(f, f') \rightarrow \text{Hom}_{\text{Hom}_c}(C,C)(\text{id}_C, g \circ f')
\]

is given by the formation of right adjuncts (see Example 6.1.2.2 and Remark 6.1.2.4), and is therefore bijective by (Proposition 6.1.2.5). Assertion (2) follows by a similar argument. □
**Variant 6.1.3.2.** Let $\mathcal{C}$ be a 2-category, let $f : C \to D$ and $g : D \to C$ be 1-morphisms of $\mathcal{C}$, and let $\epsilon : f \circ g \Rightarrow \text{id}_D$ be the counit of an adjunction. Then:

1. For every 1-morphism $f' : C \to D$, the function
   \[ \text{Hom}_{\mathcal{C}}(C,D)(f',f) \to \text{Hom}_{\mathcal{C}}(D,D)(f' \circ g, \text{id}_D) \quad \gamma \mapsto \epsilon(\gamma \circ \text{id}_g) \]
   is a bijection.

2. For every 1-morphism $g' : D \to C$, the function
   \[ \text{Hom}_{\mathcal{C}}(D,\mathcal{C})(g',g) \to \text{Hom}_{\mathcal{C}}(D,D)(f \circ g', \text{id}_D) \quad \beta \mapsto \epsilon(\text{id}_f \circ \beta) \]
   is a bijection.

**Proof.** Apply Proposition 6.1.3.1 to the conjugate 2-category $\mathcal{C}^c$.

**Corollary 6.1.3.3.** Let $\mathcal{C}$ be a 2-category, let $f : C \to D$ and $g : D \to C$ be 1-morphisms of $\mathcal{C}$, and let $(\eta, \epsilon)$ be an adjunction between $f$ and $g$. Let $g' : D \to C$ be another 1-morphism of $\mathcal{C}$. Then:

1. For every 2-morphism $\eta' : \text{id}_C \Rightarrow g' \circ f$, there is a unique 2-morphism $\beta : g \Rightarrow g'$ for which $\eta'$ is equal to the composition $\text{id}_C \eta \Rightarrow g \circ f \Rightarrow g' \circ f$. Moreover, $\beta$ is an isomorphism if and only if $\eta'$ is the unit of an adjunction.

2. For every 2-morphism $\epsilon' : f \circ g' \Rightarrow \text{id}_D$, there is a unique 2-morphism $\gamma : g' \Rightarrow g$ for which $\epsilon'$ factors as a composition $f \circ g' \Rightarrow f \circ f \Rightarrow \text{id}_D$. Moreover, $\gamma$ is an isomorphism if and only $\epsilon'$ is the counit of an adjunction.

**Proof.** We will prove (1); the proof of (2) similar. Let $\eta' : \text{id}_C \Rightarrow g' \circ f$ be a 2-morphism of $\mathcal{C}$. It follows from Proposition 6.1.3.1 that there is a unique 2-morphism $\beta : g \Rightarrow g'$ satisfying $\eta' = (\beta \circ \text{id}_f) \eta$. If $\beta$ is an isomorphism, then $\eta'$ is the unit of an adjunction by virtue of Remark 6.1.1.5. Conversely, suppose that $\eta'$ is the unit of an adjunction. To prove that $\beta$ is an isomorphism, it will suffice to show that for every 1-morphism $g'' : D \to C$, precomposition with $\beta$ induces a bijection $\text{Hom}_{\mathcal{C}}(D,C)(g',g'') \to \text{Hom}_{\mathcal{C}}(D,C)(g,g'')$. This is clear: we have a commutative diagram

\[
\begin{array}{ccc}
\text{Hom}_{\mathcal{C}}(D,C)(g',g'') & \xrightarrow{\beta} & \text{Hom}_{\mathcal{C}}(D,C)(g,g'') \\
\eta' \downarrow & & \eta \downarrow \\
\text{Hom}_{\mathcal{C}}(C,C)(\text{id}_C,g'' \circ f), & & \\
\end{array}
\]

where the vertical maps are bijective by virtue of Proposition 6.1.3.1. 

\[\square\]
Proposition 6.1.3.4. Let \( C \) be a 2-category containing 1-morphisms \( f, f' : C \to D \) which admit \((\eta, \epsilon)\) between \( f \) and \( g \) and \((\eta', \epsilon')\) between \( f' \) and \( g' \). Then every 2-morphism \( \beta : f \Rightarrow f' \) determines a 2-morphism \( \beta^R : g' \Rightarrow g \), which is uniquely determined by either of the following properties:

(1) The diagram

\[
\begin{align*}
\text{id}_C & \xrightarrow{\eta} \ g \circ f \\
\downarrow \eta' & \quad \downarrow \text{id}_\circ \beta \\
g' \circ f' & \xrightarrow{\beta \circ \text{id}_\circ f} \ g \circ f'
\end{align*}
\]

commutes (in the category \( \text{Hom}_C(C, C) \)).

(2) The diagram

\[
\begin{align*}
f \circ g' & \xrightarrow{\text{id}_f \circ \beta^R} \ f \circ g \\
\downarrow \beta \circ \text{id}_g & \quad \downarrow \epsilon \\
f' \circ g' & \xrightarrow{\epsilon'} \ \text{id}_D
\end{align*}
\]

commutes (in the category \( \text{Hom}_C(D, D) \)).

Proof. It follows from Corollary 6.1.3.3 that there is a unique morphism \( \beta^R \) satisfying condition (1). We will prove that \( \beta^R \) also satisfies condition (2) (it is also uniquely determined by condition (2), by virtue of Corollary 6.1.3.3). Note (2) is equivalent to the assertion that \( \epsilon'(\beta \circ \text{id}_{g'}) \) is the left adjunct of \( \rho_{g}^{-1} \beta^R \) with respect to \( \epsilon \) (in the sense of Construction 6.1.2.1). By virtue of Proposition 6.1.2.5 this is equivalent to the assertion that \( \rho_{g}^{-1} \beta^R \) is the right adjunct of \( \epsilon'(\beta \circ \text{id}_{g'}) \) with respect to \( \eta \). This follows from the commutativity of
the outer rectangle in the diagram

\[
g' \xrightarrow{\lambda_{g'}^{-1}} id_C \circ g' \xrightarrow{\eta_{id_{g'}}} (g \circ f) \circ g' \xrightarrow{\alpha_{g,f,g'}^{-1}} g \circ (f \circ g')
\]

\[
g' \circ (f' \circ g') \xrightarrow{\beta_{g'} \circ (id_{f'} \circ id_{g'})} g \circ (f' \circ g') \xrightarrow{id_g \circ \epsilon' \circ (\beta \circ id_{g'})} id_{g'} \circ \epsilon'
\]

\[
g' \xrightarrow{\rho_{g'}^{-1}} g' \circ id_D
\]

\[
g \xrightarrow{\rho_g^{-1}} g \circ id_D
\]

in the category $\text{Hom}_C(D,C)$. Here the upper middle square commutes by virtue of condition (1), the rectangle on the left commutes by virtue of the assumption that $(\eta,\epsilon)$ is an adjunction, and the commutativity of the rest of the diagram follows by the naturality properties of the associativity and unit constraints of the 2-category $\mathcal{C}$.

\[
\square
\]

**Notation 6.1.3.5.** Let $\mathcal{C}$ be a 2-category containing a pair of objects $C$ and $D$, and let $\text{LHom}_C(C,D)$ denote the full subcategory of $\text{Hom}_C(C,D)$ spanned by those 1-morphisms $f : C \to D$ which admit a right adjoint $g : D \to C$. In this case, Corollary 6.1.3.3 guarantees that the 1-morphism $g$ is determined uniquely up to isomorphism. We will sometimes abuse terminology by referring to $g$ as the right adjoint of $f$ and denoting it by $f^R$. The construction $f \mapsto f^R$ extends to a functor of categories $\text{LHom}_C(C,D)^{op} \to \text{Hom}_C(D,C)$, which carries each 2-morphism $\beta : f \Rightarrow f'$ to the 2-morphism $\beta^R : f'^R \Rightarrow f^R$ described in Proposition 6.1.3.4.

**Warning 6.1.3.6.** Let $\mathcal{C}$ be a 2-category and let $f : C \to D$ be a 1-morphism of $\mathcal{C}$. It follows from Corollary 6.1.3.3 that if $f$ admits a right adjoint $f^R$, then $f^R$ is characterized (up to canonical isomorphism) by the requirement that it represents the functor

\[
\text{Hom}_C(C,D)^{op} \to \text{Set} \quad g \mapsto \text{Hom}_{\text{Hom}_C(D,D)}(f \circ g, id_D).
\]
Beware that it is possible for this functor to be representable by a 1-morphism \( g : D \to C \) which is not a right adjoint to \( f \) (in which case \( f \) cannot admit any right adjoint); see Warning 6.1.6.16.

The preceding discussion has an obvious counterpart for left adjoints:

**Corollary 6.1.3.7.** Let \( C \) be a 2-category, let \( f : C \to D \) and \( g : D \to C \) be 2-morphisms of \( C \), and let \((\eta, \epsilon)\) be an adjunction between \( f \) and \( g \). Let \( f' : C \to D \) be another 1-morphism of \( C \). Then:

1. For every 2-morphism \( \eta' : id_C \Rightarrow g \circ f' \), there is a unique 2-morphism \( \beta : f \Rightarrow f' \) for which \( \eta' \) is equal to the composition \( id_C \eta \Rightarrow g \circ f \Rightarrow g \circ f' \). Moreover, \( \beta \) is an isomorphism if and only if \( \eta' \) is the unit of an adjunction.

2. For every 2-morphism \( \epsilon' : f' \circ g \Rightarrow id_D \), there is a unique 2-morphism \( \gamma : f' \Rightarrow f \) for which \( \epsilon' \) factors as a composition \( f' \circ g \Rightarrow \gamma \Rightarrow id_D \). Moreover, \( \gamma \) is an isomorphism if and only \( \epsilon' \) is the counit of an adjunction.

**Proof.** Apply Corollary 6.1.3.7 to the opposite 2-category \( C^{op} \).

**Notation 6.1.3.8.** Let \( C \) be a 2-category containing a pair of objects \( C \) and \( D \), and let \( RHom_C(D,C) \) denote the full subcategory of \( Hom_C(D,C) \) spanned by those 1-morphisms \( g : D \to C \) which admit a left adjoint \( f : C \to D \). In this case, Corollary 6.1.3.3 guarantees that the 1-morphism \( f \) is uniquely determined up to isomorphism. We will sometimes abuse terminology by referring to \( f \) as the left adjoint of \( g \) and denoting it by \( g^L \). The construction \( g \mapsto g^L \) determines an equivalence of categories \( RHom_C(D,C) \to LHom_C(C,D)^{op} \), which is homotopy inverse to the functor \( f \mapsto f^R \) described in Notation 6.1.3.5.

### 6.1.4 Adjoints of Isomorphisms

Let \( C \) be a 2-category and let \( f : C \to D \) be an isomorphism in \( C \), so that \( f \) admits a homotopy inverse \( g : D \to C \) (Definition 2.2.8.17). Then the 1-morphism \( g \) is both right adjoint and left adjoint to \( f \). More precisely, we have the following:

**Proposition 6.1.4.1.** Let \( C \) be a 2-category, let \( f : C \to D \) and \( g : D \to C \) be 1-morphisms of \( C \), and let \( \eta : id_C \Rightarrow g \circ f \) be a 2-morphism of \( C \). Assume that either \( f \) or \( g \) is an isomorphism in \( C \). Then \( \eta \) is the unit of an adjunction (in the sense of Definition 6.1.2.10) if and only if it is an isomorphism in the category \( Hom_C(C,C) \).

We will give the proof of Proposition 6.1.4.1 at the end of this section.

**Corollary 6.1.4.2.** Let \( C \) be a 2-category and let \( f : C \to D \) be an isomorphism in \( C \). Then any homotopy inverse to \( f \) is both a left adjoint and a right adjoint of \( f \).
Proof. Let \( g : D \to C \) be a homotopy inverse to \( f \), so that there exists an isomorphism \( \eta : \text{id}_C \xrightarrow{\sim} g \circ f \) in the category \( \text{Hom}_C(C,C) \). It follows from Proposition 6.1.4.1 that \( \eta \) is the unit of an adjunction, and therefore exhibits \( g \) as a right adjoint to \( f \). A similar argument shows that \( g \) is left adjoint to \( f \).

Remark 6.1.4.3. Let \( C \) be a 2-category and let \( f : C \to D \) be a 1-morphism of \( C \). By definition, \( f \) is an isomorphism if and only if there exists a 1-morphism \( g : D \to C \) together with isomorphisms 

\[
\eta : \text{id}_C \xrightarrow{\sim} g \circ f \quad \epsilon : f \circ g \xrightarrow{\sim} \text{id}_D
\]

in the categories \( \text{Hom}_C(C,C) \) and \( \text{Hom}_C(D,D) \), respectively. The main content of Proposition 6.1.4.1 is that, if such isomorphisms exist, then we can choose \( \eta \) and \( \epsilon \) to be compatible in the sense that they satisfy conditions (Z1) and (Z2) of Definition 6.1.1.1. Note that in this case, \( \eta \) is determined by \( \epsilon \) and vice versa (Proposition 6.1.2.9).

Corollary 6.1.4.4. Let \( C \) be a 2-category, let \( f : C \to D \) and \( g : D \to C \) be 1-morphisms of \( C \), and let \((\eta,\epsilon)\) be an adjunction between \( f \) and \( g \). The following conditions are equivalent:

1. The 1-morphism \( f \) is an isomorphism in \( C \).
2. The 1-morphism \( g \) is an isomorphism in \( C \).
3. The 2-morphisms \( \eta \) and \( \epsilon \) are isomorphisms in \( \text{Hom}_C(C,C) \) and \( \text{Hom}_C(D,D) \), respectively. In particular, \( f \) and \( g \) are homotopy inverse to one another.

Proof. The implication (3) \( \Rightarrow \) (1) and (3) \( \Rightarrow \) (2) are immediate from the definitions, and the reverse implications follow by applying Proposition 6.1.4.1 to \( C \) and the conjugate 2-category \( C^c \).

Warning 6.1.4.5. In the situation of Corollary 6.1.4.4, it is possible for the unit \( \eta : \text{id}_C \xrightarrow{\sim} g \circ f \) to be an isomorphism while the counit \( \epsilon : f \circ g \xrightarrow{\sim} \text{id}_D \) is not, or vice versa (in which case, the 1-morphisms \( f \) and \( g \) cannot be isomorphisms).

We will deduce Proposition 6.1.4.1 from the following more general result:

Proposition 6.1.4.6. Let \( C \) be a 2-category, let \( f : C \to D \) and \( g : D \to C \) be 1-morphisms of \( C \), and let \( \eta : \text{id}_C \Rightarrow g \circ f \) be a 2-morphism of \( C \) which satisfies the following conditions:

- The 2-morphisms

\[
(\text{id}_f \circ \eta) : f \circ \text{id}_C \Rightarrow f \circ (g \circ f) \quad (\eta \circ \text{id}_g) : \text{id}_C \circ g \Rightarrow (g \circ f) \circ g
\]

are isomorphisms.
For every object $T \in C$, the composition functor $\text{Hom}_C(T, D) \xrightarrow{g_\circ} \text{Hom}_C(T, C)$ is fully faithful.

Then $\eta$ is the unit of an adjunction $(\eta, \epsilon)$. Moreover, the counit map $\epsilon : f \circ g \Rightarrow \text{id}_D$ is an isomorphism.

Proof. Since postcomposition with $g$ induces a fully faithful functor $\text{Hom}_C(D, D) \rightarrow \text{Hom}_C(D, C)$, there is a unique 2-morphism $\epsilon : f \circ g \Rightarrow \text{id}_D$ for which the horizontal composition $\text{id}_g \circ \epsilon$ is equal to the composite map $g \circ (f \circ g) \alpha_{g,f,g} \Rightarrow (g \circ f) \circ g (\eta \circ \text{id}_g)^{-1} \Rightarrow \text{id}_C \circ g \lambda_g \Rightarrow g \rho_g^{-1} \Rightarrow g \otimes \text{id}_D$.

Moreover, $\epsilon$ is an isomorphism and the pair $(\eta, \epsilon)$ automatically satisfies condition $(Z2)$ of Definition [6.1.1.1]. Let $\beta$ denote the composition $f \rho_f^{-1} \Rightarrow f \circ \text{id}_C \Rightarrow (f \circ g) \circ f \Rightarrow (g \circ f) \circ (g \circ f) \Rightarrow (g \circ f) \circ (\eta \circ \text{id}_g)^{-1} \Rightarrow \text{id}_D \circ f \lambda_f \Rightarrow f$.

Since $\epsilon$ and $\text{id}_f \circ \eta$ are isomorphisms, it follows that $\beta$ is an isomorphism. Applying Corollary [6.1.2.8], we see that $\beta^2 = \beta$, so that $\beta = \text{id}_f$. □

Proof of Proposition [6.1.4.1]. Let $C$ be a 2-category, let $f : C \rightarrow D$ and $g : D \rightarrow C$ be 1-morphisms in $C$, and assume that $g$ is an isomorphism (the case where $f$ is an isomorphism can be treated by applying a similar argument in the opposite 2-category $C^{\text{op}}$). Suppose first that $\eta : \text{id}_C \Rightarrow g \circ f$ is an isomorphism in the category $\text{Hom}_C(C, C)$. It follows that the horizontal compositions $(\text{id}_f \circ \eta) : f \Rightarrow f \circ (g \circ f)$ and $(\eta \circ \text{id}_g) : g \Rightarrow (g \circ f) \circ g$ are isomorphisms in $\text{Hom}_C(C, D)$ and $\text{Hom}_C(D, C)$, respectively. For each object $T \in C$, our assumption that $g$ is an isomorphism guarantees that the composition functor $\text{Hom}_C(T, D) \xrightarrow{g_\circ} \text{Hom}_C(T, C)$ is an equivalence of categories, and therefore fully faithful. Invoking the criterion of Proposition [6.1.4.7], we conclude that $\eta$ is the unit of an adjunction.

We now prove the converse. Suppose that the 2-morphism $\eta : \text{id}_C \Rightarrow g \circ f$ is the unit of an adjunction. Our assumption that $g$ is an isomorphism guarantees that we can choose a 1-morphism $f' : C \rightarrow D$ and an isomorphism $\eta' : \text{id}_C \Rightarrow g \circ f'$ in the category $\text{Hom}_C(C, C)$. It follows from the first part of the proof that $\eta'$ is the unit of an adjunction. Applying Corollary [6.1.3.7], we deduce that there is a unique isomorphism $\beta : f \xrightarrow{\sim} f'$ for which $\eta'$ is equal to the composition $\text{id}_C \eta \Rightarrow g \circ f \xRightarrow{\text{id}_g \circ \beta} g \circ f'$.  

6.1. ADJUNCTIONS IN 2-CATEGORIES 1117
Since $\eta'$ and $(\text{id}_g \circ \beta)$ are isomorphisms in the category $\text{Hom}_C(C, C)$, it follows that $\eta$ is also an isomorphism.

We close this section by proving a converse of Proposition 6.1.4.6, which characterizes adjunctions $(\eta, \epsilon)$ for which the counit $\epsilon$ is an isomorphism.

**Proposition 6.1.4.7.** Let $C$ be a 2-category, let $f : C \to D$ and $g : D \to C$ be 1-morphisms of $C$, and let $(\eta, \epsilon)$ be an adjunction between $f$ and $g$. The following conditions are equivalent:

1. The 2-morphism $\epsilon : f \circ g \Rightarrow \text{id}_D$ is an isomorphism.

1'. The 1-morphism $f \circ g$ is an isomorphism.

2. The 2-morphisms

   $$(\text{id}_f \circ \eta) : f \circ \text{id}_C \Rightarrow f \circ (g \circ f) \quad (\eta \circ \text{id}_g) : \text{id}_C \circ g \Rightarrow (g \circ f) \circ g$$

   are isomorphisms. Moreover, for every object $T \in C$, the functor $\text{Hom}_C(T, C) \xrightarrow{f \circ} \text{Hom}_C(T, D)$ is essentially surjective.

2'. The 2-morphism $\eta \circ \text{id}_g : \text{id}_C \circ g \Rightarrow (g \circ f) \circ g$ is an isomorphism. Moreover, for every object $T \in C$, the composite functor

   $\text{Hom}_C(T, D) \xrightarrow{g \circ} \text{Hom}_C(T, C) \xrightarrow{f \circ} \text{Hom}_C(T, D)$

   is essentially surjective.

3. For every object $T \in C$, the functor $\text{Hom}_C(T, D) \xrightarrow{g \circ} \text{Hom}_C(T, C)$ is fully faithful.

3'. The functor $\text{Hom}_D(D, D) \xrightarrow{g \circ} \text{Hom}_C(D, C)$ is fully faithful.

**Proof.** We first show that (1) and (1') are equivalent. If $\epsilon$ is an isomorphism, then $f \circ g$ is isomorphic to $\text{id}_D$ (as an object of the category $\text{Hom}_D(D, D)$) and is therefore an isomorphism of $C$ (Remark 2.2.8.23). Conversely, suppose that $f \circ g$ is an isomorphism. Then it is invertible when viewed as an object of the monoidal category $\text{End}_C(D)$. Since $(\eta, \epsilon)$ is an adjunction, we can regard $f \circ g$ as a coalgebra object of $\text{End}_C(D)$ with counit $\epsilon$ (see Remark [?]). Applying Proposition 2.1.5.23 (to the monoidal category $\text{End}_C(D)^{op}$), we deduce that $\epsilon$ is an isomorphism.

We now show that (1) implies (2). Assume that $\epsilon : f \circ g \Rightarrow \text{id}_D$ is an isomorphism. Axiom (Z1) of Definition 6.1.1.1 guarantees that the composition

$$f \xRightarrow{\sim} f \circ \text{id}_C \xRightarrow{\text{id}_f \circ \eta} f \circ (g \circ f) \xRightarrow{\sim} (f \circ g) \circ f \xRightarrow{\text{cof}_f} \text{id}_D \circ f \xRightarrow{\sim} f$$

is equal to the identity 2-morphism $\text{id}_f$, which proves that the horizontal composition $\text{id}_f \circ \eta$ is an isomorphism in $\text{Hom}_C(C, D)$. Similarly, it follows from axiom (Z2) of Definition
6.1. ADJUNCTIONS IN 2-CATEGORIES

6.1.1.1 that the horizontal composition \( \eta \circ \text{id}_g \) is an isomorphism in \( \text{Hom}_C(D, C) \). For every 1-morphism \( d : T \to D \) in \( C \), the map

\[
  f \circ (g \circ d) \xrightarrow{\alpha_{f,g,d}} (f \circ g) \circ d \xrightarrow{\circ \text{id}_d} \text{id}_D \circ d \xrightarrow{\lambda_d} d
\]

is an isomorphism, so that \( d \) belongs to the essential image of the functor \( \text{Hom}_C(T, C) \xrightarrow{f} \text{Hom}_C(T, D) \).

We now show that (2) implies (2'). Let \( d : T \to D \) be a 1-morphism of \( C \). If the functor \( \text{Hom}_C(T, C) \xrightarrow{f} \text{Hom}_C(T, D) \) is essentially surjective, then \( d \) is isomorphic to \( f \circ c \) for some 1-morphism \( c : T \to C \) of \( C \). If \( \text{id}_f \circ \eta \) is an isomorphism, then the chain of isomorphisms

\[
  f \circ c \cong (f \circ \text{id}_C) \circ c \xrightarrow{(\text{id}_f \circ \eta) \circ \text{id}_c} (f \circ (g \circ f)) \circ c \cong f \circ ((g \circ f) \circ c) \cong f \circ (g \circ (f \circ c))
\]

shows that \( d \) belongs to the essential image of the composite functor

\[
  \text{Hom}_C(T, D) \xrightarrow{g^o} \text{Hom}_C(T, C) \xrightarrow{f} \text{Hom}_C(T, D).
\]

We next show that (2') implies (3). Fix an object \( T \in C \) and a pair of 1-morphisms \( d, d' : T \to D \); we wish to show that the composition map

\[
  \text{Hom}_{\text{Hom}_C(T, D)}(d', d) \to \text{Hom}_{\text{Hom}_C(T, C)}(g \circ d', g \circ d)
\]

is a bijection. By virtue of assumption (2'), we may assume that \( d' = f \circ c \), where \( c : T \to C \) is a 1-morphism of the form \( g \circ d'' \). By virtue of Proposition 6.1.9, the composition

\[
  \text{Hom}_{\text{Hom}_C(T, D)}(f \circ c, d) \xrightarrow{\sim} \text{Hom}_{\text{Hom}_C(T, C)}(g \circ (f \circ c), g \circ d) \xrightarrow{(\text{id}_c \circ \text{id}_g) \circ \text{id}_d} \text{Hom}_{\text{Hom}_C(T, C)}(\text{id}_C \circ c, g \circ d) \xrightarrow{\sim} \text{Hom}_{\text{Hom}_C(T, C)}(c, g \circ d)
\]

is a bijection. It will therefore suffice to show that the 2-morphism \( (\eta \circ \text{id}_c) : \text{id}_C \circ c \Rightarrow (g \circ f) \circ c \) is an isomorphism. This follows from assumption (2'), since \( (\eta \circ \text{id}_c) \) can be rewritten as a composition

\[
  \text{id}_C \circ (g \circ d') \xrightarrow{\sim} (\text{id}_C \circ g) \circ d'' \xrightarrow{(\text{id}_g \circ \text{id}_D) \circ \text{id}_d} ((g \circ f) \circ g) \circ d'' \xrightarrow{\sim} (g \circ f) \circ (g \circ d').
\]

The implication (3) \( \Rightarrow (3') \) is clear. We will complete the proof by showing that (3') implies (1). Assume that (3') is satisfied; we wish to show that the 2-morphism \( \epsilon : f \circ g \Rightarrow \text{id}_D \) is an isomorphism. To prove this, it will suffice to show that for every 1-morphism \( u : D \to D \),
vertical precomposition with $\epsilon$ induces a bijection $\hom_{\text{End}_C(D)}(\text{id}_D, u) \to \hom_{\text{End}_C(D)}(f \circ g, u)$. We now observe that this map fits into a commutative diagram

$$
\begin{align*}
\hom_{\text{End}_C(D)}(\text{id}_D, u) &\xrightarrow{\epsilon} \hom_{\text{End}_C(D)}(f \circ g, u) \\
\downarrow \text{id}_g \circ &\quad \downarrow \\
\hom_{\hom_C(D,C)}(g \circ \text{id}_D, g \circ u) &\xrightarrow{\sim} \hom_{\hom_C(D,C)}(g, g \circ u)
\end{align*}
$$

where the bottom horizontal map is induced by the right unit constraint $\rho_g : g \circ \text{id}_D \sim g$, the right vertical map is given by the formation of right adjuncts with respect to $\eta$ (and is therefore bijective by virtue of Corollary 6.1.2.6), and the left vertical map is bijective by virtue of assumption (3').

### 6.1.5 Composition of Adjunctions

We now show that the formation of right and left adjoints is compatible with composition of 1-morphisms.

**Construction 6.1.5.1.** Let $\mathcal{C}$ be a 2-category containing objects $C$, $D$, and $E$, together with 1-morphisms

$$
f : C \to D \quad f' : D \to E \quad g : D \to C \quad g' : E \to D
$$

and 2-morphisms $\eta : \text{id}_C \Rightarrow g \circ f$ and $\eta' : \text{id}_D \Rightarrow g' \circ f'$. We let $c(\eta, \eta')$ denote the 2-morphism given by the composition

$$
\text{id}_C \xRightarrow{\eta} g \circ f \xRightarrow{\sim} g \circ (\text{id}_D \circ f) \xRightarrow{\eta'} g \circ ((g' \circ f') \circ f) \xRightarrow{\sim} g \circ (g' \circ (f' \circ f)),
$$

where the unlabeled isomorphisms are given by the unit and associativity constraints of $\mathcal{C}$. We will refer to $c(\eta, \eta')$ as the contraction of $\eta$ and $\eta'$.

**Remark 6.1.5.2.** In the situation of Construction 6.1.5.1, let $\mathcal{C}^{\text{op}}$ be the opposite of the 2-category $\mathcal{C}$, so that we can identify $\eta$ and $\eta'$ with 2-morphisms

$$
\eta^{\text{op}} : \text{id}_{\mathcal{C}^{\text{op}}} \Rightarrow f^{\text{op}} \circ g^{\text{op}} \quad \eta'^{\text{op}} : \text{id}_{\mathcal{D}^{\text{op}}} \Rightarrow f'^{\text{op}} \circ g'^{\text{op}}.
$$

Then the 2-morphism $c(\eta, \eta')^{\text{op}}$ can be identified with the contraction $c(\eta'^{\text{op}}, \eta^{\text{op}})$, formed in the 2-category $\mathcal{C}^{\text{op}}$. In other words, $c(\eta, \eta')$ can also be computed as the composition

$$
\text{id}_C \xRightarrow{\eta} g \circ f \xRightarrow{\sim} (g \circ \text{id}_D) \circ f \xRightarrow{\eta'} (g \circ (g' \circ f')) \circ f \xRightarrow{\sim} ((g \circ g') \circ f') \circ f \xRightarrow{\sim} (g \circ g') \circ (f' \circ f).
$$
6.1. ADJUNCTIONS IN 2-CATEGORIES

This follows from the commutativity of the diagram

![Diagram]

in the category $\text{Hom}_{\mathcal{C}}(C,C)$. Here the upper triangle commutes by virtue of the triangle identity (Proposition 2.2.1.14), the middle square commutes by the naturality of the associativity constraints of $\mathcal{C}$, and the lower region commutes by virtue of the pentagon identity.

**Proposition 6.1.5.3.** Let $\mathcal{C}$ be a 2-category containing objects $C$, $D$, and $E$, together with 1-morphisms

$$f : C \to D \quad g : D \to C \quad f' : D \to E \quad g' : E \to D$$
and 2-morphisms \( \eta : \text{id}_C \Rightarrow g \circ f \) and \( \eta' : \text{id}_D \Rightarrow g' \circ f' \). Let \( T \) be another object of \( C \) equipped with 1-morphisms \( c : T \to C \) and \( e : T \to E \). Then the diagram

\[
\begin{array}{ccc}
\text{Hom}_{\text{Hom}_c(T,E)}((f' \circ f) \circ c, e) & \xrightarrow{\alpha_{f',f,c}} & \text{Hom}_{\text{Hom}_c(T,E)}((f' \circ (f \circ c), e) \\
\downarrow & & \downarrow \\
\text{Hom}_{\text{Hom}_c(T,D)}(f \circ c, g' \circ e) & \xrightarrow{\alpha_{g,g',e}} & \text{Hom}_{\text{Hom}_c(T,C)}(c, (g \circ g') \circ e)
\end{array}
\]

is commutative. Here the right vertical maps are given by the formation of right adjuncts with respect to \( \eta \) and \( \eta' \) (in the sense of Construction 6.1.2.1), while the left vertical map is given by the formation of right adjuncts with respect to the contraction \( c(\eta, \eta') \) of Construction 6.1.5.1.

**Proof.** Fix a 2-morphism \( \beta : (f' \circ f) \circ c \Rightarrow e \) in \( C \). Clockwise and counterclockwise composition around the outside of the diagram (6.1) determines two elements of \( \text{Hom}_{\text{Hom}_c(T,C)}(c, (g \circ g') \circ e) \), and we wish to prove that these two elements are the same. Unwinding the definitions, we see that these elements can be obtained as the vertical composition of \( c \xrightarrow{\lambda_{c}^3} \text{id}_C \xrightarrow{\eta_{id_C}} (g \circ f) \circ c \)

with 2-morphisms given by clockwise and counterclockwise composition around the outside.
of the diagram

\[
\begin{array}{ccc}
(gf)c & \sim & g(fc) \\
\lambda_f^{-1} \sim & & \lambda_f^{-1} \sim \\
(g(id_D f))c & \sim & g((id_D f)c) \\
\eta' & & \eta' \\
(g((g'f')f))c & \sim & g((g'(f')f)c) \\
\sim & & \sim \\
(g(g'(f'))f)c & \sim & g(g'(f')(f)c) \\
\sim & & \sim \\
((gg')(f'f))c & \sim & (gg')(f'f)c \\
\beta & & \beta \\
\end{array}
\]

in the category $\text{Hom}_C(T, C)$; here denote the composition of 1-morphisms $u$ and $v$ in $C$ by $uv$ (rather than $u \circ v$) to simplify the notation, and the unlabeled isomorphisms are given by the associativity constraints of $C$. It will therefore suffice to observe that this diagram is commutative. The commutativity of the pentagonal regions follows from the pentagon identity in $C$, the commutativity of the triangle from Proposition 2.2.1.16, and the commutativity of each square from the naturality of the associativity constraints of $C$.

\[\text{Corollary 6.1.5.4.}\]

Let $C$ be a 2-category containing objects $C$, $D$, and $E$, together with 1-morphisms $f : C \to D$ and $g : D \to C$, and 2-morphisms $\eta : \text{id}_C \Rightarrow g \circ f$ and $\eta' : \text{id}_D \Rightarrow g' \circ f'$. If $\eta$ and $\eta'$ are units of adjunctions, then the contraction $c(\eta, \eta') : \text{id}_C \Rightarrow (g \circ g') \circ (f' \circ f)$ is also the unit of an adjunction.

\[\text{Proof.}\] Combine Proposition 6.1.5.3 with the criterion of Proposition 6.1.2.9.

From Corollary 6.1.5.4 we can extract the following slightly less precise consequence:
Corollary 6.1.5.5. Let $\mathcal{C}$ be a 2-category containing objects $C$, $D$, and $E$, together with 1-morphisms

$$f : C \to D \quad g : D \to C \quad f' : D \to E \quad g' : E \to D.$$ 

If $f$ is left adjoint to $g$ and $f'$ is left adjoint to $g'$, then $f' \circ f$ is left adjoint to $g \circ g'$.

Corollary 6.1.5.6. Let $\mathcal{C}$ be a 2-category containing 1-morphisms $u : C \to D$ and $v : D \to E$. If $u$ and $v$ admit left adjoints, then $v \circ u$ admits a left adjoint. If $u$ and $v$ admit right adjoints, then $v \circ u$ admits a right adjoint.

We can also formulate a more precise version of Corollary 6.1.5.4, which explicitly describes the counit of a composite adjunction. For this, we need a variant of Construction 6.1.5.1:

Construction 6.1.5.7. Let $\mathcal{C}$ be a 2-category containing objects $C$, $D$, and $E$, together with 1-morphisms $f : C \to D$ $g : D \to C$ $f' : D \to E$ $g' : E \to D$ and 2-morphisms $\epsilon : f \circ g \Rightarrow \text{id}_D$ and $\epsilon' : f' \circ g' \Rightarrow \text{id}_E$ be 2-morphisms of $\mathcal{C}$. We let $c(\epsilon, \epsilon')$ denote the 2-morphism given by the composition

$$(f' \circ f) \circ (g \circ g') \Rightarrow f' \circ (f \circ (g \circ g')) \Rightarrow f' \circ ((f \circ g) \circ g') \Rightarrow f' \circ (f \circ g) \circ g' \Rightarrow f' \circ g' \Rightarrow \text{id}_E$$

We will refer to $c(\epsilon, \epsilon')$ as the contraction of $\epsilon$ and $\epsilon'$.

Remark 6.1.5.8. In the situation of Construction 6.1.5.7, we can identify $\epsilon$ and $\epsilon'$ with 2-morphisms

$$\epsilon^c : \text{id}_D \Rightarrow f^c \circ g \quad \epsilon'^c : \text{id}_E \Rightarrow f'^c \circ g'^c$$

in the conjugate 2-category $\mathcal{C}^c$ (Construction 2.2.3.4). The contraction $c(\epsilon, \epsilon')$ can then be described as the conjugate of the 2-morphism $c(\epsilon'^c, \epsilon^c)$ obtained by applying Construction 6.1.5.1 to the 2-category $\mathcal{C}^c$.

Corollary 6.1.5.9. Let $\mathcal{C}$ be a 2-category containing objects $C$, $D$, and $E$, together with 1-morphisms

$$f : C \to D \quad g : D \to C \quad f' : D \to E \quad g' : E \to D.$$ 

Let $(\eta, \epsilon)$ be an adjunction between $f$ and $g$, and let $(\eta', \epsilon')$ be an adjunction between $f'$ and $g'$. Then the pair $(c(\eta, \eta'), c(\epsilon, \epsilon'))$ is an adjunction between $f' \circ f$ and $g \circ g'$. Here $c(\eta, \eta')$ is the contraction of $\eta$ with $\eta'$ (in the sense of Construction 6.1.5.1), and $c(\epsilon, \epsilon')$ is the contraction of $\epsilon$ with $\epsilon'$ (in the sense of Construction 6.1.5.7).
Proof. By virtue of Proposition 6.1.5.3 and Corollary 6.1.2.6, it will suffice to show that for every object \( T \in C \) equipped with 1-morphisms \( c : T \to C \) and \( e : T \to E \), the diagram

\[
\begin{array}{ccc}
\text{Hom}_{\text{Hom}_c(T,E)}(f' \circ f \circ c, e) & \xrightarrow{\alpha_{f',f,c}} & \text{Hom}_{\text{Hom}_c(T,E)}(f' \circ (f \circ c), e) \\
\text{Hom}_{\text{Hom}_c(T,D)}(f \circ c, g' \circ e) & \xrightarrow{\alpha_{g,g',e}} & \text{Hom}_{\text{Hom}_c(T,C)}(c, (g \circ g') \circ e) \\
\text{Hom}_{\text{Hom}_c(T,C)}(c, (g \circ g') \circ e) & \xrightarrow{\lambda_{g,g',e}} & \text{Hom}_{\text{Hom}_c(T,D)}(f \circ c, g' \circ e) \\
\end{array}
\]

commutes, where the right vertical maps are given by the formation of left adjuncts with respect to \( \epsilon \) and \( \epsilon' \), and the left vertical is given by the formation of left adjuncts with respect to the contraction \( c(\epsilon, \epsilon') \) of Construction 6.1.5.7. This follows by applying Proposition 6.1.5.3 to the conjugate 2-category \( C^c \). \( \square \)

6.1.6 Duality in Monoidal Categories

We now specialize the theory of adjunctions to the setting of 2-categories of the form \( BC \) (Example 2.2.2.5), where \( C \) is a monoidal category. Throughout this section, we write \( 1 \) for the unit object of a monoidal category \( C \).

Definition 6.1.6.1. Let \( C \) be a monoidal category containing objects \( X \) and \( Y \). A duality datum is a pair \((\text{coev}, \text{ev})\), where \( \text{coev} : 1 \to Y \otimes X \) and \( \text{ev} : X \otimes Y \to 1 \) are morphisms of \( C \) satisfying the following compatibility conditions:

(Z1) The composition

\[
X \xrightarrow{\rho_X^{-1}} X \otimes 1 \xrightarrow{id_X \otimes \text{coev}} X \otimes (Y \otimes X) \xrightarrow{\alpha_{X,Y,X}} (X \otimes Y) \otimes X \xrightarrow{\text{ev} \otimes id_X} 1 \otimes X \xrightarrow{\lambda_X} X
\]

is equal to the identity morphism \( id_X \). Here the isomorphism \( \alpha_{X,Y,X} \) is the associativity constraint for the monoidal category \( C \), and the isomorphisms \( \lambda_X \) and \( \rho_X \) are the left and right unit constraints of Construction 2.1.2.17.

(Z2) The composition

\[
Y \xrightarrow{\lambda_Y^{-1}} 1 \otimes Y \xrightarrow{\text{coev} \otimes id_Y} (Y \otimes X) \otimes Y \xrightarrow{\alpha_{Y,X,Y}} Y \otimes (X \otimes Y) \xrightarrow{id_Y \otimes \text{ev}} Y \otimes 1 \xrightarrow{\rho_Y} Y
\]

is equal to the identity morphism \( id_Y \).
If these conditions are satisfied, then we will refer to coev as the *coevaluation morphism* of the duality datum \((\text{coev}, \text{ev})\), and to ev as the *evaluation morphism* of the duality datum \((\text{coev}, \text{ev})\). In this case, we say that the pair \((\text{coev}, \text{ev})\) exhibits \(X\) as a left dual of \(Y\), also that it exhibits \(Y\) as a right dual of \(X\).

**Remark 6.1.6.2 (Duals as Adjoints).** Let \(\mathcal{C}\) be a monoidal category containing objects \(X\) and \(Y\), which we regard as 1-morphisms of the 2-category \(\mathcal{B}\mathcal{C}\) described in Example 2.2.2.5. Suppose we are given a pair of morphisms

\[
\text{coev} : 1 \to Y \otimes X \quad \text{ev} : X \otimes Y \to 1
\]

in \(\mathcal{C}\), which we identify with 2-morphisms of \(\mathcal{B}\mathcal{C}\). Then the pair \((\text{coev}, \text{ev})\) is a duality datum in the monoidal category \(\mathcal{C}\) (in the sense of Definition 6.1.6.1) if and only if it is an adjunction in the 2-category \(\mathcal{B}\mathcal{C}\) (in the sense of Definition 6.1.1.1).

**Remark 6.1.6.3 (Adjoints as Duals).** Let \(\mathcal{C}\) be a 2-category, let \(X\) be an object of \(\mathcal{C}\), let \(f, g : X \to X\) be 1-morphisms of \(\mathcal{C}\), and let \(\eta : \text{id}_X \to g \circ f\) and \(\epsilon : f \circ g \to \text{id}_X\) be 1-morphisms of \(\mathcal{C}\). Then the pair \((\eta, \epsilon)\) is an adjunction in the 2-category \(\mathcal{C}\) (in the sense of Definition 6.1.1.1) if and only if it is a duality datum in the monoidal category \(\text{End}_{\mathcal{C}}(X)\) of Remark 2.2.1.7.

**Remark 6.1.6.4.** Let \(\mathcal{C}\) be a monoidal category containing objects \(X\) and \(Y\) and morphisms

\[
\text{coev} : 1 \to Y \otimes X \quad \text{ev} : X \otimes Y \to 1
\]

Then:

- The pair \((\text{coev}, \text{ev})\) is a duality datum in the monoidal category \(\mathcal{C}\) if and only if it is a duality datum in the reverse monoidal category \(\mathcal{C}^{\text{rev}}\) of Example 2.1.3.5. Note that passage to the reverse monoidal category reverses the roles of \(X\) and \(Y\): if \(X\) is the left dual of \(Y\) in the monoidal category \(\mathcal{C}\), then it is the right dual of \(Y\) in the monoidal category \(\mathcal{C}^{\text{rev}}\) (and vice-versa).

- The pair \((\text{coev}, \text{ev})\) is a duality datum in \(\mathcal{C}\) if and only if the pair \((\text{ev}^{\text{op}}, \text{coev}^{\text{op}})\) is a duality datum in the opposite monoidal category \(\mathcal{C}^{\text{op}}\) (see Example 2.1.3.4). Note that passage to the opposite monoidal category reverses the roles of evaluation and coevaluation: \(\text{ev}^{\text{op}}\) is the coevaluation morphism for the duality datum \((\text{ev}^{\text{op}}, \text{coev}^{\text{op}})\), while \(\text{coev}^{\text{op}}\) is the evaluation morphism. Similarly, if \(X\) is the left dual of \(Y\) in the monoidal category \(\mathcal{C}\), then it is the right dual of \(Y\) in the opposite monoidal category \(\mathcal{C}^{\text{op}}\) (and vice-versa).

**Proposition 6.1.6.5.** Let \(\mathcal{C}\) be a monoidal category and let \(\text{ev} : X \otimes Y \to 1\) be a morphism of \(\mathcal{C}\). The following conditions are equivalent:

\[
\text{coev} : 1 \to Y \otimes X \quad \text{ev} : X \otimes Y \to 1.
\]
6.1. ADJUNCTIONS IN 2-CATEGORIES

(1) For every pair of objects \( C, D \in \mathcal{C} \), the composite map

\[
\begin{align*}
\text{Hom}_C(C,Y \otimes D) & \rightarrow \text{Hom}_C(X \otimes C, X \otimes (Y \otimes D)) \\
\cong & \text{Hom}_C(X \otimes C, (X \otimes Y) \otimes D) \\
\xrightarrow{ev} & \text{Hom}_C(X \otimes C, 1 \otimes D) \\
\cong & \text{Hom}_C(X \otimes C, D)
\end{align*}
\]

is a bijection.

(2) For every pair of objects \( C, D \in \mathcal{C} \), the composite map

\[
\begin{align*}
\text{Hom}_C(C,D \otimes X) & \rightarrow \text{Hom}_C(C \otimes Y, (D \otimes X) \otimes Y) \\
\cong & \text{Hom}_C(C \otimes Y, D \otimes (X \otimes Y)) \\
\xrightarrow{ev} & \text{Hom}_C(C \otimes Y, D \otimes 1) \\
\cong & \text{Hom}_C(C \otimes Y, D)
\end{align*}
\]

is a bijection.

(3) There exists a morphism \( \text{coev} : 1 \rightarrow Y \otimes X \) for which the pair \((\text{coev}, \text{ev})\) is a duality datum, in the sense of Definition 6.1.6.1. Moreover, if these conditions are satisfied, then the morphism \( \text{coev} : 1 \rightarrow Y \otimes X \) is unique.

Proof. Apply Proposition 6.1.2.13 to the 2-category \( BC \) of Example 2.2.2.5.

Definition 6.1.6.6. Let \( \mathcal{C} \) be a monoidal category. We will say that a morphism \( \text{ev} : X \otimes Y \rightarrow 1 \) in \( \mathcal{C} \) is a duality datum if it satisfies the equivalent conditions of Proposition 6.1.6.5; that is, if there exists a morphism \( \text{coev} : 1 \rightarrow Y \otimes X \) for which the pair \((\text{coev}, \text{ev})\) is a duality datum in the sense of Definition 6.1.6.1.

Applying Proposition 6.1.6.5 to the opposite monoidal category \( \mathcal{C}^{\text{op}} \), we obtain the following:

Variant 6.1.6.7. Let \( \mathcal{C} \) be a monoidal category and let \( \text{coev} : 1 \rightarrow Y \otimes X \) be a morphism of \( \mathcal{C} \). The following conditions are equivalent:

1. For every pair of objects \( C, D \in \mathcal{C} \), the composite map

\[
\begin{align*}
\text{Hom}_C(X \otimes C, D) & \rightarrow \text{Hom}_C(Y \otimes (X \otimes C), Y \otimes D) \\
\cong & \text{Hom}_C((Y \otimes X) \otimes C, Y \otimes D)) \\
\xrightarrow{\text{coev}} & \text{Hom}_C(1 \otimes C, Y \otimes D) \\
\cong & \text{Hom}_C(C, Y \otimes D)
\end{align*}
\]

is a bijection.
(2) For every pair of objects $C, D \in \mathcal{C}$, the composite map
\[
\text{Hom}_\mathcal{C}(C \otimes Y, D) \xrightarrow{\text{coev}} \text{Hom}_\mathcal{C}(C \otimes 1, D \otimes X) \cong \text{Hom}_\mathcal{C}(C, D \otimes X)
\]
is a bijection.

(3) There exists a morphism $ev : X \otimes Y \to 1$ for which the pair $(\text{coev}, ev)$ is a duality datum, in the sense of Definition 6.1.6.1.

Moreover, if these conditions are satisfied, then the morphism $ev : X \otimes Y \to 1$ is unique.

**Definition 6.1.6.8.** Let $\mathcal{C}$ be a monoidal category. We will say that a morphism $\text{coev} : 1 \to Y \otimes X$ in $\mathcal{C}$ is a duality datum if it satisfies the equivalent conditions of Variant 6.1.6.7 that is, if there exists a morphism $ev : X \otimes Y \to 1$ for which the pair $(\text{coev}, ev)$ is a duality datum in the sense of Definition 6.1.6.1.

**Definition 6.1.6.9.** Let $\mathcal{C}$ be a monoidal category. Then:

- We say that an object $X \in \mathcal{C}$ is right dualizable if there exists an object $Y \in \mathcal{C}$ and a duality datum $ev : X \otimes Y \to 1$. In this case, we will also say that $Y$ is a right dual of $X$, or that the morphism $ev$ exhibits $Y$ as a right dual of $X$.

- We say that an object $Y \in \mathcal{C}$ is left dualizable if there exists an object $X \in \mathcal{C}$ and a duality datum $ev : X \otimes Y \to 1$. In this case, we will also say that $X$ is a left dual of $Y$, or that the morphism $ev$ exhibits $X$ as a left dual of $Y$.

**Example 6.1.6.10.** Let $\mathcal{C}$ be a monoidal category. We say that an object $X \in \mathcal{C}$ is invertible if there exists an object $Y \in \mathcal{C}$ such that the tensor products $Y \otimes X$ and $X \otimes Y$ are isomorphic to the unit object $1$. If this condition is satisfied, then any choice of isomorphism $1 \cong Y \otimes X$ is a duality datum (this is a special case of Proposition 6.1.4.1). In particular, the object $Y$ is a right dual of $X$. Similarly, $Y$ is a left dual of $X$.

**Exercise 6.1.6.11.** Let $\mathcal{C}$ be a category which admits finite products, and regard $\mathcal{C}$ as equipped with the monoidal structure given by cartesian products (Example 2.1.3.2). Show that an object $X \in \mathcal{C}$ is left (or right) dualizable if and only if it is isomorphic to the final object $1$.

**Exercise 6.1.6.12.** Let $k$ be a field and let $\text{Vect}_k$ denote the category of vector spaces over $k$, equipped with the monoidal structure described in Example 2.1.3.1. Show that an object $V \in \text{Vect}_k$ is left (or right) dualizable if and only if it is finite-dimensional as a vector space over $k$. 
It is instructive to contrast Definition 6.1.6.6 with a slightly more general notion of duality.

**Definition 6.1.6.13.** Let $C$ be a monoidal category containing objects $X$ and $Y$. We will say that a morphism $ev : X \otimes Y \to 1$ exhibits $Y$ as a weak right dual of $X$ if, for every object $W \in C$, the composite map

$$\text{Hom}_C(W,Y) \to \text{Hom}_C(X \otimes W, X \otimes Y) \xrightarrow{ev} \text{Hom}_C(X \otimes W, 1)$$

is bijective. We say that $ev$ exhibits $X$ as a weak left dual of $Y$ if, for every object $Z \in C$, the composite map

$$\text{Hom}_C(Z,X) \to \text{Hom}_C(Z \otimes Y, X \otimes Y) \xrightarrow{ev} \text{Hom}_C(Z \otimes Y, 1)$$

is bijective.

**Remark 6.1.6.14.** Let $C$ be a monoidal category and let $X$ be an object of $C$. It follows immediately from the definition that if there exists a morphism $ev : X \otimes Y \to 1$ which exhibits $Y$ as a weak right dual of $X$, then the pair $(Y, ev)$ is unique up to isomorphism and depends functorially on $X$. To emphasize this dependence we will sometimes denote the object $Y$ by $^\vee Y$ and abuse terminology by referring to it as the weak right dual of $X$.

Similarly, if $Y$ is a fixed object of $C$ and there exists a morphism $ev : X \otimes Y \to 1$ which exhibits $X$ as a weak left dual of $Y$, then the pair $(X, ev)$ is uniquely determined up to isomorphism and depends functorially on $Y$. We will emphasize this dependence by denoting the object $X$ by $^\vee Y$ and referring to it as the weak left dual of $Y$.

**Proposition 6.1.6.15.** Let $C$ be a monoidal category and let $ev : X \otimes Y \to 1$ be a morphism of $C$. Then:

1. If the morphism $ev$ exhibit $Y$ as a right dual of $X$ (Definition 6.1.6.6), then it exhibits $Y$ as a weak right dual of $X$ (Definition 6.1.6.13). The converse holds if $X$ is right dualizable.

2. If the morphism $ev$ exhibits $X$ as a left dual of $Y$, then it exhibits $X$ as a weak left dual of $Y$. The converse holds if $Y$ is left dualizable.

**Proof.** We will prove (1); the proof of (2) is similar. If $ev : X \otimes Y \to 1$ is a duality datum, then it exhibits $Y$ as a weak right dual of $X$ by virtue of Variant 6.1.3.2 (applied to the 2-category $B C$). Conversely, suppose that $ev$ exhibits $Y$ as a weak right dual of $X$. If there exists another object $Y' \in C$ and a duality datum $ev' : X \otimes Y' \to 1$, then the universal property of $Y$ guarantees that there is a unique morphism $u : Y' \to X$ for which $ev'$ is equal to the composite map $X \otimes Y' \xrightarrow{id_X \otimes u} X \otimes Y \xrightarrow{ev} 1$. Since $ev'$ exhibits $Y'$ as a weak right dual of $X$, the morphism $u$ must be an isomorphism, so that the morphism $ev$ is also a duality datum. □
Warning 6.1.6.16. In the situation of Proposition 6.1.6.15, it is possible for an object $X \in \mathcal{C}$ to admit a weak right dual which is not a right dual. For example, let $\mathcal{C} = \text{Vect}_k$ be the category of vector spaces over a field $k$, equipped with the monoidal structure of Example 2.1.3.1. Let $V$ be a vector space over $k$ and let $V^* = \text{Hom}_k(V, k)$ be its dual space. Then the evaluation map

$$\text{ev} : V \otimes_k V^* \to k \quad v \otimes \lambda \mapsto \lambda(v)$$

exhibits $V^*$ as a weak (right) dual of $V$ (in the sense of Definition 6.1.6.13). However, it is a duality datum only when $V$ is finite-dimensional over $k$ (Exercise 6.1.6.12).

Remark 6.1.6.17. Let $\mathcal{C}$ be a monoidal category containing objects $X$ and $Y$. If both $X$ and $Y$ are right dualizable, then the tensor product $X \otimes Y$ is also right dualizable; moreover we have a canonical isomorphism $(X \otimes Y)^\vee \simeq Y^\vee \otimes X^\vee$ (see Corollary 6.1.5.4 for a more precise statement). Similarly, if both $X$ and $Y$ are left dualizable, then the tensor product $X \otimes Y$ is left dualizable, and there is a canonical isomorphism $^\vee(X \otimes Y) \simeq ^\vee Y \otimes ^\vee X$.

Exercise 6.1.6.18. Let $\mathcal{C}$ be a monoidal category containing objects $X$ and $Y$. Show that, if $X$ is weakly right dualizable and $Y$ is right dualizable, then the tensor product $X \otimes Y$ is weakly right dualizable (and that there is a canonical isomorphism $(X \otimes Y)^\vee \simeq Y^\vee \otimes X^\vee$).

6.2 Adjoint Functors Between $\infty$-Categories

6.2.1 Adjunctions of $\infty$-Categories

We now adapt Definition 6.1.0.2 to the setting of $\infty$-categories.

Definition 6.2.1.1. Let $F : \mathcal{C} \to \mathcal{D}$ and $G : \mathcal{D} \to \mathcal{C}$ be functors of $\infty$-categories. We will say that a pair of natural transformations $\eta : \text{id}_\mathcal{C} \to G \circ F$ and $\epsilon : F \circ G \to \text{id}_\mathcal{D}$ are compatible up to homotopy if the following conditions are satisfied:

(Z1) The identity isomorphism $\text{id}_F : F : F \to F$ is a composition of the natural transformations

$$F = F \circ \text{id}_\mathcal{C} \overset{\text{id}_F \circ \eta}{\longrightarrow} F \circ G \circ F \quad F \circ G \circ F \overset{\epsilon \circ \text{id}_F}{\longrightarrow} \text{id}_\mathcal{D} \circ F = F$$

in the $\infty$-category $\text{Fun}(\mathcal{C}, \mathcal{D})$, in the sense of Definition 1.3.4.1.

(Z2) The identity isomorphism $\text{id}_G : G : G \to G$ is a composition of the natural transformations

$$G = \text{id}_\mathcal{D} \circ G \overset{\text{id}_\mathcal{D} \circ \epsilon}{\longrightarrow} G \circ F \circ G \quad G \circ F \circ G \overset{\text{id}_G \circ \epsilon}{\longrightarrow} G \circ \text{id}_\mathcal{D} = G$$

in the $\infty$-category $\text{Fun}(\mathcal{D}, \mathcal{C})$. 
We say that a natural transformation $\eta : \text{id}_C \to G \circ F$ is the unit of an adjunction if there exists a natural transformation $\epsilon : F \circ G \to \text{id}_D$ which is compatible with $\eta$ up to homotopy.

We say that a natural transformation $\epsilon : F \circ G \to \text{id}_D$ is the counit of an adjunction if there exists a natural transformation $\eta : \text{id}_C \to G \circ F$ which is compatible with $\epsilon$ up to homotopy.

**Definition 6.2.1.2.** Let $F : C \to D$ and $G : D \to C$ be functors of $\infty$-categories. We say that $F$ is a left adjoint of $G$, or that $G$ is a right adjoint of $F$, if there exists a natural transformation $\eta : \text{id}_C \to G \circ F$ which is the unit of an adjunction between $F$ and $G$. In this case, we say that $\eta$ exhibits $F$ as a left adjoint of $G$ and also that it exhibits $G$ as a right adjoint of $F$. Equivalently, $F$ is a left adjoint of $G$ if there exists a natural transformation $\epsilon : F \circ G \to \text{id}_D$ which is the counit of an adjunction between $F$ and $G$; in this case, we say that $\epsilon$ exhibits $F$ as a left adjoint of $G$ and also that it exhibits $G$ as a right adjoint of $F$.

**Notation 6.2.1.3.** Let $F : C \to D$ be a functor between $\infty$-categories. We say that $F$ is a left adjoint, or that $F$ admits a right adjoint, if there exists a functor $G : D \to C$ which is right adjoint to $F$. We let $L\text{Fun}(C, D)$ denote the full subcategory of $\text{Fun}(C, D)$ spanned by those functors $F : C \to D$ which are left adjoints.

Let $G : D \to C$ be a functor between $\infty$-categories. We say that $G$ is a right adjoint, or that $G$ admits a left adjoint, if there exists a functor $F : C \to D$ which is left adjoint to $G$. We let $R\text{Fun}(D, C)$ denote the full subcategory of $\text{Fun}(D, C)$ spanned by those functors $G : D \to C$ which are right adjoints.

**Remark 6.2.1.4.** Let $h_2\text{QCat}$ be the homotopy 2-category of $\infty$-categories (see Construction 4.5.1.23). Suppose we are given functors of $\infty$-categories $F : C \to D$ and $G : D \to C$, which we regard as 1-morphisms in the 2-category $h_2\text{QCat}$. Let $\eta : \text{id}_C \to G \circ F$ and $\epsilon : F \circ G \to \text{id}_D$ be natural transformations and let $[\eta]$ and $[\epsilon]$ denote their homotopy classes, which we regard as 2-morphisms in $h_2\text{QCat}$. Then $\eta$ and $\epsilon$ are compatible up to homotopy (in the sense of Definition 6.1.1.1) if and only if the pair $([\eta], [\epsilon])$ is an adjunction in the 2-category $h_2\text{QCat}$ (in the sense of Definition 6.1.1.1).

**Remark 6.2.1.5.** Let $F : C \to D$ and $G : D \to C$ be functors of $\infty$-categories, and let $\eta : \text{id}_C \to G \circ F$ and $\epsilon : F \circ G \to \text{id}_D$ be natural transformations. Axioms $(Z1)$ and $(Z2)$ of Definition 6.2.1.1 can be restated as follows:

$(Z1)$ There exists a 2-simplex $\sigma$ of the $\infty$-category $\text{Fun}(C, D)$ with boundary as indicated in the diagram

\[
\begin{array}{ccc}
F \circ G \circ F & \xrightarrow{\epsilon \circ \text{id}_F} & \text{id}_D \circ F \\
\downarrow{\text{id}_F \circ \eta} & & \downarrow{\epsilon} \\
F \circ \text{id}_C & & \text{id}_D \circ F.
\end{array}
\]
There exists a 2-simplex $\tau$ of the $\infty$-category $\text{Fun}(D, C)$ with boundary as indicated in the diagram

$\eta \circ \text{id}_G \quad \text{id}_G \circ \epsilon \quad \text{id}_G \circ \epsilon$ $\quad \text{id}_G \circ \epsilon$ $\eta \circ \text{id}_G$ $\text{id}_C \circ G$ $\eta \circ \text{id}_G$ $\text{id}_C \circ G$ $G \circ \text{id}_D$.

In this case, we will say that the 2-simplices $\sigma$ and $\tau$ witness the axioms $(Z1)$ and $(Z2)$, respectively.

**Remark 6.2.1.6.** Let $F : C \to D$ and $G : D \to C$ be functors of $\infty$-categories, and let $\eta : \text{id}_C \to G \circ F$ be a natural transformation. It follows from Remark 6.2.1.4 that the condition that $\eta$ is the unit of an adjunction (in the sense of Definition 6.2.1.1) depends only on the homotopy class $[\eta]$, regarded as a morphism in the category $\text{hFun}(C, C)$. Moreover, if $\epsilon : F \circ G \to \text{id}_D$ is a counit which is compatible with $\eta$ up to homotopy, then the homotopy class $[\epsilon]$ is uniquely determined (see Proposition 6.1.2.9). Beware that it is only the homotopy class of $\epsilon$ that is uniquely determined: if $\epsilon' : F \circ G \to \text{id}_D$ is homotopic to $\epsilon$, then it is also compatible with $\eta$ up to homotopy.

**Remark 6.2.1.7.** Let $F : C \to D$ and $G : D \to C$ be functors of $\infty$-categories and let $\eta : \text{id}_C \to G \circ F$ be a natural transformation. Then $\eta$ is the unit of an adjunction between $F$ and $G$ if and only if the opposite natural transformation $\eta^{\text{op}} : G^{\text{op}} \circ F^{\text{op}} \to \text{id}_{C^{\text{op}}}$ is the counit of an adjunction between the functors $G^{\text{op}} : D^{\text{op}} \to C^{\text{op}}$ and $F^{\text{op}} : C^{\text{op}} \to D^{\text{op}}$. Note that in this case, $\eta^{\text{op}}$ exhibits $G^{\text{op}}$ as the left adjoint of $F^{\text{op}}$.

**Remark 6.2.1.8** (Composition of Adjoints). Let $F : C \to D$ and $F' : D \to E$ be functors of $\infty$-categories which admit right adjoints. Then the composite functor $(F' \circ F) : C \to E$ also admits a right adjoint. More precisely, if $G : D \to C$ and $G' : E \to D$ are right adjoints of $F$ and $F'$, respectively, then the composite functor $(G \circ G') : E \to C$ is right adjoint to $(F' \circ F) : C \to E$ (see Corollary 6.1.5.5).

**Example 6.2.1.9.** Let $F : C \to D$ and $G : D \to C$ be functors between ordinary categories, and suppose we are given natural transformations $\eta : \text{id}_C \to G \circ F$ and $\epsilon : F \circ G \to \text{id}_D$. Then the pair $(\eta, \epsilon)$ is an adjunction between $F$ and $G$ (in the sense of Definition 6.1.0.2) if and only if the induced maps

$$N_{\bullet}(\eta) : \text{id}_{N_{\bullet}(C)} \to N_{\bullet}(G) \circ N_{\bullet}(F) \quad N_{\bullet}(\epsilon) : N_{\bullet}(F) \circ N_{\bullet}(G) \to \text{id}_{N_{\bullet}(D)}$$

are compatible up to homotopy, in the sense of Definition 6.2.1.1. In particular:
• A natural transformation $\eta : \text{id}_C \to G \circ F$ is the unit of an adjunction between functors of ordinary categories $F$ and $G$ if and only if $N_\bullet(\eta) : N_\bullet(C) \to N_\bullet(G) \circ N_\bullet(F)$ is the unit of an adjunction between functors of $\infty$-categories $N_\bullet(F)$ and $N_\bullet(G)$.

• A natural transformation $\epsilon : F \circ G \to \text{id}_D$ is the counit of an adjunction between functors of ordinary categories $F$ and $G$ if and only if $N_\bullet(\epsilon) : N_\bullet(F) \circ N_\bullet(G) \to \text{id}_N(D)$ is the unit of an adjunction between functors of $\infty$-categories $N_\bullet(F)$ and $N_\bullet(G)$.

• A functor of ordinary categories $F : C \to D$ admits a right adjoint $G : D \to C$ if and only if the induced functor of $\infty$-categories $N_\bullet(F) : N_\bullet(C) \to N_\bullet(D)$ admits a right adjoint (in which case $N_\bullet(G)$ is a right adjoint of $N_\bullet(F)$).

• A functor of ordinary categories $G : D \to C$ admits a left adjoint $F : C \to D$ if and only if the induced functor of $\infty$-categories $N_\bullet(G) : N_\bullet(D) \to N_\bullet(C)$ admits a left adjoint (in which case $N_\bullet(F)$ is a left adjoint of $N_\bullet(G)$).

Proposition 3.1.6.9 generalizes to the setting of $\infty$-categories:

**Remark 6.2.1.10.** Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories which admits a right adjoint $G : \mathcal{D} \to \mathcal{C}$. The existence of natural transformations

$$\eta : \text{id}_C \to G \circ F \quad \epsilon : F \circ G \to \text{id}_D$$

guarantee that $F$ and $G$ are simplicial homotopy inverses of one another, in the sense of Definition 3.1.6.1. In particular, $F$ and $G$ are homotopy equivalences of simplicial sets.

**Example 6.2.1.11.** Let $F : \mathcal{C} \to \mathcal{D}$ be an equivalence of $\infty$-categories, and let $G : \mathcal{D} \to \mathcal{C}$ be a homotopy inverse of $F$. Then $G$ is also a right adjoint of $F$. More precisely, any isomorphism $\eta : \text{id}_C \to G \circ F$ in the functor $\infty$-category $\text{Fun}(\mathcal{C}, \mathcal{C})$ is the unit of an adjunction between $F$ and $G$ (Proposition 6.1.4.1). Similarly, $G$ is a left adjoint of $F$.

**Remark 6.2.1.12.** Let $F : X \to Y$ be a morphism of Kan complexes. Then $F$ admits a right adjoint (in the sense of Notation 6.2.1.3) if and only if $F$ is a homotopy equivalence. This follows by combining Remark 6.2.1.10 with Example 6.2.1.11.

Remark 6.2.1.12 can be regarded as a special case of the following more general assertion:

**Proposition 6.2.1.13.** Let $F : \mathcal{C} \to \mathcal{D}$ and $G : \mathcal{D} \to \mathcal{C}$ be functors of $\infty$-categories and let

$$\eta : \text{id}_C \to G \circ F \quad \epsilon : F \circ G \to \text{id}_D$$

be natural transformations which are compatible up to homotopy. Let $\mathcal{C}' \subseteq \mathcal{C}$ be the full subcategory spanned by those objects $C \in \mathcal{C}$ for which the unit $\eta_C : C \to (G \circ F)(C)$ is an isomorphism, and let $\mathcal{D}' \subseteq \mathcal{D}$ be the full subcategory spanned by those objects $D \in \mathcal{D}$ for which the counit $\epsilon_D : (F \circ G)(D) \to D$ is an isomorphism. Then $F$ and $G$ restrict to functors $F' : \mathcal{C}' \to \mathcal{D}'$ and $G' : \mathcal{D}' \to \mathcal{C}'$ which are homotopy inverse to one another.
Proof. Let $C$ be an object of $\mathcal{C}'$, so that $\eta_C : C \to (G \circ F)(C)$ is an isomorphism. Since $\eta$ and $\epsilon$ are compatible up to homotopy, the identity morphism $\text{id}_{F(C)}$ is a composition of $F(\eta_C) : F(C) \to (F \circ G \circ F)(C)$ with $\epsilon_{F(C)} : (F \circ G \circ F)(C) \to F(C)$ in the $\infty$-category $\mathcal{D}$. It follows that $\epsilon_{F(C)}$ is an isomorphism in $\mathcal{D}$ (Remark 1.3.6.3), so that $F(C)$ belongs to the full subcategory $\mathcal{D}' \subseteq \mathcal{D}$. Setting $F' = F|_{\mathcal{C}'}$, we obtain a functor $F' : \mathcal{C}' \to \mathcal{D}'$. A similar argument shows that we can regard $G' = G|_{\mathcal{D}'}$ as a functor from $\mathcal{D}'$ to $\mathcal{C}'$. The unit morphism $\eta$ restricts to a natural transformation of functors $\eta' : \text{id}_{\mathcal{C}'} \to G' \circ F'$. By construction, $\eta'$ carries each object $C \in \mathcal{C}'$ to an isomorphism, and is therefore an isomorphism in the functor $\infty$-category $\text{Fun}(\mathcal{C}', \mathcal{C}')$ (Theorem 4.4.4.4). Similarly, the counit $\epsilon$ restricts to a natural isomorphism $\epsilon' : F' \circ G' \to \text{id}_{\mathcal{D}'}$, so that $F'$ and $G'$ are homotopy inverse to one another. \hfill \Box

Proposition 6.2.1.14. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories which admits a right adjoint. Let $G : \mathcal{D} \to \mathcal{C}$ be another functor of $\infty$-categories and let $\eta : \text{id}_{\mathcal{C}} \to G \circ F$ be a natural transformation. The following conditions are equivalent:

(1) The natural transformation $\eta$ is the unit of an adjunction between the $\infty$-categories $\mathcal{C}$ and $\mathcal{D}$.

(2) The induced map $\text{id}_{\mathcal{hC}} \to hG \circ hF$ is the unit of an adjunction between the homotopy categories $h\mathcal{C}$ and $h\mathcal{D}$.

Proof. The implication (1) $\Rightarrow$ (2) follows from the observation that the formation of homotopy categories defines a (strict) functor of 2-categories

$$h_2 \text{QCat} \to \text{Cat} \quad C \mapsto hC,$$

and therefore carries adjunctions to adjunctions (see Exercise 6.1.1.6). We will show that (2) implies (1). By assumption, the functor $F$ admits a right adjoint $G' : \mathcal{D} \to \mathcal{C}$. Let $\eta' : \text{id}_{\mathcal{C}} \to F \circ G'$ be the unit of an adjunction. Applying Corollary 6.1.3.3 we deduce that there exists a natural transformation $\gamma : G' \to G$ such that $\eta$ is a composition of the natural transformations

$$\eta' : \text{id}_{\mathcal{C}} \to F \circ G' \quad (\text{id}_F \circ \gamma) : F \circ G' \to F \circ G$$

in the $\infty$-category $\text{Fun}(\mathcal{C}, \mathcal{C})$. If assumption (2) is satisfied, then the image of $\gamma$ in the functor category $\text{Fun}(h\mathcal{D}, h\mathcal{C})$ is an isomorphism: that is, $\gamma$ carries each object $D \in \mathcal{D}$ to an isomorphism $\gamma_D : G'(D) \to G(D)$ in the $\infty$-category $\mathcal{C}$. Applying Theorem 4.4.4.4 we conclude that $\gamma$ is an isomorphism in the $\infty$-category $\text{Fun}(\mathcal{D}, \mathcal{C})$, so that the criterion of Corollary 6.1.3.3 guarantees that $\eta$ is also the unit of an adjunction. \hfill \Box

Corollary 6.2.1.15. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories and let $hF : h\mathcal{C} \to h\mathcal{D}$ be the induced functor of homotopy categories. If $F$ admits a right adjoint $G$, then $hF$ also admits a right adjoint, which can be identified with the functor $hG$.  

\hfill \Box
6.2. ADJOINT FUNCTORS BETWEEN ∞-CATEGORIES

Warning 6.2.1.16. The implication (2) ⇒ (1) of Proposition 6.2.1.14 generally fails if the functor $F : C \to D$ does not have a right adjoint. For example, let $X$ be a simply connected Kan complex, let $F : \Delta^0 \to X$ be the map corresponding to a vertex $x \in X$, and let $G : X \to \Delta^0$ be the projection map. Since $X$ is simply connected, the functors $hF$ and $hG$ are equivalences of ordinary categories. In particular, the identity transformation from $\text{id}_{\Delta^0} = G \circ F$ to itself determines unit of an adjunction between $hF$ and $hG$. However, the functors $F$ and $G$ cannot be adjoint unless the Kan complex $X$ is contractible (see Remark 6.2.1.10).

Let $F : C \to D$ and $G : D \to C$ be functors between ∞-categories and let $\eta : \text{id}_C \to G \circ F$ be a natural transformation. By virtue of Variant 6.1.2.11, the natural transformation $\eta$ exhibits $hG$ as a right adjoint to $hF$ if and only if, for every pair of objects $C \in C$ and $D \in D$, the composite map

$$
\text{Hom}_{hD}(F(C), D) \xrightarrow{\eta} \pi_0(\text{Hom}_C((G \circ F)(C), G(D))) \xrightarrow{\circ [\eta_C]} \pi_0(\text{Hom}_C(C, G(D))) = \text{Hom}_{hC}(C, G(D))
$$

is a bijection. If $\eta$ exhibits $G$ as a right adjoint to $F$, then we can say more:

Proposition 6.2.1.17. Let $F : C \to D$ and $G : D \to C$ be functors between ∞-categories and let $\eta : \text{id}_C \to G \circ F$ be the unit of an adjunction. Then, for every pair of objects $C \in C$ and $D \in D$, the composite map

$$
\text{Hom}_D(F(C), D) \xrightarrow{\eta} \text{Hom}_C((G \circ F)(C), G(D)) \xrightarrow{\circ [\eta_C]} \text{Hom}_C(C, G(D))
$$

is an isomorphism in the homotopy category $hKan$; here the second map is given by the composition law of Construction 4.6.8.9.

Proof. It will suffice to show that, for every Kan complex $T$, the induced map

$$
\pi_0(\text{Fun}(T, \text{Hom}_D(F(C), D))) = \text{Hom}_{hKan}(T, \text{Hom}_D(F(C), D)) \xrightarrow{\theta} \text{Hom}_{hKan}(T, \text{Hom}_C(C, G(D))) = \pi_0(\text{Fun}(T, \text{Hom}_C(C, G(D))))
$$

is bijective. Let $C \in \text{Fun}(T, C)$ and $D \in \text{Fun}(T, D)$ be the constant morphisms taking the values $C$ and $D$, respectively. Unwinding the definitions, we see that $\theta$ can be identified with the map

$$
\text{Hom}_{h\text{Fun}(T,D)}(F \circ C, D) \to \text{Hom}_{h\text{Fun}(T,C)}(C, G \circ D)
$$
given by the formation of right adjoints with respect to the homotopy class \([\eta]\) (regarded as a 2-morphism in the category \(h\mathbb{Q}\text{Cat}\)). The bijectivity of \(\theta\) now follows from the criterion of Proposition \[6.1.2.9.\]

**Remark 6.2.1.18.** We will see later that the converse of Proposition \[6.2.1.17\] also holds: if \(F : \mathcal{C} \to \mathcal{D}\) and \(G : \mathcal{D} \to \mathcal{C}\) are functors of \(\infty\)-categories and \(\eta : \text{id}_\mathcal{C} \to G \circ F\) is a natural transformation which induces a homotopy equivalence \(\text{Hom}_\mathcal{D}(F(C), D) \simeq \text{Hom}_\mathcal{C}(C, G(D))\) for every pair of objects \((C, D) \in \mathcal{C} \times \mathcal{D}\), then \(\eta\) is the unit of an adjunction between \(F\) and \(G\) (Corollary \[6.2.4.5\]).

**Remark 6.2.1.19.** Let \(F : \mathcal{C} \to \mathcal{D}\) be a functor of \(\infty\)-categories. It follows from Proposition \[6.1.3.4\] that if \(F\) admits a right adjoint \(G\), then \(G\) is well-defined up to isomorphism as an object of the functor \(\infty\)-category \(\text{Fun}(\mathcal{D}, \mathcal{C})\). We will sometimes emphasize this by referring to \(G\) as the right adjoint of \(F\) and denoting it by \(F^R\). By virtue of Notation \[6.1.3.8\], the construction \(F \mapsto F^R\) determines an equivalence of homotopy categories \(h\text{LFun}(\mathcal{C}, \mathcal{D}) \to h\text{RFun}(\mathcal{D}, \mathcal{C})^{op}\). We will see later that this construction can be upgraded to an equivalence of \(\infty\)-categories \(\text{LFun}(\mathcal{C}, \mathcal{D}) \simeq \text{RFun}(\mathcal{D}, \mathcal{C})^{op}\) (see Proposition \[?\]).

**Warning 6.2.1.20.** Let \(\mathcal{C}\) and \(\mathcal{D}\) be \(\infty\)-categories. The following data are essentially equivalent to one another:

- The datum of a functor \(F : \mathcal{C} \to \mathcal{D}\) which admits a right adjoint.
- The datum of a functor \(G : \mathcal{D} \to \mathcal{C}\) which admits a left adjoint.
- The datum of a triple \((F, G, \eta)\), where \(F : \mathcal{C} \to \mathcal{D}\) and \(G : \mathcal{D} \to \mathcal{C}\) are functors and \(\eta : \text{id}_\mathcal{C} \to G \circ F\) is the unit of an adjunction between \(F\) and \(G\).
- The datum of a triple \((F, G, \epsilon)\), where \(F : \mathcal{C} \to \mathcal{D}\) and \(G : \mathcal{D} \to \mathcal{C}\) are functors and \(\epsilon : F \circ G \to \text{id}_\mathcal{D}\) is the counit of an adjunction between \(F\) and \(G\).
- The datum of a quintuple \((F, G, \eta, \epsilon, \sigma)\), where \(F : \mathcal{C} \to \mathcal{D}\) and \(G : \mathcal{D} \to \mathcal{C}\) are functors, \(\eta : \text{id}_\mathcal{C} \to G \circ F\) and \(\epsilon : F \circ G \to \text{id}_\mathcal{D}\) are natural transformations which are compatible up to homotopy, and \(\sigma : \Delta^2 \to \text{Fun}(\mathcal{C}, \mathcal{D})\) is a 2-simplex witnessing axiom (Z1) of Definition \[6.2.1.1\] (see Remark \[6.2.1.5\]).
- The datum of a quintuple \((F, G, \eta, \epsilon, \tau)\), where \(F : \mathcal{C} \to \mathcal{D}\) and \(G : \mathcal{D} \to \mathcal{C}\) are functors, \(\eta : \text{id}_\mathcal{C} \to G \circ F\) and \(\epsilon : F \circ G \to \text{id}_\mathcal{D}\) are natural transformations which are compatible up to homotopy, and \(\tau : \Delta^2 \to \text{Fun}(\mathcal{D}, \mathcal{C})\) is a 2-simplex witnessing axiom (Z2) of Definition \[6.2.1.1\].

The following data are not equivalent to the above (or to each other):
The datum of a pair \((F,G)\), where \(F : \mathcal{C} \to \mathcal{D}\) and \(G : \mathcal{D} \to \mathcal{C}\) are functors which are adjoint to one another.

The datum of a quadruple \((F,G,\eta,\epsilon)\), where \(F : \mathcal{C} \to \mathcal{D}\) and \(G : \mathcal{D} \to \mathcal{C}\) are functors, \(\eta : \text{id}_\mathcal{C} \to G \circ F\) and \(\epsilon : F \circ G \to \text{id}_\mathcal{D}\) are natural transformations which are compatible up to homotopy,

The datum of a sextuple \((F,G,\eta,\epsilon,\sigma,\tau)\), where \(F : \mathcal{C} \to \mathcal{D}\) and \(G : \mathcal{D} \to \mathcal{C}\) are functors, \(\eta : \text{id}_\mathcal{C} \to G \circ F\) and \(\epsilon : F \circ G \to \text{id}_\mathcal{D}\) are natural transformations, and \(\sigma : \Delta^2 \to \text{Fun}(\mathcal{C},\mathcal{D})\) and \(\tau : \Delta^2 \to \text{Fun}(\mathcal{D},\mathcal{C})\) are 2-simplices witnessing axioms \((Z1)\) and \((Z2)\) of Definition 6.2.1.1.

To say that a functor \(F : \mathcal{C} \to \mathcal{D}\) is left adjoint to a functor \(G : \mathcal{D} \to \mathcal{C}\) is somewhat imprecise: one should really specify a witness to the adjointness of \(F\) and \(G\), which can take the form of either a unit \(\eta : \text{id}_\mathcal{C} \to G \circ F\) or a counit \(\epsilon : F \circ G \to \text{id}_\mathcal{D}\). Given both a unit \(\eta\) and a counit \(\epsilon\), one can further demand evidence of their compatibility, which can take the form of a 2-simplex \(\sigma : \Delta^2 \to \text{Fun}(\mathcal{C},\mathcal{D})\) witnessing axiom \((Z1)\) or a 2-simplex \(\tau : \Delta^2 \to \text{Fun}(\mathcal{D},\mathcal{C})\) witnessing axiom \((Z2)\). If one specifies both of the witnesses \(\sigma\) and \(\tau\), then one can further demand a witness to the compatibility of \(\sigma\) with \(\tau\); we will return to this point in §[?].

### 6.2.2 Reflective Subcategories

Let \(\mathcal{C}\) be an \(\infty\)-category. Our goal in this section is to characterize those full subcategories \(\mathcal{C}' \subseteq \mathcal{C}\) for which the inclusion functor \(\mathcal{C}' \hookrightarrow \mathcal{C}\) admits a left or right adjoint.

**Definition 6.2.2.1.** Let \(\mathcal{C}\) be an \(\infty\)-category and let \(\mathcal{C}' \subseteq \mathcal{C}\) be a full subcategory. We say that a morphism \(u : X \to Y\) in \(\mathcal{C}\) exhibits \(Y\) as a \(\mathcal{C}'\)-reflection of \(X\) if \(Y\) belongs to \(\mathcal{C}'\) and, for every object \(Z \in \mathcal{C}'\), the precomposition map \(\text{Hom}_\mathcal{C}(Y,Z) \xrightarrow{\circ [u]} \text{Hom}_\mathcal{C}(X,Z)\) is an isomorphism in the homotopy category \(\text{hKan}\). We say that \(u\) exhibits \(X\) as a \(\mathcal{C}'\)-coreflection of \(Y\) if \(X\) belongs to \(\mathcal{C}'\) and, for every object \(W \in \mathcal{C}'\), the postcomposition map \(\text{Hom}_\mathcal{C}(W,X) \xrightarrow{[u] \circ} \text{Hom}_\mathcal{C}(W,Y)\) is an isomorphism in the homotopy category \(\text{hKan}\).

We say that a subcategory \(\mathcal{C}' \subseteq \mathcal{C}\) is reflective if it is full and, for every object \(X \in \mathcal{C}\), there exists a morphism \(u : X \to Y\) which exhibits \(Y\) as a \(\mathcal{C}'\)-reflection of \(X\). We say that the subcategory \(\mathcal{C}'\) is coreflective if if is full and, for every object \(Y \in \mathcal{C}\), there exists a morphism \(u : X \to Y\) which exhibits \(X\) as a \(\mathcal{C}'\)-coreflection of \(Y\).

**Remark 6.2.2.2.** Let \(\mathcal{C}\) be an \(\infty\)-category and let \(\mathcal{C}' \subseteq \mathcal{C}\) be a full subcategory, so that we can identify \(\mathcal{C}'^{\text{op}}\) with a full subcategory of the opposite \(\infty\)-category \(\mathcal{C}^{\text{op}}\). Then:

- A morphism \(u : X \to Y\) in \(\mathcal{C}\) exhibits \(Y\) as a \(\mathcal{C}'\)-reflection of \(X\) if and only if \(u^{\text{op}} : Y^{\text{op}} \to X^{\text{op}}\) exhibits \(Y^{\text{op}}\) as a \(\mathcal{C}'^{\text{op}}\)-coreflection of \(X^{\text{op}}\).
• The subcategory $C' \subseteq C$ is reflective if and only if the subcategory $C'^{\text{op}} \subseteq C^{\text{op}}$ is coreflective.

Remark 6.2.2.3. Let $C$ be an $\infty$-category, let $C' \subseteq C$ be a full subcategory, and suppose we are given a pair of morphisms $u : X \to Y$ and $w : X \to Z$ of $C$, where $Y$ and $Z$ belong to the subcategory $C'$. If $u$ exhibits $Y$ as a $C'$-reflection of $X$, then we can realize $w$ as a composition of $u$ with another morphism $v : Y \to Z$ of $C'$, which is uniquely determined up to homotopy. Moreover, $v$ is an isomorphism if and only if $w$ exhibits $Z$ as a $C'$-reflection of $X$. Stated more informally: a $C'$-reflection of $X$, if it exists, is unique up to isomorphism.

Example 6.2.2.4. Let $C$ be an $\infty$-category, let $C' \subseteq C$ be a full subcategory, and let $u : X \to Y$ be a morphism of $C$. If $X$ belongs to the subcategory $C'$, then $u$ exhibits $Y$ as a $C'$-reflection of $X$ if and only if it is an isomorphism. Similarly, if $Y$ belongs to $C'$, then $u$ exhibits $X$ as a $C'$-coreflection of $Y$ if and only if it is an isomorphism.

Example 6.2.2.5. Let $C$ be an $\infty$-category, and let $C' \simeq C \star \{X\}$ denote the right cone on $C$. Then the cone point $\{X\}$ is a reflective subcategory of $C$.

Example 6.2.2.6. Let $S$ denote the $\infty$-category of spaces (Construction 5.6.1.1) and let $QC$ denote the $\infty$-category of (small) $\infty$-categories (Construction 5.6.4.1). Then $S$ is a reflective and coreflective subcategory of $QC$. If $C$ is a small $\infty$-category, then the inclusion map $C^\simeq \to C$ exhibits the core $C^\simeq$ as a $S$-coreflection of $C$ (this follows by combining Proposition 4.4.3.16 with Remark 5.6.4.6), and the comparison map $C \to \text{Ex}^\infty(C)$ exhibits the Kan complex $\text{Ex}^\infty(C)$ as a $S$-reflection of $C$ (this follows by combining Proposition 3.3.6.7 with Remark 5.6.4.6).

Our first goal is to prove the following:

Proposition 6.2.2.7. Let $C$ be an $\infty$-category, let $C' \subseteq C$ be a full subcategory, and let $\iota : C' \hookrightarrow C$ be the inclusion map. Then $\iota$ admits a left adjoint if and only if $C'$ is a reflective subcategory of $C$. Similarly, $\iota$ admits a right adjoint if and only if $C'$ is a coreflective subcategory of $C$.

The first step toward proving Proposition 6.2.2.7 is to show that if $X \in C$ is an object which admits a $C'$-reflection $u : X \to Y$, then the pair $(u, Y)$ can be chosen to depend functorially on $X$.

Definition 6.2.2.8. Let $C$ be an $\infty$-category, let $C' \subseteq C$ be a full subcategory, and let $L : C \to C$ be a functor. We will say that a natural transformation $\eta : \text{id}_C \to L$ exhibits $L$ as a $C'$-reflection functor if, for every object $X \in C$, the morphism $\eta_X : X \to L(X)$ exhibits $L(X)$ as a $C'$-reflection of $C$, in the sense of Definition 6.2.2.1. We say that a natural transformation $\epsilon : L \to \text{id}_C$ exhibits $L$ as a $C'$-coreflection functor if, for every object $Y \in C$, the morphism $\epsilon_Y : L(Y) \to Y$ exhibits $L(Y)$ as a $C'$-coreflection of $Y$. 
In the situation of Definition 6.2.2.8, the assumption that \( \eta : \text{id}_C \to L \)
exhibits \( L \) as a \( C' \)-reflection functor guarantees in particular that for every object \( X \in C \),
the image \( L(X) \) belongs to the full subcategory \( C' \subseteq C \). Consequently, we can also view \( L \)
as a functor from \( C \) to \( C' \).

**Remark 6.2.2.9.** In the situation of Definition 6.2.2.8, the assumption that \( \eta : \text{id}_C \to L \)
exhibits \( L \) as a \( C' \)-reflection functor guarantees in particular that for every object \( X \in C \),
the image \( L(X) \) belongs to the full subcategory \( C' \subseteq C \). Consequently, we can also view \( L \)
as a functor from \( C \) to \( C' \).

**Lemma 6.2.2.10.** Let \( C \) be an \( \infty \)-category and let \( C' \subseteq C \) be a full subcategory. Then \( C' \)
is reflective if and only if there exists a functor \( L : C \to C' \) and a natural transformation \( \eta : \text{id}_C \to L \)
which exhibits \( L \) as a \( C' \)-reflection functor.

**Proof.** Assume that \( C' \) is a reflective subcategory of \( C \); we will show that there exists a functor \( L : C \to C' \)
and a natural transformation \( \eta : \text{id}_C \to L \) which exhibits \( L \) as a \( C' \)-reflection functor (the reverse implication is immediate from the definitions). Let \( \mathcal{E} \) be
the full subcategory of \( C \times \Delta^1 \) spanned by those objects \((X, i)\) having the property that if \( i = 1 \), then \( X \) belongs to the full subcategory \( C' \). Let \( \pi : \mathcal{E} \to \Delta^1 \)
denote the projection map. Let \( \bar{u} : (X, 0) \to (Y, 1) \) be a morphism in \( \mathcal{E} \), corresponding to a morphism \( u : X \to Y \)
in \( C \) for which the target \( Y \) belongs to \( C' \). By virtue of Corollary 5.1.2.3, the morphism \( \bar{u} \) is \( \pi \)-cocartesian if and only if \( u \) exhibits \( Y \) as a \( C' \)-localization of \( X \). Consequently, our assumption that \( C' \) is a reflective subcategory of \( C \) guarantees that \( \pi \) is a cocartesian fibration
of \( \infty \)-categories. Applying Proposition 5.2.2.8, we deduce that there exists a functor
\[
L : C \simeq \{0\} \times \Delta^1, \mathcal{E} \to \{1\} \times \Delta^1, \mathcal{E} \simeq C'
\]
and a morphism \( \bar{\eta} : \text{id}_C \to L \) in the \( \infty \)-category \( \text{Fun}(C, \mathcal{E}) \) which carries each object \( X \in C \)
to a \( \pi \)-cocartesian morphism \((X, 0) \to (L(X), 1)\) in \( \mathcal{E} \). Composing with the projection map \( \pi : \mathcal{E} \to \Delta^1 \), we obtain a natural transformation \( \eta : \text{id}_C \to L \) in \( \text{Fun}(C, C) \) which exhibits \( L \)
as a \( C' \)-reflection functor.

**Proposition 6.2.2.11.** Let \( C \) be an \( \infty \)-category, let \( C' \subseteq C \) be a full subcategory, and let \( \iota : C' \to C \) be the inclusion map. Let \( L : C \to C' \) be a functor of \( \infty \)-categories and let \( \eta : \text{id}_C \to \iota \circ L \) be a natural transformation. The following conditions are equivalent:

1. The natural transformation \( \eta \) is the unit of an adjunction: that is, it exhibits \( L \) as a left
adjoint to the inclusion functor \( C' \to C \).

2. The natural transformation \( \eta \) exhibits \( L \) as a \( C' \)-reflection functor: that is, for every
object \( X \in C \), the morphism \( \eta_X : X \to L(X) \) exhibits \( L(X) \) as a \( C' \)-reflection of \( X \).

3. For every object \( X \in C \), the morphism \( L(\eta_X) : L(X) \to L(L(X)) \) is an isomorphism in
\( C' \). Moreover, if \( X \) belongs to \( C' \), then \( \eta_X : X \to L(X) \) is an isomorphism.

Moreover, if these conditions are satisfied, then any natural transformation \( \epsilon : L \circ \iota \to \text{id}_{C'} \)
which is compatible with \( \eta \) up to homotopy (in the sense of Definition 6.2.1.1) is an
isomorphism in the functor \( \infty \)-category \( \text{Fun}(C', C') \).
Proof. We first show that (1) implies (2). Let \( X \) be an object of \( \mathcal{C} \), so that \( \eta \) determines a morphism \( \eta_X : X \to L(X) \). For every object \( Y \in \mathcal{C}' \), Proposition 6.2.1.17 guarantees that composition with the homotopy class \([\eta_X]\) induces an isomorphism
\[
\text{Hom}_{\mathcal{C}'}(L(X), Y) = \text{Hom}_{\mathcal{C}}(L(X), Y) \overset{\circ[\eta_X]}{\to} \text{Hom}_{\mathcal{C}}(X, Y)
\]
in the homotopy category \( \text{hKan} \). It follows that \( \eta_X \) exhibits \( L(X) \) as a \( \mathcal{C}' \)-reflection of \( X \). Allowing \( X \) to vary, we conclude that \( \eta \) exhibits \( L \) as a \( \mathcal{C}' \)-reflection functor.

We now show that (2) implies (3). Assume that, for every object \( X \in \mathcal{C} \), the morphism \( \eta_X : X \to L(X) \) exhibits \( L(X) \) as a \( \mathcal{C}' \)-reflection of \( X \). Note that we have a commutative diagram
\[
\begin{array}{ccc}
X & \xrightarrow{\eta_X} & L(X) \\
\downarrow{\eta_X} & & \downarrow{\eta_{L(X)}} \\
L(X) & \xrightarrow{L(\eta_X)} & L(L(X))
\end{array}
\]
in the \( \infty \)-category \( \mathcal{C} \), obtained by applying the natural transformation \( \eta \) to the morphism \( \eta_X : X \to L(X) \). For each object \( Y \in \mathcal{C} \), we obtain a commutative diagram of sets
\[
\begin{array}{ccc}
\text{Hom}_{\mathcal{C}'}(X, Y) & \overset{\circ[\eta_X]}{\leftarrow} & \text{Hom}_{\mathcal{C}}(L(X), Y) \\
\downarrow{\circ[\eta_X]} & & \downarrow{\circ[\eta_{L(X)}]} \\
\text{Hom}_{\mathcal{C}'}(L(X), Y) & \overset{\circ[L(\eta_X)]}{\leftarrow} & \text{Hom}_{\mathcal{C}}(L(L(X)), Y).
\end{array}
\]

If \( Y \) belongs to the subcategory \( \mathcal{C}' \subseteq \mathcal{C} \), then the vertical maps and the upper horizontal map in this diagram are bijective. It follows that the lower horizontal map is bijective as well. Allowing \( Y \) to vary, we deduce that the homotopy class \([L(\eta_X)]\) is an isomorphism in the homotopy category \( \text{hC}' \), so that \( L(\eta_X) \) is an isomorphism in the \( \infty \)-category \( \mathcal{C}' \). In the special case where \( X \) belongs to \( \mathcal{C}' \), Example 6.2.2.4 guarantees that \( \eta_X \) is already an isomorphism before applying the functor \( L \).

We now show that (3) implies (1). Note that \( \eta \) determines natural transformations
\[
\eta' : L \to L \circ \iota \circ L \quad (X \in \mathcal{C}) \mapsto (L(\eta_X) \in \text{Hom}_{\mathcal{C}'}(L(X), L(L(X))))
\]
\[
\eta'' : \iota \circ \iota \circ L \to L \quad (Y \in \mathcal{C}') \mapsto (\eta_Y \in \text{Hom}_{\mathcal{C}}(Y, L(Y))).
\]
If condition (3) is satisfied, then Theorem 4.4.4.4 guarantees that \( \eta' \) and \( \eta'' \) are isomorphisms in the \( \infty \)-categories \( \text{Fun}(\mathcal{C}, \mathcal{C}') \) and \( \text{Fun}(\mathcal{C}', \mathcal{C}) \), respectively. Invoking the criterion of Proposition 6.1.4.6, we conclude that \( \eta \) is the unit of an adjunction. \qed
6.2. ADJOINT FUNCTORS BETWEEN ∞-CATEGORIES

Proof of Proposition 6.2.2.7. Let \( C \) be an \( ∞ \)-category, let \( C' \subseteq C \) be a full subcategory. It follows from Proposition 6.2.2.11 that the inclusion functor \( C' \hookrightarrow C \) admits a left adjoint if and only if there exists a functor \( L : C \rightarrow C' \) and a natural transformation \( \eta : \text{id}_C \rightarrow L \) which exhibits \( L \) as a \( C' \)-reflection functor. By virtue of Lemma 6.2.2.10, this is equivalent to the requirement that \( C' \) is a reflective subcategory of \( C \). The analogous characterization of coreflective subcategories follows by a similar argument.

Example 6.2.2.12. Combining Example 6.2.2.6 with Proposition 6.2.2.7, we see that the inclusion functor \( S \hookrightarrow QC \) admits both a right adjoint (given on objects by the construction \( C \mapsto \text{Ex}^\infty(C) \)) and a left adjoint (given on objects by the construction \( C \mapsto \text{Ex}^\infty(\text{C}^\infty) \)).

Corollary 6.2.2.13. Let \( G : D \rightarrow C \) be a functor of \( ∞ \)-categories. The following conditions are equivalent:

1. The functor \( G \) is fully faithful and the essential image of \( G \) is a reflective subcategory of \( C \).
2. The functor \( G \) is fully faithful and admits a left adjoint \( F : C \rightarrow D \).
3. There exist a functor \( F : C \rightarrow D \) and a natural isomorphism \( \epsilon : F \circ G \rightarrow \text{id}_D \) which is the counit of an adjunction between \( F \) and \( G \).
4. The functor \( G \) admits a left adjoint \( F : C \rightarrow D \) for which the composition \( (F \circ G) : D \rightarrow D \) is an equivalence of \( ∞ \)-categories.

Proof. Let \( C' \subseteq C \) be the essential image of \( G \). If \( G \) is fully faithful, then it induces an equivalence \( D \rightarrow C' \) (Corollary 4.6.2.19). The equivalence (1) \( \iff \) (2) follows by applying Proposition 6.2.2.7 to the subcategory \( C' \subseteq C \), and the implication (2) \( \Rightarrow \) (3) follows by applying Proposition 6.2.2.11 to the subcategory \( C' \subseteq C \). To show that (3) \( \Rightarrow \) (2), we observe that if a natural isomorphism \( \epsilon : F \circ G \rightarrow \text{id}_D \) is the counit of an adjunction, then \( G \) restricts to an equivalence of \( D \) with a full subcategory of \( C \) (Proposition 6.2.1.13), and is therefore fully faithful. The equivalence (3) \( \iff \) (4) is a special case of Proposition 6.1.4.7.

Corollary 6.2.2.14. Let \( C \) be an \( ∞ \)-category, let \( L \) be a functor from \( C \) to itself, and let \( \eta : \text{id}_C \rightarrow L \) be a natural transformation. The following conditions are equivalent:

1. For every object \( X \in C \), the morphisms \( L(\eta_X) : L(X) \rightarrow L(L(X)) \) and \( \eta_{L(X)} : L(X) \rightarrow L(L(X)) \) are isomorphisms.
2. There exists a full subcategory \( C' \subseteq C \) for which \( \eta \) exhibits \( L \) as a \( C' \)-reflection functor, in the sense of Definition 6.2.2.8.
Proof. The implication (2) ⇒ (1) follows from Proposition 6.2.2.11. Conversely, suppose that condition (1) is satisfied, and let \( \mathcal{C}' \subseteq \mathcal{C} \) be the full subcategory spanned by those objects of the form \( L(X) \) for \( X \in \mathcal{C} \). Assumption (1) guarantees that \( \eta_Y \) is an isomorphism for each \( Y \in \mathcal{C}' \), so that \( \eta \) exhibits \( L \) as a \( \mathcal{C}' \)-reflection functor by virtue of Proposition 6.2.2.11.

Exercise 6.2.2.15. In the situation of Corollary 6.2.2.14, let \( \mathcal{C}' \subseteq \mathcal{C} \) be a full subcategory of \( \mathcal{C} \). Show that \( \eta \) exhibits \( L \) as a \( \mathcal{C}' \)-reflection functor if and only if the following conditions are satisfied:

- For each object \( X \in \mathcal{C} \), the object \( L(X) \) is contained in \( \mathcal{C}' \).
- For each object \( Y \in \mathcal{C}' \), there exists an isomorphism \( Y \to L(X) \) for some object \( X \in \mathcal{C} \).

If the subcategory \( \mathcal{C}' \subseteq \mathcal{C} \) is replete (Example 4.4.1.11), then it is uniquely determined by these conditions.

Reflective subcategories are stable under pullback along cocartesian fibrations:

Proposition 6.2.2.16. Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of \( \infty \)-categories and let \( \mathcal{C}' \subseteq \mathcal{C} \) be a reflective subcategory. Then the pullback \( \mathcal{E}' = \mathcal{C}' \times_{\mathcal{C}} \mathcal{E} \) is a reflective subcategory of \( \mathcal{E} \). Moreover, a morphism \( f : X \to Y \) in \( \mathcal{E} \) exhibits \( Y \) as a \( \mathcal{E}' \)-reflection of \( X \) if and only if it satisfies the following pair of conditions:

1. The morphism \( f \) is \( U \)-cocartesian.
2. The morphism \( U(f) : U(X) \to U(Y) \) exhibits \( U(Y) \) as a \( \mathcal{C}' \)-reflection of \( U(X) \) in the \( \infty \)-category \( \mathcal{C} \).

Proof. We first show that, if \( f : X \to Y \) is a morphism of \( \mathcal{E} \) satisfying conditions (1) and (2), then \( f \) exhibits \( Y \) as a \( \mathcal{E}' \)-reflection of \( X \). It follows from condition (2) that \( U(Y) \) belongs to \( \mathcal{C}' \), so that \( Y \) belongs to \( \mathcal{E}' \). It will therefore suffice to show that for each object \( Z \in \mathcal{E} \), precomposition with \( f \) induces a homotopy equivalence \( \theta : \text{Hom}_{\mathcal{E}}(Y, Z) \to \text{Hom}_{\mathcal{C}}(X, Z) \). Let us abuse notation by identifying \( \theta \) with the restriction map \( \{ f \} \times_{\text{Hom}_{\mathcal{E}}(X, Y)} \text{Hom}_{\mathcal{E}}(X, Y, Z) \to \text{Hom}_{\mathcal{C}}(X, Z) \), so that we have a commutative diagram of Kan complexes

\[
\begin{array}{ccc}
\{ f \} \times_{\text{Hom}_{\mathcal{E}}(X, Y)} \text{Hom}_{\mathcal{E}}(X, Y, Z) & \xrightarrow{\theta} & \text{Hom}_{\mathcal{C}}(X, Z) \\
\downarrow & & \downarrow \\
\{ U(f) \} \times_{\text{Hom}_{\mathcal{C}}(U(X), U(Y))} \text{Hom}_{\mathcal{C}}(U(X), U(Y), U(Z)) & \xrightarrow{\tilde{\theta}} & \text{Hom}_{\mathcal{C}}(U(X), U(Z)).
\end{array}
\]

Assumption (1) guarantees that this diagram is a homotopy pullback square (Proposition 5.1.2.1), and assumption (2) guarantees that \( \tilde{\theta} \) is a homotopy equivalence of Kan complexes. Applying Corollary 3.4.1.5, we conclude that \( \theta \) is also a homotopy equivalence.
6.2. ADJOINT FUNCTORS BETWEEN $\infty$-CATEGORIES

We now show that $E'$ is a reflective subcategory of $E$. Fix an object $X \in E$. Since $C'$ is a reflective subcategory of $C$, there exists a morphism $\overline{f} : U(X) \rightarrow Y$ in $C$ which exhibits $Y$ as a $C'$-reflection of $U(X)$. Since $U$ is a cocartesian fibration, we can write $\overline{f} = U(f)$ for some $U$-cocartesian morphism $f : X \rightarrow Y$ of $E$. By construction, the morphism $f$ satisfies conditions (1) and (2), and therefore exhibits $Y$ as an $E'$-reflection of $X$.

To complete the proof, it will suffice to show that if $h : X \rightarrow Z$ is another morphism which exhibits $Z$ as an $E'$-reflection of $X$, then $h$ also satisfies conditions (1) and (2). By virtue of Remark 6.2.2.3 there exists a 2-simplex of $E$, where $g : Y \rightarrow Z$ is an isomorphism of $E'$. In particular, $g$ is $U$-cocartesian (Proposition 5.1.1.8), so that $h$ satisfies (1) by virtue of Corollary 5.1.2.4. Since $U(g)$ is an isomorphism in $C'$, condition (2) follows from Remark 6.2.2.3.

6.2.3 Correspondences

Let $U : E \rightarrow C$ be a cocartesian fibration of $\infty$-categories. To every morphism $e : C \rightarrow D$ of $C$, Proposition 5.2.2.8 supplies a covariant transport functor $e! : E_C = \{C\} \times_C E \rightarrow \{D\} \times_C E = E_D$, which is well-defined up to isomorphism. Our goal in this section is to show that $U$ is a cartesian fibration if and only if each of the functors $e! : E_C \rightarrow E_D$ admits a right adjoint (Proposition 6.2.3.5). Moreover, if this condition is satisfied, then the right adjoint to $e!$ is given by the contravariant transport functor $e^* : E_D \rightarrow E_C$ of Proposition 5.2.2.16. We begin by analyzing the special case $C = \Delta^1$.

Lemma 6.2.3.1. Let $E$ be an $\infty$-category equipped with a functor $U : E \rightarrow \Delta^1$, having fibers $E_0 = \{0\} \times_{\Delta^1} E$ and $E_1 = \{1\} \times_{\Delta^1} E$. Let $f : X \rightarrow Y$ be a morphism of $E$. Then:

- The morphism $f$ exhibits $X$ as a $E_0$-coreflection of $Y$ (in the sense of Definition 6.2.2.1) if and only if $X$ belongs to $E_0$ and $f$ is $\pi$-cartesian.
- The morphism $f$ exhibits $Y$ as a $E_1$-reflection of $X$ if and only if $Y$ belongs to $E_1$ and $f$ is $\pi$-cocartesian.

Proof. This is a special case of Corollary 5.1.2.3.
Corollary 6.2.3.2. Let $\mathcal{E}$ be an $\infty$-category equipped with a functor $U : \mathcal{E} \to \Delta^1$. Then:

- The functor $U$ is a cartesian fibration if and only if the full subcategory $\{0\} \times_{\Delta^1} \mathcal{E} \subseteq \mathcal{E}$ is coreflective.

- The functor $U$ is a cocartesian fibration if and only if the full subcategory $\{1\} \times_{\Delta^1} \mathcal{E} \subseteq \mathcal{E}$ is reflective.

Remark 6.2.3.3. Let $U : \mathcal{E} \to \Delta^1$ be a functor of $\infty$-categories having fibers $\mathcal{E}_0 = \{0\} \times_{\Delta^1} \mathcal{E}$ and $\mathcal{E}_1 = \{1\} \times_{\Delta^1} \mathcal{E}$. Suppose that $U$ is a cocartesian fibration, so that the full subcategory $\mathcal{E}_1 \subseteq \mathcal{E}$ is reflective (Corollary 6.2.3.2). By virtue of Lemma 6.2.2.10 there exists a $\mathcal{E}_1$-reflection functor $L : \mathcal{E} \to \mathcal{E}_1$. Then the restriction $L|_{\mathcal{E}_0} : \mathcal{E}_0 \to \mathcal{E}_1$ is given by covariant transport along the unique nondegenerate edge $e$ of $\Delta^1$ (in the sense of Definition 5.2.2.4). More precisely, if $\eta : \text{id}_{\mathcal{E}_0} \to L$ is a natural transformation which exhibits $L$ as a $\mathcal{E}_1$-reflection functor, then $\eta$ carries each object $X \in \mathcal{E}$ to a $U$-cocartesian morphism $\eta_X : X \to L(X)$, so that $\eta$ restricts to a natural transformation $\text{id}_{\mathcal{E}_0} \to L|_{\mathcal{E}_0}$ which witnesses $L|_{\mathcal{E}_0}$ as given by covariant transport along $e$.

Similarly, if $U$ is a cartesian fibration, then the full subcategory $\mathcal{E}_0 \subseteq \mathcal{E}$ is coreflective; if $L' : \mathcal{E} \to \mathcal{E}_0$ is a $\mathcal{E}_0$-coreflection functor, then the restriction $L'|_{\mathcal{E}_1} : \mathcal{E}_1 \to \mathcal{E}_0$ is given by contravariant transport along $e$, in the sense of Definition 5.2.2.14.

Proposition 6.2.3.4. Let $\mathcal{E}$ be an $\infty$-category equipped with a cocartesian fibration $U : \mathcal{E} \to \Delta^1$, having fibers $\mathcal{E}_0 = \{0\} \times_{\Delta^1} \mathcal{E}$ and $\mathcal{E}_1 = \{1\} \times_{\Delta^1} \mathcal{E}$. Let $F : \mathcal{E}_0 \to \mathcal{E}_1$ be a functor given by covariant transport along the nondegenerate edge $e$ of $\Delta^1$. Then the functor $F$ admits a right adjoint if and only if $U$ is a cartesian fibration. In this case, the right adjoint to $F$ is given by contravariant transport along $e$.

Proof. Let $i_0 : \mathcal{E}_0 \hookrightarrow \mathcal{E}$ and $i_1 : \mathcal{E}_1 \hookrightarrow \mathcal{E}$ denote the inclusion maps. Since $U$ is a cocartesian fibration, $\mathcal{E}_1$ is a reflective subcategory of $\mathcal{E}$ (Corollary 6.2.3.2). Let $L : \mathcal{E} \to \mathcal{E}_1$ be a $\mathcal{E}_1$-reflection functor (Lemma 6.2.2.10). Without loss of generality, we may assume that the functor $F : \mathcal{E}_0 \to \mathcal{E}_1$ factors as a composition $\mathcal{E}_0 \xrightarrow{i_0} \mathcal{E} \xrightarrow{L} \mathcal{E}_1$ (Remark 6.2.3.3). Note that $L$ is a left adjoint to the inclusion $i_1 : \mathcal{E}_1 \hookrightarrow \mathcal{E}$ (Proposition 6.2.2.11).

Suppose that $U$ is also a cartesian fibration, so that the subcategory $\mathcal{E}_0 \subseteq \mathcal{E}$ is coreflective (Corollary 6.2.3.2). Let $L' : \mathcal{E} \to \mathcal{E}_0$ be a $\mathcal{E}_0$-coreflection functor (Corollary 6.2.3.2), so that $L'$ can be regarded as a right adjoint to $i_0$ (Proposition 6.2.2.11). Invoking Remark 6.2.1.8 we conclude that the composite functor $F = L \circ i_0$ has a right adjoint $G$, given by the composition $L' \circ i_1 = L'|_{\mathcal{E}_1}$. Moreover, Remark 6.2.3.3 guarantees that $G : \mathcal{E}_1 \to \mathcal{E}_0$ is given by contravariant transport along $e$.

We now prove the converse. Suppose that the functor $F : \mathcal{E}_0 \to \mathcal{E}_1$ admits a right adjoint $G : \mathcal{E}_1 \to \mathcal{E}_0$. Fix an object $Z \in \mathcal{E}_1$; we wish to show that there exists an object $Y \in \mathcal{E}_0$ and a $U$-cartesian morphism $f : Y \to Z$. Let $\epsilon : F \circ G \to \text{id}_{\mathcal{E}_1}$ be the counit of an adjunction.
between $F$ and $G$. Set $Y = G(Z)$, so that $\epsilon$ determines a morphism $\epsilon_Y : F(Y) \to Z$ in the $\infty$-category $\mathcal{E}_1$. Let $\eta : \text{id}_L \to L$ be a natural transformation which exhibits $L$ as a $\mathcal{E}_1$-reflection functor, so that $\eta$ determines a morphism $\eta_Y : Y \to F(Y)$. Let $f : Y \to Z$ be a composition of $\eta_Y$ with $\epsilon_Z$. We will complete the proof by showing that $f$ is $U$-cartesian. To prove this, it will suffice to show that for every object $X \in \mathcal{E}_0$, the composite map

$$\Hom_{\mathcal{E}_0}(X,Y) \xrightarrow{[\eta_Y]} \Hom_{\mathcal{E}}(X,F(Y)) = \Hom_{\mathcal{E}}(X,(F \circ G)(Z)) \xrightarrow{[\epsilon_Z]} \Map_{\mathcal{E}}(X,Z)$$

is an isomorphism in the homotopy category $\text{hKan}$ (see Corollary 5.1.2.3). Unwinding the definitions, we see that this map factors as a composition

$$\Hom_{\mathcal{E}_0}(X,G(Z)) \xrightarrow{F} \Hom_{\mathcal{E}_1}(F(X),(F \circ G)(Z)) \xrightarrow{[\eta_Z]} \Hom_{\mathcal{E}_1}(F(X),Z) \xrightarrow{\circ [\eta_Y]} \Hom_{\mathcal{E}}(X,Z),$$

where the composition of the first two maps is an isomorphism in $\text{hKan}$ because $\epsilon$ is the counit of an adjunction (see Proposition 6.2.1.17), and third is an isomorphism because $\eta_X$ exhibits $F(X)$ as a $\mathcal{E}_1$-reflection of $X$. 

\begin{proposition}
Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets. The following conditions are equivalent:

1. The morphism $U$ is a cartesian fibration of simplicial sets.

2. For every edge $e : C \to D$ of the simplicial set $\mathcal{C}$, the covariant transport functor $e_! : \mathcal{E}_C \to \mathcal{E}_D$ of Notation 5.2.2.9 admits a right adjoint.

Moreover, if these conditions are satisfied and $e : C \to D$ is an edge of $\mathcal{C}$, then the contravariant transport functor $e^* : \mathcal{E}_D \to \mathcal{E}_C$ of Notation 5.2.2.17 is right adjoint to $e_!$.

\end{proposition}

\begin{proof}
Assume first that condition (1) is satisfied and let $e : C \to D$ be an edge of the simplicial set $\mathcal{C}$, which we identify with a morphism $\Delta^1 \to \mathcal{C}$. Applying Proposition 6.2.3.4 to the projection map $\Delta^1 \times_{\mathcal{C}} \mathcal{E} \to \Delta^1$, we deduce that the covariant transport functor $e_! : \mathcal{E}_C \to \mathcal{E}_D$ is right adjoint to the contravariant transport functor $e^* \mathcal{E}_D \to \mathcal{E}_C$, which proves (2).

We now show that (2) implies (1). By virtue of Proposition 5.1.4.7, we may assume without loss of generality that $\mathcal{C} = \Delta^n$ is a standard simplex. For $0 \leq i \leq n$, let $\mathcal{E}_i$ denote the fiber $\{i\} \times_{\Delta^n} \mathcal{E}$, which we regard as a full subcategory of $\mathcal{E}$. We wish to show that, for every pair of integers $0 \leq j < k \leq n$ and every object $Z \in \mathcal{E}_k$, there exists an object $Y \in \mathcal{E}_j$ and a $U$-cartesian morphism $g : Y \to Z$ in $\mathcal{E}$. It follows from Proposition 6.2.3.5 that the projection map $N_*(\{j < k\}) \times_{\Delta^n} \mathcal{E} \to N_*(\{j < k\})$ is a cartesian fibration, we can choose an object $Y \in \mathcal{E}_j$ and a morphism $g : Y \to Z$ which is locally $U$-cartesian. We will complete the proof by showing that $g$ is $U$-cartesian. To prove this, we must show that for each integer $0 \leq i \leq j$ and each object $W \in \mathcal{E}_i$, composition with the homotopy class $[g]$
induces an isomorphism $\text{Hom}_E(W, Y) \xrightarrow{[g] \circ} \text{Hom}_E(W, Z)$ in the homotopy category of Kan complexes $\text{hKan}$ (see Corollary 5.1.2.3). Since $U$ is a cocartesian fibration, we can choose a $U$-cocartesian morphism $f : W \to X$, where $X$ belongs to $E_i$. We conclude by observing that there is a commutative diagram

$$
\begin{array}{ccc}
\text{Hom}_E(X, Y) & \xrightarrow{[g] \circ} & \text{Hom}_E(X, Z) \\
\sim & \circ[f] & \sim & \circ[f] \\
\text{Hom}_E(W, Y) & \xrightarrow{[g] \circ} & \text{Hom}_E(W, Z)
\end{array}
$$

in the homotopy category $\text{hKan}$, where the upper horizontal map is an isomorphism by virtue of our assumption that $g$ is locally $U$-cartesian, and the vertical maps are isomorphisms by virtue of our assumption that $f$ is $U$-cocartesian (Corollary 5.1.2.3).

### 6.2.4 Local Existence Criterion

Let $G : D \to C$ be a functor between categories. Suppose that $G$ admits a left adjoint $F : C \to D$. For each object $X \in C$, the value $F(X) \in D$ is determined, up to canonical isomorphism, by the property that it corepresents the functor $Z \mapsto \text{Hom}_D(X, G(Z))$: that is, there exists a bijection $\text{Hom}_D(Y, Z) \simeq \text{Hom}_C(X, G(Z))$ which depends functorially on $Z$. This observation has a converse: if, for every object $X \in C$, the functor

$$
D \to \text{Set} \quad Z \mapsto \text{Hom}_C(X, G(Z))
$$

is corepresentable by an object of $D$, then the functor $G$ admits a left adjoint $F : C \to D$ (Corollary 6.2.4.4). Our goal in this section is to establish a counterpart of this criterion in the $\infty$-categorical setting. We begin with a simple observation.

**Proposition 6.2.4.1.** Let $G : D \to C$ be a functor of $\infty$-categories. Then $G$ admits a left adjoint if and only if, for every object $X \in C$, the following condition is satisfied:

$$(\ast_X) \quad \text{There exists an object } Y \in D \text{ and a morphism } u : X \to G(Y) \in C \text{ such that, for every object } Z \in D, \text{ the composite map}

\begin{align*}
\text{Hom}_D(Y, Z) & \xrightarrow{G} \text{Hom}_C(G(Y), G(Z)) \\
& \xrightarrow{\circ[u]} \text{Hom}_C(X, G(Z))
\end{align*}

\text{is a homotopy equivalence of Kan complexes.}

**Proof.** We first prove necessity. Suppose that there exists a functor $F : C \to D$ and a natural transformation $\eta : \text{id}_C \to G \circ F$ which exhibits $F$ as a left adjoint of $G$. Fix an object $X \in C$
and set \( Y = F(X) \). Then \( \eta \) determines a morphism \( \eta_X : X \to G(Y) \) which satisfies the requirement of condition \((\ast_X)\) (Proposition 6.2.1.17).

We now prove sufficiency. Let \( \mathcal{E} \) denote the relative join \( \mathcal{C} \star \mathcal{D} \) and let \( U : \mathcal{E} \to \Delta^1 \) be the cartesian fibration of Proposition 5.2.3.15. Let us abuse notation by identifying the fibers \( \{0\} \times_{\Delta^1} \mathcal{E} \) and \( \{1\} \times_{\Delta^1} \mathcal{E} \) with \( \mathcal{C} \) and \( \mathcal{D} \), respectively. Fix an object \( X \in \mathcal{C} \), and suppose that there exists an object \( Y \in \mathcal{D} \) together with a morphism \( u : X \to G(Y) \) satisfying the requirement of condition \((\ast_X)\). Then we can identify \( u \) with a morphism \( f : X \to Y \) in the \( \infty \)-category \( \mathcal{E} \). Our assumption on \( u \) guarantees that the morphism \( f \) is \( U \)-cocartesian (see Corollary 5.1.2.3). Consequently, if condition \((\ast_X)\) is satisfied for every object \( X \in \mathcal{C} \), then \( U \) is a cocartesian fibration. Applying Proposition 6.2.3.4, we conclude that \( G \) admits a left adjoint. \( \square \)

**Corollary 6.2.4.2.** Let \( G : \mathcal{D} \to \mathcal{C} \) be a functor of \( \infty \)-categories. The following conditions are equivalent:

1. The functor \( G \) admits a left adjoint \( F : \mathcal{C} \to \mathcal{D} \).
2. For every left fibration \( \tilde{\mathcal{C}} \to \mathcal{C} \), if the \( \infty \)-category \( \tilde{\mathcal{C}} \) has an initial object, then the \( \infty \)-category \( \mathcal{D} \times_{\mathcal{C}} \tilde{\mathcal{C}} \) also has an initial object.
3. For every object \( X \in \mathcal{C} \), the \( \infty \)-category \( \mathcal{D} \times_{\mathcal{C}} \mathcal{C}_{X/} \) has an initial object.
4. For every corepresentable \( h \text{Kan} \)-enriched functor \( \lambda : h\mathcal{C} \to h \text{Kan} \), the composite functor
   \[
   h\mathcal{D} \xrightarrow{hG} h\mathcal{C} \xrightarrow{\lambda} h \text{Kan}
   \]
   is also corepresentable (in the sense of Definition 5.7.6.10).
5. For every corepresentable functor \( \lambda : \mathcal{C} \to \mathcal{S} \) of \( \infty \)-categories, the composite functor
   \[
   \mathcal{D} \xrightarrow{C} \mathcal{C} \xrightarrow{\lambda} \mathcal{S}
   \]
   is also corepresentable (in the sense of Definition 5.7.6.1).

**Proof.** The equivalence \((1) \iff (4)\) is a reformulation of Proposition 6.2.4.1. The implication \((2) \Rightarrow (3)\) is immediate. To see that \((3) \Rightarrow (4)\), observe that if \( \lambda : h\mathcal{C} \to h \text{Kan} \) is an \( h \text{Kan} \)-enriched functor which is corepresentable by an object \( X \in \mathcal{C} \), then \( \lambda \circ hG \) is isomorphic to the enriched homotopy transport representation of the left fibration \( \mathcal{D} \times_{\mathcal{C}} \mathcal{C}_{X/} \to \mathcal{D} \). If \( \mathcal{D} \times_{\mathcal{C}} \mathcal{C}_{X/} \) has an initial object, then this functor is corepresentable by virtue of Proposition 5.7.6.21.

The implication \((4) \Rightarrow (5)\) follows from Remark 5.7.6.11. We will complete the proof by showing that \((5) \Rightarrow (2)\). Let \( U : \tilde{\mathcal{C}} \to \mathcal{C} \) be a left fibration, and let \( \text{Tr}_{\tilde{\mathcal{C}}/\mathcal{C}} : \mathcal{C} \to \mathcal{S} \).
be a covariant transport representation for $U$ (see Definition 5.7.5.1). If $\overline{C}$ has an initial object, then the functor $\text{Tr}_{\overline{C}/C}$ is corepresentable (Proposition 5.7.6.21). Assumption (3) then guarantees that the functor $\text{Tr}_{\overline{C}/C} \circ G$ is also corepresentable. Identifying $\text{Tr}_{\overline{C}/C} \circ G$ with the covariant transport representation of the left fibration $D \times_{C} \overline{C} \to D$, we see that the $\infty$-category $D \times_{C} \overline{C}$ also has an initial object (Proposition 5.7.6.21).

Remark 6.2.4.3. Let $G : D \to C$ be a functor of $\infty$-categories which satisfies the equivalent conditions of Corollary 6.2.4.2, so that $G$ admits a left adjoint $F : C \to D$. For each object $X \in C$, the value $F(X) \in D$ admits several characterizations:

- The object $F(X)$ corepresents the $\text{hKan}$-enriched functor
  
  $$hD \xrightarrow{hG} hC \xrightarrow{\text{Hom}_{C}(X, \cdot)} h\text{Kan}.$$  

- The object $F(X)$ corepresents the functor of $\infty$-categories
  
  $$D \xrightarrow{G} C \xrightarrow{hX} S,$$

  where $hX$ is the functor corepresented by $X$.

- The object $F(X)$ is the image in $D$ of an initial object of the $\infty$-category $D \times_{C} \overline{C}/$.

Corollary 6.2.4.4. Let $G : D \to C$ be a functor between ordinary categories. The following conditions are equivalent:

(1) The functor $G$ admits a right adjoint $F : C \to D$.

(2) For every object $X \in C$, the set-valued functor

$$D \to \text{Set} \quad Z \mapsto \text{Hom}_{C}(X, G(Z))$$

is corepresentable.

Corollary 6.2.4.5. Let $F : C \to D$ and $G : D \to C$ be functors between $\infty$-categories, and let $\eta : \text{id}_{C} \to G \circ F$ be a natural transformation. The following conditions are equivalent:

(1) The natural transformation $\eta$ is the unit of an adjunction between $F$ and $G$.

(2) For every pair of objects $X \in C$ and $Y \in D$, the composite map

$$\text{Hom}_{D}(F(X), Y) \xrightarrow{G} \text{Hom}_{C}((G \circ F)(X), G(Y)) \xrightarrow{\eta_{X,Y}} \text{Hom}_{C}(X, G(Y))$$

is a homotopy equivalence of Kan complexes.
The functor $F$ admits a right adjoint. Moreover, for every pair of objects $X \in C$ and $Y \in D$, the composite map

\[ \text{Hom}_{hD}(F(X), U) \xrightarrow{G} \text{Hom}_{hC}((G \circ F)(X), G(Y)) \xrightarrow{\circ \eta_X} \text{Hom}_{hC}(X, G(Y)) \]

is a bijection.

Proof. The implication (1) $\Rightarrow$ (2) follows from Proposition 6.2.1.17; the implication (2) $\Rightarrow$ (3) follows from Proposition 6.2.4.1. We will complete the proof by showing that (3) $\Rightarrow$ (1). Note that, if condition (3) is satisfied, then the natural transformation $\eta$ exhibits $hG : hD \to hC$ as a right adjoint of the functor $hF : hC \to hD$ (see Variant 6.1.2.11). Invoking Proposition 6.2.1.14, we deduce that $\eta$ is the unit of an adjunction between $F$ and $G$. \qed

Corollary 6.2.4.6. Let $G : D \to C$ be a functor of $\infty$-categories and let $u : K \to D$ be a morphism of simplicial sets, so that $G$ induces a functor of coslice $\infty$-categories $G' : D/u \to C/_{(G\circ u)}$. If the functor $G$ admits a left adjoint, then the functor $G'$ also admits a left adjoint.

Proof. We will use the criterion of Corollary 6.2.4.2. Fix an object $X \in C/_{(G\circ u)}$; we wish to show that the $\infty$-category

\[ \mathcal{E} = D/u \times_{C/_{(G\circ u)}} (C/_{(G\circ u)})_{X/} \]

has an initial object. Let $X$ denote the image of $X$ in the $\infty$-category $C$. Unwinding the definitions, we can identify $X$ with a morphism of simplicial sets $\pi : K \to (D \times_C C_X)/\pi$, and $\mathcal{E}$ with the slice $\infty$-category $(D \times_C C_X)/\pi$. Since $G$ admits a left adjoint, the $\infty$-category $D \times_C C_X$ has an initial object (Corollary 6.2.4.2). Applying Corollary 7.1.3.20, we conclude that $\mathcal{E}$ also has an initial object. \qed

6.3 Localization

Let $C$ be a category and let $W$ be a collection of morphisms in $C$. One can then construct a new category by formally adjoining an inverse to each morphism of $W$.

Definition 6.3.0.1. Let $F : C \to D$ be a functor between categories and let $W$ be a collection of morphisms of $C$. We say that $F$ exhibits $D$ as a strict localization of $C$ with respect to $W$ if, for every category $\mathcal{E}$, precomposition with $F$ induces a bijection

\[ \{\text{Functors } D \to \mathcal{E}\} \]

\[ \{\text{Functors } C \to \mathcal{E} \text{ carrying each } w \in W \text{ to an isomorphism in } \mathcal{E}\}. \]
Remark 6.3.0.2 (Existence and Uniqueness). Let $C$ be a category and let $W$ be a collection of morphisms in $C$. Then there exists a category $W^{-1}C$ and a functor $F : C \to W^{-1}C$ which exhibits $W^{-1}C$ as a strict localization of $C$ with respect to $W$. Moreover, the category $W^{-1}C$ is determined uniquely up to isomorphism. In what follows, we will sometimes abuse terminology by referring to $W^{-1}C$ as the strict localization of $C$ with respect to $W$. Explicitly, the category $W^{-1}C$ can be constructed from $C$ by adjoining a new morphism $w^{-1} : Y \to X$ for each morphism $w : X \to Y$ of $W$, and imposing the relations $w^{-1} \circ w = \text{id}_X$ and $w \circ w^{-1} = \text{id}_Y$. From this description, we see that the functor $F$ induces a bijection $\text{Ob}(C) \simeq \text{Ob}(W^{-1}C)$.

Example 6.3.0.3. Let Kan denote the category of Kan complexes and let $h\text{Kan}$ denote the homotopy category of Kan complexes (Construction 3.1.5.10). Then the quotient functor $\text{Kan} \to h\text{Kan}$ exhibits $h\text{Kan}$ as a strict localization of $\text{Kan}$ with respect to the collection of all homotopy equivalences (see Corollary 3.1.7.6).

Warning 6.3.0.4. Let $C$ be a category and let $W$ be a collection of morphisms of $C$. If $C$ is small, then the strict localization $W^{-1}C$ is also small. Beware that if $C$ is only assumed to be locally small (Definition [?]), then $W^{-1}C$ need not be locally small. However, one can often ensure that $W^{-1}C$ is small by imposing additional assumptions on the collection of morphisms $W$.

Remark 6.3.0.5. Let $C$ be a category, let $W$ be a collection of morphisms of $C$, and let $F : C \to W^{-1}C$ be a functor which exhibits $W^{-1}C$ as a strict localization of $C$ with respect to $W$. Then, for every category $\mathcal{E}$, the precomposition functor $\text{Fun}(W^{-1}C, \mathcal{E}) \to \text{Fun}(C, \mathcal{E})$ induces an isomorphism from $\text{Fun}(W^{-1}C, \mathcal{E})$ to the full subcategory of $\text{Fun}(C, \mathcal{E})$ spanned by those functors $C \to \mathcal{E}$ which carry each element $w \in W$ to an isomorphism in $\mathcal{E}$. Bijectivity at the level of objects follows immediately from the definition. At the level of morphisms, it follows from the bijectivity of the map

$$\{\text{Functors } W^{-1}C \to \text{Fun}([1], \mathcal{E})\}$$

$$\to$$

$$\{\text{Functors } C \to \text{Fun}([1], \mathcal{E}) \text{ carrying } W \text{ to isomorphisms}\}.$$
6.3. LOCALIZATION

\textbf{Definition 6.3.0.6.} Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor between categories and let \( W \) be a collection of morphisms of \( \mathcal{C} \). We will say that \( F \) \textit{exhibits} \( \mathcal{D} \) \textit{as a 1-categorical localization of} \( \mathcal{C} \) \textit{with respect to} \( W \) if, for every category \( \mathcal{E} \), precomposition with \( F \) induces a fully faithful functor \( \text{Fun}(\mathcal{D}, \mathcal{E}) \to \text{Fun}(\mathcal{C}, \mathcal{E}) \) whose essential image consists of those functors \( \mathcal{C} \to \mathcal{E} \) which carry each \( w \in W \) to an isomorphism in \( \mathcal{E} \).

\textbf{Example 6.3.0.7.} Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor between categories. If \( F \) exhibits \( \mathcal{D} \) as a \textit{strict localization} of \( \mathcal{C} \) with respect to \( W \), then \( F \) exhibits \( \mathcal{D} \) as a 1-categorical localization of \( \mathcal{C} \) with respect to \( W \) (see Remark 6.3.0.5). The converse is false (except in the trivial case where \( \mathcal{C} \) is empty).

\textbf{Example 6.3.0.8.} Let \( \text{Set}_\Delta \) denote the category of simplicial sets, and let \( \text{hKan} \) denote the homotopy category of Kan complexes (Construction 3.1.5.10). Then the fibrant replacement functor \( \text{Ex}^\infty : \text{Set}_\Delta \to \text{hKan} \) exhibits \( \text{hKan} \) as a 1-categorical localization of \( \text{Set}_\Delta \) with respect to the collection \( W \) of weak homotopy equivalences (see Variant 3.1.7.7). However, it does not exhibit \( \text{hKan} \) as a strict localization of \( \text{Set}_\Delta \) with respect to \( W \) (since it is not bijective on objects).

\textbf{Remark 6.3.0.9.} Let \( \mathcal{C} \) be a category, let \( W \) be a collection of morphisms in \( \mathcal{C} \), and let \( F : \mathcal{C} \to \mathcal{W}^{-1}\mathcal{C} \) be a functor which exhibits \( \mathcal{W}^{-1}\mathcal{C} \) as a strict localization of \( \mathcal{C} \) with respect to \( W \). Let \( G : \mathcal{C} \to \mathcal{D} \) be another functor. Then \( G \) exhibits \( \mathcal{D} \) as a 1-categorical localization of \( \mathcal{C} \) with respect to \( W \) if and only if the following conditions are satisfied:

- The functor \( G \) carries each \( w \in W \) to an isomorphism in \( \mathcal{D} \), and therefore factors uniquely as a composition \( \mathcal{C} \xrightarrow{F} \mathcal{W}^{-1}\mathcal{C} \xrightarrow{G'} \mathcal{D} \).
- The functor \( G' : \mathcal{W}^{-1}\mathcal{C} \to \mathcal{D} \) is an equivalence of categories.

Our goal in this section is to adapt the notion of localization to the setting of \( \infty \)-categories. We begin in §6.3.1 by introducing an \( \infty \)-categorical counterpart of Definition 6.3.0.6. Given an \( \infty \)-category \( \mathcal{C} \) and a collection \( W \) of morphisms of \( \mathcal{C} \), we say that a functor of \( \infty \)-categories \( F : \mathcal{C} \to \mathcal{D} \) \textit{exhibits} \( \mathcal{D} \) \textit{as a localization of} \( \mathcal{C} \) \textit{with respect to} \( W \) if, for every \( \infty \)-category \( \mathcal{E} \), precomposition with \( F \) induces a fully faithful functor of \( \infty \)-categories \( \text{Fun}(\mathcal{D}, \mathcal{E}) \to \text{Fun}(\mathcal{C}, \mathcal{E}) \) whose essential image consists of those functors which carry each element of \( W \) to an isomorphism in \( \mathcal{E} \) (Definition 6.3.1.9). In §6.3.2 we show that such a localization always exists (Proposition 6.3.2.1) and is uniquely determined up to equivalence (Remark 6.3.2.2); we will often emphasize this uniqueness by denoting the \( \infty \)-category \( \mathcal{D} \) by \( \mathcal{C}[W^{-1}] \).

Let \( \mathcal{C} \) be an ordinary category, and let \( W \) be a collection of morphisms of \( \mathcal{C} \). Then \( W \) can also be regarded as a collection of morphisms of the \( \infty \)-category \( \text{N}_\bullet(\mathcal{C}) \). By virtue of Proposition 6.3.2.1 there exists a functor of \( \infty \)-categories \( F : \text{N}_\bullet(\mathcal{C}) \to \mathcal{D} \) which exhibits
$\mathcal{D}$ as a localization of $N_\bullet(\mathcal{C})$ with respect to $W$. In this case, it is not hard to see that the induced map $\mathcal{C} \simeq hN_\bullet(\mathcal{C}) \xrightarrow{hF} h\mathcal{D}$ exhibits the homotopy category $h\mathcal{D}$ as a 1-categorical localization of $\mathcal{C}$ with respect to $W$, in the sense of Definition 6.3.0.6 (Example 6.3.1.18). Beware that, in this situation, the unit map $\mathcal{D} \to N_\bullet(h\mathcal{D})$ is generally not an equivalence. In other words, the formation of localizations (in the $\infty$-categorical setting) generally does not carry ordinary categories to ordinary categories, even up to equivalence. In fact, we prove in §6.3.7 that every $\infty$-category $\mathcal{D}$ can be obtained by localizing (the nerve of) a partially ordered set (Theorem 6.3.7.1). The proof will make use of some basic stability properties for the class of localizations, which we establish in §6.3.4.

In general, it is very difficult to give an explicit description of the localization of an $\infty$-category $\mathcal{C}$ with respect to a class of morphisms $W$. In §6.3.5, we study a special case in which such a description is available. We will say that a localization functor $F : \mathcal{C} \to \mathcal{C}[W^{-1}]$ is reflective if it admits a right adjoint. In this case, the right adjoint $G : \mathcal{C}[W^{-1}] \to \mathcal{C}$ is automatically fully faithful, and its essential image is a reflective subcategory $\mathcal{C}' \subseteq \mathcal{C}$ (Proposition 6.3.3.13). In this case, we can identify $\mathcal{C}[W^{-1}]$ with $\mathcal{C}'$, which can be characterized as the full subcategory of $\mathcal{C}$ spanned by the $W$-local objects (Definition 6.3.3.1). Reflective localizations are extremely common in practice, and will play a central role in the theory of locally presentable $\infty$-categories which we develop in §6.3.4.

**Warning 6.3.0.10.** It also is possible to contemplate a version of Definition 6.3.0.1 in the $\infty$-categorical setting. Let $\mathcal{C}$ be an $\infty$-category and let $W$ be a collection of morphisms of $\mathcal{C}$. Let us say that a functor of $\infty$-categories $F : \mathcal{C} \to \mathcal{D}$ exhibits $\mathcal{D}$ as a strict localization of $\mathcal{C}$ with respect to $W$ if, for every $\infty$-category $\mathcal{E}$, precomposition with $F$ induces a bijection

$$\{\text{Functors } \mathcal{D} \to \mathcal{E}\} \quad \text{versus} \quad \{\text{Functors } \mathcal{C} \to \mathcal{E} \text{ carrying each } w \in W \text{ to an isomorphism in } \mathcal{E}\}$$

However, this definition is useless. One can show that an $\infty$-category $\mathcal{C}$ admits a strict localization with respect to $W$ only in the trivial case where every element of $W$ is already an isomorphism in $\mathcal{C}$ (in which case we can take $F$ to be the identity functor $\text{id}_\mathcal{C} : \mathcal{C} \to \mathcal{C}$). Roughly speaking, the problem is that if $w : X \to Y$ is an isomorphism in an $\infty$-category $\mathcal{C}$, then the homotopy inverse isomorphism $w^{-1} : Y \to X$ is only well-defined up to homotopy (or up to a contractible space of choices), in contrast with classical category theory where the inverse isomorphism $w^{-1}$ is unique.

### 6.3.1 Localizations of $\infty$-Categories
We begin by introducing some terminology.

**Notation 6.3.1.1.** Let $C$ be a simplicial set, let $W$ be a collection of edges of $C$, and let $\mathcal{E}$ be an $\infty$-category. We let $\text{Fun}(C[W^{-1}], \mathcal{E})$ denote the full subcategory of $\text{Fun}(C, \mathcal{E})$ spanned by those morphisms $F : C \to \mathcal{E}$ that carry each edge of $W$ to an isomorphism in $\mathcal{E}$.

**Remark 6.3.1.2.** In the context of Notation 6.3.1.1, we will usually be interested in the situation where the simplicial set $C$ is an $\infty$-category (as suggested by the notation). However, it will be technically convenient to allow more general simplicial sets as well.

**Example 6.3.1.3.** Let $C$ be a simplicial set and let $W$ be a collection of degenerate edges of $C$. Then, for every $\infty$-category $\mathcal{E}$, we have $\text{Fun}(C[W^{-1}], \mathcal{E}) = \text{Fun}(C, \mathcal{E})$.

**Example 6.3.1.4.** Let $C$ be a simplicial set and let $W$ be a collection of edges of $C$. If $\mathcal{E}$ is a Kan complex, then $\text{Fun}(C[W^{-1}], \mathcal{E}) = \text{Fun}(C, \mathcal{E})$ (see Proposition 1.3.6.10).

**Example 6.3.1.5.** Let $W = \{\text{id}_{\Delta^1}\}$ consist of the single nondegenerate edge of the standard 1-simplex $\Delta^1$. For every $\infty$-category $\mathcal{E}$, $\text{Fun}(\Delta^1[W^{-1}], \mathcal{E})$ is the full subcategory $\text{Isom}(\mathcal{E}) \subseteq \text{Fun}(\Delta^1, \mathcal{E})$ spanned by the isomorphisms in $\mathcal{E}$ (Example 4.4.1.13).

**Example 6.3.1.6.** Let $C$ be a simplicial set and let $hC$ denote its homotopy category (Definition 1.2.5.1). Let $W$ be a collection of edges of $C$, let $[W]$ denote the collection of morphisms in $hC$ which belong to the image of $W$, and let $F : hC \to D$ be a functor of ordinary categories which exhibits $D$ as a strict localization of $hC$ with respect to $[W]$ (Definition 6.3.0.1). If $\mathcal{E}$ is an ordinary category, then we have a canonical isomorphism of simplicial sets

$$\text{Fun}(C[W^{-1}], N_\bullet(\mathcal{E})) \simeq N_\bullet(\text{Fun}(D, \mathcal{E})).$$

**Remark 6.3.1.7.** Let $C$ and $D$ be simplicial sets and let $W$ be a collection of edges of $C$. For every $\infty$-category $\mathcal{E}$, the canonical isomorphism $\text{Fun}(C, \text{Fun}(D, \mathcal{E})) \simeq \text{Fun}(D, \text{Fun}(C, \mathcal{E}))$ restricts to an isomorphism of full subcategories

$$\text{Fun}(C[W^{-1}], \text{Fun}(D, \mathcal{E})) \simeq \text{Fun}(D, \text{Fun}(C[W^{-1}], \mathcal{E})).$$

This follows immediately from the criterion of Theorem 4.4.4.4.

**Remark 6.3.1.8.** Let $C$ be a simplicial set, let $W$ be a collection of edges of $C$, and let $\mathcal{E}$ be an $\infty$-category. Then the full subcategory $\text{Fun}(C[W^{-1}], \mathcal{E}) \subseteq \text{Fun}(C, \mathcal{E})$ is replete. That is, if $F, F' : C \to \mathcal{E}$ are isomorphic objects of $\text{Fun}(C, \mathcal{E})$, then $F$ carries edges of $W$ to isomorphisms in $\mathcal{E}$ if and only if $F'$ carries edges of $W$ to isomorphisms in $\mathcal{E}$ (see Example 4.4.1.13).
**Definition 6.3.1.9.** Let \( F : \mathcal{C} \to \mathcal{D} \) be a morphism of simplicial sets and let \( W \) be a collection of edges of \( \mathcal{C} \). We say that \( F \) exhibits \( \mathcal{D} \) as a localization of \( \mathcal{C} \) with respect to \( W \) if, for every \( \infty \)-category \( \mathcal{E} \), the precomposition map \( \operatorname{Fun}(\mathcal{D}, \mathcal{E}) \overset{\circ F}{\longrightarrow} \operatorname{Fun}(\mathcal{C}, \mathcal{E}) \) is fully faithful, and its essential image is the full subcategory \( \operatorname{Fun}(\mathcal{C}[W^{-1}], \mathcal{E}) \subseteq \operatorname{Fun}(\mathcal{C}, \mathcal{E}) \).

**Remark 6.3.1.10.** Let \( F : \mathcal{C} \to \mathcal{D} \) be a morphism of simplicial sets. If \( F \) exhibits \( \mathcal{D} \) as a localization of \( \mathcal{C} \) with respect to a collection of edges \( W \), then, for every \( \infty \)-category \( \mathcal{E} \) and every morphism \( G : \mathcal{D} \to \mathcal{E} \), the composite map \( (G \circ F) : \mathcal{C} \to \mathcal{E} \) carries each element of \( W \) to an isomorphism in \( \mathcal{E} \). In particular, if \( \mathcal{D} \) itself is an \( \infty \)-category, then \( F \) carries each element of \( W \) to an isomorphism in \( \mathcal{D} \).

**Exercise 6.3.1.11.** Let \( \mathcal{C} \) be a simplicial set, let \( W \) be a collection of edges of \( \mathcal{C} \), and let \( F, F' : \mathcal{C} \to \mathcal{D} \) be a pair of diagrams taking values in an \( \infty \)-category \( \mathcal{D} \). Suppose that \( F \) and \( F' \) are isomorphic when viewed as objects of the \( \infty \)-category \( \operatorname{Fun}(\mathcal{C}, \mathcal{D}) \). Show that \( F \) exhibits \( \mathcal{D} \) as a localization of \( \mathcal{C} \) with respect to \( W \) if and only if \( F' \) exhibits \( \mathcal{D} \) as a localization of \( \mathcal{C} \) with respect to \( W \).

**Example 6.3.1.12.** Let \( F : \mathcal{C} \to \mathcal{D} \) be a morphism of simplicial sets and let \( W \) be a collection of degenerate edges of \( \mathcal{C} \). Then \( F \) exhibits \( \mathcal{D} \) as a localization of \( \mathcal{C} \) with respect to \( W \) if and only if it is a categorical equivalence of simplicial sets (see Proposition 4.5.3.8).

**Proposition 6.3.1.13.** Let \( F : \mathcal{C} \to \mathcal{D} \) be a morphism of simplicial sets and let \( W \) be a collection of edges of \( \mathcal{C} \). The following conditions are equivalent:

1. The morphism \( F \) exhibits \( \mathcal{D} \) as a localization of \( \mathcal{C} \) with respect to \( W \) (Definition 6.3.1.9).

2. For every \( \infty \)-category \( \mathcal{E} \), the functor \( \operatorname{Fun}(\mathcal{D}, \mathcal{E}) \overset{\circ F}{\longrightarrow} \operatorname{Fun}(\mathcal{C}, \mathcal{E}) \) factors through the full subcategory \( \operatorname{Fun}(\mathcal{C}[W^{-1}], \mathcal{E}) \) and induces an equivalence of \( \infty \)-categories \( \operatorname{Fun}(\mathcal{D}, \mathcal{E}) \to \operatorname{Fun}(\mathcal{C}[W^{-1}], \mathcal{E}) \).

3. For every \( \infty \)-category \( \mathcal{E} \), the functor \( \operatorname{Fun}(\mathcal{D}, \mathcal{E}) \overset{\circ F}{\longrightarrow} \operatorname{Fun}(\mathcal{C}, \mathcal{E}) \) factors through the full subcategory \( \operatorname{Fun}(\mathcal{C}[W^{-1}], \mathcal{E}) \) and induces a homotopy equivalence of Kan complexes \( \operatorname{Fun}(\mathcal{D}, \mathcal{E})^\simeq \to \operatorname{Fun}(\mathcal{C}[W^{-1}], \mathcal{E})^\simeq \).

4. For every \( \infty \)-category \( \mathcal{E} \), the functor \( \operatorname{Fun}(\mathcal{D}, \mathcal{E}) \overset{\circ F}{\longrightarrow} \operatorname{Fun}(\mathcal{C}, \mathcal{E}) \) factors through the full subcategory \( \operatorname{Fun}(\mathcal{C}[W^{-1}], \mathcal{E}) \) and induces a bijection of sets \( \pi_0(\operatorname{Fun}(\mathcal{D}, \mathcal{E})^\simeq) \to \pi_0(\operatorname{Fun}(\mathcal{C}[W^{-1}], \mathcal{E})^\simeq) \).

**Proof.** The equivalence (1) \( \iff \) (2) follows from Corollary 4.6.2.19 (and the repleteness of the full subcategory \( \operatorname{Fun}(\mathcal{C}[W^{-1}], \mathcal{E}) \subseteq \operatorname{Fun}(\mathcal{C}, \mathcal{E}) \)). The implication (2) \( \implies \) (3) follows from Remark 4.5.1.19 and the implication (3) \( \implies \) (4) from Remark 3.1.6.5. We will complete the proof by showing that (4) \( \implies \) (2). Assume that \( F : \mathcal{C} \to \mathcal{D} \) satisfies condition (4), and
let $\mathcal{E}$ be an $\infty$-category; we wish to show that the precomposition functor $\text{Fun}(\mathcal{D}, \mathcal{E}) \xrightarrow{\circ F} \text{Fun}(\mathcal{C}[W^{-1}], \mathcal{E})$ is an equivalence of $\infty$-categories. For this, it will suffice to show that for every simplicial set $\mathcal{B}$, the induced map

$$\theta : \pi_0(\text{Fun}(\mathcal{B}, \text{Fun}(\mathcal{D}, \mathcal{E}))^\simeq) \rightarrow \pi_0(\text{Fun}(\mathcal{B}, \text{Fun}(\mathcal{C}[W^{-1}], \mathcal{E}))^\simeq)$$

is a bijection. Using Remark 6.3.1.7, we can identify $\theta$ with the map

$$\pi_0(\text{Fun}(\mathcal{D}, \text{Fun}(\mathcal{B}, \mathcal{E}))^\simeq) \rightarrow \pi_0(\text{Fun}(\mathcal{C}[W^{-1}], \text{Fun}(\mathcal{B}, \mathcal{E}))^\simeq),$$

which is bijective by virtue of assumption (4).

\[\square\]

**Example 6.3.1.14.** Let $W = \{\text{id}_{\Delta^1}\}$ consist of the single nondegenerate edge of the standard 1-simplex $\Delta^1$. Then the projection map $\Delta^1 \rightarrow \Delta^0$ exhibits $\Delta^0$ as a localization of $\Delta^1$ with respect to $W$. To prove this, it will suffice to show that for every $\infty$-category $\mathcal{E}$, the construction $X \mapsto \text{id}_X$ induces an equivalence of $\infty$-categories $\mathcal{E} = \text{Fun}(\Delta^0, \mathcal{E}) \rightarrow \text{Fun}(\Delta^1[W^{-1}], \mathcal{E}) = \text{Isom}(\mathcal{E})$, which follows from Corollary 4.5.3.13.

**Remark 6.3.1.15.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a morphism of simplicial sets which exhibits $\mathcal{D}$ as a localization of $\mathcal{C}$ with respect to a collection of edges $W$, and let $U : \mathcal{E} \rightarrow \mathcal{E}$ be an isofibration of $\infty$-categories. Then, for every diagram $\mathcal{D} \rightarrow \mathcal{E}$, precomposition with $F$ induces a fully faithful functor

$$\text{Fun}_{/\mathcal{E}}(\mathcal{D}, \mathcal{E}) \rightarrow \text{Fun}_{/\mathcal{E}}(\mathcal{C}, \mathcal{E}),$$

whose essential image is spanned by those functors $G : \mathcal{C} \rightarrow \mathcal{E}$ which carry each edge of $W$ to an isomorphism in the $\infty$-category $\mathcal{E}$. This follows by applying Corollary 4.5.2.26 to the diagram

$$\begin{array}{ccc}
\text{Fun}(\mathcal{D}, \mathcal{E}) & \xrightarrow{\circ F} & \text{Fun}(\mathcal{C}[W^{-1}], \mathcal{E}) \\
U \downarrow & & \downarrow \\
\text{Fun}(\mathcal{D}, \mathcal{E}) & \xrightarrow{} & \text{Fun}(\mathcal{C}[W^{-1}], \mathcal{E}).
\end{array}$$

**Remark 6.3.1.16.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a morphism of simplicial sets which exhibits $\mathcal{D}$ as a localization of $\mathcal{C}$ with respect to a collection of edges $W$. Then, for every Kan complex $\mathcal{E}$, precomposition with $F$ induces a homotopy equivalence of Kan complexes

$$\text{Fun}(\mathcal{D}, \mathcal{E}) \xrightarrow{\circ F} \text{Fun}(\mathcal{C}[W^{-1}], \mathcal{E}) = \text{Fun}(\mathcal{C}, \mathcal{E})$$

(see Example 6.3.1.4). It follows that $F$ is a weak homotopy equivalence of simplicial sets.
Remark 6.3.1.17. Let $F : \mathcal{C} \to \mathcal{D}$ be a morphism of simplicial sets which exhibits $\mathcal{D}$ as a localization of $\mathcal{C}$ with respect to a collection of edges $W$. Let $[W]$ denote the collection of morphisms in the homotopy category $\text{h}\mathcal{C}$ which belong to the image of $W$. Then the induced functor $\text{h}F : \text{h}\mathcal{C} \to \text{h}\mathcal{D}$ exhibits the homotopy category $\text{h}\mathcal{D}$ as a 1-categorical localization of $\text{h}\mathcal{C}$ with respect to $[W]$, in the sense of Definition 6.3.0.6. This follows immediately from Example 6.3.1.6.

Example 6.3.1.18. Let $\mathcal{C}$ be an ordinary category and let $W$ be a collection of morphisms of $\mathcal{C}$, which we identify with edges of the simplicial set $\text{N}_\bullet(\mathcal{C})$. Let $F : \text{N}_\bullet(\mathcal{C}) \to \mathcal{D}$ be a morphism of simplicial sets which exhibits $\mathcal{D}$ as a localization of $\text{N}_\bullet(\mathcal{C})$ with respect to $W$. Then the induced functor $\mathcal{C} \simeq \text{hN}_\bullet(\mathcal{C}) \xrightarrow{\text{h}F} \text{h}\mathcal{D}$ exhibits the homotopy category $\text{h}\mathcal{D}$ as a 1-categorical localization of $\mathcal{C}$ with respect to $W$, in the sense of Definition 6.3.0.6.

Remark 6.3.1.19. Let $F : \mathcal{C} \to \mathcal{D}$ and $G : \mathcal{D} \to \mathcal{E}$ be morphisms of simplicial sets, and let $W$ be a collection of edges of $\mathcal{C}$. If any two of the following three conditions is satisfied, then so is the third:

- The morphism $F$ exhibits $\mathcal{D}$ as a localization of $\mathcal{C}$ with respect to $W$.
- The morphism $G \circ F$ exhibits $\mathcal{E}$ as a localization of $\mathcal{C}$ with respect to $W$.
- The morphism $G$ is a categorical equivalence of simplicial sets.

Proposition 6.3.1.20. Let $F : \mathcal{C} \to \mathcal{D}$ be a morphism of simplicial sets, where $\mathcal{D}$ is an $\infty$-category, and let $W$ be the collection of all edges of $\mathcal{C}$. The following conditions are equivalent:

1. The morphism $F$ exhibits $\mathcal{D}$ as a localization of $\mathcal{C}$ with respect to $W$.
2. The $\infty$-category $\mathcal{D}$ is a Kan complex and $F$ is a weak homotopy equivalence of simplicial sets.

Proof. We first prove that (2) implies (1). Assume that $\mathcal{D}$ is a Kan complex and that $F : \mathcal{C} \to \mathcal{D}$ is a weak homotopy equivalence; we wish to show that $F$ exhibits $\mathcal{D}$ as a localization of $\mathcal{C}$ with respect to $W$. By virtue of Proposition 6.3.1.13, it will suffice to show that for every $\infty$-category $\mathcal{E}$, composition with $F$ induces a homotopy equivalence of Kan complexes $\theta : \text{Fun}(\mathcal{D}, \mathcal{E})^\simeq \to \text{Fun}(\mathcal{C}[W^{-1}], \mathcal{E})^\simeq$. Since $\mathcal{D}$ is a Kan complex, Proposition 4.4.3.20 allows us to identify $\theta$ with the canonical map

$$\text{Fun}(\mathcal{D}, \mathcal{E})^\simeq \xrightarrow{\circ F} \text{Fun}(\mathcal{C}, \mathcal{E})^\simeq,$$

which is a homotopy equivalence by virtue of our assumption that $F$ is a weak homotopy equivalence.
We now show that (1) implies (2). Assume that $F$ exhibits $D$ as a localization of $C$ with respect to $W$. Invoking Remark 6.3.1.16, we deduce that $F$ is a weak homotopy equivalence. We wish to show that $D$ is a Kan complex. Choose a weak homotopy equivalence $G : D \rightarrow E$, where $E$ is a Kan complex (Corollary 3.1.7.2). Then the composite map $(G \circ F) : C \rightarrow E$ is also a weak homotopy equivalence (Remark 3.1.6.16). Invoking the implication $(2) \Rightarrow (1)$, we conclude that $G \circ F$ exhibits $E$ as a localization of $C$ with respect to $W$. It follows from Remark 6.3.1.19 that $G$ is an equivalence of $\infty$-categories. Since $E$ is a Kan complex, it follows that the $\infty$-category $D$ is also a Kan complex (Remark 4.5.1.21).

**Proposition 6.3.1.21** (Transitivity). Let $F : C \rightarrow C'$ and $F' : C' \rightarrow C''$ be morphisms of simplicial sets. Let $W$ and $W'$ be collections of edges of $C$ satisfying the following conditions:

- The morphism $F$ exhibits $C'$ as a localization of $C$ with respect to $W$.
- The morphism $F'$ exhibits $C''$ as a localization of $C'$ with respect to $F(W')$.

Then the composite morphism $(F' \circ F) : C \rightarrow C''$ exhibits $C''$ as a localization of $C$ with respect to $W \cup W'$.

**Proof.** Let $E$ be an $\infty$-category; we wish to prove that precomposition with $F' \circ F$ induces an equivalence from $\text{Fun}(C'', E)$ to the full subcategory $\text{Fun}(C[(W \cup W')^{-1}], E) \subseteq \text{Fun}(C, E)$.

We have a commutative diagram

$$
\begin{array}{ccc}
\text{Fun}(C'', E) & \xrightarrow{\circ F} & \text{Fun}(C'[F(W')^{-1}], E) \\
\downarrow & & \downarrow \\
\text{Fun}(C', E) & \xrightarrow{\circ F'} & \text{Fun}(C[W^{-1}], E)
\end{array}
$$

where the horizontal functors on the left and lower right are equivalences of $\infty$-categories. Since the square is a pullback and the vertical maps are isofibrations (Remark 6.3.1.8), it follows that the horizontal map on the upper right is also an equivalence of $\infty$-categories (Corollary 4.5.2.23).

**Corollary 6.3.1.22.** Let $C$ be a simplicial set, let $W$ and $W'$ be collections of edges of $C$, and let $F : C \rightarrow D$ be a morphism of simplicial sets which exhibits $D$ as a localization of $C$ with respect to $W$. Suppose that, for every edge $w \in W'$, the image $F(w)$ is a degenerate edge of $D$. Then $F$ also exhibits $D$ as a localization of $C$ with respect to $W \cup W'$.

**Proof.** Combine Proposition 6.3.1.21 with Example 6.3.1.12.
6.3.2 Existence of Localizations

Our goal in this section is to prove the following:

**Proposition 6.3.2.1 (Existence of Localizations).** Let $\mathcal{C}$ be a simplicial set and let $W$ be a collection of edges of $\mathcal{C}$. Then there exists an $\infty$-category $\mathcal{D}$ and a morphism of simplicial sets $F : \mathcal{C} \to \mathcal{D}$ which exhibits $\mathcal{D}$ as a localization of $\mathcal{C}$ with respect to $W$.

**Remark 6.3.2.2 (Uniqueness of Localizations).** Let $\mathcal{C}$ be a simplicial set and let $W$ be a collection of edges of $\mathcal{C}$. Proposition 6.3.2.1 asserts that there exists an $\infty$-category $\mathcal{D}$ and a morphism $F : \mathcal{C} \to \mathcal{D}$ which exhibits $\mathcal{D}$ as a localization of $\mathcal{C}$ with respect to $W$. In this case, for every $\infty$-category $\mathcal{E}$, composition with $F$ induces a bijection

$$\text{Hom}_{\operatorname{hCat}_\infty}(\mathcal{D}, \mathcal{E}) = \pi_0(\text{Fun}(\mathcal{D}, \mathcal{E})) \to \pi_0(\text{Fun}(\mathcal{C}[-1], \mathcal{E}))$$

(Proposition 6.3.1.13). In other words, the $\infty$-category $\mathcal{D}$ corepresents the functor

$$\text{hCat}_\infty \to \text{Set} \quad \mathcal{E} \mapsto \pi_0(\text{Fun}(\mathcal{C}[-1], \mathcal{E}))$$

It follows that $\mathcal{D}$ is uniquely determined (up to canonical isomorphism) as an object of the homotopy category $\text{hCat}_\infty$. We will sometimes emphasize this uniqueness by referring to $\mathcal{D}$ as the localization of $\mathcal{C}$ with respect to $W$, and denoting it by $\mathcal{C}[-1]$. Beware that the localization $\mathcal{C}[-1]$ is not well-defined up to isomorphism as a simplicial set: in fact, any equivalent $\infty$-category can also be regarded as a localization of $\mathcal{C}$ with respect to $W$ (Remark 6.3.1.19).

**Warning 6.3.2.3.** Let $\mathcal{C}$ be a simplicial set, let $W$ be a collection of edges of $\mathcal{C}$, and let $\mathcal{E}$ be an $\infty$-category. We have now given two different definitions for the $\infty$-category $\text{Fun}(\mathcal{C}[-1], \mathcal{E})$:

1. According to Notation 6.3.1, $\text{Fun}(\mathcal{C}[-1], \mathcal{E})$ denotes the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{E})$ spanned by those diagrams $F : \mathcal{C} \to \mathcal{E}$ which carry each edge of $W$ to an isomorphism in $\mathcal{E}$.

2. By the convention of Remark 6.3.2.2, $\mathcal{C}[-1]$ denotes an $\infty$-category equipped with a diagram $F : \mathcal{C} \to \mathcal{C}[-1]$ which exhibits $\mathcal{C}[-1]$ as a localization of $\mathcal{C}$ with respect to $W$. We can then consider the $\infty$-category of functors from $\mathcal{C}[-1]$ to $\mathcal{E}$, which we will temporarily denote by $\text{Fun}'(\mathcal{C}[-1], \mathcal{E})$. Beware that these $\infty$-categories are not identical. However, they are equivalent: if $F : \mathcal{C} \to \mathcal{C}[-1]$ exhibits $\mathcal{C}[-1]$ as a localization of $\mathcal{C}$ with respect to $W$, then composition with $F$ induces an equivalence of $\infty$-categories $\text{Fun}(\mathcal{C}[-1], \mathcal{E}) \to \text{Fun}'(\mathcal{C}[-1], \mathcal{E})$ (Proposition 6.3.1.13). Note that the $\infty$-category $\text{Fun}(\mathcal{C}[-1], \mathcal{E})$ does not depend on any auxiliary
choices: it is well-defined up to equality as a simplicial subset of \( \text{Fun}(\mathcal{C}, \mathcal{E}) \). By contrast, the \( \infty \)-category \( \text{Fun}'(\mathcal{C}[W^{-1}], \mathcal{E}) \) depends on the choice of the functor \( F : \mathcal{C} \to \mathcal{C}[W^{-1}] \) (and is therefore well-defined up to equivalence, but not up to isomorphism).

Our proof of Proposition 6.3.2.1 will make use of the following:

**Lemma 6.3.2.4.** Let \( Q \) be a contractible Kan complex, let \( e : \Delta^1 \hookrightarrow Q \) be a monomorphism of simplicial sets, and let \( W = \{ \text{id}_{\Delta^1} \} \) consist of the single nondegenerate edge of \( \Delta^1 \). Then, for any \( \infty \)-category \( \mathcal{E} \), precomposition with \( e \) induces a trivial Kan fibration of simplicial sets

\[
\theta : \text{Fun}(Q, \mathcal{E}) \to \text{Fun}(\Delta^1[W^{-1}], \mathcal{E}) = \text{Isom}(\mathcal{E}).
\]

**Proof.** Since \( e \) is a monomorphism, Corollary 4.4.5.3 immediately implies that \( \theta \) is an isofibration when regarded as a functor from \( \text{Fun}(Q, \mathcal{E}) \) to \( \text{Fun}(\Delta^1, \mathcal{E}) \). Using the pullback diagram

\[
\begin{array}{ccc}
\text{Fun}(Q, \mathcal{E}) & \xrightarrow{\theta} & \text{Fun}(Q, \mathcal{E}) \\
\downarrow & & \downarrow \theta \\
\text{Isom}(\mathcal{E}) & \xrightarrow{\theta} & \text{Fun}(\Delta^1, \mathcal{E}),
\end{array}
\]

we deduce that \( \theta \) is also an isofibration when regarded as a functor from \( \text{Fun}(Q, \mathcal{E}) \) to \( \text{Isom}(\mathcal{E}) \). Consequently, to show that \( \theta \) is a trivial Kan fibration, it will suffice to show that it is an equivalence of \( \infty \)-categories (Proposition 4.5.5.20). In other words, we are reduced to proving that the morphism \( e \) exhibits \( Q \) as a localization of \( \Delta^1 \) with respect to \( W \). Let \( q : Q \to \Delta^0 \) denote the projection map. Since \( Q \) is contractible, the morphism \( q \) is an equivalence of \( \infty \)-categories. By virtue of Remark 6.3.1.19, we are reduced to proving that the composite map \( \Delta^1 \xrightarrow{e} Q \xrightarrow{q} \Delta^0 \) exhibits \( \Delta^0 \) as a localization of \( \Delta^1 \) with respect to \( W \), which follows from Example 6.3.1.14. \( \square \)

We will deduce Proposition 6.3.2.1 from the following more precise result:

**Proposition 6.3.2.5.** Let \( F : \mathcal{C} \to \mathcal{D} \) be a morphism of simplicial sets, where \( \mathcal{D} \) is an \( \infty \)-category. Let \( W \) be a collection of edges of \( \mathcal{C} \) such that, for each \( w \in W \), the image \( F(w) \) is an isomorphism in \( \mathcal{D} \). Then \( F \) factors as a composition

\[
\mathcal{C} \xrightarrow{G} \mathcal{C}[W^{-1}] \xrightarrow{H} \mathcal{D},
\]

where \( G \) exhibits \( \mathcal{C}[W^{-1}] \) as a localization of \( \mathcal{C} \) with respect to \( W \) and \( H \) is an inner fibration (so that \( \mathcal{C}[W^{-1}] \) is also an \( \infty \)-category). Moreover, this factorization can be chosen to depend functorially on the diagram \( F : \mathcal{C} \to \mathcal{D} \) and the collection of edges \( W \), in such a way that the construction \( (F : \mathcal{C} \to \mathcal{D}, W) \mapsto \mathcal{C}[W^{-1}] \) commutes with filtered colimits.
Proof. For each element \( w \in W \), the image \( F(w) \) can be regarded as a morphism from \( \Delta^1 \) to the core \( D^\simeq \). By virtue of Proposition 3.1.7.1, we can (functorially) choose a factorization of this morphism as a composition

\[
\Delta^1 \xrightarrow{i_w} Q_w \xrightarrow{q_w} D^\simeq,
\]

where \( i_w \) is anodyne and \( q_w \) is a Kan fibration. Since \( D^\simeq \) is a Kan complex, \( Q_w \) is also a Kan complex, which is contractible by virtue of the fact that \( i_w \) is anodyne. Form a pushout diagram of simplicial sets

\[
\begin{array}{ccc}
\prod_{w \in W} \Delta^1 & \xrightarrow{i} & \mathcal{C} \\
\downarrow & & \downarrow i \\
\prod_{w \in W} Q_w & \xrightarrow{q} & \mathcal{C}'.
\end{array}
\]

We first claim that \( i : \mathcal{C} \to \mathcal{C}' \) exhibits \( \mathcal{C}' \) as a localization of \( \mathcal{C} \) with respect to \( W \). Let \( \mathcal{E} \) be an \( \infty \)-category. Note that if \( G : \mathcal{C} \to \mathcal{E} \) is a morphism of simplicial sets which factors through \( \mathcal{C}' \), then for each \( w \in W \) the morphism \( G(w) \) belongs to the image of a functor \( Q_w \to \mathcal{E} \), and is therefore an isomorphism in \( \mathcal{E} \). It follows that composition with \( i \) induces a functor \( \theta : \text{Fun}(\mathcal{C}', \mathcal{E}) \to \text{Fun}(\mathcal{C}[W^{-1}], \mathcal{E}) \), and we wish to show that \( \theta \) is an equivalence of \( \infty \)-categories. This follows by inspecting the commutative diagram

\[
\begin{array}{cccc}
\text{Fun}(\mathcal{C}', \mathcal{E}) & \xrightarrow{\theta} & \text{Fun}(\mathcal{C}[W^{-1}], \mathcal{E}) & \xrightarrow{} \text{Fun}(\mathcal{C}, \mathcal{E}) \\
\downarrow & & \downarrow & \\
\prod_{w \in W} \text{Fun}(Q_w, \mathcal{E}) & \xrightarrow{\theta'} & \prod_{w \in W} \text{Isom}(\mathcal{E}) & \xrightarrow{} \prod_{w \in W} \text{Fun}(\Delta^1, \mathcal{E}).
\end{array}
\]

The outer rectangle is a pullback square by the definition of \( \mathcal{C}' \), and the right square is a pullback by the definition of \( \text{Fun}(\mathcal{C}[W^{-1}], \mathcal{E}) \). It follows that the left square is also a pullback. Lemma 6.3.2.4 implies that \( \theta' \) is a trivial Kan fibration, so that \( \theta \) is also a trivial Kan fibration (hence an equivalence of \( \infty \)-categories by Proposition 4.5.3.11).

Note that the morphism \( F : \mathcal{C} \to \mathcal{D} \) and the collection of morphisms \( \{ q_w : Q_w \to D^\simeq \subseteq \mathcal{D} \}_{w \in W} \) can be amalgamated to a single morphism of simplicial sets \( F' : \mathcal{C}' \to \mathcal{D} \). Applying Proposition 4.1.3.2, we can (functorially) factor \( F' \) as a composition \( \mathcal{C}' \xrightarrow{G'} \mathcal{C}[W^{-1}] \xrightarrow{H} \mathcal{D} \), where \( G' \) is inner anodyne and \( H \) is an inner fibration. We conclude by observing that the composite map \( G = (G' \circ i) : \mathcal{C} \to \mathcal{C}[W^{-1}] \) exhibits \( \mathcal{C}[W^{-1}] \) as a localization of \( \mathcal{C} \) with respect to \( W \), by virtue of Remark 6.3.1.19. \( \square \)

Proof of Proposition 6.3.2.7. Apply Proposition 6.3.2.5 in the special case \( \mathcal{D} = \Delta^0 \). \( \square \)
Variant 6.3.2.6. Let $\kappa$ be an uncountable cardinal, and let $F : \mathcal{C} \to \mathcal{D}$ be a morphism of simplicial sets which exhibits $\mathcal{D}$ as a localization of $\mathcal{C}$ with respect to some collection of edges $W$ (Definition 6.3.1.9). If $\mathcal{C}$ is essentially $\kappa$-small, then $\mathcal{D}$ is essentially $\kappa$-small.

Proof. Without loss of generality, we may assume that $F$ is a monomorphism of simplicial sets. Choose a categorical equivalence of simplicial sets $u : \mathcal{C} \to \mathcal{C}'$, where $\mathcal{C}'$ is $\kappa$-small, and form a pushout diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{u} & \mathcal{C}' \\
\downarrow F & & \downarrow F' \\
\mathcal{D} & \xrightarrow{v} & \mathcal{D}'
\end{array}
\] (6.2)

Then (6.2) is a categorical pushout square (Example 4.5.4.12), so $v$ is also a categorical equivalence (Proposition 4.5.4.10). Moreover, the morphism $F'$ exhibits $\mathcal{D}'$ as a localization of $\mathcal{C}'$ with respect to $u(W)$ (Corollary 6.3.4.3). We may therefore replace $F$ by $F'$, and thereby reduce to proving Variant 6.3.2.6 in the special case where $\mathcal{C}$ is $\kappa$-small. In particular, set of edges $W$ is $\kappa$-small.

Let $Q$ be a contractible Kan complex which is equipped with a monomorphism $\Delta^1 \hookrightarrow Q$ and has only countably many simplices. Form a pushout diagram of simplicial sets

\[
\begin{array}{ccc}
\prod_{w \in W} \Delta^1 & \longrightarrow & \mathcal{C} \\
\downarrow G & & \downarrow G' \\
\prod_{w \in W} Q & \longrightarrow & \mathcal{C}'
\end{array}
\]

so that $\mathcal{C}'$ is $\kappa$-small (Remark 5.4.4.6). It follows from Corollary 6.3.4.3 that the morphism $G$ exhibits $\mathcal{C}'$ as a localization of $\mathcal{C}$ with respect to $W$. Using Proposition 5.4.5.5, we can choose an inner anodyne morphism $\mathcal{C}' \hookrightarrow \mathcal{C}''$, where $\mathcal{C}''$ is a $\kappa$-small $\infty$-category. Then $\mathcal{C}''$ is also a localization of $\mathcal{C}$ with respect to $W$, so Remark 6.3.2.2 supplies a categorical equivalence of simplicial sets $\mathcal{D} \to \mathcal{C}''$. It follows that $\mathcal{D}$ is essentially $\kappa$-small, as desired. \qed

6.3.3 Reflective Localizations

Let $\mathcal{C}$ be an $\infty$-category and let $W$ be a collection of morphisms of $\mathcal{C}$. In §6.3.2, we proved that there exists a functor $F : \mathcal{C} \to \mathcal{C}[W^{-1}]$ which exhibits $\mathcal{C}[W^{-1}]$ as the localization of $\mathcal{C}$ with respect to $W$ (Proposition 6.3.2.1). The construction of §6.3.2 was fairly inexplicit, and gave little information about the structure of the localization $\mathcal{C}[W^{-1}]$ other than its universal property. In this section, we study a special class of localizations which can be described more concretely, by identifying them with reflective (or coreflective) subcategories of $\mathcal{C}$.
**Definition 6.3.3.1.** Let \( C \) be an \( \infty \)-category and let \( W \) be a collection of morphisms of \( C \). We say that an object \( Z \in C \) is \( W \)-*local* if, for every morphism \( w : X \to Y \) belonging to \( W \), precomposition with the homotopy class \([w]\) induces an isomorphism 
\[ \text{Hom}_C(Y, Z) \xrightarrow{\circ [w]} \text{Hom}_C(X, Z) \]
in the homotopy category \( \text{hKan} \). We say that \( Z \) is \( W \)-*colocal* if, for every morphism \( w : Y \to X \) belonging to \( W \), postcomposition with the homotopy class \([w]\) induces an isomorphism 
\[ \text{Hom}_C(Z, Y) \xrightarrow{\circ [w]} \text{Hom}_C(Z, X) \]
in the homotopy category \( \text{hKan} \).

**Definition 6.3.3.2.** Let \( C \) be an \( \infty \)-category and let \( W \) be a collection of morphisms of \( C \). We say that \( W \) is *localizing* if the following conditions are satisfied:

1. Every isomorphism of \( C \) is contained in \( W \).
2. The collection of morphisms \( W \) satisfies the two-out-of-three property. That is, for every 2-simplex

\[
\begin{array}{ccc}
X & \xrightarrow{w} & Z \\
\downarrow^u & & \downarrow^v \\
Y & \xrightarrow{\quad} & Z \\
\end{array}
\]

of \( C \), if any two of the morphisms \( u, v, \) and \( w \) belong to \( W \), then so does the third.
3. For every object \( Y \in C \), there exists a morphism \( w : Y \to Z \) which belongs to \( W \), where the object \( Z \) is \( W \)-local.

We say that \( W \) is *colocalizing* if it satisfies conditions (1) and (2) together with the following dual version of (3):

1. For every object \( Y \in C \), there exists a morphism \( w : X \to Y \) which belongs to \( W \), where \( X \) is \( W \)-colocal.

**Remark 6.3.3.3.** Let \( C \) be an \( \infty \)-category and let \( W \) be a collection of morphisms of \( C \), which we also view as a collection of morphisms in the opposite \( \infty \)-category \( C^{\text{op}} \). Then an object \( Z \in C \) is \( W \)-local (in the sense of Definition 6.3.3.1) if and only if it is \( W \)-colocal when viewed as an object of \( C^{\text{op}} \). The collection of morphisms \( W \) is localizing (in the sense of Definition 6.3.3.2) if and only if it is colocalizing when viewed as a collection of morphisms of \( C^{\text{op}} \).

**Remark 6.3.3.4.** Let \( C \) be an \( \infty \)-category, let \( W \) be a collection of morphisms of \( C \), and let \( w : X \to Y \) be a morphism which belongs to \( W \). Then, for every \( W \)-local object \( Z \) of \( C \), precomposition with the homotopy class \([w]\) induces a bijection 
\[ \text{Hom}_{hC}(Y, Z) \xrightarrow{\circ [w]} \text{Hom}_{hC}(X, Z) \]
in the homotopy category \( hC \). In particular, if the objects \( X \) and \( Y \) are \( W \)-local, then \( w \) is an isomorphism.
Proposition 6.3.3.5. Let $\mathcal{C}$ be an $\infty$-category, let $W$ be a collection of morphisms of $\mathcal{C}$ which is localizing, and let $\mathcal{C}'$ denote the full subcategory of $\mathcal{C}$ spanned by the $W$-local objects. Then:

1. The full subcategory $\mathcal{C}' \subseteq \mathcal{C}$ is reflective (Definition 6.2.2.1).

2. Let $L : \mathcal{C} \to \mathcal{C}'$ be a left adjoint to the inclusion functor $\iota : \mathcal{C}' \hookrightarrow \mathcal{C}$. Then $L$ exhibits $\mathcal{C}'$ as a localization of $\mathcal{C}$ with respect to $W$, in the sense of Definition 6.3.1.9.

3. A morphism $f : X \to Y$ of $\mathcal{C}$ belongs to $W$ if and only if $L(f)$ is an isomorphism in the $\infty$-category $\mathcal{C}'$.

Proof. Let $X$ be an object of $\mathcal{C}$. Our assumption that $W$ is localizing guarantees that there exists a morphism $w : X \to Y$ which belongs to $W$, where $Y$ is $W$-local. Note that, if $Z$ is any $W$-local object of $\mathcal{C}$, then composition with the homotopy class $[w]$ induces an isomorphism $\text{Hom}_\mathcal{C}(Y, Z) \xrightarrow{\circ [w]} \text{Hom}_\mathcal{C}(X, Z)$ in the homotopy category $\text{hKan}$. It follows that $w$ exhibits $Y$ as a $\mathcal{C}'$-reflection of $X$, in the sense of Definition 6.2.2.1. This proves (1).

It follows from (1) that the inclusion functor $\iota : \mathcal{C}' \hookrightarrow \mathcal{C}$ admits a left adjoint (Proposition 6.2.2.7). Choose a functor $L : \mathcal{C} \to \mathcal{C}'$ and a natural transformation $\eta : \text{id}_\mathcal{C} \to \iota \circ L$ which is the unit of an adjunction between $L$ and $\iota$. Then, for every object $X \in \mathcal{C}$, the morphism $\eta_X : X \to L(X)$ exhibits $L(X)$ as a $\mathcal{C}'$-reflection of $X$ (Proposition 6.2.2.11). Since $W$ is localizing, we can also choose a morphism $w : X \to Y$ of $W$, where $Y$ belongs to $\mathcal{C}'$. Arguing as above, we see that $w$ also exhibits $Y$ as a $\mathcal{C}'$-reflection of $X$. It follows from Remark 6.2.2.3 that we can realize $\eta_X$ as a composition of $w$ with an isomorphism $Y \to L(X)$ in the $\infty$-category $\mathcal{C}$. Since $W$ contains all isomorphisms and is closed under composition, it follows that $\eta_X$ also belongs to $W$.

We now prove (3). Let $f : X \to Y$ be a morphism of $\mathcal{C}$. We then have a commutative diagram

$$
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow{\eta_X} & & \downarrow{\eta_Y} \\
L(X) & \xrightarrow{L(f)} & L(Y),
\end{array}
$$

where $\eta_X$ and $\eta_Y$ belong to $W$. Since $W$ satisfies the two-out-of-three property, it follows that $f$ belongs to $W$ if and only if $L(f)$ belongs to $W$. Since $L(X)$ and $L(Y)$ are $W$-local objects of $\mathcal{C}$, this is equivalent to the requirement that $L(f)$ is an isomorphism (Remark 6.3.3.4).

We now prove (2) using the criterion of Proposition 6.3.1.13. Let $\mathcal{E}$ be an $\infty$-category and let $\text{Fun}(\mathcal{C}[W^{-1}], \mathcal{E})$ denote the full subcategory of $\text{Fun}(\mathcal{C}, \mathcal{E})$ spanned by those functors
which carry each morphism of $W$ to an isomorphism of $E$ (Notation 6.3.1.1). It follows from (2) that precomposition with the functor $L$ induces a map

$$\theta : \pi_0(\text{Fun}(C', E) \cong) \rightarrow \pi_0(\text{Fun}(C[W^{-1}], E) \cong).$$

We wish to show that $\theta$ is bijective. To prove injectivity, we observe that the construction $[F] \mapsto [F|_{C}]$ determines a left inverse to $\theta$ (any functor $F' : C' \rightarrow E$ is isomorphic to the restriction $(F' \circ L)|_{C'}$ via the natural transformation $\eta$). To prove surjectivity, let $F : C \rightarrow E$ be any functor. Then $\eta$ induces a natural transformation $\eta' : F \rightarrow F|_{C'} \circ L$, which carries each object $X \in C$ to the morphism $F(\eta_X) : F(X) \rightarrow (F \circ L)(X)$. If $F$ carries each morphism of $W$ to an isomorphism in $E$, then $\eta'$ is a natural isomorphism (Theorem 4.4.4.4). In particular, $F$ is isomorphic to $F|_{C'} \circ L$ so that the isomorphism class $[F]$ belongs to the image of $\theta$. \hfill \Box

**Notation 6.3.3.6.** Let $C$ be an $\infty$-category and let $W$ be a localizing collection of morphisms of $C$. We will often write $C[W^{-1}]$ for the full subcategory of $C$ spanned by the $W$-local objects. By virtue of Proposition 6.3.3.5, this is consistent with Remark 6.3.2.2: that is, we can regard $C[W^{-1}]$ as a localization of $C$ with respect to $W$. This convention is very convenient, since the full subcategory of $W$-local objects is uniquely determined by $C$ and $W$. However, it has the potential to create confusion in some situations: see Warning 6.3.3.8 below.

Proposition 6.3.3.5 has a counterpart for colocalizing collections of morphisms:

**Variant 6.3.3.7.** Let $C$ be an $\infty$-category, let $W$ be a collection of morphisms of $C$ which is colocalizing, and let $C'$ denote the full subcategory of $C$ spanned by the $W$-colocal objects. Then:

1. The full subcategory $C' \subseteq C$ is coreflective.

2. Let $L : C \rightarrow C'$ be a right adjoint to the inclusion functor $\iota : C' \hookrightarrow C$. Then $L$ exhibits $C'$ as a localization of $C$ with respect to $W$.

3. A morphism $f : X \rightarrow Y$ of $C$ belongs to $W$ if and only if $L(f)$ is an isomorphism in the $\infty$-category $C'$.

**Warning 6.3.3.8.** Let $C$ be an $\infty$-category and let $W$ be a collection of morphisms of $C$ which is both localizing and colocalizing. In this case, Proposition 6.3.3.5 and Variant 6.3.3.7 provide two different concrete realizations of the localization $C[W^{-1}]$, given by the full subcategories $C' \subseteq C \supseteq C''$ spanned by the $W$-local and $W$-colocal objects of $C$, respectively. Note that $C'$ and $C''$ are necessarily equivalent as abstract $\infty$-categories. More precisely, if $F : C \rightarrow C[W^{-1}]$ is a functor which exhibits $C[W^{-1}]$ as the localization of $C$ with respect to $W$, then the restrictions

$$C' \overset{F|_{C'}}{\longrightarrow} C[W^{-1}] \overset{F|_{C''}}{\longleftarrow} C''$$
are equivalences of $\infty$-categories. Beware that $\mathcal{C}'$ and $\mathcal{C}''$ usually do not coincide when regarded as subcategories of $\mathcal{C}$.

Proposition 6.3.3.5 admits a converse:

**Proposition 6.3.3.9.** Let $\mathcal{C}$ be an $\infty$-category, let $\mathcal{C}' \subseteq \mathcal{C}$ be a reflective subcategory, and let $L: \mathcal{C} \to \mathcal{C}'$ be a left adjoint to the inclusion functor $\iota: \mathcal{C}' \hookrightarrow \mathcal{C}$. Let $W$ be the collection of all morphisms $f: X \to Y$ of $\mathcal{C}$ for which $L(f)$ is an isomorphism in $\mathcal{C}'$. Then:

1. The collection $W$ is localizing (Definition 6.3.3.2).
2. Every object of $\mathcal{C}'$ is $W$-local (Definition 6.3.3.1).
3. If $\mathcal{C}'$ is replete, then every $W$-local object of $\mathcal{C}$ belongs to $\mathcal{C}'$.

**Proof.** We first prove (2). Let $Z$ be an object of $\mathcal{C}'$ and let $w: X \to Y$ be a morphism of $\mathcal{C}$ which belongs to $W$; we wish to show that precomposition with the homotopy class $[w]$ induces an isomorphism

\[ \theta: \text{Hom}_\mathcal{C}(Y, Z) \to \text{Hom}_\mathcal{C}(X, Z) \]

in the homotopy category $\text{hKan}$. Using Proposition 6.2.1.17, we can identify $\theta$ with the map

\[ \text{Hom}_{\mathcal{C}'}(L(Y), Z) \to \text{Hom}_{\mathcal{C}'}(L(X), Z), \]

which is invertible by virtue of our assumption that $L(w)$ is an isomorphism of $\mathcal{C}'$.

We now prove (1). It follows immediately from the definitions that $W$ contains all isomorphisms of $\mathcal{C}$ and satisfies the two-out-of-three property. Let $\eta: \text{id}_\mathcal{C} \to \iota \circ L$ be the unit of an adjunction. Then $\eta$ carries each object $X \in \mathcal{C}$ to a morphism $\eta_X: X \to L(X)$, where $L(X)$ belongs to $\mathcal{C}'$ and is therefore $W$-local (by virtue of (2)). Moreover, $L(\eta_X)$ is an isomorphism in $\mathcal{C}'$ (Proposition 6.2.2.11), so $\eta_X$ belongs to $W$.

We now prove (3). Suppose that $X$ is a $W$-local object of $\mathcal{C}$. Then $\eta_X: X \to L(X)$ is a morphism between $W$-local objects of $\mathcal{C}$. Since $\eta_X$ belongs to $W$, it follows that $\eta_X$ is an isomorphism (Remark 6.3.3.4). If the full subcategory $\mathcal{C}' \subseteq \mathcal{C}$ is replete, we conclude that $X$ belongs to $\mathcal{C}'$.

**Corollary 6.3.3.10.** Let $\mathcal{C}$ be an $\infty$-category. Then there is a canonical bijection

\[
\{\text{Localizing collections of morphisms of } \mathcal{C}\} \overset{\sim}{\longrightarrow} \{\text{Reflective replete subcategories of } \mathcal{C}\},
\]

which carries a localizing collection of morphisms $W$ to the full subcategory $\mathcal{C}' \subseteq \mathcal{C}$ spanned by the $W$-local objects.
CHAPTER 6. ADJOINT FUNCTORS

Proof. Combine Proposition 6.3.3.5 and Proposition 6.3.3.9.

Definition 6.3.3.11. Let $F : C \to D$ be a functor of $\infty$-categories. We say that $F$ is a reflective localization if it exhibits $D$ as a localization of $C$ with respect to $W$, where $W$ is a localizing collection of morphisms of $C$. We say that $F$ is a coreflective localization if it exhibits $D$ as a localization of $C$ with respect to $W$, where $W$ is a colocalizing collection of morphisms of $C$.

Remark 6.3.3.12. Let $F : C \to D$ be a reflective localization functor. Then $F$ exhibits $D$ as the localization of $C$ with respect to some localizing collection of morphisms $W$. The collection $W$ is then uniquely determined: it is the collection of all morphisms $u : X \to Y$ of $C$ for which $F(u)$ is an isomorphism of $D$. To prove this, we can assume without loss of generality that $D = C[W^{-1}]$ is the full subcategory of $C$ spanned by the $W$-local objects and that $F$ is a left adjoint to the inclusion functor $C[W^{-1}] \to C$, in which case it follows from Proposition 6.3.3.5.

Reflective localization functors admit many characterizations:

Proposition 6.3.3.13. Let $F : C \to D$ be a functor of $\infty$-categories. The following conditions are equivalent:

1. The functor $F$ is a reflective localization.
2. The functor $F$ admits a right adjoint and exhibits $D$ as the localization of $C$ with respect to some collection of morphisms $W$ of $C$.
3. The functor $F$ admits a fully faithful right adjoint $G : D \to C$.
4. There exists a functor $G : D \to C$ and a natural isomorphism $\epsilon : F \circ G \sim \text{id}_D$ which is the counit of an adjunction between $F$ and $G$.
5. The functor $F$ admits a right adjoint $G$ for which the composition $(F \circ G) : D \to D$ is an equivalence of $\infty$-categories.

Proof. Note that any of these conditions guarantee that $F$ admits a right adjoint $G : D \to C$. The equivalence (1) $\iff$ (3) $\iff$ (4) $\iff$ (5) follow by applying Corollary 6.2.2.13 to the functor $G$, and the implication (1) $\Rightarrow$ (2) is immediate. We will complete the proof by showing that (2) implies (4). Assume that $F$ exhibits $D$ as the localization of $C$ with respect to a collection of morphisms $W$, and let $\epsilon : F \circ G \to \text{id}_D$ be the counit of an adjunction. We wish to show that $\epsilon$ is an isomorphism. By virtue of Proposition 6.1.4.7 (applied to the opposite of the 2-category $\underline{h}_2 \mathbf{QCat}$), it will suffice to show that for any $\infty$-category $E$, precomposition with the isomorphism class $[F] \in \pi_0(\text{Fun}(C, D)^\simeq)$ induces a monomorphism

$$
\pi_0(\text{Fun}(D, E)^\simeq) \xrightarrow{[F]} \pi_0(\text{Fun}(C, E)^\simeq),
$$
which follows immediately from our assumption on $F$.

**Corollary 6.3.3.14.** Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories. Then $F$ is an equivalence if and only if it satisfies the following pair of conditions:

1. The functor $F$ is conservative. That is, a morphism $u$ of $\mathcal{C}$ is an isomorphism if and only if $F(u)$ is an isomorphism in $\mathcal{D}$.

2. The functor $F$ admits a fully faithful right adjoint $G : \mathcal{D} \to \mathcal{C}$.

**Proof.** Suppose that conditions (1) and (2) are satisfied; we will show that $F$ is an equivalence of $\infty$-categories (the converse is immediate from the definitions). Combining assumption (2) with Proposition 6.3.3.13, we can choose a functor $G : \mathcal{D} \to \mathcal{C}$ and a natural isomorphism $\epsilon : F \circ G \simeq \text{id}_{\mathcal{D}}$ which is the counit of an adjunction between $F$ and $G$. Let $\eta : \text{id}_{\mathcal{C}} \to G \circ F$ be a natural transformation which is compatible up to homotopy with $\epsilon$, in the sense of Definition 6.2.1.1. We will complete the proof by showing that $\eta$ is also an isomorphism. Fix an object $C \in \mathcal{C}$, we wish to show that the map $\eta_C : C \to (G \circ F)(C)$ is an isomorphism in the $\infty$-category $\mathcal{C}$ (Theorem 4.4.4.4). By virtue of assumption (1), it will suffice to show that $F(\eta_C)$ is an isomorphism in the $\infty$-category $\mathcal{D}$. The compatibility of $\eta$ and $\epsilon$ guarantees that the diagram

\[
\begin{array}{ccc}
(F \circ G \circ F)(C) & \xrightarrow{\epsilon_{F(C)}} & F(C) \\
\downarrow^{F(\eta_C)} & & \downarrow^{\text{id}} \\
F(C) & \xrightarrow{\epsilon_{F(C)}} & F(C)
\end{array}
\]

commutes in the homotopy category $h\mathcal{D}$. Since $\epsilon_{F(C)}$ is an isomorphism, it follows that $F(\eta_C)$ is also an isomorphism (Remark 1.3.6.3).

---

### 6.3.4 Stability Properties of Localizations

Our goal in this section is to record some basic formal properties of the localization construction $\mathcal{C} \mapsto \mathcal{C}[W^{-1}]$ introduced in §6.3.2. We first show that localization commutes with the formation of filtered colimits. More precisely, we have the following:

**Proposition 6.3.4.1.** Let $F : \mathcal{C} \to \mathcal{D}$ be a morphism of simplicial sets which is given as the colimit (in the arrow category $\text{Fun}([1], \text{Set}_\Delta)$) of a filtered diagram of morphisms $\{F_\alpha : \mathcal{C}_\alpha \to \mathcal{D}_\alpha\}$. Assume that:

- Each morphism $F_\alpha$ exhibits $\mathcal{D}_\alpha$ as a localization of $\mathcal{C}_\alpha$ with respect to some collection of edges $W_\alpha$.

- Each of the transition maps $\mathcal{C}_\alpha \to \mathcal{C}_\beta$ of the diagram carries $W_\alpha$ into $W_\beta$. 

Let us regard $W = \lim W_\alpha$ as a collection of edges of the simplicial set $\mathcal{C}$. Then $F$ exhibits $D$ as a localization of $\mathcal{C}$ with respect to $W$.

**Proof.** Using Corollary 4.1.3.3, we can choose a compatible family of inner anodyne morphisms $G_\alpha : D_\alpha \to E_\alpha$, where each $E_\alpha$ is an $\infty$-category. Set $\mathcal{E} = \lim E_\alpha$, so that the morphisms $G_\alpha$ determine a map of simplicial sets $G : D \to \mathcal{E}$. Since each $G_\alpha$ is a categorical equivalence of simplicial sets, each of the composite maps $(G_\alpha \circ F_\alpha) : C_\alpha \to E_\alpha$ exhibits $E_\alpha$ as a localization of $C_\alpha$ with respect to $W_\alpha$. In particular, each of the morphisms $G_\alpha \circ F_\alpha$ carries edges of $W_\alpha$ to isomorphisms in the $\infty$-category $E_\alpha$ (Remark 6.3.1.10). Applying Proposition 6.3.2.5, we can (functorially) factor each of the morphisms $G_\alpha \circ F_\alpha$ as a composition

$$
C_\alpha \xrightarrow{G_\alpha} C_\alpha[W_\alpha^{-1}] \xrightarrow{F_\alpha'} E_\alpha,
$$

where each $C_\alpha[W_\alpha^{-1}]$ is an $\infty$-category, each of the morphisms $G_\alpha'$ exhibits $C_\alpha[W_\alpha^{-1}]$ as a localization of $C_\alpha$ with respect to $W_\alpha$, and the colimit map $G' : \mathcal{C} \to \lim C_\alpha[W_\alpha^{-1}]$ exhibits $\mathcal{C}[W^{-1}] = \lim C_\alpha[W_\alpha^{-1}]$ as a localization of $\mathcal{C}$ with respect to $W$. We then have a filtered diagram of commutative squares

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{D} \\
\downarrow G' & & \downarrow G \\
\mathcal{C}[W^{-1}] & \xrightarrow{F'} & \mathcal{E}
\end{array}
\]

having colimit

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{D} \\
\downarrow G' & & \downarrow G' \\
\mathcal{C}[W^{-1}] & \xrightarrow{F'} & \mathcal{E}
\end{array}
\]

Applying Remark 6.3.1.19, we deduce that each of the morphisms $F'_\alpha$ is a categorical equivalence of simplicial sets. Since the collection of categorical equivalences is stable under filtered colimits (Corollary 4.5.7.2), the morphism $F'$ is also a categorical equivalence of simplicial sets. Applying Remark 6.3.1.19 again, we deduce that $F' \circ G'$ exhibits $\mathcal{E}$ as a localization of $\mathcal{C}$ with respect to $W$. Since each $G_\alpha$ is a categorical equivalence, Corollary 4.5.7.2 also guarantees that $G$ is a categorical equivalence. Using the equality $G \circ F = F' \circ G'$ and applying Remark 6.3.1.19 again, we conclude that $F$ exhibits $D$ as a localization of $\mathcal{C}$ with respect to $W$, as desired. $\square$
We now show that localization is compatible with the formation of categorical pushout squares.

**Proposition 6.3.4.2.** Suppose we are given a commutative diagram of simplicial sets with the following properties:

(a) The back face is a categorical pushout square of simplicial sets.

(b) The morphism of simplicial sets $F_{01} : C_{01} \to D_{01}$ exhibits $D_{01}$ as a localization of $C_{01}$ with respect to some collection of edges $W_{01}$.

(c) The morphism of simplicial sets $F_0 : C_0 \to D_0$ exhibits $D_0$ as a localization of $C_0$ with respect to some collection of edges $W_0$ containing $G(W_{01})$.

(d) The morphism of simplicial sets $F_1 : C_1 \to D_1$ exhibits $D_1$ as a localization of $C_1$ with respect to some collection of edges $W_1$ containing $H(W_{01})$.

Then the following conditions are equivalent:
(1) The front face

\[
\begin{array}{c}
\mathcal{D}_{01} \\
\downarrow \\
\mathcal{D}_{1} \\
\downarrow \\
\mathcal{D}
\end{array}
\]

is a categorical pushout square of simplicial sets.

(2) The morphism of simplicial sets $F : \mathcal{C} \to \mathcal{D}$ exhibits $\mathcal{D}$ as a localization of $\mathcal{C}$ with respect to the collection of edges $W = H'(W_0) \cup G'(W_1)$.

Proof. Let $\mathcal{E}$ be an $\infty$-category. Assumption (a) guarantees that the diagram of Kan complexes

\[
\begin{array}{c}
\text{Fun}(\mathcal{C}, \mathcal{E}) \cong \\
\downarrow \\
\text{Fun}(\mathcal{C}_0, \mathcal{E}) \cong \\
\downarrow \\
\text{Fun}(\mathcal{C}_1, \mathcal{E}) \cong \\
\downarrow \\
\text{Fun}(\mathcal{C}_01, \mathcal{E}) \cong
\end{array}
\]

is a homotopy pullback square. Applying Proposition 3.4.1.14, we deduce that the diagram of summands

\[
\begin{array}{c}
\text{Fun}(\mathcal{C}[W^{-1}], \mathcal{E}) \cong \\
\downarrow \\
\text{Fun}(\mathcal{C}_0[W_0^{-1}], \mathcal{E}) \cong \\
\downarrow \\
\text{Fun}(\mathcal{C}_1[W_1^{-1}], \mathcal{E}) \cong \\
\downarrow \\
\text{Fun}(\mathcal{C}_01[W_01^{-1}], \mathcal{E}) \cong
\end{array}
\]

is a homotopy pullback square. Applying Proposition 3.4.1.14, we deduce that the diagram of summands

\[
\begin{array}{c}
\text{Fun}(\mathcal{C}[W^{-1}], \mathcal{E}) \cong \\
\downarrow \\
\text{Fun}(\mathcal{C}_0[W_0^{-1}], \mathcal{E}) \cong \\
\downarrow \\
\text{Fun}(\mathcal{C}_1[W_1^{-1}], \mathcal{E}) \cong \\
\downarrow \\
\text{Fun}(\mathcal{C}_01[W_01^{-1}], \mathcal{E}) \cong
\end{array}
\]

is a homotopy pullback square. Applying Proposition 3.4.1.14, we deduce that the diagram of summands

\[
\begin{array}{c}
\text{Fun}(\mathcal{C}[W^{-1}], \mathcal{E}) \cong \\
\downarrow \\
\text{Fun}(\mathcal{C}_0[W_0^{-1}], \mathcal{E}) \cong \\
\downarrow \\
\text{Fun}(\mathcal{C}_1[W_1^{-1}], \mathcal{E}) \cong \\
\downarrow \\
\text{Fun}(\mathcal{C}_01[W_01^{-1}], \mathcal{E}) \cong
\end{array}
\]

is a homotopy pullback square.

(2) Precomposition with $F$ induces a homotopy equivalence of Kan complexes

\[
\text{Fun}(\mathcal{D}, \mathcal{E}) \cong \circ F \to \text{Fun}(\mathcal{C}[W^{-1}], \mathcal{E}) \cong.
\]
We now observe that condition (1) is equivalent to the requirement that \((1_E)\) holds for every \(\infty\)-category \(E\) (by definition), and condition (2) is equivalent to the requirement that \((2_E)\) holds for every \(\infty\)-category \(E\) (Proposition 6.3.1.13).

**Corollary 6.3.4.3.** Suppose we are given a categorical pushout diagram of simplicial sets

\[
\begin{array}{ccc}
C & \xrightarrow{G} & C' \\
\downarrow F & & \downarrow F' \\
D & \xrightarrow{F} & D',
\end{array}
\]

where \(F\) exhibits \(D\) as a localization of \(C\) with respect to some collection of edges \(W\). Then \(F'\) exhibits \(D'\) as a localization of \(C'\) with respect to \(F(W)\).

**Proof.** Apply Proposition 6.3.4.2 to the cubical diagram

**Example 6.3.4.4** (Contracting an Edge). Let \(C\) be a simplicial set and let \(e\) be an edge of \(C\) which corresponds to a monomorphism of simplicial sets \(\Delta^1 \hookrightarrow C\) (that is, the source and target of \(e\) are distinct when regarded as vertices of \(C\)). Let \(C'\) denote the simplicial set...
obtained from $\mathcal{C}$ by collapsing the edge $e$, so that we have a pushout square of simplicial sets

$$
\begin{array}{ccc}
\Delta^1 & \xrightarrow{e} & \mathcal{C} \\
\downarrow & & \downarrow T \\
\Delta^0 & \xrightarrow{} & \mathcal{C}'.
\end{array}
$$

Since the horizontal maps in this diagram are monomorphisms, it is also a categorical pushout square (Example 4.5.4.12). Combining Corollary 6.3.4.3 with Example 6.3.1.14, we see that $T$ exhibits $\mathcal{C}'$ as a localization of $\mathcal{C}$ with respect to the singleton $W = \{e\}$.

### 6.3.5 Fiberwise Localization

Suppose we are given a commutative diagram of $\infty$-categories

$$
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{F} & \mathcal{E}' \\
\downarrow U & & \downarrow U' \\
\mathcal{C} & \xrightarrow{G} & \mathcal{C}',
\end{array}
$$

where $U$ and $U'$ are cocartesian fibrations and the functor $F$ carries $U$-cocartesian morphisms of $\mathcal{E}$ to $U'$-cocartesian morphisms of $\mathcal{E}'$. For each object $C \in \mathcal{C}$, write $F_C : \mathcal{E}_C \rightarrow \mathcal{E}'_{G(C)}$ for the induced map of fibers. It follows from Theorem 5.1.5.1 that if the functors $\{F_C\}_{C \in \mathcal{C}}$ and $G$ are equivalences of $\infty$-categories, then $F$ is also an equivalence of $\infty$-categories. Our goal in this section is to prove a generalization of this result, which gives a sufficient condition for $F$ to exhibit $\mathcal{E}'$ as a localization of $\mathcal{E}$.

**Theorem 6.3.5.1.** Suppose we are given a commutative diagram of simplicial sets

$$
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{F} & \mathcal{E}' \\
\downarrow U & & \downarrow U' \\
\mathcal{C} & \xrightarrow{F} & \mathcal{C}',
\end{array}
$$

which satisfies the following conditions:

1. The morphisms $U$ and $U'$ are cocartesian fibrations.
2. The morphism $F$ carries $U$-cocartesian edges of $\mathcal{E}$ to $U'$-cocartesian edges of $\mathcal{E}'$. 
For every vertex \( C \in \mathcal{C} \), the induced functor of \( \infty \)-categories \( F_C : \mathcal{E}_C \rightarrow \mathcal{E}_C' \) exhibits \( \mathcal{E}_C' \) as the localization of \( \mathcal{E}_C \) with respect to some collection of morphisms \( W_C \) of \( \mathcal{E}_C \).

The morphism \( G \) exhibits \( \mathcal{C}' \) as a localization of \( \mathcal{C} \) with respect to some collection of morphisms \( \mathcal{W} \) of \( \mathcal{C} \).

Set \( W_- = \bigcup_{C \in \mathcal{C}} W_C \) and let \( W_+ \) be the collection of all \( U \)-cocartesian edges \( e \) such that \( U(e) \) belongs to \( \mathcal{W} \). Then \( F \) exhibits \( \mathcal{E}' \) as a localization of \( \mathcal{E} \) with respect to \( W_- \cup W_+ \).

We begin by proving a special case of Theorem 6.3.5.1 where \( F \) is assumed to be an isomorphism.

**Proposition 6.3.5.2.** Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{F} & \mathcal{E}' \\
\downarrow{U} & & \downarrow{U'} \\
\mathcal{C} & \xrightarrow{G} & \mathcal{C}'
\end{array}
\]

with the following properties:

1. The morphisms \( U \) and \( U' \) are cocartesian fibrations.
2. The morphism \( F \) carries \( U \)-cocartesian edges of \( \mathcal{E} \) to \( U' \)-cocartesian edges of \( \mathcal{E}' \).
3. For every vertex \( C \in \mathcal{C} \), the induced functor of \( \infty \)-categories \( F_C : \mathcal{E}_C \rightarrow \mathcal{E}_C' \) exhibits \( \mathcal{E}_C' \) as the localization of \( \mathcal{E}_C \) with respect to some collection of morphisms \( W_C \).

Set \( W = \bigcup_{C \in \mathcal{C}} W_C \), which we regard as a collection of edges of the simplicial set \( \mathcal{E} \). Then \( F \) exhibits \( \mathcal{E}' \) as a localization of \( \mathcal{E} \) with respect to \( W \).

**Proof of Proposition 6.3.5.2.** Let \( \mathcal{D} \) be an \( \infty \)-category, so that precomposition with \( F \) induces a functor \( F^* : \text{Fun}(\mathcal{E}', \mathcal{D}) \rightarrow \text{Fun}(\mathcal{E}, \mathcal{D}) \). We wish to show that the functor \( F^* \) is fully faithful, and that its essential image is the full subcategory \( \text{Fun}(\mathcal{E}[W^{-1}], \mathcal{D}) \subseteq \text{Fun}(\mathcal{E}, \mathcal{D}) \). To prove this, let \( \mathcal{B} \) denote the direct image \( \text{Res}_{\mathcal{E}/\mathcal{C}}(\mathcal{E} \times \mathcal{D}) \) and let \( \pi : \mathcal{B} \rightarrow \mathcal{C} \) be the projection map, and define \( \mathcal{B}' = \text{Res}_{\mathcal{E}'/\mathcal{C}}(\mathcal{E}' \times \mathcal{D}) \) and \( \pi' : \mathcal{B}' \rightarrow \mathcal{C} \) similarly. Combining assumption (1) with Proposition 5.3.6.6, we see that \( \pi \) and \( \pi' \) are cartesian fibrations.

For each vertex \( C \in \mathcal{C} \), let us identify the fibers \( \mathcal{B}_C = \{ C \} \times_\mathcal{C} \mathcal{B} \) and \( \mathcal{B}'_C = \{ C \} \times_\mathcal{C} \mathcal{B}' \) with the \( \infty \)-categories \( \text{Fun}(\mathcal{E}_C, \mathcal{D}) \) and \( \text{Fun}(\mathcal{E}_C', \mathcal{D}) \), respectively. Precomposition with \( F \) induces a morphism of simplicial sets \( G : \mathcal{B}' \rightarrow \mathcal{B} \) satisfying \( \pi \circ G = \pi' \), given on each fiber by the functor

\[
G_C : \mathcal{B}'_C = \text{Fun}(\mathcal{E}_C', \mathcal{D}) \xrightarrow{\circ F_C} \text{Fun}(\mathcal{E}_C, \mathcal{D}) = \mathcal{B}.
\]
Combining assumption (2) with Proposition 5.3.6.6, we see that $G$ carries $\pi'$-cartesian edges of $\mathcal{B}'$ to $\pi$-cartesian edges of $\mathcal{B}$. In particular, for every edge $e : X \to Y$ of $\mathcal{C}$, the diagram of $\infty$-categories

\[
\begin{array}{ccc}
\mathcal{B}_Y & \xrightarrow{e^*} & \mathcal{B}_X \\
G_Y & \downarrow & G_X \\
\mathcal{B}_Y & \xrightarrow{e^*} & \mathcal{B}_X
\end{array}
\] (6.4)

commutes up to isomorphism, where the horizontal functors are given by contravariant transport along $e$ (see Remark 5.2.8.5).

Let us identify the vertices of $\mathcal{B}$ with pairs $(C, \rho)$, where $C$ is a vertex of $\mathcal{C}$ and $\rho : \mathcal{E}_C \to \mathcal{D}$ is a functor of $\infty$-categories. Let $\mathcal{B}^0 \subseteq \mathcal{B}$ denote the full simplicial subset spanned by those vertices $(C, \rho)$ for which the functor $\rho$ carries each edge of $W_C$ to an isomorphism in the $\infty$-category $\mathcal{D}$. It follows from assumption (3) that for every vertex $C$, the functor $G_C : \mathcal{B}'_C \to \mathcal{B}_C$ is fully faithful, and its essential image can be identified with the full subcategory $\mathcal{B}^0_C = \{C\} \times_C \mathcal{B}^0 \subseteq \mathcal{B}_C$. Combining this observation with the homotopy commutativity of the diagram (6.3.5.2), we see that for every edge $e : X \to Y$ in $\mathcal{E}$, the contravariant transport functor $e^* : \mathcal{B}_Y \to \mathcal{B}_X$ carries $\mathcal{B}_Y^0$ into $\mathcal{B}_X^0$. It follows that $\pi$ restricts to a cartesian fibration of simplicial sets $\pi^0 : \mathcal{B}^0 \to \mathcal{C}$, and that an edge of $\mathcal{B}^0$ is $\pi^0$-cartesian if and only if it is $\pi$-cartesian when viewed as an edge of $\mathcal{B}$ (Proposition 5.1.6.14). We complete the proof by observing that $F^* : \text{Fun}(\mathcal{E}', \mathcal{D}) \to \text{Fun}(\mathcal{E}[W^{-1}], \mathcal{D})$ can be identified with the functor

$$\text{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{B}') \to \text{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{B}^0)$$

given by precomposition with $G$, and is therefore an equivalence of $\infty$-categories.

**Corollary 6.3.5.3.** Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets. Suppose that, for every vertex $C \in \mathcal{C}$, the $\infty$-category $\mathcal{E}_C = \{C\} \times_\mathcal{C} \mathcal{E}$ is weakly contractible. Let $W$ be the collection of all edges $e$ of $\mathcal{E}$ having the property that $U(e)$ is a degenerate edge of $\mathcal{C}$. Then $U$ exhibits $\mathcal{C}$ as a localization of $\mathcal{E}$ with respect to $W$.

**Proof.** For each vertex $C \in \mathcal{C}$, let $W_C$ be the collection of all morphisms in the $\infty$-category $\mathcal{E}_C$. Since $\mathcal{E}_C$ is weakly contractible, the projection map $\mathcal{E}_C \to \{C\}$ exhibits $\{C\}$ as a localization of $\mathcal{E}_C$ with respect to $W_C$ (Proposition 6.3.1.20). The desired result now follows.
by applying Proposition \ref{6.3.5} to the commutative diagram

\[
\begin{array}{c}
\mathcal{E} \\
\downarrow \ 
\end{array}
\quad
\begin{array}{c}
U \\
\downarrow \\
\mathcal{C}
\end{array}
\quad
\begin{array}{c}
\mathcal{E}' \\
\downarrow \\
\mathcal{C}'
\end{array}
\]

\[
\begin{array}{c}
\mathcal{E} \\
\downarrow \ 
\end{array}
\quad
\begin{array}{c}
\mathcal{E}' \\
\downarrow \\
\mathcal{C}'
\end{array}
\]

We now consider another special case of Theorem \ref{6.3.5.1}.

\begin{proposition}
Suppose we are given a pullback diagram of simplicial sets

\[
\begin{array}{c}
\mathcal{E} \\
\downarrow \ 
\end{array}
\quad
\begin{array}{c}
F \\
\downarrow \\
\mathcal{C}'
\end{array}
\quad
\begin{array}{c}
\mathcal{E}' \\
\downarrow \\
\mathcal{C}
\end{array}
\quad
\begin{array}{c}
\mathcal{E} \\
\downarrow \ 
\end{array}
\quad
\begin{array}{c}
\mathcal{E}' \\
\downarrow \\
\mathcal{C}
\end{array}
\]

where \( U \) and \( U' \) are cocartesian fibrations. Suppose that \( F \) exhibits \( \mathcal{C}' \) as a localization of \( \mathcal{C} \) with respect to some collection of edges \( \mathcal{W} \), and let \( \mathcal{W} \) denote the collection of \( U \)-cocartesian edges \( e \) of \( \mathcal{E} \) which satisfy \( U(e) \in \mathcal{W} \). Then \( F \) exhibits \( \mathcal{E}' \) as a localization of \( \mathcal{E} \) with respect to \( \mathcal{W} \).

\end{proposition}

\begin{proof}
Using Corollary \ref{4.1.3.3} we can choose an inner anodyne map \( \mathcal{C}' \hookrightarrow \mathcal{C}'' \), where \( \mathcal{C}'' \) is an \( \infty \)-category. By virtue of Proposition \ref{5.7.7.2} we can assume that \( U' \) is the pullback of a cocartesian fibration of simplicial sets \( U'' : \mathcal{E}'' \to \mathcal{C}'' \). Applying Proposition \ref{5.3.6.1} we deduce that the inclusion map \( \mathcal{E}' \hookrightarrow \mathcal{E}'' \) is a categorical equivalence of simplicial sets. We may therefore replace \( U' \) by \( U'' \), and thereby reduce to proving Proposition \ref{6.3.5} in the special case where \( \mathcal{C} \) is an \( \infty \)-category.

Fix an \( \infty \)-category \( \mathcal{D} \). We wish to show that the functor \( F^* : \text{Fun}(\mathcal{E}', \mathcal{D}) \to \text{Fun}(\mathcal{E}, \mathcal{D}) \) is fully faithful and that its essential image is the full subcategory \( \text{Fun}(\mathcal{E}[W^{-1}], \mathcal{D}) \subseteq \text{Fun}(\mathcal{E}, \mathcal{D}) \). Let \( \mathcal{B}' = \text{Res}_{\mathcal{C}'}(\mathcal{E}' \times \mathcal{D}) \) and \( \pi' : \mathcal{B}' \to \mathcal{C} \) be as in the proof of Proposition \ref{6.3.5}, so that we have canonical isomorphisms

\[
\text{Fun}(\mathcal{E}, \mathcal{D}) \simeq \text{Fun}_{/\mathcal{C}'}(\mathcal{C}, \mathcal{B}') \quad \text{Fun}(\mathcal{E}, \mathcal{D}) \simeq \text{Fun}_{/\mathcal{C}'}(\mathcal{C}, \mathcal{B}')
\]

Note that a morphism \( G : \mathcal{E} \to \mathcal{D} \) carries each edge of \( W \) to an isomorphism in \( \mathcal{D} \) if and only if the corresponding object \( g \in \text{Fun}_{/\mathcal{C}'}(\mathcal{C}, \mathcal{B}') \) carries each element \( \tau \in \mathcal{W} \) to a \( \pi' \)-cartesian edge of \( \mathcal{B}' \) (see Proposition \ref{5.3.6.6}). Since \( \bar{F} \) carries each edge \( \bar{e} \in \mathcal{W} \) to an isomorphism
in $C'$, this is equivalent to the requirement that $g(\bar{e})$ is an isomorphism in $B'$ (Proposition 5.1.1.8). We are therefore reduced to showing that composition with $F$ induces a fully faithful functor $\text{Fun}_{/C'}(C, B') \to \text{Fun}_{/C}(C, B')$, whose essential image is spanned by those functors $g \in \text{Fun}_{/C'}(C, B')$ which carry each edge of $W$ to an isomorphism in $B'$. This is a special case of Remark 6.3.1.15.

Corollary 6.3.5.5. Suppose we are given a pullback diagram of simplicial sets

$$
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{F} & \mathcal{E}' \\
\downarrow U & & \downarrow U' \\
C & \xrightarrow{F} & C',
\end{array}
$$

where $U$ and $U'$ are left fibrations. Suppose that $F$ exhibits $C'$ as a localization of $C$ with respect to some collection of edges $W$. Then $F$ exhibits $\mathcal{E}'$ as a localization of $\mathcal{E}$ with respect to $W = U^{-1}(W)$.

Proof. Combine Proposition 6.3.5.4 with Proposition 5.1.4.14.

Proof of Theorem 6.3.5.1. Suppose we are given a commutative diagram of simplicial sets

$$
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{F} & \mathcal{E}' \\
\downarrow U & & \downarrow U' \\
C & \xrightarrow{F} & C',
\end{array}
$$

(6.5)

which satisfies the hypotheses of Theorem 6.3.5.1. Fix an $\infty$-category $\mathcal{D}$. We wish to show that precomposition with $F$ induces a fully faithful functor $F^* : \text{Fun}(\mathcal{E}', \mathcal{D}) \to \text{Fun}(\mathcal{E}, \mathcal{D})$, whose essential image consists of those morphisms $G : \mathcal{E} \to \mathcal{D}$ which carry each edge of $W_- \cup W_+$ to an isomorphism in $\mathcal{D}$. Let $\pi : C \times_C \mathcal{E}' \to \mathcal{E}'$ be given by projection onto the second factor. Note that the pair $(U, F)$ determines a morphism of simplicial sets $\bar{F} : \mathcal{E} \to C \times_C \mathcal{E}'$ satisfying $\pi \circ \bar{F} = F$, so that $F^*$ factors as a composition

$$
\text{Fun}(\mathcal{E}', \mathcal{D}) \xrightarrow{\pi^*} \text{Fun}(C \times_C \mathcal{E}', \mathcal{D}) \xrightarrow{\bar{F}^*} \text{Fun}(\mathcal{E}, \mathcal{D}).
$$

Let $W'$ be the collection of all edges of $C \times_C \mathcal{E}'$ of the form $(\bar{e}, f)$, where $\bar{e}$ belongs to $\overline{W}$ and $f$ is a $U'$-cocartesian edge of $\mathcal{E}'$. It follows from Proposition 6.3.5.4 that the functor $\pi^*$ is fully faithful, and that its essential image consists of those morphisms $G' : C \times_C \mathcal{E}' \to \mathcal{D}$.
6.3. LOCALIZATION

which carry each edge of $W'$ to an isomorphism in $\mathcal{D}$. Applying Proposition 6.3.5.2, we see that the functor $\tilde{F}^*$ is also fully faithful, and that its essential image consists of those morphisms $G : \mathcal{E} \to \mathcal{D}$ which carry each edge of $W_-$ to an isomorphism in $\mathcal{D}$. To complete the proof, it will suffice to show the following:

(*) A morphism of simplicial sets $G' : \mathcal{C} \times \mathcal{C}' \mathcal{E}' \to \mathcal{D}$ carries each edge of $W'$ to an isomorphism in $\mathcal{D}$ if and only if $G' \circ \tilde{F}$ carries each edge of $W_+$ to an isomorphism in $\mathcal{D}$.

The “only if” assertion is immediate (since $\tilde{F}(W_+)$ is contained in $W'$). The converse follows from the observation that every edge $(e, f)$ is isomorphic, when viewed as an object of the $\infty$-category $\text{Fun}/\mathcal{C}(\Delta^1, \mathcal{C} \times \mathcal{C}' \mathcal{E}')$, to $\tilde{F}(e)$, where $e : X \to Y$ is any $U$-cocartesian edge of $\mathcal{E}$ for which $U(e) = \tilde{e}$ and $F(X)$ is isomorphic to the domain of $f$ as an object of the $\infty$-category $\{X\} \times \mathcal{C}' \mathcal{E}'$. 

We close this section with a variant of the preceding results.

**Proposition 6.3.5.6.** Let $F : \mathcal{C} \to \mathcal{D}$ be a morphism of simplicial sets which exhibits $\mathcal{D}$ as a localization of $\mathcal{C}$ with respect to a collection of edges $W$. Let $K$ be any simplicial set, and let $W_K$ denote the collection of edges $e = (e', e'')$ of the product $K \times \mathcal{C}$ for which $e'$ is a degenerate edge of $K$ and $e''$ belongs to $W$. Then the induced map $F_K : K \times \mathcal{C} \to K \times \mathcal{D}$ exhibits $K \times \mathcal{D}$ as the localization of $K \times \mathcal{C}$ with respect to $W_K$.

**Proof.** Let $\mathcal{E}$ be an $\infty$-category, and let

$$\theta : \text{Fun}(K \times \mathcal{D}, \mathcal{E}) \to \text{Fun}(K \times \mathcal{C}, \mathcal{E})$$

be the functor given by precomposition with $F_K$. We wish to show that $F_K$ is fully faithful, and that its essential image is the full subcategory $\text{Fun}((K \times \mathcal{C})[W_K^{-1}], \mathcal{E})$ of Notation 6.3.1.1. Unwinding the definitions, we can identify $\theta$ with the functor

$$\theta' : \text{Fun}(\mathcal{D}, \text{Fun}(K, \mathcal{E})) \to \text{Fun}(\mathcal{C}, \text{Fun}(K, \mathcal{E}))$$

given by precomposition with $F$. Under this identification $\text{Fun}((K \times \mathcal{C})[W_K^{-1}], \mathcal{E})$ corresponds to the full subcategory $\text{Fun}(\mathcal{C}[W^{-1}], \text{Fun}(K, \mathcal{E})) \subseteq \text{Fun}(\mathcal{C}, \text{Fun}(K, \mathcal{E}))$ (see Theorem 4.4.4.4), so that the desired result follows from our assumption on the functor $F$. 

**6.3.6 Universal Localizations**
The formation of localizations is generally not compatible with fiber products. If

\[
\begin{array}{ccc}
X' & \rightarrow & X \\
\downarrow f' & & \downarrow f \\
S' & \rightarrow & S
\end{array}
\]

is a pullback diagram of simplicial sets where the morphism \( f \) exhibits \( S \) as a localization of \( X \) (with respect to some collection of edges of \( X \)), then the morphism \( f' \) need not have the same property. To address this point, it will be convenient to introduce a more restrictive notion of localization.

**Definition 6.3.6.1.** Let \( f : X \rightarrow S \) be a morphism of simplicial sets. We will say that \( f \) is universally localizing if, for every morphism of simplicial sets \( S' \rightarrow S \), the projection map \( S' \times_S X \rightarrow S' \) exhibits \( S' \) as a localization of \( S' \times_S X \) with respect to some collection of edges \( W \).

If \( f : X \rightarrow S \) is a universally localizing morphism of simplicial sets, then it exhibits \( S \) as a localization of \( X \) with respect to some collection of edges \( W \). It is possible to be more precise: we can take \( W \) to be the collection of edges of \( X \) having degenerate image in \( S \).

**Proposition 6.3.6.2.** Let \( f : X \rightarrow S \) be a morphism of simplicial sets. For every morphism \( T \rightarrow S \), let \( W_T \) denote the collection of all edges \( w = (w_T, w_X) \) of the fiber product \( T \times_S X \) for which \( w_T \) is a degenerate edge of \( T \). The following conditions are equivalent:

1. For every morphism of simplicial sets \( T \rightarrow S \), the projection map \( T \times_S X \rightarrow T \) exhibits \( T \) as a localization of \( T \times_S X \) with respect to \( W_T \).
2. The morphism \( f \) is universally localizing, in the sense of Definition 6.3.6.1.
3. For every simplex \( \sigma : \Delta^n \rightarrow S \), the projection map \( \Delta^n \times_S X \rightarrow \Delta^n \) exhibits \( \Delta^n \) as a localization of \( \Delta^n \times_S X \) with respect to some collection of edges of \( \Delta^n \times_S X \).
4. For every simplex \( \sigma : \Delta^n \rightarrow S \), the projection map \( \Delta^n \times_S X \rightarrow \Delta^n \) exhibits \( \Delta^n \) as a localization of \( \Delta^n \times_S X \) with respect to \( W_{\Delta^n} \).

**Proof.** The implications \( (1) \Rightarrow (2) \Rightarrow (3) \) are immediate. We next show that \( (3) \) implies \( (4) \). Let \( \sigma \) be an \( n \)-simplex of \( S \), and suppose that the projection map \( \pi : \Delta^n \times_S X \rightarrow \Delta^n \) exhibits \( \Delta^n \) as a localization of \( \Delta^n \times_S X \) with respect to some collection of edges \( W \). Since \( \Delta^n \) is an \( \infty \)-category in which every isomorphism is an identity morphism, the diagram \( \pi \) must carry each edge of \( W \) to a degenerate edge of \( \Delta^n \): that is, we have \( W \subseteq W_{\Delta^n} \).
Applying Corollary 6.3.1.22 we deduce that $\pi$ also exhibits $\Delta^n$ as a localization of $\Delta^n \times_S X$ with respect to $W_{\Delta^n}$.

We now complete the proof by showing that (4) implies (1). Let us say that a simplicial set $T$ is good if, for every morphism $T \to S$, the projection map $T \times_S X \to T$ exhibits $T$ as a localization of $T \times_S X$ with respect to $W_T$. Assume that condition (4) is satisfied, so that every standard simplex $\Delta^n$ is good. We wish to show that every simplicial set $T$ is good. Using Proposition 6.3.4.1 we see that the collection of good simplicial sets is closed under filtered colimits; we may therefore assume without loss of generality that $T$ is finite. If $T = \emptyset$, the result is obvious. We may therefore assume that $T$ has dimension $n$ for some integer $n \geq 0$. We proceed by induction on $n$ and on the number of nondegenerate $n$-simplices of $T$. Fix a nondegenerate $n$-simplex $\sigma : \Delta^n \to T$. Using Proposition 1.1.3.13 we see that there is a pushout square of simplicial sets

$$
\begin{array}{ccc}
\partial \Delta^n & \to & \Delta^n \\
\downarrow & & \downarrow \sigma \\
T' & \to & T,
\end{array}
$$

where $T'$ is a simplicial set of dimension $\leq n$ having fewer nondegenerate $n$-simplices than $T$. By virtue of Proposition 6.3.4.2 to show that $T$ is good, it will suffice to show that the simplicial sets $\Delta^n$, $\partial \Delta^n$, and $T'$ are good. In the first case this follows from assumption (4), and in the remaining cases it follows from our inductive hypothesis. 

\[\square\]

**Corollary 6.3.6.3.** Let $f : X \to S$ be a universally localizing morphism of simplicial sets, and let $W$ be the collection of edges $w$ of $X$ for which $f(w)$ is a degenerate edge of $S$. Then $f$ exhibits $S$ as a localization of $X$ with respect to $W$.

**Remark 6.3.6.4.** Let $f : X \to S$ be a universally localizing morphism of simplicial sets. Then $f$ is a weak homotopy equivalence (see Remark 6.3.1.16).

**Remark 6.3.6.5.** Let $X$ be a simplicial set. Then the projection map $X \to \Delta^0$ is universally localizing if and only if $X$ is weakly contractible. This follows by combining Propositions 6.3.1.20 and 6.3.5.6.

**Remark 6.3.6.6.** Suppose we are given a pullback diagram of simplicial sets

$$
\begin{array}{ccc}
X' & \to & X \\
\downarrow f' & & \downarrow f \\
S' & \to & S.
\end{array}
$$
If \( f \) is universally localizing, then \( f' \) is universally localizing.

**Proposition 6.3.6.7.** Let \( f : X \to S \) be a universally localizing morphism of simplicial sets. Then \( f \) is surjective.

**Proof.** Let \( \sigma : \Delta^n \to S \) be an \( n \)-simplex of \( S \); we wish to show that \( \sigma \) can be lifted to an \( n \)-simplex of \( X \). Assume otherwise, so that the inclusion map \( \partial \Delta^n \times_S X \to \Delta^n \times_S X \) is an isomorphism. We have a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\partial \Delta^n \times_S X & \sim & \Delta^n \times_S X \\
\downarrow & & \downarrow \\
\partial \Delta^n & \to & \Delta^n,
\end{array}
\]

where the vertical maps are weak homotopy equivalences (see Remarks 6.3.6.6 and 6.3.6.4). It follows that the inclusion \( \partial \Delta^n \to \Delta^n \) is also a weak homotopy equivalence, which is a contradiction (since the relative homology group \( H_n(\Delta^n, \partial \Delta^n; \mathbb{Z}) \cong \mathbb{Z} \) is nonzero).

**Proposition 6.3.6.8.** Let \( f : X \to Y \) and \( g : Y \to Z \) be universally localizing morphisms of simplicial sets. Then the composition \( (g \circ f) : X \to Z \) is universally localizing.

**Proof.** Suppose we are given a morphism of simplicial sets \( Z' \to Z \). Set \( X' = Z' \times_Z X \), and let \( W \) be the collection of those edges \( w \) of \( X' \) having degenerate image in \( Z' \). We will show that the projection map \( \pi : X' \to Z' \) exhibits \( Z' \) as a localization of \( X' \) with respect to \( W \). Set \( Y' = Z' \times_Z Y \), so that \( \pi \) factors as a composition \( X' \xrightarrow{f'} Y' \xrightarrow{g'} Z' \). It follows from Proposition 6.3.6.7 (and Remark 6.3.6.6) that \( f' \) is a surjection of simplicial sets. In particular, the image \( f'(W) \) is the collection of all edges \( u \) of \( Y' \) having the property that \( g'(u) \) is a degenerate edge of \( Z' \).

Let \( W_0 \subseteq W \) be the collection of those edges \( w \) of \( X' \) for which \( f'(w) \) is a degenerate edge of \( Y' \). Applying Proposition 6.3.6.2 we conclude that \( f' \) exhibits \( Y' \) as a localization of \( X' \) with respect to \( W_0 \), and that \( g' \) exhibits \( Z' \) as a localization of \( Y' \) with respect to \( f'(W) \). Applying Proposition 6.3.1.21 we conclude that \( \pi = g' \circ f' \) exhibits \( Z' \) as the localization of \( X' \) with respect to \( W_0 \cup W = W \), as desired.

**Corollary 6.3.6.9.** Let \( f : X \to S \) be a universally localizing morphism of simplicial sets, and let \( K \) be a weakly contractible simplicial set. Then the composite map \( X \times K \to X \xrightarrow{f} S \) is universally localizing.

**Proof.** By virtue of Proposition 6.3.6.8 it will suffice to show that the projection map \( X \times K \to X \) is universally localizing. Using Remark 6.3.6.6 we can reduce to the case \( X = \Delta^n \), in which case the desired result follows from Remark 6.3.6.5.
**Proposition 6.3.6.10.** The collection of universally localizing morphisms is closed under the formation of filtered colimits (when regarded as a full subcategory of the arrow category \( \text{Fun}([1], \text{Set}_\Delta) \)).

**Proof.** Suppose that \( f : X \to S \) is a morphism of simplicial sets which can be realized as the colimit of a filtered diagram \( \{ f_\alpha : X_\alpha \to S_\alpha \} \) in the category \( \text{Fun}([1], \text{Set}_\Delta) \), where each \( f_\alpha \) is universally localizing. We wish to show that \( f \) is universally localizing. Fix a morphism of simplicial sets \( T \to S \) and let \( W \) be the collection of all edges \( w = (w_T, w_X) \) of \( T \times_S X \) for which \( w_T \) is a degenerate edge of \( T \). Note that the projection map \( f_T : T \times_S X \to T \) can be realized as a filtered colimit of morphisms \( f_{T,\alpha} : T \times_S X_\alpha \to T \times_S S_\alpha \). For each index \( \alpha \), let \( W_\alpha \) denote the collection of edges of \( T \times_S X_\alpha \) having degenerate image in \( T \). Since \( f_\alpha \) is universally localizing, Proposition 6.3.6.2 guarantees that \( f_{T,\alpha} \) exhibits \( T \times_S X_\alpha \) as a localization of \( T \times_S X_\alpha \) with respect to \( W_\alpha \). Applying Proposition 6.3.4.1 we conclude that \( f_T \) exhibits \( T \) as a localization of \( T \times_S X \) with respect to \( W \). \( \square \)

**Proposition 6.3.6.11.** Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccccccccc}
X_01 & \longrightarrow & X_0 & \longrightarrow & X_1 & \longrightarrow & X & \longrightarrow & S_1 & \longrightarrow & S \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
S_01 & \longrightarrow & S_0 & \longrightarrow & S & \longrightarrow & S & \longrightarrow & \text{S} \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
X_01 & \longrightarrow & X_0 & \longrightarrow & X & \longrightarrow & S_1 & \longrightarrow & S \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
S_1 & \longrightarrow & S & \longrightarrow & S & \longrightarrow & S & \longrightarrow & \text{S} \\
\end{array}
\]

(6.6)

with the following properties:

(a) The front and back faces

\[
\begin{array}{cccccc}
S_01 & \longrightarrow & S_0 & \longrightarrow & S \\
\downarrow & & \downarrow & & \downarrow \\
S_1 & \longrightarrow & S \\
\end{array}
\quad \begin{array}{cccccc}
X_01 & \longrightarrow & X_0 & \longrightarrow & X \\
\downarrow & & \downarrow & & \downarrow \\
X_1 & \longrightarrow & X \\
\end{array}
\]
are pushout squares.

(b) The morphisms $S_{01} \to S_0$ and $X_{01} \to X_0$ are monomorphisms.

(c) The morphisms $f_{01}, f_0,$ and $f_1$ are universally localizing.

Then the morphism $f$ is universally localizing.

Proof. Fix a morphism of simplicial sets $T \to S$; we wish to show that the projection map $f_T : T \times_S X \to T$ exhibits $T$ as a localization of $T \times_S X$ with respect to some collection of morphisms $W$. Since the hypotheses of Proposition 6.3.6.11 are stable with respect to pullback, we may assume without loss of generality that $T = S$. Let $W_0$ be the collection of edges $w$ of $X_0$ having the property that $f_0(w)$ is a degenerate edge of $S_0$, and define $W_1$ and $W_{01}$ similarly. Combining assumption (c) with Proposition 6.3.6.2, we conclude that the morphism $f_0$ (respectively $f_1, f_{01}$) exhibits the simplicial set $S_0$ (respectively $S_1, S_{01}$) as a localization of $X_0$ (respectively $X_1, X_{01}$) with respect to $W_0$ (respectively $W_1, W_{01}$). Let $W$ be the collection of edges of $X$ given by the union of the images of $W_0$ and $W_1$. Note that conditions (a) and (b) guarantee that the front and back faces of the diagram (6.6) are categorical pushout squares (Proposition 4.5.4.11). Applying Proposition 6.3.4.2, we conclude that $f$ exhibits $S$ as a localization of $X$ with respect to $W$.

6.3.7 Subdivision and Localization

Our goal in this section is to prove the following:

**Theorem 6.3.7.1.** Let $S$ be a simplicial set. Then there exists a partially ordered set $(A, \leq)$ and a universally localizing morphism $N_\bullet(A) \to S$.

Our proof of Theorem 6.3.7.1 will make use of the subdivision construction introduced in §3.3.3.

**Proposition 6.3.7.2.** Let $S$ be a simplicial set, let $\text{Sd}(S)$ denote the subdivision of $S$ (Definition 3.3.3.1), and let $\lambda_S : \text{Sd}(S) \to S$ denote the last vertex map (Construction 3.3.4.3). Then $\lambda_S$ is universally localizing.

**Remark 6.3.7.3.** Let $S$ be a simplicial set. Combining Proposition 6.3.7.2 with Remark 6.3.6.4, we recover the assertion that the last vertex map $\lambda_S : \text{Sd}(S) \to S$ is a weak homotopy equivalence. In other words, we can regard Proposition 6.3.7.2 as a refinement of 6.3.7.2.

**Proof of Proposition 6.3.7.2** By virtue of Proposition 6.3.6.10, we may assume without loss of generality that the simplicial set $S$ is finite. If $S$ is empty, there is nothing to prove. We may therefore assume that $S$ has dimension $n$ for some integer $n \geq 0$. We proceed by induction on $n$ and on the number of nondegenerate $n$-simplices of $S$. Fix a nondegenerate
6.3. LOCALIZATION

\( n \)-simplex \( \sigma : \Delta^n \to S \). Using Proposition 1.1.3.13 we see that there is a pushout square of simplicial sets

\[
\begin{array}{ccc}
\partial \Delta^n & \to & \Delta^n \\
\downarrow & \ & \downarrow \sigma \\
S' & \to & S
\end{array}
\]

where \( S' \) is a simplicial set of dimension \( \leq n \) having fewer nondegenerate \( n \)-simplices than \( S \). Applying Proposition 6.3.6.11 to the commutative diagram

\[
\begin{array}{ccc}
\text{Sd}(\partial \Delta^n) & \to & \text{Sd}(\Delta^n) \\
\downarrow \lambda_{\partial \Delta^n} & \ & \downarrow \lambda_{\Delta^n} \\
\partial \Delta^n & \to & \Delta^n \\
\downarrow & \ & \downarrow \\
\text{Sd}(S') & \to & \text{Sd}(S) \\
\downarrow \lambda_{S'} & \ & \downarrow \lambda_S \\
S' & \to & S
\end{array}
\]

we are reduced to showing that the morphisms \( \lambda_{S'}, \lambda_{\partial \Delta^n}, \) and \( \lambda_{\Delta^n} \) are universally localizing. In the first two cases, this follows from our inductive hypothesis. We are therefore reduced to proving Proposition 6.3.7.2 in the special case where \( S = \Delta^n \) is a standard simplex.

Using Example 3.3.3.5, we can identify the subdivision \( \text{Sd}(S) = \text{Sd}(\Delta^n) \) with the nerve of the partially ordered set \( \text{Chain}[n] \) of nonempty subsets \( P \subseteq [n] \). We wish to show that, for every morphism of simplicial sets \( \alpha : T \to S \), the projection map \( \pi : T \times_S \text{Sd}(S) \to T \) exhibits \( T \) as a localization of \( T \times_S \text{Sd}(S) \) with respect to some collection of edges. By virtue of Proposition 6.3.6.2 we can assume without loss of generality that \( T = \Delta^m \) is a standard simplex, so that \( \alpha \) can be identified with a nondecreasing map of linearly ordered sets \( [m] \to [n] \). Unwinding the definitions, we can identify \( T \times_S \text{Sd}(S) \) with the nerve of the partially ordered set \( A \subseteq [m] \times \text{Chain}[n] \) consisting of those pairs \( (i, P) \) satisfying \( \max(P) = \alpha(i) \). Under this identification, the projection map \( \pi \) is induced by the morphism of partially ordered sets

\[
A \to [m] \quad (i, P) \mapsto i.
\]
It follows that $\pi$ is a reflective localization: it has a fully faithful right adjoint, given by
the construction $i \mapsto (i, \{0 < 1 < \cdots < \alpha(i)\})$. The desired result is now a consequence of
Proposition 6.3.3.9.

Using Proposition 6.3.7.2 we can immediately deduce that Theorem 6.3.7.1 holds for a
large class of simplicial sets $S$.

**Definition 6.3.7.4.** Let $S$ be a simplicial set. We say that $S$ is **nonsingular** if, for every
nondegenerate $n$-simplex $\sigma$ of $S$, the corresponding map $\sigma : \Delta^n \to S$ is a monomorphism of
simplicial sets.

**Remark 6.3.7.5.** Recall that a simplicial set $S$ is **braced** if the collection of nondegenerate
simplices of $S$ is closed under the face operators (Definition 3.3.1.1). Every nonsingular
simplicial set is braced. However, the converse is false. For example, the quotient $\Delta^1/\partial\Delta^1$
is braced, but is not nonsingular.

**Example 6.3.7.6.** Let $(A, \leq)$ be a partially ordered set. Then the nerve $N_\bullet(A)$ is a
nonsingular simplicial set. In particular, for every integer $n \geq 0$, the standard simplex $\Delta^n$ is
nonsingular.

**Remark 6.3.7.7.** Let $S$ be a nonsingular simplicial set. Then every simplicial subset $S' \subseteq S$
is also nonsingular.

**Remark 6.3.7.8.** Let $S$ be a simplicial set which can be written as a union of a collection
of simplicial subsets $\{S_\alpha \subseteq S\}$. If each $S_\alpha$ is nonsingular, then $S$ is nonsingular.

**Remark 6.3.7.9.** Let $S$ and $T$ be nonsingular simplicial sets. Then the join $S \ast T$ is
nonsingular. In particular, if $S$ is nonsingular, then the cone $S^\ast$ is also nonsingular.

**Remark 6.3.7.10.** Let $S$ be a simplicial set, and let $\text{Sub}_\Delta(S)$ denotes the collection of
simplicial subsets $K \subseteq S$ which are isomorphic to a standard simplex. We regard $\text{Sub}_\Delta(S)$
as a partially ordered set with respect to inclusion. If $S$ is nonsingular, the construction

$$(\sigma : \Delta^n \to S) \mapsto (\text{im}(\sigma) \subseteq S)$$

determines an isomorphism of categories $\Delta_S^{\text{nd}} \simeq \text{Sub}_\Delta(S)$, where $\Delta_S^{\text{nd}}$ denotes the category of
nondegenerate simplices of $S$ (Notation 3.3.3.9). Combining this observation with Proposition
3.3.3.15, we obtain an isomorphism of simplicial sets $N_\bullet(\text{Sub}_\Delta(S)) \simeq Sd(S)$.

**Corollary 6.3.7.11.** Let $S$ be a nonsingular simplicial set. Then the last vertex map
determines a universally localizing morphism $N_\bullet(\text{Sub}_\Delta(S)) \to S$.

**Proof.** Combine Proposition 6.3.7.2 with Remark 6.3.7.10.
For our purposes, Corollary 6.3.7.11 is a poor replacement for Theorem 6.3.7.1: an \(\infty\)-category \(C\) is rarely nonsingular when regarded as a simplicial set (see Exercise 3.3.1.2). We will deduce the general form of Theorem 6.3.7.1 by combining Corollary 6.3.7.11 with the following result:

**Proposition 6.3.7.12.** Let \(S\) be a simplicial set. Then there exists a universally localizing morphism \(\varphi : \tilde{S} \to S\), where \(\tilde{S}\) is nonsingular.

The proof of Proposition 6.3.7.12 will make use of the following:

**Lemma 6.3.7.13.** Let \(\{S_\alpha\}\) be a diagram of simplicial sets. Then the limit \(\lim_{\alpha} S_\alpha\) is also nonsingular.

**Proof.** By virtue of Remark 6.3.7.7, it will suffice to show that the product \(S = \prod_\alpha S_\alpha\) is nonsingular. Let \(\sigma : \Delta^n \to S\) be a nondegenerate simplex of \(S\); we wish to show that \(\sigma\) is a monomorphism of simplicial sets. For each index \(\alpha\), Proposition 1.1.3.4 guarantees that there exists a commutative diagram

\[
\begin{array}{ccc}
\Delta^n & \xrightarrow{\sigma} & S \\
\downarrow \tau_\alpha & & \downarrow \tau_\alpha \\
\Delta^\alpha & \xrightarrow{\sigma_\alpha} & S_\alpha,
\end{array}
\]

where \(\sigma_\alpha\) is a nondegenerate simplex \(S_\alpha\). Our assumption that \(S_\alpha\) is nondegenerate guarantees that \(\sigma_\alpha\) is a monomorphism of simplicial sets, so that the product map

\[
\prod_\alpha \Delta^\alpha \xrightarrow{\prod_\alpha \sigma_\alpha} \prod_\alpha S_\alpha = S
\]

is also a monomorphism. It will therefore suffice to show that \(\tau = \{\tau_\alpha\}\) determines a monomorphism of simplicial sets \(\Delta^n \to \prod_\alpha \Delta^\alpha\). Since \(\prod_\alpha \Delta^\alpha\) can be identified with the nerve of the partially ordered set \(\prod_\alpha [n_\alpha]\), it is a nonsingular simplicial set (Example 6.3.7.6). It will therefore suffice to show that \(\tau\) is nondegenerate, which follows immediately from our assumption that \(\sigma\) is nondegenerate.

**Proof of Proposition 6.3.7.12.** Let \(S\) be a simplicial set. For each integer \(k \geq 0\), let \(\text{sk}_k(S)\) denote the \(k\)-skeleton of \(S\) (Construction 1.1.3.5). We will construct a commutative diagram

\[
\begin{array}{ccc}
\text{sk}_0(S) & \xrightarrow{\varphi_0} & \text{sk}_1(S) & \xrightarrow{\varphi_1} & \text{sk}_2(S) & \rightarrow & \cdots \\
\downarrow \varphi_0 & & \downarrow \varphi_1 & & \downarrow \varphi_2 & & \downarrow \\
\text{sk}_0(S) & \rightarrow & \text{sk}_1(S) & \rightarrow & \text{sk}_2(S) & \rightarrow & \cdots
\end{array}
\]
where each of the horizontal maps is a monomorphism, each of the vertical maps is universally localizing, and each of the simplicial sets \( \tilde{s}_k(S) \) is nonsingular. It then follows from Remark 6.3.7.8 that the colimit \( \tilde{S} = \varprojlim_k \tilde{s}_k(S) \) is nonsingular. Applying Proposition 6.3.6.10 we conclude that the morphisms \( \varphi_k \) determine a universally localizing morphism \( \varphi : S \to S \).

The construction of the morphisms \( \varphi_k : \tilde{s}_k(S) \to s_k(S) \) proceeds by induction. If \( k = 0 \), we can take \( \tilde{s}_k(S) = s_k(S) \) and \( \varphi_k \) to be the identity morphism. Let us therefore assume that \( k > 0 \), and that the morphism \( \varphi_{k-1} : \tilde{s}_{k-1}(S) \to s_{k-1}(S) \) has already been constructed. Let \( S_k^{\text{nd}} \) denote the set of nondegenerate \( k \)-simplices of \( S \), let \( T \) denote the coproduct \( \bigsqcup_{\sigma \in S_k^{\text{nd}}} \Delta^k \), and let \( T_0 \subseteq T \) denote the coproduct \( \bigsqcup_{\sigma \in S_k^{\text{nd}}} \partial \Delta^k \), so that Proposition 1.1.3.13 supplies a pushout diagram

\[
\begin{array}{ccc}
T_0 & \longrightarrow & T \\
\downarrow & & \downarrow \\
sk_{k-1}(S) & \longrightarrow & sk_k(S).
\end{array}
\]

Note that \( T \) is nonsingular (Example 6.3.7.6), so the simplicial subset \( T_0 \subseteq T \) is also nonsingular (Remark 6.3.7.7). Let \( \tilde{T}_0 \) denote the fiber product \( T_0 \times_{sk_{k-1}(S)} \tilde{s}_{k-1}(S) \), and we define \( \tilde{s}_k(S) \) to be the pushout of the diagram

\[
\begin{array}{ccc}
(\tilde{s}_{k-1}(S) \times \tilde{T}_0^\circ) & \hookrightarrow & \tilde{T}_0 \hookrightarrow (T \times \tilde{T}_0^\circ).
\end{array}
\]

Note that the cone point of \( \tilde{T}_0^\circ \) determines an embedding \( \tilde{s}_{k-1}(S) \to \tilde{s}_k(S) \). Moreover, we have a commutative diagram

\[
\begin{array}{ccc}
\tilde{s}_{k-1}(S) \times \tilde{T}_0^\circ & \leftarrow & \tilde{T}_0 \longrightarrow T \times \tilde{T}_0^\circ \\
\downarrow & & \downarrow \\
sk_{k-1}(S) & \leftarrow & T_0 \longrightarrow T.
\end{array}
\]

which determines an extension of \( \varphi_{k-1} \) to a map

\[
\varphi_k : \tilde{s}_k(S) \to sk_{k-1}(S) \coprod_{T_0} T \simeq sk_k(S).
\]

Since the cone \( \tilde{T}_0^\circ \) is weakly contractible, it follows from Corollary 6.3.6.9 that the vertical maps in the diagram (6.7) are universally localizing. Applying Proposition 6.3.6.11 we deduce that \( \varphi_k \) is also universally localizing.

\[\text{(6.7)}\]
6.3. LOCALIZATION

To complete the proof, it will suffice to show that the simplicial set \( \tilde{sk}_k(S) \) is nonsingular. By virtue of Remark 6.3.7.8, it will suffice to show that the simplicial subsets \( \tilde{sk}_k(S) \times N_0 \) and \( T \times \tilde{T}_0 \) are nonsingular. Since \( \tilde{sk}_k(S) \) is nonsingular (by our inductive hypothesis) and \( T \) is nonsingular (Example 6.3.7.6), we are reduced to proving that the cone \( \tilde{T}_0 \) is nonsingular (Lemma 6.3.7.13). By virtue of Remark 6.3.7.9, we can reduce further to showing that \( \tilde{T}_0 \) is nonsingular. This follows from Remark 6.3.7.7 and Lemma 6.3.7.13, since \( \tilde{T}_0 \) can be identified with a simplicial subset of the product \( T \times \tilde{sk}_k(S) \).

Remark 6.3.7.14. Let \( S \) be a finite simplicial set. In this case, each of the simplicial sets \( \tilde{sk}_k(S) \) constructed in the proof of Proposition 6.3.7.12 will also be finite. Specializing to the case \( k \geq \text{dim}(S) \), we obtain a universally localizing morphism

\[
\tilde{sk}_k(S) \to sk_k(S) = S
\]

where the simplicial set \( \tilde{sk}_k(S) \) is both finite and nonsingular.

Proof of Theorem 6.3.7.1. Let \( S \) be a simplicial set. Applying Proposition 6.3.7.12, we can choose a universally localizing morphism \( \varphi : \tilde{S} \to S \), where \( \tilde{S} \) is a nonsingular simplicial set. Let \( A = \text{Sub}_\Delta(\tilde{S}) \) denote the partially ordered set of simplicial subsets of \( \tilde{S} \) which are isomorphic to a standard simplex, so that Corollary 6.3.7.11 supplies a universally localizing morphism \( \lambda_{\tilde{S}} : N_\bullet(A) \to \tilde{S} \). Applying Proposition 6.3.6.8, we deduce that the composite morphism

\[
N_\bullet(A) \xrightarrow{\lambda_{\tilde{S}}} \tilde{S} \xrightarrow{\varphi} S
\]

is also universally localizing. 

Combining the preceding argument with Remark 6.3.7.14, we also obtain the following:

Variant 6.3.7.15. Let \( S \) be a finite simplicial set. Then there exists a finite partially ordered set \( (A, \leq) \) and a universally localizing morphism \( N_\bullet(A) \to S \).

Exercise 6.3.7.16. Let \( S \) be a simplicial set and let \( \tilde{S} \) be the smallest simplicial subset of \( S \times N_\bullet(\mathbb{Z}_{\geq 0}) \) which contains all simplices of the form \( (\sigma, \tau) \), where \( \tau \) is a nondegenerate simplicial subset of \( N_\bullet(\mathbb{Z}_{\geq 0}) \) (that is, it corresponds to a strictly increasing sequence of nonnegative integers). Show that \( \tilde{S} \) is nonsingular, and that projection onto the first factor determines a universally localizing morphism \( \tilde{S} \to S \).
Chapter 7

Limits and Colimits

In this chapter, we extend the classical theory of limits and colimits to the setting of higher category theory. Let $F : C \to D$ be a functor of $\infty$-categories. We say that an object $Y \in D$ is a limit of $F$ if there exists a natural transformation $\alpha : Y \to F$ having the following universal property: for every object $X \in C$, composition with $\alpha$ induces a homotopy equivalence of Kan complexes

$$\text{Hom}_C(X, Y) \to \text{Hom}_{\text{Fun}(C, D)}(X, F)$$

here $X, Y \in \text{Fun}(C, D)$ denote the constant functors taking the values $X$ and $Y$, respectively. In this case, the object $Y$ is uniquely determined up to isomorphism; to emphasize this, we often denote $Y$ by $\lim_{\leftarrow} (F)$, or by $\lim_{C \in C} (F(C))$. In §7.1, we summarize the formal properties of this notion (as well as the dual notion of colimit, which plays an equally essential role in the theory).

Throughout this book, we will often be faced with the problem of computing (or describing) the limit of a diagram $F : C \to D$. In such situations, it is useful to have some flexibility to modify the $\infty$-category $C$. In §7.2, we introduce the notion of a left cofinal morphism of simplicial sets $e : C' \to C$ (Definition 7.2.1.1). If $e : C' \to C$ is left cofinal, then an object of $D$ is a limit of $F$ if and only if it is a limit of the composite map $F' = F \circ e$ (see Corollary 7.2.2.11 and Corollary 7.4.5.11 for a converse). When $C$ is an $\infty$-category, cofinality admits a simple characterization: a morphism $e : C' \to C$ is left cofinal if and only if, for each object $C \in C$, the simplicial set $C' \times_C C/C$ is weakly contractible (Theorem 7.2.3.1). We will encounter many situations where this criterion is easy to verify. In such cases, it is harmless to replace $C$ by $C'$ for the purpose of calculating the limit of a diagram $F : C \to D$.

In §7.3, we consider another important technique for computing limits. Suppose we are given a cartesian fibration of $\infty$-categories $U : \mathcal{E} \to \mathcal{C}$. Under some mild assumptions, one can show that the limit of a diagram $F : \mathcal{E} \to \mathcal{D}$ obeys a transitivity formula, which we can
write informally as

$$\lim_{X \in E} (F(X)) \simeq \lim_{\tilde{C} \in \tilde{C}} \lim_{X \in E_C} F(X).$$

More precisely, suppose that for every object $C \in \mathcal{C}$, the diagram $F_C = F|_{E_C}$ admits a limit in the $\infty$-category $\mathcal{D}$. Then one can construct a new functor $G : \mathcal{C} \to \mathcal{D}$, given on objects by the formula $G(C) = \varprojlim (F_C)$; we refer to $G$ as a right Kan extension of $F$ along $U$ (see Definition 7.3.1.2 and Proposition 7.3.4.4). Moreover, an object of the $\infty$-category $\mathcal{D}$ is a limit of the functor $F$ if and only if it is a limit of the functor $G$ (Corollary 7.3.6.20).

The remainder of this chapter is devoted to studying limits and colimits in special situations. Let $\mathcal{S}$ denote the $\infty$-category of spaces (Construction 5.6.1.1). For any $\infty$-category $\mathcal{C}$, Corollary 5.7.0.6 supplies a bijection from the set of isomorphism classes of functors $\mathcal{F} : \mathcal{C} \to \mathcal{S}$ and the set of equivalence classes of left fibrations $U : \mathcal{E} \to \mathcal{C}$ (having essentially small fibers). In §7.4 we use this identification to give an explicit description of limits and colimits in $\mathcal{S}$:

1. The Kan complex $\text{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ parametrizing sections of $U$ is a limit of the diagram $\mathcal{F}$.
2. A Kan complex $X$ is a colimit of $\mathcal{F}$ if and only if there exists a weak homotopy equivalence $\mathcal{E} \to X$ (Corollary 7.4.5.4).

These assertions are special cases of more general results which apply to diagrams taking values in the $\infty$-category $\mathcal{QC} \supset \mathcal{S}$; see Theorems 7.4.1.1 and 7.4.3.6.

Recall that the $\infty$-category $\mathcal{S}$ is defined as the homotopy coherent nerve of the ordinary category of Kan complexes $\text{Kan}$. In particular, if $\mathcal{F}_0 : \mathcal{C}_0 \to \text{Kan}$ is a functor between ordinary categories, then passing to the homotopy coherent nerve gives a functor of $\infty$-categories $\mathcal{F} : \mathcal{C} \to \mathcal{S}$, where $\mathcal{C} = \mathcal{N}_\bullet(\mathcal{C}_0)$. In this case, there is a natural candidate for the corresponding left fibration $U : \mathcal{E} \to \mathcal{C}$, obtained by taking $\mathcal{E}$ to be the weighted nerve $\mathcal{N}_\bullet(\mathcal{C}_0)$ of Definition 5.3.3.1. In §7.5 we combine this observation with assertions (1) and (2) to compare limits and colimits in the $\infty$-category $\mathcal{S}$ with the classical theory of homotopy limits and colimits introduced by Bousfield and Kan in [5].

In §7.6 we provide a detailed discussion of some special classes of limits which arise frequently in practice, such as products (Definition 7.6.1.3), powers (Definition 7.6.2.1), pullbacks (Definition 7.6.3.1), equalizers (Definition 7.6.3.1), and sequential limits (Definition 7.6.6.1). From these primitives, many other examples can be constructed: for example, arbitrary limits in an $\infty$-category $\mathcal{D}$ can be built by combining products and equalizers (see Corollary 7.6.5.25 and Proposition 7.6.7.8).

7.1 Limits and Colimits
CHAPTER 7. LIMITS AND COLIMITS

Let $\mathcal{K}$ and $\mathcal{C}$ be categories. For every object $X \in \mathcal{C}$, let $X$ denote the constant functor from $\mathcal{K}$ to $\mathcal{C}$, carrying each object of $\mathcal{K}$ to $X$ and each morphism of $\mathcal{K}$ to the identity morphism $\text{id}_X$. If $U : \mathcal{K} \to \mathcal{C}$ is an arbitrary functor, then a limit of $U$ is an object of $\mathcal{C}$ which represents the functor $X \mapsto \text{Hom}_{\text{Fun}(\mathcal{K}, \mathcal{C})}(X, U)$. This can be formulated more precisely as follows:

**Definition 7.1.0.1.** Let $F : \mathcal{K} \to \mathcal{C}$ be a functor between categories. Let $Y$ be an object of $\mathcal{C}$ and let $\alpha : Y \to F$ be a natural transformation of functors. We say that the natural transformation $\alpha$ exhibits $Y$ as a limit of $F$ if the following condition is satisfied:

$\ast$ For every object $X \in \mathcal{C}$, composition with $\alpha$ induces a bijection from $\text{Hom}_\mathcal{C}(X, Y)$ to the set $\text{Hom}_{\text{Fun}(\mathcal{K}, \mathcal{C})}(X, F)$ of natural transformations from $X$ to $F$.

Our goal in this section is to introduce an $\infty$-categorical counterpart of Definition 7.1.0.1. Let $\mathcal{C}$ be an $\infty$-category, let $F : \mathcal{K} \to \mathcal{C}$ be a diagram, let $\alpha : Y \to F$ be a natural transformation. For every object $X \in \mathcal{C}$, composition with $\alpha$ induces a map of Kan complexes $\text{Hom}_\mathcal{C}(X, Y) \to \text{Hom}_{\text{Fun}(\mathcal{K}, \mathcal{C})}(X, F)$, which is well-defined up to homotopy. We will say that $\alpha$ exhibits $Y$ as a limit of $F$ if this map is a homotopy equivalence for each $X \in \mathcal{C}$ (Definition 7.1.1.1). In §7.1.1, we provide a detailed analysis of this notion and its formal properties (as well as the dual notion of colimit, which is defined in a similar way).

In §4.6.6, we introduced the notion of a final object of an $\infty$-category $\mathcal{C}$ (Definition 4.6.6.1). This can be regarded as a special case of the general theory of limits: an object $Y \in \mathcal{C}$ is final if and only if it is a limit of the empty diagram (Example 7.1.1.6). Conversely, if $K$ is an arbitrary simplicial set equipped with a diagram $F : K \to \mathcal{C}$, we will see that a natural transformation $\alpha : Y \to F$ exhibits $Y$ as a limit of $F$ if and only if it is final when viewed as an object of $\infty$-category $\mathcal{C} \times_{\text{Fun}(K, \mathcal{C})}\{F\}$ (Proposition 7.1.2.1). Recall that $\mathcal{C} \times_{\text{Fun}(K, \mathcal{C})}\{F\}$ is equivalent (but not isomorphic) to the slice $\infty$-category $\mathcal{C}/F$ (Theorem 4.6.4.17). In §7.1.2, we use this observation to reformulate the notion of limit: an object $Y$ is a limit of a diagram $F : K \to \mathcal{C}$ if there exists a diagram $\overline{F} : K^\triangleright \to \mathcal{C}$ which carries the cone point of $K^\triangleright$ to the object $Y$ and which is final when viewed as an object of the slice $\infty$-category $\mathcal{C}/F$ (Corollary 7.1.2.2). In this situation, we will refer to $\overline{F}$ as a limit diagram in the $\infty$-category $\mathcal{C}$ (Definition 7.1.2.4).

In §7.1.3, we study the dependence of $K$-indexed limits on the ambient $\infty$-category in which they are formed. We say that a functor of $\infty$-categories $G : \mathcal{C} \to \mathcal{D}$ preserves $K$-indexed limits if, for every diagram $F : K \to \mathcal{C}$, the induced functor $\mathcal{C}/F \to \mathcal{D}/(G_0 F)$ carries final objects of $\mathcal{C}/F$ to final objects of $\mathcal{D}/(G_0 F)$ (Definition 7.1.3.4). We illustrate the concept in this section with a few elementary examples (and will encounter many others later in this book):
7.1. LIMITS AND COLIMITS

• If \( G : \mathcal{C} \to \mathcal{D} \) is an equivalence of \( \infty \)-categories, then it preserves \( K \)-indexed limits for every simplicial set \( K \) (Proposition 7.1.3.9).

• Let \( \mathcal{C} \) be an \( \infty \)-category which admits \( K \)-indexed limits, and let \( f : A \to \mathcal{C} \) be any morphism of simplicial sets. Then the coslice \( \infty \)-category \( \mathcal{C}_{f/} \) also admits \( K \)-indexed limits, and the projection map \( \mathcal{C}_{f/} \to \mathcal{C} \) preserves \( K \)-indexed limits (Corollary 7.1.3.20).

• Let \( G : \mathcal{C} \to \mathcal{D} \) be a right fibration of \( \infty \)-categories, and suppose that \( \mathcal{D} \) admits \( K \)-indexed limits. If \( K \) is weakly contractible, then the \( \infty \)-category \( \mathcal{C} \) also admits \( K \)-indexed limits, and the right fibration \( F \) preserves \( K \)-indexed limits (Corollary 7.1.5.18).

For many applications, it will be useful to consider a relative version of the theory of limit diagrams. Let \( U : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories. We say that an object \( Y \in \mathcal{C} \) is \( U \)-final if, for every object \( X \in \mathcal{C} \), the functor \( U \) induces a homotopy equivalence \( \text{Hom}_\mathcal{C}(X, Y) \to \text{Hom}_\mathcal{D}(U(X), U(Y)) \) (Definition 7.1.4.1). We say that a diagram \( \overline{F} : K^\circ \to \mathcal{C} \) with restriction \( F = \overline{F}|_K \) is a \( U \)-limit diagram if it is \( U/F \)-final when regarded as an object of the \( \infty \)-category \( \mathcal{C}_{/F} \), where \( U/F : \mathcal{C}_{/F} \to \mathcal{D}_{/(U \circ F)} \) is the projection map (Definition 7.1.5.1).

In the special case \( \mathcal{D} = \Delta^0 \), we recover the usual notions of final object and limit diagram, respectively (Examples 7.1.4.2 and 7.1.5.3). Moreover, most of the basic features of final objects and limit diagrams have counterparts in the relative setting, which we summarize in §7.1.4 and §7.1.5. Even if one is ultimately interested in the “absolute” theory, the language of relative limits is a useful tool: we illustrate this point in §7.1.6 by using the relative language to study limits in an \( \infty \)-category of the form \( \text{Fun}(B, \mathcal{C}) \) (our main result is that, under mild assumptions, such limits can be computed pointwise: see Proposition 7.1.6.1)

Remark 7.1.0.2. The preceding discussion has centered around the theory of limits. There is also a dual theory of colimits in the \( \infty \)-categorical setting, which can be obtained by passing to opposite \( \infty \)-categories. Every assertion concerning limits has a counterpart for colimits (and vice versa). We will often use this implicitly (for example, by stating a result only for colimits but later using the dual assertion for limits).

7.1.1 Limits and Colimits in \( \infty \)-Categories

Let \( \mathcal{C} \) be an \( \infty \)-category and let \( K \) be a simplicial set. For each object \( X \in \mathcal{C} \), we let \( X \in \text{Fun}(K, \mathcal{C}) \) denote the constant diagram \( K \to \{X\} \to \mathcal{C} \). Note that the construction \( X \mapsto X \) determines a functor of \( \infty \)-categories \( \mathcal{C} \to \text{Fun}(K, \mathcal{C}) \), carrying each morphism \( f : X \to Y \) to a natural transformation \( f : X \to Y \).

Definition 7.1.1.1. Let \( \mathcal{C} \) be an \( \infty \)-category containing an object \( Y \), let \( K \) be a simplicial set, and let \( u : K \to \mathcal{C} \) be a diagram. We say that a natural transformation \( \alpha : Y \to u \) exhibits \( Y \) as a limit of \( u \) if the following condition is satisfied:
For each object $X \in C$, the composition

$$\text{Hom}_C(X, Y) \to \text{Hom}_{\text{Fun}(K, C)}(X, Y) \xrightarrow{[\alpha]_0} \text{Hom}_{\text{Fun}(K, C)}(X, u)$$

is an isomorphism in the homotopy category $\text{h Kan}$, where the second map is described in Notation 4.6.8.15.

We will say that a natural transformation $\beta : u \to Y$ exhibits $Y$ as a colimit of $u$ if the following dual condition is satisfied:

For each object $Z \in C$, the composition

$$\text{Hom}_C(Y, Z) \to \text{Hom}_{\text{Fun}(K, C)}(Y, Z) \xrightarrow{\circ [\beta]} \text{Hom}_{\text{Fun}(K, C)}(u, Z)$$

is an isomorphism in the homotopy category $\text{h Kan}$.

**Remark 7.1.1.2.** Stated more informally, a natural transformation $\alpha : Y \to u$ exhibits $Y$ as a limit of $u$ if and only if postcomposition with $\alpha$ induces a homotopy equivalence $\text{Hom}_C(X, Y) \to \text{Hom}_{\text{Fun}(K, C)}(X, u)$ for each object $X \in C$. Similarly, a natural transformation $\beta : u \to Y$ exhibits $Y$ as a colimit of $u$ if and only if precomposition with $\beta$ induces a homotopy equivalence $\text{Hom}_C(Y, Z) \to \text{Hom}_{\text{Fun}(K, C)}(u, Z)$ for each object $Z \in C$.

**Remark 7.1.1.3.** Let $C$ be an $\infty$-category containing an object $Y$ and let $u : K \to C$ be a diagram. Then a natural transformation $\alpha : Y \to u$ exhibits $Y$ as a limit of $u$ if and only if exhibits $Y$ as a colimit of the induced diagram $u^{\text{op}} : K^{\text{op}} \to C^{\text{op}}$, when regarded as a morphism in the $\infty$-category $\text{Fun}(K^{\text{op}}, C^{\text{op}}) \simeq \text{Fun}(K, C)^{\text{op}}$.

**Example 7.1.1.4.** Let $C$ be an ordinary category, let $K$ be a simplicial set, and suppose we are given a diagram $u : K \to N_\bullet(C)$, which we can identify with a functor of ordinary categories $U : hK \to C$ (see Proposition 1.3.5.7). If $Y$ is an object of $C$, then we can use Corollary 1.4.3.5 to identify natural transformations $Y \to u$ (of diagrams in the $\infty$-category $N_\bullet(C)$) with natural transformations $Y \to U$ (of diagrams in the ordinary category $C$). Under this identification, a natural transformation $Y \to u$ exhibits $Y$ as a limit of $u$ (in the $\infty$-categorical sense of Definition 7.1.1.1) if and only if it exhibits $Y$ as a limit of $U$ (in the classical sense of Definition 7.1.0.1).

**Example 7.1.1.5.** Let $C$ be an $\infty$-category and let $f : X \to Y$ be a morphism in $C$. The following conditions are equivalent:

- The morphism $f$ is an isomorphism from $X$ to $Y$ in the $\infty$-category $C$ (Definition 1.3.6.1).
- The morphism $f$ exhibits $X$ as a limit of the diagram $\{Y\} \hookrightarrow C$. 

7.1. LIMITS AND COLIMITS

- The morphism \( f \) exhibits \( Y \) as a colimit of the diagram \( \{X\} \hookrightarrow \mathcal{C} \).

**Example 7.1.1.6.** Let \( \mathcal{C} \) be an \( \infty \)-category. Then an object \( Y \in \mathcal{C} \) is initial (in the sense of Definition 4.6.6.1) if and only if it is a colimit of the empty diagram \( \emptyset \hookrightarrow \mathcal{C} \). Similarly, \( Y \) is final if and only if it is a limit of the empty diagram.

**Remark 7.1.1.7.** Let \( \mathcal{C} \) be an \( \infty \)-category, let \( u : K \to \mathcal{C} \) be a diagram, and let \( Y \in \mathcal{C} \) be an object. If \( \alpha : Y \to u \) is a natural transformation, then the condition that \( \alpha \) exhibits \( Y \) as a limit of \( u \) depends only on its homotopy class \([\alpha]\) (as a morphism in the \( \infty \)-category \( \text{Fun}(K, \mathcal{C}) \)). Similarly, if \( \beta : u \to Y \) is a natural transformation, then the condition that \( \beta \) exhibits \( Y \) as a colimit of \( u \) depends only on its homotopy class \([\beta]\).

**Remark 7.1.1.8.** Let \( \mathcal{C} \) be an \( \infty \)-category containing an object \( Y \), let \( K \) be a simplicial set, and let \( \beta : u \to u' \) be an isomorphism in the \( \infty \)-category \( \text{Fun}(K, \mathcal{C}) \). Suppose we are given a natural transformation \( \alpha : Y \to u \), and let \( \alpha' : Y \to u' \) be any composition of \( \alpha \) with \( \beta \). Then \( \alpha \) exhibits \( Y \) as a limit of \( u \) if and only if \( \alpha' \) exhibits \( Y \) as a limit of \( u \). Similarly, if \( \gamma' : u' \to Y \) is a natural transformation and \( \gamma : u \to Y \) is a composition of \( \beta \) with \( \gamma' \), then \( \gamma \) exhibits \( Y \) as a colimit of \( u \) if and only if \( \gamma' \) exhibits \( Y \) as a colimit of \( u' \).

**Remark 7.1.1.9.** Let \( \mathcal{C} \) be an \( \infty \)-category, let \( u : K \to \mathcal{C} \) be a diagram, and let \( f : X \to Y \) be a morphism in \( \mathcal{C} \). Suppose we are given a natural transformation of diagrams \( \beta : Y \to u \), and let \( \alpha : X \to u \) be a composition of \( \beta \) with the constant natural transformation \( \underline{f} : X \to Y \). Then any two of the following three properties imply the third:

- The natural transformation \( \alpha \) exhibits \( X \) as a limit of the diagram \( u \).
- The natural transformation \( \beta \) exhibits \( Y \) as a limit of the diagram \( u \).
- The morphism \( f : X \to Y \) is an isomorphism in the \( \infty \)-category \( \mathcal{C} \).

**Remark 7.1.1.10.** Let \( F : \mathcal{C} \to \mathcal{D} \) be a fully faithful functor of \( \infty \)-categories, let \( u : K \to \mathcal{C} \) be a diagram, and let \( Y \in \mathcal{C} \) be an object equipped with a natural transformation \( \alpha : Y \to u \). If \( F(\alpha) : F(Y) \to (F \circ u) \) exhibits \( F(Y) \) as a limit of the diagram \( (F \circ u) : K \to \mathcal{D} \), then \( \alpha \) exhibits \( Y \) as a limit of \( u \). The converse holds if \( F \) is an equivalence of \( \infty \)-categories.

**Definition 7.1.1.11.** Let \( \mathcal{C} \) be an \( \infty \)-category and let \( u : K \to \mathcal{C} \) be a diagram. We say that an object \( Y \in \mathcal{C} \) is a limit of \( u \) if there exists a natural transformation \( \alpha : Y \to u \) which exhibits \( Y \) as a limit of \( u \), in the sense of Definition 7.1.1.1. We say that \( Y \) is a colimit of \( u \) if there exists a natural transformation \( \beta : u \to Y \) which exhibits \( Y \) as a colimit of \( u \).

**Proposition 7.1.1.12.** Let \( \mathcal{C} \) be an \( \infty \)-category and let \( u : K \to \mathcal{C} \) be a diagram. Then:

- Suppose that the diagram \( u \) has limit \( Y \in \mathcal{C} \). Then an object \( X \in \mathcal{C} \) is a limit of \( u \) if and only if it is isomorphic to \( Y \).
• Suppose that the diagram \( u \) has colimit \( Y \in \mathcal{C} \). Then an object \( X \in \mathcal{C} \) is a colimit of \( u \) if and only if it is isomorphic to \( Y \).

Proof. Let \( \beta : Y \to u \) be a natural transformation which exhibits \( Y \) as a limit of the diagram \( u \). For any object \( X \) and any natural transformation \( \alpha : X \to u \), there exists a morphism \( f : X \to Y \) such that \( \alpha \) is a composition of \( \beta \) with the constant natural transformation \( f : X \to Y \). If \( \alpha \) also exhibits \( X \) as a limit of the diagram \( u \) (Remark 7.1.1.9), then \( f \) is an isomorphism; in particular, \( X \) is isomorphic to \( Y \). Conversely, if \( f : X \to Y \) is an isomorphism, then any composition of \( f \) with \( \beta \) is a natural transformation \( X \to u \) which exhibits \( X \) as a limit of \( u \) (Remark 7.1.1.9), so that \( X \) is a limit of \( Y \). This proves the first assertion; the proof of the second follows by applying the same argument to the opposite \( \infty \)-category \( \mathcal{C}^{\text{op}} \).

Notation 7.1.1.13. Let \( \mathcal{C} \) be an \( \infty \)-category and let \( u : K \to \mathcal{C} \) be a diagram. It follows from Proposition 7.1.1.12 that, if the diagram \( f \) admits a limit \( Y \), then the isomorphism class of the object \( Y \) depends only on the diagram \( u \). To emphasize this dependence, we will often denote \( Y \) by \( \lim \Rightarrow (u) \) and refer to it as the limit of the diagram \( u \). Similarly, if \( u \) admits a colimit \( X \in \mathcal{C} \), we will often denote \( X \) by \( \lim \Leftarrow (u) \) and refer to it as the colimit of the diagram \( u \). Beware that this terminology is somewhat abusive, since the objects \( \lim \Rightarrow (u) \) and \( \lim \Leftarrow (u) \) are only well-defined up to isomorphism.

In situations where the limit \( \lim \Rightarrow (u) \) and colimit \( \lim \Leftarrow (u) \) are defined, they depend functorially on the diagram \( u : K \to \mathcal{C} \).

Definition 7.1.1.14. Let \( \mathcal{C} \) be an \( \infty \)-category and let \( K \) be a simplicial set. We will say that \( \mathcal{C} \) admits \( K \)-indexed limits if, for every diagram \( u : K \to \mathcal{C} \), there exists an object \( Y \in \mathcal{C} \) which is a limit of \( u \). We will say that \( \mathcal{C} \) admits \( K \)-indexed colimits if, for every diagram \( u : K \to \mathcal{C} \), there exists an object \( X \in \mathcal{C} \) which is a colimit of \( u \).

Variant 7.1.1.15. It will often be useful to extend the terminology of Definition 7.1.1.14, replacing the individual simplicial set \( K \) by a collection of simplicial sets. For example:

- We say that an \( \infty \)-category \( \mathcal{C} \) admits finite limits if, for every finite simplicial set \( K \) (Definition 3.5.1.1), every diagram \( f : K \to \mathcal{C} \) admits a limit.

- We say that an \( \infty \)-category \( \mathcal{C} \) admits finite colimits if, for every finite simplicial set \( K \), every diagram \( f : K \to \mathcal{C} \) admits a colimit.

- We say that an \( \infty \)-category \( \mathcal{C} \) admits small limits if, for every (small) simplicial set \( K \), every diagram \( f : K \to \mathcal{C} \) admits a limit.

- We say that an \( \infty \)-category \( \mathcal{C} \) admits small colimits if, for every (small) simplicial set \( K \), every diagram \( f : K \to \mathcal{C} \) admits a colimit.
Remark 7.1.1.16. Let \( u : K \to K' \) be a categorical equivalence of simplicial sets. Then an \( \infty \)-category \( C \) admits \( K \)-indexed colimits if and only if it admits \( K' \)-indexed colimits.

Let \( C \) be an \( \infty \)-category. For every simplicial set \( K \), precomposition with the projection map \( K \to \Delta^0 \) determines a functor
\[
\delta : C \simeq \text{Fun}(\Delta^0, C) \to \text{Fun}(K, C).
\]
We will refer to \( \delta \) as the diagonal functor: it carries each object \( X \in C \) to the constant diagram \( X : K \to C \) taking the value \( X \).

Proposition 7.1.1.17. Let \( C \) be an \( \infty \)-category and let \( K \) be a simplicial set. Then:

- The \( \infty \)-category \( C \) admits \( K \)-indexed limits if and only if the diagonal functor \( \delta : C \to \text{Fun}(K, C) \) admits a right adjoint \( G \). If this condition is satisfied, then the right adjoint \( G : \text{Fun}(K, C) \to C \) carries each diagram \( u : K \to C \) to a limit \( \varprojlim (u) \in C \).

- The \( \infty \)-category \( C \) admits \( K \)-indexed colimits if and only if the diagonal functor \( \delta : C \to \text{Fun}(K, C) \) admits a left adjoint \( F \). In this condition is satisfied, then the left adjoint \( F : \text{Fun}(K, C) \to C \) carries each diagram \( u : K \to C \) to a colimit \( \varinjlim (u) \in C \).

Proof. Apply Proposition 6.2.4.1. \( \square \)

7.1.2 Limit and Colimit Diagrams

Let \( C \) be an \( \infty \)-category, let \( u : K \to C \) be a diagram, and let \( C \times_{\text{Fun}(K, C)} \{u\} \) denote the oriented fiber product of Construction 4.6.4.1. By definition, we can identify objects of \( C \times_{\text{Fun}(K, C)} \{u\} \) with pairs \( (Y, \alpha) \), where \( Y \) is an object of \( C \) and \( \alpha : Y \to u \) is a natural transformation (here \( Y \) denotes the constant diagram \( K \to \{Y\} \to C \)). Using Proposition 5.7.6.21, we can reformulate Definition 7.1.1.1 as follows:

Proposition 7.1.2.1. Let \( C \) be an \( \infty \)-category containing an object \( Y \), let \( u : K \to C \) be a diagram, and let \( Y : K \to C \) denote the constant taking the value. Then:

- A natural transformation \( \alpha : Y \to u \) exhibits \( Y \) as a limit of the diagram \( u \) if and only if it is final when regarded as an object of the oriented fiber product \( C \times_{\text{Fun}(K, C)} \{u\} \).

- A natural transformation \( \beta : u \to Y \) exhibits \( Y \) as a colimit of the diagram \( u \) if and only if it is initial when regarded as an object of the oriented fiber product \( \{u\} \times_{\text{Fun}(K, C)} C \).

Proof. We will prove the first assertion; the second follows by a similar argument. Projection onto the first factor determines a right fibration \( \theta : C \times_{\text{Fun}(K, C)} \{u\} \to C \). For each object \( X \in C \), we can identify \( \theta^{-1}(X) \) with the morphism space \( \text{Hom}_{\text{Fun}(K, C)}(X, u) \). Let
\[
\rho_X : \text{Hom}_{\text{Fun}(K, C)}(Y, u) \times \text{Hom}_C(X, Y) \to \text{Hom}_{\text{Fun}(K, C)}(X, u)
\]
be the parametrized contravariant transport map of Variant 5.2.8.6. Using Remark 5.2.8.5 and Proposition 5.2.8.7, we see that \( \rho_X \) factors as a composition

\[
\Hom_{\Fun(K,C)}(Y, u) \times \Hom_C(X,Y) \xrightarrow{\rho_X} \Hom_{\Fun(K,C)}(Y, u) \times \Hom_{\Fun(K,C)}(X,Y) \xrightarrow{\delta} \Hom_{\Fun(K,C)}(X,u),
\]
given on objects by the construction \( (\alpha,f) \mapsto \alpha \circ f \). It follows that a natural transformation \( \alpha : Y \to u \) exhibits \( Y \) as a limit of \( u \) if and only if, for every object \( X \in C \), the restriction \( \rho_X \mid_{\{\alpha\} \times \Hom_C(X,Y)} \) is a homotopy equivalence of Kan complexes. By virtue of Proposition 5.7.6.21, this is equivalent to the requirement that \( \alpha \) is final when regarded as an object of the \( \infty \)-category \( \tilde{C} \times_{\Fun(K,C)} \{u\} \).

Corollary 7.1.2.2. Let \( C \) be an \( \infty \)-category, let \( u : K \to C \) be a diagram, and let \( Y \in C \) be an object. The following conditions are equivalent:

1. The object \( Y \) is a limit of the diagram \( u \).
2. The object \( Y \) represents the right fibration \( C \times_{\Fun(K,C)} \{u\} \to C \) given by projection onto the first factor.
3. The object \( Y \) represents the right fibration \( C/_{u} \to C \) of Proposition 4.3.6.1.

Proof. The equivalence (1) \( \Leftrightarrow \) (2) follows immediately from Proposition 7.1.2.1, and the equivalence (2) \( \Leftrightarrow \) (3) follows from the observation that the slice diagonal \( C/_{u} \to \tilde{C} \times_{\Fun(K,C)} \{u\} \) of Construction 4.6.4.13 is an equivalence of \( \infty \)-categories (Theorem 4.6.4.17).

Corollary 7.1.2.3. Let \( C \) be an \( \infty \)-category and let \( u : K \to C \) be a diagram. The following conditions are equivalent:

1. The diagram \( u \) has a limit in \( C \).
2. The oriented fiber product \( C \times_{\Fun(K,C)} \{u\} \to C \) has a final object.
3. The slice \( \infty \)-category \( C/_{u} \) has a final object.

Let \( u : K \to C \) be a diagram in an \( \infty \)-category \( C \). If \( Y \) is an object of \( C \), then supplying a natural transformation of diagrams \( \alpha : Y \to u \) is equivalent to giving a morphism of simplicial sets \( \overline{u} : \Delta^0 \circ K \to C \) satisfying \( \overline{u}|_{\Delta^0} = Y \) and \( \overline{u}|_{K} \), where

\[
\Delta^0 \circ K = \Delta^0 \coprod_{\{(0) \times K\}} (\Delta^1 \times K)
\]

is the simplicial set introduced in Notation 4.5.8.3. In practice, a datum of this type can be somewhat cumbersome to work with. For example, if \( K \) is an \( \infty \)-category, then \( \Delta^0 \circ K \) need not be an \( \infty \)-category. It is therefore often convenient to work with the following variant of Definition 7.1.1.1.
Definition 7.1.2.4. Let $\mathcal{C}$ be an $\infty$-category, let $K$ be a simplicial set, and let $\overline{u} : K^\circ \to \mathcal{C}$ be a morphism of simplicial sets carrying the cone point of $K^\circ$ to an object $Y \in \mathcal{C}$. Set $u = \overline{u}|_K$, so that the diagram $\overline{u}$ can be identified with an object of the slice $\infty$-category $\mathcal{C}/u$. We will say that $\overline{u}$ is a limit diagram if it is a final object of $\mathcal{C}/u$. If this condition is satisfied, we say that $\overline{u}$ exhibits $Y$ as a limit of the diagram $u$.

Variant 7.1.2.5. Let $\mathcal{C}$ be an $\infty$-category, let $K$ be a simplicial set, and let $\overline{u} : K^\circ \to \mathcal{C}$ be a morphism of simplicial sets carrying the cone point of $K^\circ$ to an object $Y \in \mathcal{C}$. Set $u = \overline{u}|_K$, so that the diagram $\overline{u}$ can be identified with an object of the coslice $\infty$-category $\mathcal{C}_{u/}$. We will say that $\overline{u}$ is a colimit diagram if it is an initial object of $\mathcal{C}_{u/}$. If this condition is satisfied, we say that $\overline{u}$ exhibits $Y$ as a colimit of the diagram $u$.

Remark 7.1.2.6. Let $\overline{u} : K^\circ \to \mathcal{C}$ be as in Definition 7.1.2.4. Then $\overline{u}$ is a limit diagram if and only if the composite map

$$\Delta^1 \times K \simeq K \ast_K K \to \Delta^0 \ast_{\Delta^0} K = K^\circ \xrightarrow{\overline{u}} \mathcal{C}$$

corresponds to a natural transformation $\alpha : Y \to u$ which exhibits $Y$ as a limit of $u$, in the sense of Definition 7.1.1.1. This follows from the characterization of Proposition 7.1.2.1, together with the observation that the slice diagonal $\mathcal{C}/u \to \mathcal{C} \times_{\operatorname{Fun}(K,\mathcal{C})} \{u\}$ of Construction 4.6.4.13 is an equivalence of $\infty$-categories (Theorem 4.6.4.17).

Remark 7.1.2.7. Let $\mathcal{C}$ be an $\infty$-category and let $u : K \to \mathcal{C}$ be a diagram. Then an object $Y \in \mathcal{C}$ is a limit of $u$ (in the sense of Definition 7.1.1.1) if and only if there exists a diagram $\overline{u} : K^\circ \to \mathcal{C}$ which exhibits $Y$ as a limit of $u$. This is a reformulation of Corollary 7.1.2.2. Similarly, $Y$ is a colimit of $u$ if and only if there exists a diagram $\overline{u}' : K^\circ \to \mathcal{C}$ which exhibits $Y$ as a colimit of $u$.

Remark 7.1.2.8. Let $\mathcal{C}$ be an $\infty$-category and let $f : K \to \mathcal{C}$ be a morphism of simplicial sets. An extension $\overline{f} : K^\circ \to \mathcal{C}$ is a colimit diagram in $\mathcal{C}$ if and only if the opposite map $\overline{f}^{\operatorname{op}} : (K^{\operatorname{op}})^\circ \to \mathcal{C}^{\operatorname{op}}$ is a limit diagram in the $\infty$-category $\mathcal{C}^{\operatorname{op}}$.

Example 7.1.2.9. Let $\mathcal{C}$ be an $\infty$-category. Then an object $Y \in \mathcal{C}$ is final (in the sense of Definition 4.6.6.1) if and only if the map

$$(\emptyset)^\circ \simeq \Delta^0 \xrightarrow{Y} \mathcal{C}$$

is a limit diagram in $\mathcal{C}$. Similarly, $Y$ is initial if and only if the map

$$(\emptyset)^{\operatorname{op}} \simeq \Delta^0 \xrightarrow{Y} \mathcal{C}$$

is a colimit diagram in $\mathcal{C}$.
Example 7.1.2.10. Let $\mathcal{C}$ be an $\infty$-category and let $f : X \to Y$ be a morphism of $\mathcal{C}$. The following conditions are equivalent:

- The morphism $f$ is an isomorphism.
- When regarded as a morphism $(\Delta^0)^{\triangleright} \to \mathcal{C}$, $f$ is a limit diagram.
- When regarded as a morphism $(\Delta^0)^{\rhd} \to \mathcal{C}$, $f$ is a colimit diagram.

This is a restatement of Proposition 4.6.6.23 (and also of Example 7.1.1.5, by virtue of Remark 7.1.2.6).

Remark 7.1.2.11. Let $\mathcal{C}$ be an $\infty$-category, let $g : B \to \mathcal{C}$ be a morphism of simplicial sets, and suppose we are given a diagram $\overline{f} : A^\triangleright \to \mathcal{C}/g$, which we can identify with a morphism of simplicial sets

$$\overline{\eta} : (A \star B)^{\triangleright} \simeq A^{\triangleright} \star B \to \mathcal{C}.$$ 

Then $\overline{f}$ is a limit diagram in the slice $\infty$-category $\mathcal{C}/g$ if and only if $\overline{\eta}$ is a limit diagram in the $\infty$-category $\mathcal{C}$.

Proposition 7.1.2.12. Let $\mathcal{C}$ be an $\infty$-category, let $K$ be a simplicial set, and let $\overline{f} : K^{\triangleright} \to \mathcal{C}$ be a morphism with restriction $f = \overline{f}|_K$. The following conditions are equivalent:

1. The morphism $\overline{f}$ is a limit diagram (Definition 7.1.2.4).
2. The restriction map $\mathcal{C}/\overline{f} \to \mathcal{C}/f$ is a trivial Kan fibration.
3. The restriction map $\mathcal{C}/\overline{f} \to \mathcal{C}/f$ is an equivalence of $\infty$-categories.
4. For every object $X \in \mathcal{C}$, the restriction map $\{X\} \times_{\mathcal{C}} \mathcal{C}/\overline{f} \to \{X\} \times_{\mathcal{C}} \mathcal{C}/f$ is a homotopy equivalence of Kan complexes.

Proof. The equivalence (1) $\iff$ (2) follows from Proposition 4.6.6.11. Note that the restriction map $\mathcal{C}/\overline{f} \to \mathcal{C}/f$ is a right fibration of $\infty$-categories (Corollary 4.3.6.11), and therefore an isofibration (Example 4.4.1.10). The equivalence (2) $\iff$ (3) now follows from Proposition 4.5.5.20 and the equivalence (3) $\iff$ (4) follows from Corollary 5.1.5.4.

Proposition 7.1.2.13. Let $\mathcal{C}$ be an $\infty$-category, let $K$ be a simplicial set, and let $\overline{p} : \overline{F} \to \overline{G}$ be a natural transformation between diagrams $\overline{F}, \overline{G} : K^{\triangleright} \to \mathcal{C}$. Assume that, for every vertex $x \in K$, the morphism $\overline{p}_x : \overline{F}(x) \to \overline{F}(x)$ is an isomorphism in $\mathcal{C}$. Then any two of the following conditions imply the third:

1. The morphism of simplicial sets $\overline{F}$ is a limit diagram in $\mathcal{C}$.
2. The morphism of simplicial sets $\overline{G}$ is a limit diagram in $\mathcal{C}$.
The natural transformation \( \rho \) carries the cone point \( 0 \in K^\circ \) to an isomorphism \( \bar{\rho}_0 : \overline{F}(0) \to \overline{F}(0) \).

**Proof.** Set \( F = \overline{F}|_K \) and \( G = \overline{G}|_K \), so that \( \bar{\rho} \) restricts to an isomorphism \( \rho : F \to G \) in the \( \infty \)-category \( \text{Fun}(K, \mathcal{C}) \) (Theorem 4.4.4.4). Set \( X = \overline{F}(0) \) and \( Y = \overline{F}(0) \), and let \( X, Y : K \to \mathcal{C} \) be the constant maps taking the values \( X \) and \( Y \), respectively. Let \( c \) denote the composition \( \Delta^1 \times K \simeq K^0 \times K^0 \to \Delta^0 \times K^0 = K^a \). Then the composition

\[
\Delta^1 \times \Delta^1 \times K \xrightarrow{\text{id} \times c} \Delta^1 \times K^a \xrightarrow{\rho} K
\]

can be identified with a commutative diagram

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow^\alpha & \swarrow^\gamma & \downarrow^\beta \\
F & \xrightarrow{\rho} & G
\end{array}
\]

in the \( \infty \)-category \( \text{Fun}(K, \mathcal{C}) \). Using Remark 7.1.2.6, we can reformulate conditions (1) and (2) as follows:

(1') The natural transformation \( \alpha \) exhibits \( X \) as a limit of \( F \).

(2') The natural transformation \( \beta \) exhibits \( Y \) as a limit of \( G \).

Since \( \rho \) is an isomorphism, we can use Remark 7.1.1.8 restate (1') as follows:

(1'') The natural transformation \( \gamma \) exhibits \( X \) as a limit of \( G \).

It will therefore suffice to show that any two of the conditions (1''), (2'), and (3) imply the third, which is a special case of Remark 7.1.1.9. \( \square \)

**Corollary 7.1.2.14.** Let \( \mathcal{C} \) be an \( \infty \)-category and let \( K \) be a simplicial set. Then:

1. Let \( \overline{\pi}, \overline{\nu} : K^a \to \mathcal{C} \) be a pair of diagrams which are isomorphic when regarded as objects of the \( \infty \)-category \( \text{Fun}(K^a, \mathcal{C}) \). Then \( \overline{\pi} \) is a limit diagram if and only if \( \overline{\nu} \) is a limit diagram.

2. Let \( \overline{\pi}, \overline{\nu} : K^p \to \mathcal{C} \) be a pair of diagrams which are isomorphic when regarded as objects of the \( \infty \)-category \( \text{Fun}(K^p, \mathcal{C}) \). Then \( \overline{\pi} \) is a colimit diagram if and only if \( \overline{\nu} \) is a colimit diagram.

**Corollary 7.1.2.15.** Let \( \mathcal{C} \) be an \( \infty \)-category, let \( K \) be a simplicial set, and suppose we are given a pair of morphisms \( u, v : K \to \mathcal{C} \) which are isomorphic as objects of the \( \infty \)-category \( \text{Fun}(K, \mathcal{C}) \). Then:
(1) The morphism \( u \) can be extended to a limit diagram \( \overline{u} : K^a \to \mathcal{C} \) if and only if \( v \) can be extended to a limit diagram \( \overline{v} : K^a \to \mathcal{C} \).

(2) The morphism \( u \) can be extended to a colimit diagram \( \overline{u} : K^o \to \mathcal{C} \) if and only if \( v \) can be extended to a colimit diagram \( \overline{v} : K^o \to \mathcal{C} \).

Proof. We will prove (1); the proof of (2) is similar. Suppose that \( u \) can be extended to a limit diagram \( \overline{u} : K^a \to \mathcal{C} \). Since the diagrams \( u \) and \( v \) are isomorphic, it follows from Corollary 4.4.5.3 that \( u \) is isomorphic to a diagram \( \overline{v} : K^a \to \mathcal{C} \) satisfying \( \overline{v}|_K = v \). Applying Corollary 7.1.2.14, we conclude that \( \overline{v} \) is also a limit diagram.

7.1.3 Preservation of Limits and Colimits

Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories. Beware that, in general, \( F \) need not carry (co)limit diagrams in \( \mathcal{C} \) to (co)limit diagrams in \( \mathcal{D} \). This motivates the following:

Definition 7.1.3.1. Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories, and let \( q : K \to \mathcal{C} \) be a diagram. Suppose that \( q \) can be extended to a limit diagram \( \overline{q} : K^a \to \mathcal{C} \). We say that the limit of \( q \) is preserved by \( F \) if the composition \( F \circ \overline{q} \) is a limit diagram in the \( \infty \)-category \( \mathcal{D} \). Similarly, if \( q \) can be extended to a colimit diagram \( \overline{q} : K^o \to \mathcal{C} \), we say that the colimit of \( q \) is preserved by \( F \) if \( F \circ \overline{q} \) is a colimit diagram in the \( \infty \)-category \( \mathcal{D} \).

Remark 7.1.3.2. In the situation of Definition 7.1.3.1, the condition that \( F \) preserves the (co)limit of a diagram \( q : K \to \mathcal{C} \) depends only on the diagram \( q \), and not on the extension \( \overline{q} \) (see Corollary 7.1.2.14).

Remark 7.1.3.3. Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories and let \( q : K \to \mathcal{C} \) be a diagram which admits a limit in \( \mathcal{C} \). Choose an object \( X \in \mathcal{C} \) and a natural transformation \( \alpha : X \to q \) which exhibits \( X \) as a limit of \( q \). Then \( F \) preserves the limit of \( q \) if and only if the natural transformation \( F(\alpha) \) exhibits the object \( F(X) \) as a limit of the diagram \( F \circ q \).

Definition 7.1.3.4. Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories and let \( K \) be a simplicial set. We will say that \( F \) preserves \( K \)-indexed limits if, for every limit diagram \( \overline{q} : K^a \to \mathcal{C} \), the composite map \( (F \circ \overline{q}) : K^a \to \mathcal{D} \) is a limit diagram in \( \mathcal{D} \). We will say that \( F \) preserves \( K \)-indexed colimits if, for every colimit diagram \( \overline{q} : K^o \to \mathcal{C} \), the composite map \( (F \circ \overline{q}) : K^o \to \mathcal{D} \) is a colimit diagram in \( \mathcal{D} \).

Example 7.1.3.5. Let \( F : \mathcal{C} \to \mathcal{D} \) be any functor of \( \infty \)-categories. Then \( F \) preserves \( \Delta^0 \)-indexed limits and colimits. By virtue of Example 7.1.2.10, this is equivalent to the observation that \( F \) carries isomorphisms in \( \mathcal{C} \) to isomorphisms in \( \mathcal{D} \) (see Remark 1.4.1.6).

Warning 7.1.3.6. In the formulation of Definition 7.1.3.1, it is not necessary to assume that the \( \infty \)-category \( \mathcal{C} \) admits \( K \)-indexed limits or colimits. For example, if \( \mathcal{C} \) is an \( \infty \)-category
which contains no limit diagrams $\overline{q} : K^\Delta \to C$, then every functor $F : C \to D$ preserves $K$-indexed limits. In practice, we will usually (but not always) apply the terminology of Definition 7.1.3.4 in cases where the $\infty$-category admits $K$-indexed limits or colimits, so that the conclusion of Definition 7.1.3.4 is non-vacuous.

**Exercise 7.1.3.7.** Let $F : C \to D$ be a functor of $\infty$-categories and let $K$ be a simplicial set. Show that $F$ preserves $K$-indexed limits if and only if it satisfies the following condition:

- For every diagram $u : K \to C$ and every natural transformation $\alpha : Y \to u$ which exhibits an object $Y \in C$ as a limit of $u$ (in the sense of Definition 7.1.1.1), the image $F(\alpha) : F(Y) \to (F \circ u)$ exhibits the object $F(Y) \in D$ as a limit of the diagram $(F \circ u) : K \to D$.

**Variant 7.1.3.8.** It will often be useful to extend the terminology of Definition 7.1.3.4, replacing the individual simplicial set $K$ by a collection of simplicial sets.

- We say that a functor of $\infty$-categories $F : C \to D$ preserves finite limits if it preserves $K$-indexed limits, for every finite simplicial set $K$.

- We say that a functor of $\infty$-categories $F : C \to D$ preserves finite colimits if it preserves $K$-indexed colimits, for every finite simplicial set $K$.

- We say that a functor of $\infty$-categories $F : C \to D$ preserves small limits if it preserves $K$-indexed limits, for every small simplicial set $K$.

- We say that a functor of $\infty$-categories $F : C \to D$ preserves small colimits if it preserves $K$-indexed colimits, for every small simplicial set $K$.

Let us begin with a trivial example.

**Proposition 7.1.3.9.** Let $F : C \to D$ be an equivalence of $\infty$-categories and let $K$ be a simplicial set. Then:

1. A morphism $\overline{u} : K^\Delta \to C$ is a limit diagram if and only if the composition $F \circ \overline{u}$ is a limit diagram in $D$.

2. A morphism $\overline{u} : K^\Delta \to C$ is a colimit diagram if and only if the composition $F \circ \overline{u}$ is a colimit diagram in $D$.

In particular, the equivalence $F$ preserves $K$-indexed limits and colimits.
**Proof.** We will prove (1); the proof of (2) is similar. Let \( \overline{\pi} : K^\circ \to \mathcal{C} \) be a diagram and set \( u = \pi|_K \). We then have a commutative diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\mathcal{C}/\pi & \longrightarrow & \mathcal{D}/(F \circ \pi) \\
\downarrow & & \downarrow \\
\mathcal{C}/u & \longrightarrow & \mathcal{D}/(F \circ \pi).
\end{array}
\]

Since \( F \) is an equivalence of \( \infty \)-categories, the horizontal maps in this diagram are also equivalences of \( \infty \)-categories (Corollary 4.6.4.19). It follows that the left vertical map is an equivalence of \( \infty \)-categories if and only if the right vertical map is an equivalence of \( \infty \)-categories. The desired result now follows from the criterion of Proposition 7.1.2.12.

**Variant 7.1.3.10.** Let \( F : \mathcal{C} \to \mathcal{D} \) be a fully faithful functor of \( \infty \)-categories and let \( \pi : K^\circ \to \mathcal{C} \) be a morphism of simplicial sets. If \( F \circ \pi \) is a limit diagram in the \( \infty \)-category \( \mathcal{D} \), then \( \pi \) is a limit diagram in the \( \infty \)-category \( \mathcal{C} \).

**Proof.** Combine Remark 7.1.10 with Exercise 7.1.3.7.

**Corollary 7.1.3.11.** Let \( F : \mathcal{C} \to \mathcal{D} \) be an equivalence of \( \infty \)-categories and let \( u : K \to \mathcal{C} \) be a morphism of simplicial sets. Then:

1. The morphism \( u \) can be extended to a limit diagram \( \overline{\pi} : K^\circ \to \mathcal{C} \) if and only if the composite map \( (F \circ u) : K \to \mathcal{D} \) can be extended to a limit diagram \( K^\circ \to \mathcal{D} \).

2. The morphism \( u \) can be extended to a colimit diagram \( \overline{\pi} : K^\circ \to \mathcal{C} \) if and only if the composite map \( (F \circ u) : K \to \mathcal{D} \) can be extended to a colimit diagram \( K^\circ \to \mathcal{D} \).

**Proof.** We will prove (1); the proof of (2) is similar. If \( u \) can be extended to a limit diagram \( \overline{\pi} : K^\circ \to \mathcal{C} \), then Proposition 7.1.3.9 guarantees that \( F \circ \pi \) is a limit diagram in \( \mathcal{D} \) extending \( F \circ u \). Conversely, suppose that \( F \circ u \) can be extended to a limit diagram \( \overline{\pi} : K^\circ \to \mathcal{D} \). Let \( G : \mathcal{D} \to \mathcal{C} \) be an equivalence of \( \infty \)-categories which is homotopy inverse to \( F \), so that \( G \circ F \) is isomorphic to the identity functor \( \text{id}_{\mathcal{C}} \). Then \( (G \circ \overline{\pi}) : K^\circ \to \mathcal{C} \) is a limit diagram in \( \mathcal{C} \) (Proposition 7.1.3.9), and the restriction \( (G \circ \overline{\pi})|_K = (G \circ F \circ u) \) is isomorphic to \( u \) as an object of the \( \infty \)-category \( \text{Fun}(K, \mathcal{C}) \). Applying Corollary 7.1.2.15, we deduce that \( u \) can be extended to a limit diagram \( \overline{\pi} : K^\circ \to \mathcal{C} \).

**Corollary 7.1.3.12.** Let \( \mathcal{C} \) and \( \mathcal{D} \) be \( \infty \)-categories which are equivalent to one another, and let \( K \) be a simplicial set. Then \( \mathcal{C} \) admits \( K \)-indexed (co)limits if and only if \( \mathcal{D} \) admits \( K \)-indexed (co)limits.
Remark 7.1.3.13. Let $F : C \to D$ be a functor of $\infty$-categories, let $K$ be a simplicial set, and let $\pi : K^\alpha \to C$ be a limit diagram with restriction $u = \pi|_K$. The following conditions are equivalent:

1. The composition $(F \circ \pi) : K^\alpha \to D$ is a limit diagram.

2. For every limit diagram $\pi' : K^\alpha \to C$ with $\pi'|_K = u$, the composition $(F \circ \pi') : K^\alpha \to D$ is a limit diagram.

The implication $(2) \Rightarrow (1)$ is immediate. For the converse, we observe that if $\pi' : K^\alpha \to C$ is another limit diagram with $\pi'|_K = u$, then $\pi$ and $\pi'$ are isomorphic when viewed as objects of the slice $\infty$-category $C/\pi$, so that $F \circ \pi$ and $F \circ \pi'$ are isomorphic when viewed as objects of the $\infty$-category $D/(F \circ \pi)$. Since $F \circ \pi$ is a final object of $D/(F \circ \pi)$, it follows that $F \circ \pi'$ is also a final object of $D/(F \circ \pi)$ (Corollary 4.6.6.16).

A conservative functor $F : C \to D$ which preserves $K$-indexed limits also reflects them:

Proposition 7.1.3.14. Let $F : C \to D$ be a conservative functor of $\infty$-categories and let $K$ be a simplicial set.

- Suppose that $C$ admits $K$-indexed limits and the functor $F$ preserves $K$-indexed limits. Then a morphism $\pi : K^\alpha \to C$ is a limit diagram in $C$ if and only if $(F \circ \pi) : K^\alpha \to D$ is a limit diagram in $D$.

- Suppose that $C$ admits $K$-indexed colimits and the functor $F$ preserves $K$-indexed colimits. Then a morphism $\pi : K^\beta \to C$ is a colimit diagram in $C$ if and only if $(F \circ \pi) : K^\beta \to D$ is a colimit diagram in $D$.

Proposition 7.1.3.14 is an immediate consequence of the following more precise assertion:

Lemma 7.1.3.15. Let $F : C \to D$ be a conservative functor of $\infty$-categories and let $u : K \to C$ be a diagram. Suppose that $u$ can be extended to a limit diagram $\pi : K^\alpha \to C$ for which the composition $(F \circ \pi) : K^\alpha \to D$ is also a limit diagram. Let $\pi' : K^\alpha \to C$ be an arbitrary extension of $u$. Then $\pi'$ is a limit diagram in $C$ if and only if $F \circ \pi'$ is a limit diagram in $D$.

Proof. Let us identify $\pi$ and $\pi'$ with objects $C$ and $C'$ of the slice $\infty$-category $C/\pi$. Our assumption that $\pi$ is a limit diagram guarantees that $C$ is a final object of $C/\pi$, so there exists a morphism $f : C' \to C$ in $C/\pi$. Note that $\pi'$ is a limit diagram if and only if the object $C'$ is also final: that is, if and only if the morphism $f$ is an isomorphism.

Let $g : D' \to D$ be the image of $f$ under the functor $F|_u : C/\pi \to D/(F \circ \pi)$. Our assumption that $F \circ \pi$ is a limit diagram guarantees that $D$ is a final object of $D/(F \circ \pi)$. Consequently, $g$
is an isomorphism if and only if the object $D'$ is also final: that is, if and only if $(F \circ \pi')$ is a limit diagram in $D$.

To complete the proof, it will suffice to show that $f$ is an isomorphism in $C/u$ if and only if $g = F/u(f)$ is an isomorphism in $D/(F \circ q)$. In fact, the functor $F/u$ is conservative: this follows from our assumption that $F$ is conservative, by virtue of Corollary 4.4.2.12.

**Definition 7.1.3.16.** Let $F : C \to D$ be a conservative functor of $\infty$-categories and let $K$ be a simplicial set. We will say that the functor $F$ creates $K$-indexed limits if the following condition is satisfied:

- Let $u : K \to C$ be a diagram for which the induced map $(F \circ u) : K \to D$ admits a limit in $D$. Then $u$ can be extended to a limit diagram $\pi : K^\triangleleft \to C$ for which the composition $(F \circ \pi) : K^\triangleleft \to D$ is a limit diagram in $D$.

We say that the functor $F$ creates $K$-indexed colimits if it satisfies the following dual condition:

- Let $u : K \to C$ be a diagram for which the induced map $(F \circ u) : K \to D$ admits a colimit in $D$. Then $u$ can be extended to a colimit diagram $q : K^{\triangleright} \to C$ for which the composition $(F \circ q) : K^{\triangleright} \to D$ is a colimit diagram in $D$.

**Remark 7.1.3.17.** Let $F : C \to D$ be a conservative functor of $\infty$-categories and let $u : K \to C$ be a diagram. Suppose that $F$ creates $K$-indexed limits and that $F \circ u$ can be extended to a limit diagram $K^{\triangleleft} \to D$. Then an extension $\pi : K^{\triangleleft} \to C$ of $u$ is a limit diagram if and only if $F \circ \pi$ is a limit diagram in $D$ (see Lemma 7.1.3.15).

**Proposition 7.1.3.18.** Let $K$ be a simplicial set, let $D$ be an $\infty$-category which admits $K$-indexed limits, and let $F : C \to D$ be a conservative functor of $\infty$-categories. The following conditions are equivalent:

1. The $\infty$-category $C$ admits $K$-indexed limits and the functor $F$ preserves $K$-indexed limits.
2. The functor $F$ creates $K$-indexed limits.

**Proof.** The implication (1) $\Rightarrow$ (2) is immediately. Conversely, suppose that (2) is satisfied and let $u : K \to C$ be a diagram. Since $D$ admits $K$-indexed limits, $F \circ u$ can be extended to a limit diagram in $D$. Since $F$ creates $K$-indexed limits, it follows that there exists a limit diagram $\pi : K^{\triangleleft} \to C$ with $\pi|_K = u$ such that $F \circ \pi$ is a limit diagram in $D$. Applying Remark 7.1.3.13, we see that this holds for every limit diagram $\pi : K^{\triangleleft} \to C$ satisfying $\pi|_K = u$, which proves (1).

The following is an important example of Definition 7.1.3.16.
Proposition 7.1.3.19. Let \( C \) be an \( \infty \)-category, let \( A \) be a simplicial set, and let \( f : A \to C \) be a diagram. Then:

1. The projection map \( C_f/ \to C \) creates \( K \)-indexed limits, for every simplicial set \( K \).
2. The projection map \( C_f/ \to C \) creates \( K \)-indexed colimits, for every simplicial set \( K \).

Proof. We will prove (1); the proof of (2) is similar. Let \( K \) be a simplicial set and let \( p : K \to C_f/ \) be a diagram, which we will identify with a morphism of simplicial sets \( q : A \star K \to C \) satisfying \( q|_A = f \). Set \( g = q|_K \), so that \( q \) can also be identified with a diagram \( f' : A \to C/g \). Suppose that \( g \) can be extended to a limit diagram \( g : K/ \to C \). Then the projection map \( C/g \to C \) is a trivial Kan fibration (Proposition 7.1.2.12), so that \( f' \) can be lifted to a diagram \( f'' : A \to C/g \). We can then identify \( f'' \) with a morphism of simplicial sets \( \overline{p} : A \star K \to C \) extending \( p \). We will complete the proof by showing that \( \overline{p} \) is a limit diagram. To prove this, it will suffice to show that \( \overline{p} \) is final when regarded as an object of the slice \( \infty \)-category \( (C_f)/p \simeq (C/g)/f' \). This follows from Proposition 4.6.6.13, since \( \overline{p} \) is a final object of \( C/g \).

Corollary 7.1.3.20. Let \( C \) be an \( \infty \)-category, let \( f : A \to C \) be a morphism of simplicial sets, and let \( K \) be an arbitrary simplicial set. Then:

1. If \( C \) admits \( K \)-indexed limits, then the coslice \( \infty \)-category \( C_f/ \) admits \( K \)-indexed limits and the projection map \( C_f/ \to C \) preserves \( K \)-indexed limits.
2. If \( C \) admits \( K \)-indexed colimits, then the slice \( \infty \)-category \( C_f/ \) admits \( K \)-indexed colimits and the projection map \( C_f/ \to C \) preserves \( K \)-indexed colimits.

Proof. Combine Propositions 7.1.3.19 and 7.1.3.18.

Corollary 7.1.3.21. Let \( F : C \to D \) be a functor of \( \infty \)-categories which admits a right adjoint \( G : D \to C \). For every simplicial set \( K \), the functor \( F \) preserves \( K \)-indexed colimits and the functor \( G \) preserves \( K \)-indexed limits.

Proof. We will show that \( F \) preserves \( K \)-indexed colimits; the assertion that \( G \) preserves \( K \)-indexed limits can be proved by a similar argument. Let \( u : K \to C \) be a morphism of simplicial sets, so that \( F \) induces a functor \( F' : C_{u/} \to D_{(Fou)/} \). We wish to show that the functor \( F' \) carries initial objects of \( C_{u/} \) to initial objects of \( D_{(Fou)/} \). It follows from Corollary 6.2.4.6 that the functor \( F' \) also admits a right adjoint. We may therefore replace \( F \) by \( F' \) and thereby reduce to the case where \( K = \emptyset \). In this case, we must show that if \( X \) is an initial object of \( C \), then \( F(X) \) is an initial object of \( D \). Choose an object \( Y \in D \); we wish to show that the morphism space \( \operatorname{Hom}_D(F(X), Y) \) is a contractible Kan complex. Proposition 6.2.1.17 supplies a homotopy equivalence of Kan complexes \( \operatorname{Hom}_D(F(X), Y) \simeq \operatorname{Hom}_C(X, G(Y)) \). We conclude by observing that the Kan complex \( \operatorname{Hom}_C(X, G(Y)) \) is contractible, by virtue of our assumption that the object \( X \in C \) is initial.
7.1.4 Relative Initial and Final Objects

In §4.6.6, we introduced the notions of initial and final object of an ∞-category $C$ (Definition 4.6.6.1). In this section, we study the more general notions of $U$-initial and $U$-final objects, where $U : C \to D$ is a functor of ∞-categories.

**Definition 7.1.4.1.** Let $U : C \to D$ be a functor of ∞-categories. We say that an object $Y \in C$ is $U$-final if, for every object $X \in C$, the functor $U$ induces a homotopy equivalence

$$\text{Hom}_C(X,Y) \to \text{Hom}_D(U(X),U(Y)).$$

We say that $Y$ is $U$-initial if, for every object $Z \in C$, the functor $U$ induces a homotopy equivalence

$$\text{Hom}_C(Y,Z) \to \text{Hom}_D(U(Y),U(Z)).$$

**Example 7.1.4.2.** Let $C$ be an ∞-category and let $U : C \to \Delta^0$ be the projection map. Then an object $Y \in C$ is $U$-initial if and only if it is initial, and $U$-final if and only if it is final.

**Remark 7.1.4.3.** Let $U : C \to D$ be a functor of ∞-categories, and let $C_0 \subseteq C$ be the full subcategory of $C$ spanned by the $U$-initial objects. Then the restriction $U|_{C_0} : C_0 \to D$ is fully faithful. Similarly, $U$ is fully faithful when restricted to the full subcategory of $U$-final objects of $C$.

**Example 7.1.4.4.** Let $U : C \to D$ be a functor of ∞-categories. The following conditions are equivalent:

- The functor $U$ is fully faithful.
- Every object of $C$ is $U$-initial.
- Every object of $C$ is $U$-final.

**Remark 7.1.4.5.** Let $U : C \to D$ be an inner fibration of ∞-categories. Then an object $Y \in C$ is $U$-initial if and only if it is $U^{\text{op}}$-final, when regarded as an object of the opposite ∞-category $C^{\text{op}}$.

**Remark 7.1.4.6 (Transitivity).** Let $U : C \to D$ and $V : D \to E$ be functors of ∞-categories, and let $Y \in C$ be an object for which $U(Y)$ is $V$-final. Then $Y$ is $U$-final if and only if it is $(V \circ U)$-final.

**Remark 7.1.4.7.** Let $U : C \to D$ be a functor of ∞-categories and let $Y \in C$ be an object. Suppose that $U(Y)$ is a final object of $D$. Then $Y$ is a final object of $C$ if and only if it is a $U$-final object of $C$ (apply Remark 7.1.4.6 in the special case $E = \Delta^0$).
Remark 7.1.4.8. Let \( U : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories, and let \( V : \mathcal{C} \to \mathcal{D} \) be another functor which is isomorphic to \( U \) (as an object of the \( \infty \)-category \( \text{Fun}(\mathcal{C}, \mathcal{D}) \)). Then an object \( Y \in \mathcal{C} \) is \( U \)-initial if and only if it is \( V \)-initial. To prove this, let \( Z \) be an object of \( \mathcal{C} \) and let \( \alpha : U \to V \) be an isomorphism of functors, so that we have a commutative diagram

\[
\begin{array}{ccc}
\text{Hom}_\mathcal{C}(Y, Z) & \xrightarrow{\text{id}} & \text{Hom}_\mathcal{D}(U(Y), U(Z)) \\
\downarrow & & \downarrow \alpha_Z \circ \downarrow \\
\text{Hom}_\mathcal{D}(V(Y), V(Z)) & \xrightarrow{\circ \alpha_Y} & \text{Hom}_\mathcal{D}(U(Y), V(Z))
\end{array}
\]

in the homotopy category \( \text{hKan} \), where the bottom horizontal and right vertical maps are homotopy equivalences. It follows that the upper horizontal map is a homotopy equivalence if and only if the left vertical map is a homotopy equivalence. Similarly, the object \( Y \) is \( U \)-final if and only if it is \( V \)-final.

Remark 7.1.4.9. Suppose we are given a commutative diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{C}' \\
\downarrow U & & \downarrow U' \\
\mathcal{D} & \xrightarrow{F_0} & \mathcal{D}'
\end{array}
\]

where the horizontal maps are equivalences of \( \infty \)-categories. Then an object \( X \in \mathcal{C} \) is \( U \)-initial if and only if \( F(X) \in \mathcal{C}' \) is \( U' \)-initial, and \( U \)-final if and only if \( F(X) \) is \( U' \)-final.

Proposition 7.1.4.10. Let \( U : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories and let \( f : X \to Y \) be a morphism in \( \mathcal{C} \) with the property that \( U(f) \) is an isomorphism. Then any two of the following three conditions imply the third:

1. The object \( X \) is \( U \)-initial.
2. The object \( Y \) is \( U \)-initial.
3. The morphism \( f \) is an isomorphism.

Proof. Fix an object \( Z \in \mathcal{C} \). We claim that any two of the following three conditions imply the third:

1. The functor \( U \) induces a homotopy equivalence \( \text{Hom}_\mathcal{C}(X, Z) \to \text{Hom}_\mathcal{C}(U(X), U(Z)) \).
2. The functor \( U \) induces a homotopy equivalence \( \text{Hom}_\mathcal{C}(Y, Z) \to \text{Hom}_\mathcal{C}(U(Y), U(Z)) \).

(1)_Z The functor \( U \) induces a homotopy equivalence \( \text{Hom}_\mathcal{C}(X, Z) \to \text{Hom}_\mathcal{C}(U(X), U(Z)) \).

(2)_Z The functor \( U \) induces a homotopy equivalence \( \text{Hom}_\mathcal{C}(Y, Z) \to \text{Hom}_\mathcal{C}(U(Y), U(Z)) \).
Precomposition \([f]\) induces a homotopy equivalence \(\text{Hom}_C(Y, Z) \to \text{Hom}_C(X, Z)\) (see Notation 4.6.8.15).

This follows from the commutativity of the diagram

\[
\begin{array}{ccc}
\text{Hom}_C(Y, Z) & \xrightarrow{\circ [f]} & \text{Hom}_C(X, Z) \\
\downarrow & & \downarrow \\
\text{Hom}_D(U(Y), U(Z)) & \xrightarrow{\circ [U(f)]} & \text{Hom}_D(U(X), U(Z))
\end{array}
\]

in the homotopy category \(\text{hKan}\), since the bottom horizontal map is a homotopy equivalence (by virtue of our assumption that \(U(f)\) is an isomorphism). Proposition 7.1.4.10 follows by allowing the object \(Z\) to vary.

**Corollary 7.1.4.11.** Let \(U : C \to D\) be a functor of \(\infty\)-categories, and let \(f : X \to Y\) be an isomorphism in \(C\). Then the object \(X\) is \(U\)-initial if and only if \(Y\) is \(U\)-initial, and the object \(X\) is \(U\)-final if and only if \(Y\) is \(U\)-final.

**Corollary 7.1.4.12 (Uniqueness).** Let \(U : C \to D\) be a functor of \(\infty\)-categories and let \(X\) and \(Y\) be \(U\)-initial objects of \(C\). Then \(X\) and \(Y\) are isomorphic if and only if \(U(X)\) and \(U(Y)\) are isomorphic as objects of \(D\).

*Proof.* Assume that there exists an isomorphism \(\overline{f} : U(X) \to U(Y)\) in the \(\infty\)-category \(D\). Since \(X\) is \(U\)-initial, the functor \(U\) induces a homotopy equivalence \(\text{Hom}_C(X, Y) \to \text{Hom}_D(U(X), U(Y))\). It follows that there exists a morphism \(f : X \to Y\) in \(C\) such that \(U(f)\) is homotopic to \(\overline{f}\). In particular, \(U(f) : U(X) \to U(Y)\) is also an isomorphism in \(D\). Applying Proposition 7.1.4.10 we deduce that \(f\) is an isomorphism. In particular, the objects \(X\) and \(Y\) are isomorphic. \(\square\)

Recall that a functor of \(\infty\)-categories \(U : C \to D\) is a *coreflective localization* if it admits a fully faithful left adjoint \(D \to C\) (Proposition 6.3.3.13). This condition has a simple formulation in terms of relatively final objects:

**Proposition 7.1.4.13.** Let \(U : C \to D\) be a functor of \(\infty\)-categories. Then \(U\) is a coreflective localization functor if and only if, for every object \(D \in D\), there exists a \(U\)-initial object \(C \in C\) and an isomorphism \(D \to U(C)\) in the \(\infty\)-category \(D\).

We will deduce Proposition 7.1.4.13 from a slightly more precise result.

**Lemma 7.1.4.14.** Let \(U : C \to D\) be a functor of \(\infty\)-categories, let \(C_0\) denote the full subcategory of \(C\) spanned by the \(F\)-initial objects, and suppose that the restriction \(U_0 = U|_{C_0}\) is essentially surjective. Then:
7.1. LIMITS AND COLIMITS

(1) The functor $U_0 : C_0 \to D$ is an equivalence of ∞-categories.

(2) Let $e : X \to Y$ be a morphism in $C$, where $X$ is $U$-initial. Then $e$ exhibits $X$ as a $C_0$-coreflection of $Y$ (in the sense of Definition 6.2.2.1) if and only if $U(e)$ is an isomorphism in the ∞-category $D$.

(3) The full subcategory $C_0 \subseteq C$ is coreflective.

(4) Let $F_0 : D \to C_0$ be a homotopy inverse of the functor $U_0$, and let $F : D \to C$ be a composition of $F_0$ with the inclusion map $i : C_0 \hookrightarrow C$. Then $F$ is a left adjoint of $U$.

(5) The functor $U$ is a coreflective localization.

Proof. Note that the functor $U_0 : C_0 \to D$ is automatically fully faithful (Remark 7.1.4.3). Our assumption that $U_0$ is essentially surjective then guarantees that it is an equivalence of ∞-categories, which proves (1).

We next prove the following:

(∗) For every object $Y \in C$, there exists a morphism $e : X \to Y$ in $C$, where $X$ is $U$-initial and $U(e)$ is an isomorphism in $D$.

To prove (∗), we observe that the essential surjectivity of $U_0$ guarantees that there exists a $U$-initial object $X \in C$ and an isomorphism $\pi : U(X) \to U(Y)$ in the ∞-category $D$. Since $X$ is $U$-initial, the functor $U$ induces a homotopy equivalence $\text{Hom}_C(X, Y) \to \text{Hom}_D(U(X), U(Y))$. Modifying $\pi$ by a homotopy, we can assume without loss of generality that $\pi = U(e)$ for some morphism $X \to Y$ of $C$.

We now prove (2). Let $e : X \to Y$ be a morphism in $C$, where the object $X$ is $U$-initial. Assume first that $U(e)$ is an isomorphism in $D$. We wish to show that, for every $U$-initial object $C \in C$, postcomposition with $e$ induces a homotopy equivalence of Kan complexes $\text{Hom}_C(C, X) \to \text{Hom}_C(C, Y)$. This follows by inspecting the commutative diagram

\[
\begin{array}{ccc}
\text{Hom}_C(C, X) & \xrightarrow{o[e]} & \text{Hom}_C(C, Y) \\
\downarrow & & \downarrow \\
\text{Hom}_D(U(C), U(X)) & \xrightarrow{o[U(e)]} & \text{Hom}_D(U(C), U(Y))
\end{array}
\]

in the homotopy category of Kan complexes hKan; here the vertical maps are homotopy equivalences by virtue of our assumption that $C$ is $U$-initial, and the bottom horizontal map is a homotopy equivalence by virtue of our assumption that $U(e)$ is an isomorphism.

We now prove the converse. Assume that $e : X \to Y$ exhibits $X$ as a $C_0$-coreflection of $Y$; we wish to show that $U(e)$ is an isomorphism. Using (∗), we can choose a $U$-initial object $X' \in C$ and a morphism $e' : X' \to Y$ such that $U(e')$ is an isomorphism in $D$. It follows
from the previous step that \( e' \) exhibits \( X' \) as a \( C_0 \)-coreflection of \( Y \). It follows that \( e \) can be realized as the composition of \( e' \) with an isomorphism \( \tau : X \to X \) in the \( \infty \)-category \( C \) (Remark 6.2.2.3). Then \( U(e) \) is a composition of the isomorphisms \( U(v) \) and \( U(e') \) in the \( \infty \)-category \( D \), and is therefore also an isomorphism.

Assertion (3) follows immediately from (2) and (*). Combining (3) with Proposition 6.2.2.7 we see that there exists a functor \( L : C \to C_0 \) and a natural transformation \( \eta : L \to \text{id}_C \) which exhibits \( L \) as a \( C_0 \)-colocalization functor: that is, it carries each object \( Y \in C \) to a morphism \( \eta_Y : L(Y) \to Y \) where \( L(Y) \) is \( U \)-initial and \( U(\eta_Y) \) is an isomorphism. In particular, \( \eta \) induces an isomorphism \( U_0 \circ L \to U \) in the \( \infty \)-category \( \text{Fun}(C,D) \) (Theorem 4.4.4.4). It follows from assumption (1) that the functor \( U_0 \) admits a homotopy inverse \( F_0 : D \to C_0 \), which is also a left adjoint of \( U_0 \) (Example 6.2.1.11). Moreover, the inclusion functor \( \iota : C_0 \hookrightarrow C \) is left adjoint to \( L \) (Proposition 6.2.2.11). It follows that the composition \( F = \iota \circ F_0 \) is left adjoint to \( U_0 \circ L \) (Remark 6.2.1.8), and therefore also to \( U \). This proves (4).

Moreover, the functor \( F \) is fully faithful (since \( F_0 \) is an equivalence of \( \infty \)-categories and \( \iota \) is the inclusion of a full subcategory), so assertion (5) follows from Proposition 6.3.3.13.

\[ \square \]

**Proof of Proposition 7.1.4.13.** Let \( U : C \to D \) be a functor of \( \infty \)-categories. Assume that \( U \) is a coreflective localization functor: we will show that, for every object \( D \in D \), there exists a \( U \)-initial object \( C \in C \) and an isomorphism \( D \to U(C) \) in \( D \) (the converse follows from Lemma 7.1.4.14). Using Proposition 6.3.3.13 we see that there exists a functor \( F : D \to C \) and a natural isomorphism \( \eta : \text{id}_D \to U \circ F \) which is the unit of an adjunction between \( F \) and \( U \). In particular, for every object \( D \in D \), we have an isomorphism \( \eta_D : D \to U(C) \) for \( C = F(D) \). We will complete the proof by showing that the object \( C \) is \( U \)-initial. Fix an object \( X \in C \); we wish to show that the functor \( U \) induces a homotopy equivalence of Kan complexes \( p : \text{Hom}_C(F(D),X) \to \text{Hom}_D((U \circ F)(D),U(X)) \). Since \( \eta_D : D \to (U \circ F)(D) \) is an isomorphism, this is equivalent to the requirement that the composite map

\[ \text{Hom}_C(F(D),X) \to \text{Hom}_D((U \circ F)(D),U(X)) \xrightarrow{\circ[\eta_D]} \text{Hom}_D(D,U(X)) \]

is a homotopy equivalence of Kan complexes, which follows from our assumption that \( \eta \) is the unit of an adjunction (Proposition 6.2.1.17).

\[ \square \]

**Corollary 7.1.4.15.** Let \( U : C \to D \) be an isofibration of \( \infty \)-categories. Then \( U \) is a coreflective localization functor if and only if, for every object \( Y \in D \), the fiber \( C_Y = \{ Y \} \times_D C \) contains an \( U \)-initial object of \( C \).

**Proof.** Assume that \( U \) is a coreflective localization functor. We will show that, for each object \( Y \in D \), the \( \infty \)-category \( C_Y \) contains a \( U \)-initial object of \( C \) (the converse follows immediately from Proposition 7.1.4.13). Using Proposition 7.1.4.13 we see that there exists a \( U \)-initial object \( X \in C \) and an isomorphism \( e : Y \to U(X) \) in \( D \). Since \( U \) is an isofibration,
7.1. LIMITS AND COLIMITS

we can lift \( \tilde{e} : \tilde{Y} \to X \) in the \( \infty \)-category \( C \). Our assumption that \( X \) is \( U \)-initial then guarantees that \( \tilde{Y} \) is also \( U \)-initial (Corollary \( \ref{cor:limits-and-colimits} \)).

\begin{proposition}
Let \( U : C \to D \) be a functor of \( \infty \)-categories. Then:
\begin{enumerate}
  \item An object \( Y \in C \) is \( U \)-initial if and only if \( U \) induces an equivalence of \( \infty \)-categories \( U' : C_{/Y} \to C \times_D D_{U(Y)/} \).
  \item An object \( Y \in C \) is \( U \)-final if and only if \( U \) induces an equivalence of \( \infty \)-categories \( U' : C_{/Y} \to C \times_D D_{/U(Y)} \).
\end{enumerate}
\end{proposition}

\begin{proof}
We will prove (2); the proof of (1) is similar. Fix an object \( Y \in C \), so that the morphism \( U'' \) of (1) fits into a commutative diagram

\[
\begin{array}{ccc}
C_{/Y} & \xrightarrow{U''} & C \times_D D_{/U(Y)} \\
\downarrow & & \downarrow \\
C \\
\end{array}
\]

where the vertical maps are right fibrations (Proposition \( \ref{prop:right-fibrations} \)). Applying Corollary \( \ref{cor:equivalence-of-categories} \), we see that \( U'' \) is an equivalence of \( \infty \)-categories if and only if, for every object \( X \in C \), the induced map of fibers

\[
U''_X : \{X\} \times_C C_{/Y} \to \{X\} \times_D D_{/U(Y)}
\]

is a homotopy equivalence of Kan complexes. By virtue of Proposition \( \ref{prop:homotopy-equivalence} \), this is equivalent to the requirement that \( U \) induces a homotopy equivalence \( \text{Hom}_C(X,Y) \to \text{Hom}_D(U(X),U(Y)) \).

\begin{corollary}
Let \( U : C \to D \) be an inner fibration of \( \infty \)-categories and let \( Y \) be an object of \( C \). The following conditions are equivalent:
\begin{enumerate}
  \item The object \( Y \) is \( U \)-initial.
  \item The induced map \( U' : C_{/Y} \to C \times_D D_{U(Y)/} \) is a trivial Kan fibration.
  \item Every lifting problem

\[
\begin{array}{ccc}
\partial \Delta^n & \xrightarrow{\sigma_0} & C \\
\uparrow \sigma_0 & & \downarrow U \\
\Delta^n & \xrightarrow{U} & D
\end{array}
\]

has a solution, provided that \( n > 0 \) and \( \sigma_0(0) = Y \).
\end{enumerate}
\end{corollary}
Proof. Since $U$ is an inner fibration, the morphism $U'$ is a left fibration (Corollary 4.3.6.9). In particular, it is a trivial Kan fibration if and only if it is an equivalence of ∞-categories (Proposition 4.5.5.20). The equivalence (1) ⇔ (2) now follows from Proposition 7.1.4.16. The equivalence (2) ⇔ (3) is immediate from the definitions.  

Corollary 7.1.4.18. Let $U : C \to D$ be an inner fibration of ∞-categories. Let $C_0 \subseteq C$ be a full subcategory of $C$ whose objects are $U$-initial, and let $D_0 \subseteq D$ be the full subcategory of $D$ spanned by objects of the form $U(C)$ for $C \in C_0$. Then the functor $U|_{C_0} : C_0 \to D_0$ is a trivial Kan fibration.

Proof. Suppose we are given a lifting problem

\[
\begin{array}{ccc}
\partial \Delta^n & \xrightarrow{\sigma_0} & C_0 \\
\downarrow & \ & \downarrow U_0 \\
\Delta^n & \xrightarrow{\sigma} & D_0.
\end{array}
\]

If $n = 0$, this lifting problem admits a solution by the definition of the subcategory $D_0 \subseteq D$. If $n > 0$, then $\sigma_0(0)$ is a $U$-initial object of $C$, so Corollary 7.1.4.17 guarantees that $\sigma_0$ can be extended to an $n$-simplex $\sigma : \Delta^n \to C$ satisfying $U(\sigma) = \sigma$. We conclude by observing that $\sigma$ automatically factors through the full subcategory $C_0$ (since every vertex of $\Delta^n$ is contained in the boundary $\partial \Delta^n$).

Proposition 7.1.4.19. Suppose we are given a commutative diagram of ∞-categories

\[
\begin{array}{ccc}
C & \xrightarrow{F} & D \\
\downarrow U & & \downarrow V \\
\mathcal{E}. & & \\
\end{array}
\]

where $U$ and $V$ are inner fibrations. Let $E \in \mathcal{E}$ be an object, and let $F_E : C_E \to D_E$ denote the corresponding restriction of $F$. Then:

1. If $X \in C_E$ is $F$-initial when viewed as an object of the ∞-category $C$, then $X$ is $F_E$-initial.

2. Assume that $U$ and $V$ are cartesian fibrations, and that the functor $F$ carries $U$-cartesian morphisms of $C$ to $V$-cartesian morphisms of $D$. If $X$ is $F_E$-initial, then it is $F$-initial when viewed as an object of $C$. 

Proof. We first prove (1). Assume that $X$ is $F$-initial. For every object $Y \in C_E$, we have a commutative diagram of Kan complexes

$$
\begin{array}{ccc}
\text{Hom}_C(X,Y) & \xrightarrow{\rho} & \text{Hom}_D(F(X),F(Y)) \\
\downarrow & & \downarrow \\
\text{Hom}_E(E,E) & \xleftarrow{\theta} & \text{Hom}_E(E,E)
\end{array}
$$

Our assumption that $X$ is $F$-initial guarantees that $\rho$ is a homotopy equivalence. Since $U$ and $V$ are inner fibrations, the vertical maps are Kan fibrations (Proposition 4.6.1.19). Applying Corollary 3.3.7.3, we conclude that $\rho$ restricts to a homotopy equivalence

$$
\text{Hom}_C(X,Y) = \text{Hom}_C(X,Y) \times_{\text{Hom}_E(E,E)} \{\text{id}_E\} \\
\to \text{Hom}_D(F(X),F(Y)) \times_{\text{Hom}_E(E,E)} \{\text{id}_E\} \\
= \text{Hom}_D(F(X),F(Y)).
$$

Allowing $Y$ to vary over objects of $C_E$, it follows that $X$ is an $F_E$-initial object of $C$.

We now prove (2). Assume that $U$ and $V$ are cartesian fibrations, that the functor $F$ carries $U$-cartesian morphisms of $C$ to $V$-cartesian morphisms of $D$, and that $X$ is $F_E$-initial. We wish to show that $X$ is $F$-initial. Fix an object $Z \in C$; we must show that the horizontal map in the diagram

$$
\begin{array}{ccc}
\text{Hom}_C(X,Z) & \xrightarrow{\theta} & \text{Hom}_D(F(X),F(Z)) \\
\downarrow & & \downarrow \\
\text{Hom}_E(U(X),U(Z)) & \xleftarrow{\rho} & \text{Hom}_E(U(X),U(Z))
\end{array}
$$

is a homotopy equivalence. Since the vertical maps are Kan fibrations (Proposition 4.6.1.19), it will suffice to show that the induced map

$$
\theta_{\overline{f}} : \text{Hom}_C(X,Z) \times_{\text{Hom}_E(U(X),U(Z))} \{\overline{f}\} \to \text{Hom}_D(F(X),F(Z)) \times_{\text{Hom}_E(U(X),U(Z))} \{\overline{f}\}
$$

is a homotopy equivalence, for each morphism $\overline{f} : U(X) \to U(Z)$ in the $\infty$-category $E$ (Corollary 3.3.7.3). Since $U$ is a cartesian fibration, we can write $\overline{f} = U(f)$, where $f : Y \to Z$ is a $U$-cartesian morphism in $C$. By assumption, the image $F(f) : F(Y) \to F(Z)$ is a $V$-cartesian morphism in the $\infty$-category $D$. Using Proposition 5.1.2.1, we can replace $\theta_{\overline{f}}$ with the morphism

$$
\text{Hom}_C(X,Y) \to \text{Hom}_D(F(X),F(Y))
$$

which is a homotopy equivalence by virtue of our assumption that $X$ is $F_E$-initial. \qed
Exercise 7.1.4.20. Let \( U : C \to \mathcal{D} \) be a cocartesian fibration of \( \infty \)-categories, and let \( C \in C \) be an object having image \( D = U(C) \) in \( \mathcal{D} \). Show that \( C \) is \( U \)-initial if and only if the following condition is satisfied:

\[ (*) \text{ For every morphism } f : D \to D' \text{ in } \mathcal{D}, \text{ the covariant transport functor } f_! : C_D \to C_{D'} \text{ carries } C \text{ to an initial object of the } \infty \text{-category } C_{D'}. \]

For a more general statement, see Proposition 7.3.8.2.

Corollary 7.1.4.21. Let \( U : C \to \mathcal{D} \) be an inner fibration of \( \infty \)-categories, and let \( C \in C \) be an object having image \( D = U(C) \) in \( \mathcal{D} \). If the object \( C \) is \( U \)-initial, then it is initial when regarded as an object of the \( \infty \)-category \( C_D = \{D\} \times_{\mathcal{D}} C \). The converse holds if \( U \) is a cartesian fibration.

Proof. Apply Proposition 7.1.4.19 in the special case where \( E = \mathcal{D} \) and \( E' = \{D\} \).

Corollary 7.1.4.22. Let \( U : C \to \mathcal{D} \) be a cartesian fibration of \( \infty \)-categories. The following conditions are equivalent:

1. For each object \( D \in \mathcal{D} \), the \( \infty \)-category \( C_D = \{D\} \times_{\mathcal{D}} C \) has an initial object.
2. The functor \( U \) is a coreflective localization: that is, it admits a fully faithful left adjoint \( F : \mathcal{D} \to C \).

Proof. Combine Corollaries 7.1.4.15 and 7.1.4.21.

7.1.5 Relative Limits and Colimits

We now introduce a relative version of Definition 7.1.2.4.

Definition 7.1.5.1. Let \( U : C \to \mathcal{D} \) be a functor of \( \infty \)-categories and let \( f : K \to C \) be a morphism of simplicial sets with restriction \( f = f|_K \), so that \( U \) induces a functor \( U_f : C_f \to D_{U(f)} \). We will say that \( f \) is a \( U \)-limit diagram if it is \( U_f \)-final when viewed as an object of the \( \infty \)-category \( C_f \). Similarly, we say that a morphism \( g : K \to C \) is a \( U \)-colimit diagram if \( g \) is \( U_g \)-initial when viewed as an object of the \( \infty \)-category \( C_g \), where \( U_g : C_g \to D_{(Ug)} \) denotes the functor induced by \( U \).

Remark 7.1.5.2. Let \( U : C \to \mathcal{D} \) be an inner fibration of \( \infty \)-categories. Then a morphism \( f : K \to C \) is a \( U \)-limit diagram if and only if the opposite map \( f^{op} : (K^{op})^{op} \to C^{op} \) is a \( U^{op} \)-colimit diagram.

Example 7.1.5.3. Let \( C \) be an \( \infty \)-category and \( U : C \to \Delta^0 \) be the projection map. Then a morphism \( f : K \to C \) is a \( U \)-limit diagram (in the sense of Definition 7.1.5.1) if and only if it is a limit diagram (in the sense of Definition 7.1.2.4). Similarly, a morphism \( g : K \to C \) is a \( U \)-colimit diagram if and only if it is a colimit diagram.
Example 7.1.5.4. Let $U : \mathcal{C} \to \mathcal{D}$ be a fully faithful functor of $\infty$-categories. Then every morphism $f : K^a \to \mathcal{C}$ is a $U$-limit diagram, and every morphism $g : K^b \to \mathcal{C}$ is a $U$-colimit diagram. This follows by combining Example 7.1.4.4 with Corollary 4.6.4.20.

Example 7.1.5.5. Let $U : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories. Then an object $C \in \mathcal{C}$ is $U$-final if and only if it is a $U$-limit diagram when viewed as a morphism of simplicial sets $(\emptyset)^a \simeq \Delta^0 \to \mathcal{C}$. Similarly, $C$ is $U$-initial if and only if it is a $U$-colimit diagram when viewed as a morphism of simplicial sets $(\emptyset)^b \simeq \Delta^0 \to \mathcal{C}$.

Remark 7.1.5.6. Suppose we are given a commutative diagram of $\infty$-categories:

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{C}' \\
\downarrow U & & \downarrow U' \\
\mathcal{D} & \xrightarrow{F'} & \mathcal{D}'
\end{array}
\]

where the horizontal maps are equivalences of $\infty$-categories. Then a morphism of simplicial sets $f : K^a \to \mathcal{C}$ is a $U$-limit diagram if and only if $F \circ f$ is a $U'$-limit diagram. Similarly, a morphism of simplicial sets $g : K^b \to \mathcal{C}$ is a $U$-colimit diagram if and only if $F \circ g$ is a $U'$-colimit diagram. This follows by combining Remark 7.1.4.9 with Corollary 4.6.4.19.

Remark 7.1.5.7. Let $U_0 : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories, and let $U_1 : \mathcal{C} \to \mathcal{D}$ be a functor which is isomorphic to $U_0$ (as an object of the $\infty$-category $\text{Fun}(\mathcal{C}, \mathcal{D})$). Then a diagram $f : K^a \to \mathcal{C}$ is a $U_0$-limit diagram if and only if it is a $U_1$-limit diagram (see Remark 7.1.4.8). This follows by applying Remark 7.1.5.6 to each square of the diagram:

\[
\begin{array}{ccc}
\mathcal{C} & \xleftarrow{\text{id}} & \mathcal{C} \\
\downarrow U_0 & & \downarrow U_1 \\
\text{Fun}(\{0\}, \mathcal{D}) & \xrightarrow{\text{ev}_0} & \text{Isom}(\mathcal{D}) \\
\end{array}
\]

where $U : \mathcal{C} \to \text{Isom}(\mathcal{D})$ classifies an isomorphism between $U_0$ and $U_1$; note that $\text{ev}_0$ and $\text{ev}_1$ are trivial Kan fibrations by virtue of Corollary 4.4.5.10.

Remark 7.1.5.8. Let $U : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories, let $f : K^a \to \mathcal{C}$ be a morphism, and set $f = f|_K$, so that $U$ induces a functor

\[
U' : \mathcal{C}_f \times_{\mathcal{D}_f} \mathcal{D}_f \to \mathcal{D}_f.
\]

By virtue of Proposition 7.1.4.16 the following conditions are equivalent:

1. The morphism $f$ is a $U$-limit diagram.
(2) The functor $U'$ is an equivalence of $\infty$-categories.

If $U$ is an inner fibration of $\infty$-categories, then the functor $U'$ is automatically a right fibration (Proposition 4.3.6.8). In this case, we can replace (1) and (2) by either of the following conditions: to the following:

(3) The functor $U'$ is a trivial Kan fibration.

(4) Each fiber of $U'$ is a contractible Kan complex.

The equivalence of (2) $\iff$ (3) follows from Proposition 4.5.5.20, and the equivalence (3) $\iff$ (4) from Proposition 4.4.2.14.

**Example 7.1.5.9.** Let $U : C \to D$ be an inner fibration of $\infty$-categories. Then:

- A morphism $e$ of $C$ is $U$-cartesian (in the sense of Definition 5.1.1.1) if and only if it is a $U$-limit diagram when viewed as a morphism of simplicial sets $(\Delta^0)^{\triangleleft} \to C$.

- A morphism $f$ of $C$ is $U$-cocartesian (in the sense of Definition 5.1.1.1) if and only if it is a $U$-colimit diagram when viewed as a morphism of simplicial sets $(\Delta^0)^{\triangleright} \to C$.

This follows by combining Remark 7.1.5.8 with Proposition 5.1.1.13.

**Example 7.1.5.10.** Let $K$ be a weakly contractible simplicial set and let $U : C \to D$ be a right fibration of $\infty$-categories. Then every morphism $\overline{f} : K^{\triangleleft} \to C$ is a $U$-limit diagram (see Proposition 4.3.7.6). Similarly, if $U$ is a left fibration, then every morphism $\overline{g} : K^{\triangleright} \to C$ is a $U$-colimit diagram.

**Remark 7.1.5.11.** Let $U : C \to D$ be an inner fibration of $\infty$-categories and let $K$ be a simplicial set. Using Remark 7.1.5.8, we see that a morphism $\overline{f} : K^{\triangleleft} \to C$ is a $U$-limit diagram if and only if every lifting problem

admits a solution, provided that $n \geq 1$ and the the restriction of $\rho$ to $\{n\} \star K \simeq K^{\triangleleft}$ coincides with $\overline{f}$.
**Proposition 7.1.5.12.** Let $U : C \to D$ be a functor of $\infty$-categories and let $\overline{f} : K^\circ \to C$. Then $\overline{f}$ is a $U$-limit diagram if and only if, for every object $C \in C$, the diagram of morphism spaces

$$
\begin{array}{ccc}
\text{Hom}_{\text{Fun}(K^\circ,C)}(C, \overline{f}) & \to & \text{Hom}_{\text{Fun}(K,C)}(C|_K, \overline{f}|_K) \\
\downarrow & & \downarrow \\
\text{Hom}_{\text{Fun}(K^\circ,D)}(U \circ C, U \circ \overline{f}) & \to & \text{Hom}_{\text{Fun}(K,D)}(U \circ C|_K, U \circ \overline{f}|_K)
\end{array}
$$

is a homotopy pullback square; here we let $C \in \text{Fun}(K^\circ, C)$ denote the constant diagram taking the value $C$.

**Proof.** Set $f = \overline{f}|_K$. Note that the restriction maps

$$
C/\overline{f} \to C/f \quad \quad C/f \to C \quad \quad D/(U \circ f) \to E/(U \circ f)
$$

are right fibrations of simplicial sets (Corollary 4.3.6.11). It follows that we can regard the map

$$
U' : C/\overline{f} \to C/f \times D/(U \circ f) \to D/(U \circ f)
$$

of Remark 7.1.5.8 as a functor between $\infty$-categories which are right-fibered over $C$. Combining Remark 7.1.5.8 with the criterion of Corollary 5.1.5.4, we see that $\overline{f}$ is a $U$-colimit diagram if and only if, for every object $C \in C$, the induced map

$$
U'_C : \{C\} \times_C C/\overline{f} \to \{C\} \times_C C/f \times D/(U \circ f) \to D/(U \circ f)
$$

is a homotopy equivalence of Kan complexes.

To complete the proof, it will suffice to show that $U'_C$ is a homotopy equivalence if and only if the diagram (7.1) is a homotopy pullback square. To see this, we note that Proposition 4.6.5.9 supplies a levelwise homotopy equivalence of (7.1) with the diagram

$$
\begin{array}{ccc}
\{C\} \times_C C/\overline{f} & \to & \{C\} \times_C C/f \\
\downarrow & & \downarrow \\
\{U(C)\} \times_D D/(U \circ f) & \to & \{U(C)\} \times_D D/(U \circ f)
\end{array}
$$

It will therefore suffice to show that (7.2) is a homotopy pullback square if and only if $U'_C$ is a homotopy equivalence (Corollary 3.4.1.12). This is a special case of Example 3.4.1.3, since the horizontal maps in the diagram (7.2) are Kan fibrations (combine Corollaries 4.3.6.11 and 4.4.3.8).
Proposition 7.1.5.13. Let \( U : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories and let \( \overline{\pi}, \overline{\nu} : K^\circ \to \mathcal{C} \) be diagrams which are isomorphic when viewed as objects of the \( \infty \)-category \( \text{Fun}(K^\circ, \mathcal{C}) \). Then \( \overline{\pi} \) is a \( U \)-limit diagram if and only if \( \overline{\nu} \) is a \( U \)-limit diagram.

Proof. We proceed as in the proof of Corollary 7.1.2.14. Let \( \text{Isom}(\mathcal{C}) \) denote the full subcategory of \( \text{Fun}(\Delta^1, \mathcal{C}) \) spanned by the isomorphisms in \( \mathcal{C} \), and define \( \text{Isom}(\mathcal{D}) \subseteq \text{Fun}(\Delta^1, \mathcal{D}) \) similarly. For \( i \in \{0, 1\} \), the evaluation functors

\[
\text{ev}_i : \text{Isom}(\mathcal{C}) \to \mathcal{C} \quad \text{ev}_i : \text{Isom}(\mathcal{D}) \to \mathcal{D}
\]

are trivial Kan fibrations (Corollary 4.4.5.10), and therefore equivalences of \( \infty \)-categories (Proposition 4.5.3.11). Our assumption that \( \overline{\pi} \) and \( \overline{\nu} \) are isomorphic guarantees that we can choose a diagram \( \overline{w} : K^\circ \to \text{Isom}(\mathcal{C}) \) satisfying \( \text{ev}_0 \circ \overline{w} = \overline{\pi} \) and \( \text{ev}_1 \circ \overline{w} = \overline{\nu} \). Applying Remark 7.1.5.6 to the commutative diagram

\[
\begin{array}{ccc}
\text{Isom}(\mathcal{C}) & \xrightarrow{\text{ev}_0} & \mathcal{C} \\
\downarrow \text{U'} & & \downarrow \text{U} \\
\text{Isom}(\mathcal{D}) & \xrightarrow{\text{ev}_0} & \mathcal{D},
\end{array}
\]

we see that \( \overline{\pi} \) is a \( U \)-limit diagram if and only if \( \overline{w} \) is a \( \text{U}' \)-limit diagram. A similar argument shows that this is equivalent to the requirement that \( \overline{\nu} \) is a \( U \)-limit diagram. \( \Box \)

Proposition 7.1.5.14 (Transitivity). Let \( U : \mathcal{C} \to \mathcal{D} \) and \( V : \mathcal{D} \to \mathcal{E} \) be functors of \( \infty \)-categories.

(1) Let \( \overline{f} : K^\circ \to \mathcal{C} \) be a morphism of simplicial sets such that \( U \circ \overline{f} \) is a \( V \)-limit diagram. Then \( \overline{f} \) is a \( U \)-limit diagram if and only if it is a \( (V \circ U) \)-limit diagram.

(2) Let \( \overline{g} : K^\circ \to \mathcal{C} \) be a morphism of simplicial sets such that \( U \circ \overline{g} \) is a \( V \)-colimit diagram. Then \( \overline{g} \) is a \( U \)-colimit diagram if and only if it is a \( (V \circ U) \)-colimit diagram.

Proof. Apply Remark 7.1.4.6 \( \Box \)

Corollary 7.1.5.15. Let \( U : \mathcal{C} \to \mathcal{D} \) and \( V : \mathcal{D} \to \mathcal{E} \) be functors of \( \infty \)-categories, where \( V \) is fully faithful. Then:

(1) A morphism \( \overline{f} : K^\circ \to \mathcal{C} \) is a \( U \)-limit diagram if and only if it is a \( (V \circ U) \)-limit diagram.

(2) A morphism \( \overline{g} : K^\circ \to \mathcal{C} \) is a \( U \)-colimit diagram if and only if it is a \( (V \circ U) \)-colimit diagram.
Proof. Combine Proposition 7.1.5.14 with Example 7.1.5.4. □

**Corollary 7.1.5.16.** Let $U : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories. Then:

1. Let $\overline{f} : K^\circ \to \mathcal{C}$ be a morphism of simplicial sets such that $U \circ \overline{f}$ is a limit diagram in $\mathcal{D}$. Then $\overline{f}$ is a limit diagram in $\mathcal{C}$ if and only if it is a $U$-limit diagram.

2. Let $\overline{g} : K^\circ \to \mathcal{C}$ be a morphism of simplicial sets such that $U \circ \overline{g}$ is a colimit diagram in $\mathcal{D}$. Then $\overline{g}$ is a colimit diagram in $\mathcal{C}$ if and only if it is a $U$-colimit diagram.

Proof. Apply Proposition 7.1.5.14 in the case $\mathcal{E} = \Delta^0$ (and use Example 7.1.5.3). □

**Corollary 7.1.5.17.** Let $K$ be a weakly contractible simplicial set and let $U : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories. If $U$ is a left fibration, then it creates $K$-indexed colimits. If $U$ is a right fibration, then it creates $K$-indexed limits.

Proof. Assume $U$ is a right fibration; we will show that it creates $K$-indexed limits (the analogous statement for left fibrations follows by a similar argument). Let $f : K \to \mathcal{C}$ be a diagram and suppose that $U \circ f$ can be extended to a limit diagram $g : K^\circ \to \mathcal{D}$. Since the inclusion $K \hookrightarrow K^\circ$ is right anodyne (Example 4.3.7.10), our assumption that $U$ is a right fibration guarantees that the lifting problem

\[
\begin{array}{ccc}
K & \xrightarrow{f} & \mathcal{C} \\
\downarrow & & \downarrow U \\
K^\circ & \xleftarrow{g} & \mathcal{D}
\end{array}
\]

has a solution. Since $K$ is weakly contractible, the morphism $\overline{f}$ is automatically a $U$-limit diagram (Example 7.1.5.10). Applying Corollary 7.1.5.16, we see that $\overline{f}$ is a limit diagram. □

**Corollary 7.1.5.18.** Let $U : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories and let $K$ be a weakly contractible simplicial set. Then:

- If $U$ is a right fibration and the $\infty$-category $\mathcal{D}$ admits $K$-indexed limits, then $\mathcal{C}$ also admits $K$-indexed limits and $U$ preserves $K$-indexed limits.

- If $U$ is a left fibration and the $\infty$-category $\mathcal{D}$ admits $K$-indexed colimits, then $\mathcal{C}$ also admits $K$-indexed colimits and $U$ preserves $K$-indexed colimits.

Proof. Combine Corollary 7.1.5.17 with Proposition 7.1.3.18. □
**Proposition 7.1.5.19** (Base Change). Suppose we are given a commutative diagram of ∞-categories

\[
\begin{array}{ccc}
C' & \rightarrow^F & D' \\
\downarrow^{G} & & \downarrow^{E'} \\
C & \rightarrow^F & D \\
\downarrow^{U} & & \downarrow^{V} \\
E & & E
\end{array}
\]

(7.3)

where each square is a pullback and the diagonal maps are inner fibrations. Let \( \bar{f} : K^\circ \rightarrow C' \) be a morphism of simplicial sets. Then:

1. If \( G \circ \bar{f} \) is an \( F \)-colimit diagram in the ∞-category \( C \), then \( \bar{f} \) is an \( F' \)-colimit diagram in the ∞-category \( C' \).

2. Assume that \( U \) and \( V \) are cartesian fibrations, and that the functor \( F \) carries \( U \)-cartesian morphisms of \( C \) to \( V \)-cartesian morphisms of \( D \). If \( \bar{f} \) is an \( F' \)-colimit diagram in the ∞-category \( C' \), then \( G \circ \bar{f} \) is an \( F \)-colimit diagram in the ∞-category \( C \).

**Proof.** Set \( f = \bar{f}|_K \). By virtue of Corollary 4.3.6.10 and Proposition 5.1.4.19 we can replace
by the commutative diagram

and thereby reduce to the special case \( K = \emptyset \). In this case, the desired result follows from Proposition 7.1.4.19.

**Corollary 7.1.5.20.** Let \( U : \mathcal{C} \to \mathcal{D} \) be an inner fibration of \( \infty \)-categories, let \( D \in \mathcal{D} \) be an object, and let

\[
\mathcal{F} : K^\circ \to \mathcal{C}_D = \{D\} \times_\mathcal{D} \mathcal{C}
\]

be a diagram. If \( \mathcal{F} \) is a \( U \)-colimit diagram in \( \mathcal{C} \), then it is a colimit diagram in the \( \infty \)-category \( \mathcal{C}_D \). The converse holds if \( U \) is a cartesian fibration.

**Proof.** Apply Proposition 7.1.5.19 in the special case \( \mathcal{E} = \mathcal{D} \) and \( \mathcal{E}' = \{D\} \).

**Remark 7.1.5.21.** Corollary 7.1.5.20 has an obvious counterpart for \( U \)-limit diagrams under the assumption that \( U : \mathcal{C} \to \mathcal{D} \) is a cocartesian fibration, which can be proved in the same way. It also has a more subtle counterpart for \( U \)-colimit diagrams when \( U \) is a cocartesian fibration (or \( U \)-limit diagrams when \( U \) is a cartesian fibration), which we will discuss in §7.3.8 (see Proposition 7.3.8.2).

### 7.1.6 Limits and Colimits of Functors

Let \( \mathcal{C} \) be an \( \infty \)-category and let \( B \) be a simplicial set. For every vertex \( b \in B \), we let

\[
ev_b : \text{Fun}(B, \mathcal{C}) \to \text{Fun}(\{b\}, \mathcal{C}) \simeq \mathcal{C}
\]

denote the functor given by evaluation at \( b \). Our goal in this section is to show that the collection of functors \( \{\ev_b\}_{b \in B} \) creates colimits in the following sense:
**Proposition 7.1.6.1.** Let \( C \) be an \( \infty \)-category, let \( B \) be a simplicial set, and let \( f : K \to \text{Fun}(B, C) \) be a diagram. Assume that, for every vertex \( b \in B \), the composite diagram

\[
K \xrightarrow{f} \text{Fun}(B, C) \xrightarrow{\text{ev}_b} C
\]

admits a colimit in the \( \infty \)-category \( C \). Then:

1. The diagram \( f \) admits a colimit in \( \text{Fun}(B, C) \).

2. Let \( \tilde{f} : K^\circ \to \text{Fun}(B, C) \) be an extension of \( f \). Then \( \tilde{f} \) is a colimit diagram if and only if, for every vertex \( b \in B \), the morphism

\[
K^\circ \xrightarrow{\tilde{f}} \text{Fun}(B, C) \xrightarrow{\text{ev}_b} C
\]

is a colimit diagram in \( C \).

**Corollary 7.1.6.2.** Let \( K \) be a simplicial set and let \( C \) be an \( \infty \)-category which admits \( K \)-indexed colimits. Then, for every simplicial set \( B \), the \( \infty \)-category \( \text{Fun}(B, C) \) also admits \( K \)-indexed colimits. Moreover, a morphism of simplicial sets \( \tilde{f} : K^\circ \to \text{Fun}(B, C) \) is a colimit diagram if and only if, for every vertex \( b \in B \), the morphism

\[
K^\circ \xrightarrow{\tilde{f}} \text{Fun}(B, C) \xrightarrow{\text{ev}_b} C
\]

is a colimit diagram in \( C \).

We will give a proof of Proposition 7.1.6.1 at the end of this section. Our strategy is to deduce Proposition 7.1.6.1 from a pair of more general results which apply to relative colimit diagrams (Corollaries 7.1.6.7 and 7.1.6.11). The increased flexibility of the relative setting will allow us to reduce to the case \( K = \emptyset \), by virtue of the following:

**Proposition 7.1.6.3.** Let \( U : C \to D \) be a functor of \( \infty \)-categories, let \( K \) be a simplicial set, and let

\[
U' : \text{Fun}(K^\circ, C) \to \text{Fun}(K, C) \times_{\text{Fun}(K, D)} \text{Fun}(K^\circ, D)
\]

be the restriction map. Then a morphism of simplicial sets \( \tilde{f} : K^\circ \to C \) is a \( U \)-colimit diagram if and only if it is \( U' \)-initial when viewed as an object of the \( \infty \)-category \( \text{Fun}(K^\circ, C) \).

**Proof.** Set \( f = \tilde{f}|_K \), so that \( U' \) restricts to a functor

\[
U'' : \{ f \} \times_{\text{Fun}(K, C)} \text{Fun}(K^\circ, C) \to \{ U \circ f \} \times_{\text{Fun}(K, D)} \text{Fun}(K^\circ, D).
\]

We have a commutative diagram

\[
\begin{array}{ccc}
\text{C}_{f/} & \to & \{ f \} \times_{\text{Fun}(K, C)} \text{Fun}(K^\circ) \\
\downarrow F_{f/} & & \downarrow U'' \\
\text{D}_{(F \circ f)/} & \to & \{ F \circ f \} \times_{\text{Fun}(K, D)} \text{Fun}(K^\circ, D),
\end{array}
\]
where the horizontal maps are equivalences of ∞-categories (see Remark 4.6.4.21). Applying Remark 7.1.4.9 we see that \( f \) is an \( \mathcal{U} \)-colimit diagram if and only if it is \( \mathcal{U}'' \)-initial when viewed as an object of the fiber \( \{f\} \times_{\text{Fun}(\mathcal{K}, \mathcal{C})} \text{Fun}(\mathcal{K}^\circ) \).

We have a commutative diagram of ∞-categories

\[
\begin{array}{ccc}
\text{Fun}(\mathcal{K}^\circ, \mathcal{C}) & \xrightarrow{U'} & \text{Fun}(\mathcal{K}, \mathcal{C}) \times_{\text{Fun}(\mathcal{K}, \mathcal{D})} \text{Fun}(\mathcal{K}^\circ, \mathcal{D}) \\
V & & \downarrow \\
\text{Fun}(\mathcal{K}, \mathcal{C}) & & \\
\end{array}
\]

Applying Corollary 5.3.7.3 we see that \( V \) and \( V' \) are cartesian fibrations and that \( U' \) carries \( V \)-cartesian morphisms of \( \text{Fun}(\mathcal{K}^\circ, \mathcal{C}) \) to \( V' \)-cartesian morphisms of \( \text{Fun}(\mathcal{K}, \mathcal{C}) \times_{\text{Fun}(\mathcal{K}, \mathcal{D})} \text{Fun}(\mathcal{K}^\circ, \mathcal{D}) \). It follows from Proposition 7.1.4.19 that \( f \) is \( \mathcal{U}'' \)-initial (when regarded as an object of \( \{f\} \times_{\text{Fun}(\mathcal{K}, \mathcal{C})} \text{Fun}(\mathcal{K}^\circ) \)) if and only if it is \( \mathcal{U}' \)-initial (when viewed as an object of \( \text{Fun}(\mathcal{K}^\circ, \mathcal{C}) \)).

\[\text{Remark 7.1.6.4.}\]

Let \( U : \mathcal{C} \to \mathcal{D} \) be a functor of ∞-categories and let \( f : \mathcal{K} \to \mathcal{C} \) be a morphism of simplicial sets having restriction \( f = f|_\mathcal{K} \). Proposition 7.1.6.3 asserts that \( f \) is a \( \mathcal{U} \)-colimit diagram if and only if, for every diagram \( g : \mathcal{K}^\circ \to \mathcal{C} \) having restriction \( g = g|_\mathcal{K} \), the diagram of Kan complexes

\[
\begin{array}{ccc}
\text{Hom}_{\text{Fun}(\mathcal{K}^\circ, \mathcal{C})}(f, g) & \xrightarrow{\text{Hom}_{\text{Fun}(\mathcal{K}, \mathcal{C})}(f, g)} & \text{Hom}_{\text{Fun}(\mathcal{K}^\circ, \mathcal{D})}(U \circ f, U \circ g) \\
\text{Hom}_{\text{Fun}(\mathcal{K}^\circ, \mathcal{D})}(U \circ f, U \circ g) & \xrightarrow{\text{Hom}_{\text{Fun}(\mathcal{K}, \mathcal{D})}(U \circ f, U \circ g)} & \text{Hom}_{\text{Fun}(\mathcal{K}, \mathcal{D})}(U \circ f, U \circ g) \\
\end{array}
\]

is a homotopy pullback square. However, it suffices to verify this condition in the special case where \( g \) is a constant diagram: that is the content of Proposition 7.1.5.12.

\[\text{Corollary 7.1.6.5.}\]

Let \( \mathcal{C} \) be an ∞-category, let \( \mathcal{K} \) be a simplicial set, and let

\[ U : \text{Fun}(\mathcal{K}^\circ, \mathcal{C}) \to \text{Fun}(\mathcal{K}, \mathcal{C}) \]

denote the restriction map. Then a morphism of simplicial sets \( f : \mathcal{K}^\circ \to \mathcal{C} \) is a colimit diagram if and only if it is \( \mathcal{U} \)-initial when viewed as an object of the ∞-category \( \text{Fun}(\mathcal{K}^\circ, \mathcal{C}) \).

\[\text{Proof.}\] Apply Proposition 7.1.6.3 in the special case \( \mathcal{D} = \Delta^0 \).
Corollary 7.1.6.6. Let $U : C \to D$ be an inner fibration of $\infty$-categories, let $B$ and $K$ be simplicial sets, and let $A \subseteq B$ be a simplicial subset which contains every vertex of $B$. Suppose we are given a lifting problem which satisfies the following condition:

(*) Let $\sigma : \Delta^n \to B$ be an $n$-simplex which does not belong to $A$, and let $a = \sigma(0)$ be the initial vertex. Then the restriction

$$f_a = f|_{\{a\} \times K^\circ} : K^\circ \to C$$

is a $U$-colimit diagram.

Then the lifting problem admits a solution $\bar{f} : B \times K^\circ \to C$.

Proof. Set $C' = \text{Fun}(K^\circ, C)$ and $D' = \text{Fun}(K, C) \times_{\text{Fun}(K, D)} \text{Fun}(K^\circ, D)$, so that $U$ induces an inner fibration $U' : C' \to D'$ (Proposition 4.1.4.1). We can then rewrite (7.4) as a lifting problem

Let $P$ be the partially ordered set of pairs $(A', g')$, where $A' \subseteq B$ is a simplicial subset containing $A$, and $g' : A' \to C'$ is a morphism satisfying $g'|_A = g$ and $U' \circ g' = g_0|_{A'}$. The partially ordered set $P$ satisfies the hypotheses of Zorn’s lemma and therefore contains a maximal element $(A_{\text{max}}, g_{\text{max}})$. To complete the proof, it will suffice to show that $A_{\text{max}} = B$. Assume otherwise: then there exists some $n$-simplex $\sigma : \Delta^n \to B$ which is not contained in $A_{\text{max}}$. Choose $n$ as small as possible, so that $\sigma$ carries the boundary $\partial \Delta^n$ into $A_{\text{max}}$. Since every vertex of $A$ is contained in $B$, we must have $n > 0$. Moreover, it follows from (*) together with Proposition 7.1.6.3 that the vertex $a = \sigma(0)$ is a $U'$-initial object of $C'$. 
Applying Corollary 7.1.4.17, we deduce that the lifting problem

\[
\begin{array}{ccc}
\partial \Delta^n & \xrightarrow{g_{\text{max}} \circ \sigma} & C' \\
\downarrow & & \downarrow \\
\Delta^n & \xrightarrow{g_0 \circ \sigma} & D'
\end{array}
\]

has a solution, which contradicts the maximality of \((A_{\text{max}}, g_{\text{max}})\).

\[\square\]

\textbf{Corollary 7.1.6.7.} Let \(U : \mathcal{C} \to \mathcal{D}\) be an inner fibration of \(\infty\)-categories, let \(B\) and \(K\) be simplicial sets, and suppose we are given a lifting problem

\[
\begin{array}{ccc}
B \times K & \xrightarrow{f} & \mathcal{C} \\
\downarrow & & \downarrow \\
B \times K^\circ & \xrightarrow{g} & \mathcal{D}
\end{array}
\]

(7.5)

Assume that, for each vertex \(b \in B\), the restriction \(f|_{\{b\} \times K}\) can be extended to a \(U\)-colimit diagram \(\overline{f}_b : K^\circ \to \mathcal{C}\) satisfying \(U \circ \overline{f}_b = g|_{\{b\} \times K^\circ}\). Then the lifting problem (7.5) admits a solution \(\overline{f} : B \times K^\circ \to \mathcal{C}\) satisfying \(\overline{f}|_{\{b\} \times K^\circ} = \overline{f}_b\) for each \(b \in B\).

\textbf{Proof.} Apply Corollary 7.1.6.6 in the special case where \(A = \text{sk}_0(B)\) is the 0-skeleton of \(B\).

\[\square\]

We can now prove a weak form of Proposition 7.1.6.1.

\textbf{Corollary 7.1.6.8.} Let \(\mathcal{C}\) be an \(\infty\)-category, let \(B\) be a simplicial set, and let \(f : K \to \text{Fun}(B, \mathcal{C})\) be a diagram. Assume that, for every vertex \(b \in B\), the diagram

\[
K \xrightarrow{f} \text{Fun}(B, \mathcal{C}) \xrightarrow{\text{ev}_b} \mathcal{C}
\]

has a colimit in \(\mathcal{C}\). Then \(f\) can be extended to a morphism \(\overline{f} : K^\circ \to \text{Fun}(B, \mathcal{C})\) having the property that each composition \(K^\circ \xrightarrow{\overline{f}} \text{Fun}(B, \mathcal{C}) \xrightarrow{\text{ev}_b} \mathcal{C}\) is a colimit diagram in \(\mathcal{C}\).

\textbf{Proof.} Apply Corollary 7.1.6.7 in the special case \(\mathcal{D} = \Delta^0\).

\[\square\]

To complete the proof of Proposition 7.1.6.1, we must show that the morphism \(\overline{f} : K^\circ \to \text{Fun}(B, \mathcal{C})\) appearing in the statement of Corollary 7.1.6.8 is a colimit diagram. As above, it will be convenient to deduce this from a stronger assertion about relative colimit diagrams.
Proposition 7.1.6.9. Let $F : C \to \mathcal{D}$ be a functor of $\infty$-categories. Let $B$ be a simplicial set and let $A$ be a simplicial subset, so that $F$ induces a functor

$$F' : \text{Fun}(B, C) \to \text{Fun}(A, C) \times_{\text{Fun}(A, \mathcal{D})} \text{Fun}(B, \mathcal{D}).$$

Suppose we are given a diagram $f : K \to \text{Fun}(B, C)$ satisfying the following condition:

(*) Let $\sigma : \Delta^n \to B$ be an $n$-simplex of $B$ which is not contained in $A$ and set $b = \sigma(0)$. Then the composite map $K \to \text{Fun}(B, C) \xrightarrow{\text{ev}_b} C$ is an $F$-colimit diagram in the $\infty$-category $C$.

Then $f$ is an $F'$-colimit diagram in the $\infty$-category $\text{Fun}(B, C)$.

Proof. As in the proof of Corollary 7.1.6.6, we can replace $F$ by the restriction functor

$$\text{Fun}(K^\circ, C) \to \text{Fun}(K, C) \times_{\text{Fun}(K, \mathcal{D})} \text{Fun}(K^\circ, \mathcal{D})$$

and thereby reduce to the special case $K = \emptyset$ (Proposition 7.1.6.3). In this case, we view $f$ as an object of the $\infty$-category $\text{Fun}(B, C)$, and we wish to show that this object is $F'$-initial.

Using Proposition 4.1.3.2 we can factor $F$ as a composition $C \xrightarrow{G} \mathcal{E} \xrightarrow{U} \mathcal{D}$, where $U$ is an inner fibration (so that $\mathcal{E}$ is an $\infty$-category) and $G$ is inner anodyne (and therefore an equivalence of $\infty$-categories). Note that we have a commutative diagram

$$\begin{array}{cccc}
\text{Fun}(B, C) & \xrightarrow{F'} & \text{Fun}(A, C) \times_{\text{Fun}(A, \mathcal{D})} \text{Fun}(B, \mathcal{D}) & \xrightarrow{G_0} & \text{Fun}(A, C) \\
\downarrow{G_0} & & & & \downarrow{G_0} \\
\text{Fun}(B, \mathcal{E}) & \xrightarrow{U'} & \text{Fun}(A, \mathcal{E}) \times_{\text{Fun}(A, \mathcal{D})} \text{Fun}(B, \mathcal{D}) & \xrightarrow{G_0} & \text{Fun}(A, \mathcal{E}),
\end{array}$$

where the vertical maps on the left and right are equivalences of $\infty$-categories (Remark 4.5.1.16). Since the square on the right is a pullback diagram and the right horizontal maps are isofibrations (Corollary 4.4.5.3), it follows that the vertical map in the middle is also an equivalence of $\infty$-categories (Corollary 4.5.2.23). Consequently, to show that $f$ is $F'$-initial, it will suffice to show that $G \circ f$ is $U'$-initial when viewed as an object of $\text{Fun}(B, \mathcal{E})$ (Remark 7.1.4.9). Since $U'$ is an inner fibration (Proposition 4.1.4.1), it will suffice to verify that $G \circ f$ satisfies the criterion of Corollary 7.1.4.17: every lifting problem

$$\begin{array}{ccc}
\partial \Delta^n & \xrightarrow{\sigma_0} & \text{Fun}(B, \mathcal{E}) \\
\downarrow & & \downarrow{U'} \\
\Delta^n & \xrightarrow{\sigma_0} & \text{Fun}(A, \mathcal{E}) \times_{\text{Fun}(A, \mathcal{D})} \text{Fun}(B, \mathcal{D})
\end{array}$$

(7.6)
has a solution, provided that $n > 0$ and $\sigma_0(0) = f$. Unwinding the definitions, we can rewrite (7.6) as a lifting problem

\[
(\partial \Delta^n \times B) \coprod_{(\partial \Delta^n \times A)} (\Delta^n \times B) \xrightarrow{g} E \\
\Delta^n \times B \xrightarrow{\Delta^n \times B} D.
\]

Since $n > 0$, every vertex of the simplicial set $\Delta^n \times B$ is contained in $\partial \Delta^n \times B$. Moreover, if $\tau : \Delta^m \to \Delta^n \times B$ is an $m$-simplex which does not belong to $(\partial \Delta^n \times B) \coprod_{(\partial \Delta^n \times A)} (\Delta^n \times B)$, then condition (\ast) (and Remark 7.1.4.9) guarantee that $g$ carries $\tau(0)$ to a $U'$-initial vertex of $E$. The existence of the desired solution now follows from Corollary 7.1.6.6 (applied in the special case $K = \emptyset$).

\begin{corollary}
Let $\mathcal{C}$ be an $\infty$-category, let $B$ be a simplicial set, let $A \subseteq B$ be a simplicial subset, and let $U : \text{Fun}(B, \mathcal{C}) \to \text{Fun}(A, \mathcal{C})$ be the restriction functor. Let $\overline{f} : K^\circ \to \text{Fun}(B, \mathcal{C})$ be a diagram satisfying the following condition:

\begin{itemize}
  \item[(\ast)] Let $\sigma : \Delta^n \to B$ be an $n$-simplex of $B$ which is not contained in $A$ and set $b = \sigma(0)$.
  \end{itemize}

Then the composite map $K^\circ \xrightarrow{\overline{f}} \text{Fun}(B, \mathcal{C}) \xrightarrow{\text{ev}_b} \mathcal{C}$ is a colimit diagram in the $\infty$-category $\mathcal{C}$.

Then $\overline{f}$ is a $U$-colimit diagram in the $\infty$-category $\text{Fun}(B, \mathcal{C})$.

\end{corollary}

\begin{proof}
Apply Proposition 7.1.6.9 in the special case $D = \Delta^0$.
\end{proof}

\begin{corollary}
Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories, let $B$ be a simplicial set, and let $F' : \text{Fun}(B, \mathcal{C}) \to \text{Fun}(B, \mathcal{D})$ be given by composition with $F$. Let $\overline{f} : K^\circ \to \text{Fun}(B, \mathcal{C})$ be a diagram. Assume that, for every vertex $b \in B$, the composition

$$K^\circ \to \text{Fun}(B, \mathcal{C}) \xrightarrow{\text{ev}_b} \mathcal{C}$$

is an $F$-colimit diagram in the $\infty$-category $\mathcal{C}$. Then $\overline{f}$ is an $F'$-colimit diagram in the $\infty$-category $\text{Fun}(B, \mathcal{C})$.

\end{corollary}

\begin{proof}
Apply Proposition 7.1.6.9 in the special case $A = \emptyset$.
\end{proof}

\begin{corollary}
Let $\mathcal{C}$ be an $\infty$-category, let $B$ be a simplicial set, and let $\overline{f} : K^\circ \to \text{Fun}(B, \mathcal{C})$ be a diagram. Assume that, for each vertex $b \in B$, the composite map $K^\circ \xrightarrow{\overline{f}} \text{Fun}(B, \mathcal{C}) \xrightarrow{\text{ev}_b} \mathcal{C}$ is a colimit diagram in $\mathcal{C}$. Then $\overline{f}$ is a colimit diagram in $\text{Fun}(B, \mathcal{C})$.

\end{corollary}
Proof. Apply Corollary 7.1.6.11 in the special case \( D = \Delta^0 \) (or Corollary 7.1.6.10 in the special case \( A = \emptyset \)).

Proof of Proposition 7.1.6.1. Let \( C \) be an \( \infty \)-category, let \( B \) be a simplicial set, and let \( f : K \to \text{Fun}(B, C) \) be a diagram. Assume that, for every vertex \( b \in B \), the composite diagram

\[
K \xrightarrow{f} \text{Fun}(B, C) \xrightarrow{ev_b} C
\]

admits a colimit in the \( \infty \)-category \( C \). Applying Corollary 7.1.6.8, we see that \( f \) admits an extension \( \overline{f} : K^\circ \to \text{Fun}(B, C) \) with the property that, for every vertex \( b \in B \), the composition \( ev_b \circ \overline{f} \) is a colimit diagram in \( C \). Applying Corollary 7.1.6.12, we see any such extension is a colimit diagram in \( \text{Fun}(B, C) \). To complete the proof, it will suffice to show the converse: if \( \overline{f}' : K^\circ \to \text{Fun}(B, C) \) is any colimit diagram extending \( f \) and \( b \in B \) is a vertex, then \( ev_b \circ \overline{f}' \) is also a colimit diagram in \( C \). In this case, the extension \( \overline{f}' \) is isomorphic to \( \overline{f} \) as an object of the \( \infty \)-category \( \text{Fun}(K^\circ, \text{Fun}(B, C)) \). It follows that \( ev_b \circ \overline{f}' \) is isomorphic to \( ev_b \circ \overline{f} \) as an object of the \( \infty \)-category \( \text{Fun}(K^\circ, C) \) and therefore a colimit diagram by virtue of Corollary 7.1.2.14.

7.2 Cofinality

Let \( C \) be an \( \infty \)-category and let \( f : B \to C \) be a diagram in \( C \) indexed by a simplicial set \( B \). In \( \S 7.1 \), we introduced the definition of a limit \( \lim \lla f \rra \) and colimit \( \lim \rra f \rra \) of the diagram \( f \) (Definition 7.1.1.11). In practice, it is often convenient to replace \( f \) by a simpler diagram having the same limit (or colimit). The primary goal of this section is to introduce a general formalism which will allow us to make replacements of this sort.

We begin in \( \S 7.2.1 \) by introducing the notions of left cofinal and right cofinal morphisms of simplicial sets (Definition 7.2.1.1). Roughly speaking, one can regard left cofinality as a homotopy-invariant replacement for the notion of left anodyne morphism introduced in Definition 4.2.4.1. More precisely, the collection of left cofinal morphisms of simplicial sets is uniquely determined by the following assertions:

- A monomorphism of simplicial sets \( f : A \hookrightarrow B \) is left cofinal if and only if it is left anodyne.
- Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
A & \xrightarrow{f} & B \\
| & | & | \\
A' & \xrightarrow{f'} & B'
\end{array}
\]
where the vertical maps are categorical equivalences. Then $f$ is left cofinal if and only if $f'$ is left cofinal (Corollary 7.2.1.21).

In §7.2.2, we connect the notion of cofinality with the theory of limits and colimits developed in §7.1. Let $C$ be an $\infty$-category, and let $g : B \to C$ be a diagram in $C$. We will show that if $f : A \to B$ is a left cofinal morphism of simplicial sets, then the limit of the diagram $g$ (if it exists) can be identified with the limit of the composite diagram $(g \circ f) : A \to C$ (Corollary 7.2.2.11). Similarly, if $f$ is right cofinal, then the colimit of $g$ can be identified with the colimit of $g \circ f$. Consequently, cofinality is a very useful tool for computing (or verifying the existence of) limits and colimits.

In §7.2.3, we specialize to the study of cofinal functors between $\infty$-categories. Our main result asserts that a functor $F : C \to D$ is right cofinal if and only if, for every object $D \in D$, the $\infty$-category $C \times_D D_{/D}$ is weakly contractible (Theorem 7.2.3.1). It follows that $F$ is a weak equivalence if it is right cofinal. In particular, the weak contractibility of each slice $C \times_D D_{/D}$ is weakly contractible guarantees that $F$ is a weak homotopy equivalence of simplicial sets: this is an $\infty$-categorical generalization of Quillen’s “Theorem A” (see Example 7.2.3.3). We will deduce Theorem 7.2.3.1 from a general fact about the stability of right cofinality with respect to pullback along cocartesian fibrations (Proposition 7.2.3.13), which is of independent interest.

We devote the second half of this section to studying properties of $\infty$-categories which are closely related to the notion of cofinality. We say that an $\infty$-category $C$ is filtered if, for every finite simplicial set $K$ and every diagram $f : K \to C$, the coslice $\infty$-category $C_{/f}$ is nonempty (Definition 7.2.4.3). In §7.2.4, we show that if this property is satisfied for every finite simplicial set $K$, then one can say more: every such coslice $\infty$-category $C_{/f}$ is weakly contractible. It follows that $C$ is filtered if and only if the diagonal map $C \to \text{Fun}(K, C)$ is right cofinal for every finite simplicial set $K$ (Proposition 7.2.4.10).

To show that an $\infty$-category $C$ is filtered, it is not necessary to show that the coslice $\infty$-category $C_{/f}$ is nonempty for every finite diagram $f : K \to C$. In §7.2.5, we show that it suffices to verify this condition in the case where $K = \partial \Delta^n$ is the boundary of a standard simplex, for each $n \geq 0$ (Lemma 7.2.5.13). Using this observation, we show that the condition that an $\infty$-category $C$ is filtered can be formulated entirely at the level of the homotopy category $hC$, viewed as an $h$Kan-enriched category (Theorem 7.2.5.5). As an application, we show that our notion of filtered $\infty$-category generalizes the classical notion of a filtered category: that is, an ordinary category $C$ is filtered if and only if the nerve $N_{\bullet}(C)$ is a filtered $\infty$-category (Corollary 7.2.5.8). We also formulate a counterpart of this result for the homotopy coherent nerve of a locally Kan simplicial category (Corollary 7.2.5.10).

Our primary interest in the notion of filtered $\infty$-category stems from the exactness properties enjoyed by filtered colimits. We will see later that a small $\infty$-category $C$ is filtered if and only if the colimit functor $\text{lim} : \text{Fun}(C, S) \to S$ preserves finite limits (Theorem [?]). In §7.2.6, we establish a version of this statement, which reformulates the condition
that $\mathcal{C}$ is filtered in terms of fiber products of $\infty$-categories which are left-fibered over $\mathcal{C}$ (Corollary 7.2.6.3). As a consequence, we show that if $F : \mathcal{C}' \to \mathcal{C}$ is a right cofinal functor of $\infty$-categories where $\mathcal{C}'$ is filtered, then $\mathcal{C}$ is also filtered (Proposition 7.2.7.1). In §7.2.7, we establish a partial converse to this assertion: if $\mathcal{C}$ is a filtered $\infty$-category, then there exists a directed partially ordered set $(A, \leq)$ and a right cofinal functor $N_\bullet(A) \to \mathcal{C}$ (Theorem 7.2.7.2).

For many applications, it will be useful to consider a generalization of the notion of filtered $\infty$-category. In §7.2.8, we introduce the larger class of sifted simplicial sets. We say that a simplicial set $K$ is sifted if, for every finite set $I$, the diagonal map $\delta : K \to K^I$ is right cofinal (Definition 7.2.8.1). Equivalently, a simplicial set $K$ is sifted if it is weakly contractible and the diagonal $K \hookrightarrow K \times K$ is right cofinal (Proposition 7.2.8.8). Every filtered $\infty$-category is sifted (Example 7.2.8.4), but the converse is false: for example, the $\infty$-category $N_\bullet(\Delta)^{op}$ is sifted (Proposition 7.2.8.10), but is not filtered.

### 7.2.1 Cofinal Morphisms of Simplicial Sets

Recall that a morphism of simplicial sets $f : A \to B$ is left anodyne if, for every left fibration $q : X \to S$, every lifting problem

![Diagram]

admits a solution (Proposition 4.2.4.5). Beware that this condition can only be satisfied if $f$ is a monomorphism of simplicial sets, and is therefore not invariant under categorical equivalence. Our goal in this section is to introduce an enlargement of the collection of left anodyne morphisms which does not suffer from this defect.

**Definition 7.2.1.1** (Joyal). Let $f : A \to B$ be a morphism of simplicial sets. We say that $f$ is left cofinal if, for every left fibration $q : \tilde{B} \to B$, precomposition with $f$ induces a homotopy equivalence of Kan complexes $\text{Fun}_{/B}(B, \tilde{B}) \to \text{Fun}_{/B}(A, \tilde{B})$ (see Corollary 4.4.2.5). We say that $f$ is right cofinal if, for every right fibration $q : \tilde{B} \to B$, precomposition with $f$ induces a homotopy equivalence of Kan complexes $\text{Fun}_{/B}(B, \tilde{B}) \to \text{Fun}_{/B}(A, \tilde{B})$.

**Remark 7.2.1.2.** Let $f : A \to B$ be a morphism of simplicial sets. Then $f$ is left cofinal if and only if the opposite morphism $f^{op} : A^{op} \to B^{op}$ is right cofinal.

**Proposition 7.2.1.3.** Let $f : A \to B$ be a morphism of simplicial sets. Then $f$ is left anodyne if and only if it is a left cofinal monomorphism. Similarly, $f$ is right anodyne if and only if it is a right cofinal monomorphism.
Proof. We will prove the first assertion; the second follows by a similar argument. Assume first that \( f \) is left anodyne. Then \( f \) is a monomorphism (Remark 4.2.4.4). For every left fibration of simplicial sets \( \tilde{B} \rightarrow B \), the restriction map \( \theta : \text{Fun}_{/B}(B, \tilde{B}) \rightarrow \text{Fun}_{/B}(A, \tilde{B}) \) is a pullback of the map

\[
\text{Fun}(B, \tilde{B}) \rightarrow \text{Fun}(B, B) \times_{\text{Fun}(A, B)} \text{Fun}(A, \tilde{B}),
\]

and is therefore a trivial Kan fibration (Proposition 4.2.5.4). In particular, \( u \) is a homotopy equivalence (Proposition 3.1.6.10). Allowing \( \tilde{B} \) to vary, we conclude that \( f \) is left cofinal.

We now prove the converse. Assume that \( f \) is a left cofinal monomorphism; we wish to show that \( f \) is left anodyne. By virtue of Proposition 4.2.4.5, it will suffice to show that for every lifting problem

\[
\begin{array}{ccc}
A & \rightarrow & X \\
\downarrow & & \downarrow q \\
B & \rightarrow & S
\end{array}
\]

admits a solution, provided that \( q \) is a left fibration of simplicial sets. Let us regard the morphism \( g \) as fixed, and consider the restriction map

\[
\theta : \text{Fun}_{/B}(B, X \times_{S} B) \rightarrow \text{Fun}_{/B}(A, X \times_{S} B).
\]

Since \( f \) is a monomorphism, the morphism \( \theta \) is a left fibration (Proposition 4.2.5.1). Since the target simplicial set \( \text{Fun}_{/B}(A, X \times_{S} B) \) is a Kan complex (Corollary 4.4.2.5), it follows that \( \theta \) is a Kan fibration (Corollary 4.4.3.8). Our assumption that \( f \) is left cofinal guarantees that \( \theta \) is a homotopy equivalence, and therefore a trivial Kan fibration (Proposition 3.2.6.15). In particular, it is surjective at the level of vertices, which guarantees that (7.7) admits a solution.

Example 7.2.1.4. Let \( \mathcal{C} \) be an \( \infty \)-category and let \( X \) be an object of \( \mathcal{C} \). Then the inclusion map \( \{X\} \hookrightarrow \mathcal{C} \) is right cofinal if and only if \( X \) is a final object of \( \mathcal{C} \). This follows by combining Proposition 7.2.1.3 with Corollary 4.6.6.25. Similarly, the inclusion map \( \{X\} \hookrightarrow \mathcal{C} \) is left cofinal if and only if \( X \) is an initial object of \( \mathcal{C} \).

Proposition 7.2.1.5. Let \( f : A \rightarrow B \) be a morphism of simplicial sets. Then:

1. If \( f \) is either left cofinal or right cofinal, then it is a weak homotopy equivalence.
2. If \( f \) is a weak homotopy equivalence and \( B \) is a Kan complex, then \( f \) is left and right cofinal.
Proof. We first prove (1). Let $X$ be a Kan complex. Then the projection map $X \times B \to B$ is a Kan fibration (Remark 3.1.1.6), and therefore both a left and a right fibration (Example 4.2.1.5). Consequently, if $f$ is either left cofinal or right cofinal, the induced map

$$\text{Fun}(B, X) \simeq \text{Fun}_{/B}(B, X \times B) \to \text{Fun}_{/B}(A, X \times B) \simeq \text{Fun}(A, X)$$

is a homotopy equivalence of Kan complexes. Allowing $X$ to vary, we conclude that $f$ is a weak homotopy equivalence.

We now prove (2). Assume that $B$ is a Kan complex and that $f$ is a weak homotopy equivalence; we will show that $f$ is left cofinal (the proof that $f$ is right cofinal is similar). Let $q : \bar{B} \to B$ be a left fibration. Since $B$ is a Kan complex, $q$ is a Kan fibration (Corollary 4.4.3.8); in particular, $\bar{B}$ is a Kan complex. Applying Corollary 3.1.3.4 we obtain a commutative diagram of Kan complexes

$$
\begin{array}{ccc}
\text{Fun}(B, \bar{B}) & \xrightarrow{of} & \text{Fun}(A, \bar{B}) \\
\downarrow{q \circ f} & & \downarrow{q \circ f} \\
\text{Fun}(B, B) & \xrightarrow{of} & \text{Fun}(A, B),
\end{array}
$$

where the vertical maps are Kan fibrations (Corollary 3.1.3.2). Our assumption that $f$ is a weak homotopy equivalences guarantees that the horizontal maps are homotopy equivalences (Proposition 3.1.6.17). Applying Proposition 3.2.8.1 we deduce that the map $\text{Fun}_{/B}(B, \bar{B}) \to \text{Fun}_{/B}(A, \bar{B})$ is also a homotopy equivalence.

**Proposition 7.2.1.6.** Let $f : A \to B$ and $g : B \to C$ be morphisms of simplicial sets, and suppose that $f$ is left cofinal. Then $g$ is left cofinal if and only if the composite map $g \circ f$ is left cofinal. In particular, the collection of left cofinal morphisms is closed under composition.

**Proof.** Let $q : \bar{C} \to C$ be a left fibration of simplicial sets, and let

$$
\begin{array}{ccc}
\text{Fun}_{/C}(C, \bar{C}) & \xrightarrow{f^*} & \text{Fun}_{/C}(B, \bar{C}) \\
\downarrow{g^*} & & \downarrow{g^*} \\
\text{Fun}_{/C}(A, \bar{C})
\end{array}
$$

be the morphisms given by precomposition with $g$ and $f$. Our assumption that $f$ is left cofinal guarantees that $f^*$ is a homotopy equivalence. It follows that $g^*$ is a homotopy equivalence if and only if $f^* \circ g^*$ is a homotopy equivalence (Remark 3.1.6.7).

**Corollary 7.2.1.7.** Let $f : A \to B$ and $g : B \to C$ be monomorphisms of simplicial sets. If both $f$ and $g \circ f$ are left anodyne, then $g$ is left anodyne. If $f$ and $g \circ f$ are right anodyne, then $g$ is right anodyne.
Proof. Combine Propositions 7.2.1.6 and 7.2.1.3.

\[\text{Warning 7.2.1.8.} \quad \text{Let } g : \Delta^1 \to \Delta^0 \text{ be the projection map and let } f : \{1\} \hookrightarrow \Delta^1 \text{ be the inclusion. Then } g \text{ and } g \circ f \text{ are left cofinal (Proposition 7.2.1.5). However, the morphism } f \text{ is not left cofinal, since it is not left anodyne (see Example 4.2.4.7). Consequently, the collection of left cofinal morphisms does not satisfy the two-out-of-three property.}\]

Proposition 7.2.1.9. Let \( A \) be a simplicial set, let \( W \) be a collection of edges of \( A \), and let \( f : A \to B \) be a morphism of simplicial sets which exhibits \( B \) as a localization of \( A \) with respect to \( W \) (see Definition 6.3.1.9). Then \( F \) is both left and right cofinal.

Proof. We will show that \( f \) is left cofinal; the proof that \( f \) is right cofinal is similar. Let \( q : \tilde{B} \to B \) be a left fibration; we wish to show that composition with \( f \) induces a homotopy equivalence \( f^* : \text{Fun}_{/B}(B, \tilde{B}) \to \text{Fun}_{/B}(A, \tilde{B}) \). Applying Corollary 5.7.7.3 (and Remark 5.7.7.4), we deduce that there exists a pullback diagram of simplicial sets

\[
\begin{array}{c}
\tilde{B} \\
\downarrow q \\
B \\
\downarrow g \\
\tilde{C} \\
\downarrow Q \\
C,
\end{array}
\]

where \( Q \) is a left fibration of \( \infty \)-categories. Let \( \text{Fun}(A[W^{-1}], C) \) denote the full subcategory of \( \text{Fun}(A, C) \) spanned by those diagrams which carry each edge of \( W \) to an isomorphism in \( C \) (Notation 6.3.1.1), and define \( \text{Fun}(A[W^{-1}], \tilde{C}) \) similarly. We have a commutative diagram of \( \infty \)-categories

\[
\begin{array}{c}
\text{Fun}(B, \tilde{C}) \\
\downarrow \circ Q \\
\text{Fun}(B, C) \\
\downarrow \circ f \\
\text{Fun}(B, C[W^{-1}]) \\
\downarrow Q_{\circ} \\
\text{Fun}(A[W^{-1}], \tilde{C}) \\
\downarrow Q_{\circ} \\
\text{Fun}(A[W^{-1}], C) \\
\downarrow Q_{\circ} \\
\text{Fun}(A, C),
\end{array}
\]

where the vertical maps on both sides are left fibrations (Corollary 4.2.5.2). Since \( Q \) is a left fibration of \( \infty \)-categories, it is conservative (Proposition 4.4.2.11), so the right side of the diagram is a pullback square. In particular, the vertical map in the middle is also a left fibration. Our assumption that \( f \) exhibits \( B \) as a localization of \( A \) with respect to \( W \) guarantees that the left horizontal maps are equivalences of \( \infty \)-categories. Applying
Corollary 4.5.2.26, we conclude that the map of fibers
\[
\Fun_{/B}(B, \tilde{B}) \simeq \{ g \} \times_{\Fun(B,C)} \Fun(B, \tilde{C}) \to \{ g \circ f \} \times_{\Fun(A,W^{-1},C)} \Fun(A,W^{-1}, \tilde{C})
\]
\[
= \{ g \circ f \} \times_{\Fun(A,C)} \Fun(A, \tilde{C})
\]
\[
\simeq \Fun_{/B}(A, \tilde{B})
\]
is an equivalence of ∞-categories, and therefore a homotopy equivalence of Kan complexes (Example 4.5.1.13).

**Corollary 7.2.1.10.** Let \( f : A \to B \) be a universally localizing morphism of simplicial sets (see Definition 6.3.6.1). Then \( f \) is both left and right cofinal.

**Corollary 7.2.1.11.** Let \( C \) be a simplicial set. Then there exists a partially ordered set \( (A, \leq) \) and a morphism of simplicial sets \( F : N_\bullet(A) \to C \) which is both left and right cofinal. Moreover, if the simplicial set \( C \) is finite, then we can arrange that the partially ordered set \( (A, \leq) \) is finite.

**Proof.** Combine Theorem 6.3.7.1 (and Variant 6.3.7.15) with Corollary 7.2.1.10.

**Corollary 7.2.1.12.** Let \( f : A \to B \) be a categorical equivalence of simplicial sets. Then \( f \) is left cofinal and right cofinal.

**Proof.** Combine Proposition 7.2.1.9 with Example 6.3.1.12.

**Corollary 7.2.1.13.** Let \( q : X \to S \) be a morphism of simplicial sets. The following conditions are equivalent:

1. The morphism \( q \) is left cofinal and a left fibration.
2. The morphism \( q \) is right cofinal and a right fibration.
3. The morphism \( q \) is a trivial Kan fibration.

**Proof.** If \( q \) is a trivial Kan fibration, then it is both a left fibration and a right fibration (Example 4.2.1.5). Moreover, \( q \) is also a categorical equivalence of simplicial sets (Proposition 4.5.3.11), hence left and right cofinal by virtue of Corollary 7.2.1.12. This proves the implications (3) ⇒ (1) and (3) ⇒ (2).

We will complete the proof by showing that (1) ⇒ (3) (the proof of the implication (2) ⇒ (3) is similar). Assume that \( q \) is a left cofinal left fibration. Then composition with \( q \) induces a homotopy equivalence of Kan complexes \( \Fun_{/S}(S, X) \to \Fun_{/S}(X, X) \). In particular, the morphism \( q \) admits a section \( f : S \to X \) such that \( \text{id}_X \) and \( q \circ f \) belong to the same connected component of \( \Fun_{/S}(X, X) \). For each vertex \( s \in S \), let \( X_s = \{ s \} \times_s X \) be the fiber of \( q \) over \( s \). Then the identity map \( \text{id} : X_s \to X_s \) is homotopic to the constant map \( X_s \to \{ f(s) \} \leftarrow X_s \). It follows that the Kan complex \( X_s \) is contractible. Allowing \( s \) to vary, we conclude that the left fibration \( q \) is a trivial Kan fibration (Proposition 4.4.2.14).
Corollary 7.2.1.14. Let $f : X \to Z$ be a morphism of simplicial sets. Then $f$ is left cofinal if and only if it factors as a composition $X \xrightarrow{f'} Y \xrightarrow{f''} Z$, where $f'$ is left anodyne and $f''$ is a trivial Kan fibration.

Proof. Suppose first that we can write $f = f'' \circ f'$, where $f'$ is left anodyne and $f''$ is a trivial Kan fibration. Proposition 7.2.1.3 guarantees that $f'$ is left cofinal, and Proposition 7.2.1.5 guarantees that $f''$ is left cofinal. Applying Proposition 7.2.1.6 we conclude that $f$ is also left cofinal.

We now prove the converse. Assume that $f : X \to Z$ is left cofinal. Applying Proposition 4.2.4.8 we can write $f$ as a composition $X \xrightarrow{f'} Y \xrightarrow{f''} Z$, where $f'$ is left anodyne and $f''$ is a left fibration. Then $f'$ is also left cofinal (Proposition 7.2.1.3). Applying Proposition 7.2.1.6 we deduce that $f''$ is left cofinal. It then follows from Corollary 7.2.1.13 that $f''$ is a trivial Kan fibration. \hfill \Box

Corollary 7.2.1.15. Suppose we are given a categorical pushout diagram of simplicial sets

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Z \\
\downarrow & & \downarrow \\
X' & \xrightarrow{f'} & Z'.
\end{array}
\]

If $f$ is left cofinal, then $f'$ is also left cofinal.

Proof. By virtue of Corollary 7.2.1.14, we may assume that $f$ factors as a composition $X \xrightarrow{g} \xrightarrow{h} Z$, where $g$ is left anodyne and $h$ is a trivial Kan fibration. Setting $Y' = Y \coprod_{X} X'$, we can expand (7.8) to a commutative diagram

\[
\begin{array}{ccc}
X & \xrightarrow{g} & Y \\
\downarrow & & \downarrow \\
X' & \xrightarrow{g'} & Y'.
\end{array}
\]

\[
\begin{array}{ccc}
& & h \\
\downarrow & & \downarrow \\
Z & \xrightarrow{h'} & Z'.
\end{array}
\]

Note that the square on the left is a pushout diagram in which the horizontal maps are monomorphisms, and therefore a categorical pushout diagram (Example 4.5.4.12). Applying Proposition 4.5.4.8 we deduce that the square on the right is also a categorical pushout diagram. Since $h$ is a categorical equivalence (Proposition 4.5.3.11), it follows that $h'$ is also a categorical equivalence (Proposition 4.5.4.10). In particular, $h'$ is left cofinal (Corollary 7.2.1.12). The morphism $g'$ is left anodyne (since it is a pushout of $g$), and is therefore also
left cofinal (Proposition 7.2.1.3). Applying Proposition 7.2.1.6 we deduce that $f' = h' \circ g'$ is also left cofinal.

**Corollary 7.2.1.16.** The collection of left cofinal morphisms of simplicial sets is closed under the formation of filtered colimits (when regarded as a full subcategory of the arrow category $\text{Fun}(\Delta[1], \text{Set})$).

*Proof.* For every morphism of simplicial sets $f : X \to Z$, let $X \xrightarrow{f'} Y \xrightarrow{f''} Z$ be the factorization of Proposition 4.2.4.8 so that $f'$ is left anodyne, $f''$ is a left fibration, and the construction $f \mapsto Q(f)$ is a functor which commutes with filtered colimits. Using Propositions 7.2.1.5 and 7.2.1.6, and Corollary 7.2.1.13, we see that $f$ is left cofinal if and only if the morphism $f'' : Q(f) \to Z$ is a trivial Kan fibration. Since the collection of trivial Kan fibrations is closed under filtered colimits (Remark 1.4.5.3), it follows that the collection of left cofinal morphisms is also closed under filtered colimits.

**Corollary 7.2.1.17.** The collection of left anodyne morphisms of simplicial sets is closed under the formation of filtered colimits (when regarded as a full subcategory of the arrow category $\text{Fun}(\Delta[1], \text{Set})$).

*Proof.* Combine Corollary 7.2.1.16 with Proposition 7.2.1.3.

**Corollary 7.2.1.18.** Let $f : X \to Z$ be a left cofinal morphism of simplicial sets. Then, for every simplicial set $K$, the product map $(f \times \text{id}_K) : X \times K \to Z \times K$ is left cofinal.

*Proof.* By virtue of Corollary 7.2.1.14, the morphism $f$ factors as a composition $X \xrightarrow{f'} Y \xrightarrow{f''} Z$, where $f'$ is left anodyne and $f''$ is a trivial Kan fibration. It follows that $f \times \text{id}_K$ factors as a composition

$$X \times K \xrightarrow{f' \times \text{id}_K} Y \times K \xrightarrow{f'' \times \text{id}_K} Z \times K.$$  

We now note that $f' \times \text{id}_K$ is left anodyne (Proposition 4.2.5.3) and $f'' \times \text{id}_K$ is a trivial Kan fibration (Remark 1.4.5.2). Applying Corollary 7.2.1.14 we deduce that $f \times \text{id}_K$ is left cofinal.

**Corollary 7.2.1.19.** Let $f : X \to Y$ and $f' : X' \to Y'$ be left cofinal morphisms of simplicial sets. Then the product map $(f \times f') : X \times X' \to Y \times Y'$ is left cofinal.

*Proof.* Factoring $f \times f'$ as a composition

$$X \times X' \xrightarrow{f \times \text{id}_{X'}} Y \times X' \xrightarrow{\text{id}_Y \times f'} Y \times Y',$$

the desired result follows by combining Corollary 7.2.1.18 with Proposition 7.2.1.6.

We now prove that cofinality is invariant under categorical equivalence.
Proposition 7.2.1.20. Let \( f : A \to B \) and \( g : B \to C \) be morphisms of simplicial sets, and suppose that \( g \) is a categorical equivalence. Then \( f \) is left cofinal if and only if \( g \circ f \) is left cofinal.

Proof. Since \( g \) is a categorical equivalence, the construction \( \tilde{C} \mapsto B \times_C \tilde{C} \) induces a bijection from equivalence classes of left fibrations over \( C \) to equivalence classes of left fibrations over \( B \) (Corollary 5.7.0.6). It follows that \( f \) is left cofinal if and only if it satisfies the following condition:

\[(\ast) \text{ For every left fibration } q : \tilde{C} \to C, \text{ the restriction map } f^* : \text{Fun}_{/C}(B, \tilde{C}) \to \text{Fun}_{/C}(A, \tilde{C}) \text{ is a homotopy equivalence of Kan complexes.}\]

It will therefore suffice to show that, for every left fibration \( q : \tilde{C} \to C \), the restriction map \( f^* : \text{Fun}_{/C}(B, \tilde{C}) \to \text{Fun}_{/C}(A, \tilde{C}) \) is a homotopy equivalence if and only if the restriction map \( (g \circ f)^* : \text{Fun}_{/C}(C, \tilde{C}) \to \text{Fun}_{/C}(A, \tilde{C}) \) is a homotopy equivalence. This is clear, since our assumption that \( g \) is a categorical equivalence guarantees that the restriction map \( g^* : \text{Fun}_{/C}(C, \tilde{C}) \to \text{Fun}_{/C}(B, \tilde{C}) \) is a homotopy equivalence (Corollary 7.2.1.12).

Corollary 7.2.1.21. Suppose we are given a commutative diagram of simplicial sets

\[
\begin{阵列}{ccc}
A & \xrightarrow{f} & B \\
\downarrow^{g} & & \downarrow^{g'} \\
A' & \xrightarrow{f'} & B',
\end{阵列}
\]

where \( g \) and \( g' \) are categorical equivalences. Then \( f \) is left cofinal if and only if \( f' \) is left cofinal.

Proof. By virtue of Proposition 7.2.1.20 the morphism \( f \) is left cofinal if and only if the composite morphism \( g' \circ f \) is left cofinal. Similarly, Proposition 7.2.1.6 guarantees that \( f' \) is left cofinal if and only if \( f' \circ g \) is left cofinal. We conclude by observing that \( g' \circ f = f' \circ g \).

Corollary 7.2.1.22. Let \( \mathcal{C} \) be an \( \infty \)-category and suppose we are given a pair of diagrams \( f_0, f_1 : K \to \mathcal{C} \) indexed by a simplicial set \( K \). Suppose that \( f_0 \) and \( f_1 \) are isomorphic as objects of the \( \infty \)-category \( \text{Fun}(K, \mathcal{C}) \). Then \( f \) is left cofinal if and only if \( g \) is left cofinal.

Proof. Let \( \text{Isom}(\mathcal{C}) \subseteq \text{Fun}(\Delta^1, \mathcal{C}) \) be the full subcategory spanned by the isomorphisms of \( \mathcal{C} \) (see Example 4.4.1.13). Let \( \text{ev}_0, \text{ev}_1 : \text{Isom}(\mathcal{C}) \to \mathcal{C} \) be the morphisms given by evaluation at the vertices \( 0, 1 \in \Delta^1 \), so that \( \text{ev}_0 \) and \( \text{ev}_1 \) are trivial Kan fibrations (Corollary 4.4.5.10). Fix
an isomorphism of $f_0$ with $f_1$, which we identify with a diagram $F : K \to \text{Isom}(\mathcal{C})$ satisfying $\text{ev}_0 \circ F = f_0$ and $\text{ev}_1 \circ F = f_1$. Applying Corollary 7.2.1.21 to the diagram

\[
\begin{array}{ccc}
K & \xrightarrow{F} & \text{Isom}(\mathcal{C}) \\
\downarrow \text{id} & & \downarrow \text{ev}_0 \\
K & \xrightarrow{f_0} & \mathcal{C},
\end{array}
\]

we deduce that $f_0$ is left cofinal if and only if $F$ is left cofinal. By the same reasoning, this is equivalent to the condition that $f_1$ is left cofinal.

\[\square\]

### 7.2.2 Cofinality and Limits

Let $\mathcal{C}$ be an $\infty$-category. In §7.1.2, we introduced the notion of a limit $\lim \leftarrow (G)$ and colimit $\lim \rightarrow (G)$ for a diagram $G : B \to \mathcal{C}$ (Definition 7.1.1.11). Our goal in this section is to show that, if $F : A \to B$ is a left cofinal morphism of simplicial sets, then the limit $\lim \leftarrow (G)$ (if it exists) can be identified with the limit $\lim \leftarrow (G \circ F)$. Similarly, if $F : A \to B$ is right cofinal, then the colimit $\lim \rightarrow (G)$ (if it exists) can be identified with the colimit $\lim \rightarrow (G \circ F)$. Our proof is based on the following characterization of (left) cofinality:

**Proposition 7.2.2.1.** Let $F : A \to B$ be a morphism of simplicial sets. The following conditions are equivalent:

1. The morphism $F$ is left cofinal (in the sense of Definition 7.2.1.1).
2. For every $\infty$-category $\mathcal{C}$ and every diagram $G : B \to \mathcal{C}$, the restriction map $\mathcal{C}/G \to \mathcal{C}/(G \circ F)$ is an equivalence of $\infty$-categories.
3. For every $\infty$-category $\mathcal{C}$ and every diagram $G : B \to \mathcal{C}$, composition with $F$ induces an equivalence of $\infty$-categories

\[
\mathcal{C} \times_{\text{Fun}(B,\mathcal{C})} \{G\} \to \mathcal{C} \times_{\text{Fun}(A,\mathcal{C})} \{G \circ F\}.
\]

4. For every $\infty$-category $\mathcal{C}$, every diagram $G : B \to \mathcal{C}$, and every object $X \in \mathcal{C}$, precomposition with $F$ induces a homotopy equivalence of Kan complexes

\[
\text{Hom}_{\text{Fun}(B,\mathcal{C})}(X, G) \to \text{Hom}_{\text{Fun}(A,\mathcal{C})}(X \circ F, G \circ F);
\]

here $X : B \to \mathcal{C}$ denotes the constant diagram taking the value $X$. 

7.2. COFINALITY

(5) For every ∞-category C, every diagram G : B → C, and every object X ∈ C, precomposition with F induces a homotopy equivalence of Kan complexes

\[ \text{Fun}_C(B, C_X) \to \text{Fun}_C(A, C_X). \]

Proof. We first show that (1) implies (2). Let F : A → B be a left cofinal morphism of simplicial sets, let C be an ∞-category, and let G : B → C be a diagram; we wish to show that precomposition with F induces an equivalence of ∞-categories θ : C/G → C/(GoF). By virtue of Corollary 7.2.1.14 we may assume without loss of generality that F is either left anodyne or a trivial Kan fibration. In the first case, the functor θ is a trivial Kan fibration (Corollary 4.3.6.13). In the second case, the morphism F admits a section s : B ↪ A. The morphism s is then a categorical equivalence, which is automatically left cofinal (Proposition 7.2.1.20) and therefore left anodyne (Remark 4.5.3.5) and therefore left cofinal (Proposition 7.2.1.3). Corollary 4.3.6.13 then implies that the map θ′ : C/(GoF) → C/(GoFoF) = C/G is a trivial Kan fibration. The morphism θ is a section of θ′, and is therefore an equivalence of ∞-categories by virtue of Remark 4.5.1.18.

We next prove the equivalences (2) ⇔ (3) ⇔ (4) ⇔ (5). Let G : B → C be as above. Applying Construction 4.6.4.13 we obtain a commutative diagram of ∞-categories

\[
\begin{array}{ccc}
C/G & \xrightarrow{\theta} & \tilde{C} \times \text{Fun}(B,C)\{G\} \\
\downarrow & & \downarrow \theta' \\
C/(GoF) & \xrightarrow{\theta'} & \tilde{C} \times \text{Fun}(A,C)\{G \circ F\},
\end{array}
\]

where the horizontal maps are equivalences of ∞-categories (Theorem 4.6.4.17). It follows that θ is an equivalence of ∞-categories if and only if θ′ is an equivalence of ∞-categories. This proves the equivalence (2) ⇔ (3). Note that the functor θ′ fits into a commutative diagram

\[
\begin{array}{ccc}
\tilde{C} \times \text{Fun}(B,C)\{G\} & \xrightarrow{\theta'} & \tilde{C} \times \text{Fun}(A,C)\{G \circ F\} \\
\downarrow & & \downarrow \\
\tilde{C} & \xrightarrow{\theta_X} & \tilde{C} \times \text{Fun}(B,C)\{G\}
\end{array}
\]

where the vertical maps are right fibrations (Corollary 4.6.4.12). Applying Corollary 5.1.6.12 and Proposition 5.1.6.5 we see that θ′ is an equivalence of ∞-categories if and only if it induces a homotopy equivalence

\[ \theta'_X : \{X\} \tilde{C} \times \text{Fun}(B,C)\{G\} \to \{X \circ F\} \tilde{C} \times \text{Fun}(A,C)\{G \circ F\} \]
for each object $X \in \mathcal{C}$, which proves the equivalence $(3) \iff (4)$. Unwinding the definitions, we can identify $\theta'$ with the lower horizontal map appearing in the diagram

\[
\begin{array}{c}
\text{Fun}_C(B, C_{X/}) \xrightarrow{\theta'_X} \text{Fun}_C(A, C_{X/}) \\
\downarrow \downarrow \\
\text{Fun}_C(B, \{X\} \tilde{x}_C \mathcal{C}) \xrightarrow{\theta''_X} \text{Fun}_C(A, \{X\} \tilde{x}_C \mathcal{C}),
\end{array}
\]

where the vertical maps are given by postcomposition with the coslice diagonal morphism $\rho : C_{X/} \to \{X\} \tilde{x}_C \mathcal{C}$. Theorem 4.6.4.17 guarantees that $\rho$ is an equivalence of $\infty$-categories. It is therefore also an an equivalence of left fibrations over $\mathcal{C}$ (Proposition 5.1.6.5), so that the vertical maps are homotopy equivalences. It follows that $\theta'_X$ is a homotopy equivalence if and only if $\theta''_X$ is a homotopy equivalence, which proves the equivalence $(4) \iff (5)$.

We now complete the proof by showing that $(5)$ implies $(1)$. Assume that condition $(5)$ is satisfied; we wish to show that $F$ is left cofinal. Let $q : \tilde{B} \to B$ be a left fibration; we must show that composition with $F$ induces a homotopy equivalence $\text{Fun}_{/B}(B, \tilde{B}) \to \text{Fun}_{/B}(A, \tilde{B})$. To prove this, we are free to replace $q : \tilde{B} \to B$ by any other left fibration which is equivalent to it (in the sense of Definition 5.1.6.1). We may therefore assume without loss of generality that there exists a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
\tilde{B} & \xrightarrow{q} & S_* \\
\downarrow & & \downarrow \text{q}_{\text{univ}} \\
B & \xrightarrow{G} & S, 
\end{array}
\]

where $q_{\text{univ}} : S_* \to S$ is the universal left fibration of Corollary 5.7.0.6. We are then reduced to proving that $F$ induces a homotopy equivalence $\text{Fun}_{/S}(B, S_*) \to \text{Fun}_S(A, S_*)$, which is a special case of $(5)$ (applied to the $\infty$-category $\mathcal{C} = S$ and the object $X = \Delta^0$).

**Corollary 7.2.2.2.** Let $U : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories and let $e : A \to B$ be a left cofinal morphism of simplicial sets. Then a morphism of simplicial sets $\overline{f} : B^\triangledown \to \mathcal{C}$ is a $U$-limit diagram if and only if the composite map

\[
A^\triangledown \xrightarrow{e^\triangledown} B^\triangledown \xrightarrow{\overline{f}} \mathcal{C}
\]

is a $U$-limit diagram.
7.2. COFINALITY

Proof. Set $f = \overline{f}_{|B}$ and apply Remark 7.1.4.9 to the commutative diagram of $\infty$-categories

$$
\begin{array}{ccc}
\mathcal{C} / f & \longrightarrow & \mathcal{C} / (f \circ e) \\
\downarrow & & \downarrow \\
\mathcal{D} / (U \circ f) & \longrightarrow & \mathcal{D} / (U \circ f \circ e),
\end{array}
$$

noting that the horizontal maps are equivalences by virtue of Proposition 7.2.2.1.

Corollary 7.2.2.3. Let $\mathcal{C}$ be an $\infty$-category and let $e : A \to B$ be a left cofinal morphism of simplicial sets. Then a morphism of simplicial sets $\overline{f} : B^\Delta \to \mathcal{C}$ is a limit diagram if and only if the composite map

$$A^\Delta \xrightarrow{e^\Delta} B^\Delta \xrightarrow{\overline{f}} \mathcal{C}$$

is a limit diagram.

Proof. Apply Corollary 7.2.2.2 in the special case $\mathcal{D} = \Delta^0$ (see Example 7.1.5.3).

Remark 7.2.2.4. The converse of Corollary 7.2.2.3 is also true: if $e : A \to B$ is a morphism of simplicial sets having the property that precomposition with the induced map $e^\Delta : A^\Delta \to B^\Delta$ carries limit diagrams to limit diagrams, then $e$ is left cofinal. Moreover, it suffices check this condition for diagrams in the $\infty$-category $\mathcal{S}$ of spaces (see Corollary 7.4.5.11).

Corollary 7.2.2.5. Let $U : \mathcal{D} \to \mathcal{E}$ be an inner fibration of $\infty$-categories and let $\mathcal{C}$ be an $\infty$-category containing an object $Y$. Then:

- If $Y$ is an initial object of $\mathcal{C}$, then a diagram $\mathcal{C}^\Delta \to \mathcal{D}$ is a $U$-limit diagram if and only if it carries $\{X\}^\Delta \simeq \Delta^1$ to a $U$-cartesian morphism of $\mathcal{D}$.

- If $Y$ is a final object of $\mathcal{K}$, then a diagram $\mathcal{C}^\Delta \to \mathcal{D}$ is a $U$-colimit diagram if and only if it carries $\{X\}^p \simeq \Delta^1$ to a $U$-cocartesian morphism of $\mathcal{D}$.

Proof. If $Y$ is an initial object of $\mathcal{K}$, then the inclusion map $\{Y\} \hookrightarrow \mathcal{K}$ is left cofinal (Corollary 4.6.6.25). The first assertion now follows by combining Corollary 7.2.2.2 with Example 7.1.5.9. The second assertion follows by a similar argument.

Corollary 7.2.2.6. Let $\mathcal{C}$ and $\mathcal{D}$ be $\infty$-categories. Then:

- If $\mathcal{C}$ has an initial object $Y$, then a functor $\mathcal{C}^\circ \to \mathcal{D}$ is a limit diagram if and only if it carries $\{Y\}^\circ \simeq \Delta^1$ to an isomorphism in the $\infty$-category $\mathcal{D}$.

- If $\mathcal{C}$ has a final object $Y$, then a functor $\mathcal{C}^\circ \to \mathcal{D}$ is a colimit diagram if and only if it carries $\{Y\}^p \simeq \Delta^1$ to an isomorphism in the $\infty$-category $\mathcal{D}$.
Proof. Apply Corollary \textit{7.2.2.5} in the special case $E = \Delta^0$ (and use Example \textit{5.1.1.4}). □

\textbf{Corollary 7.2.2.7.} Let $\mathcal{C}$ be an $\infty$-category containing an object $C \in \mathcal{C}$ and let $e : A \to B$ be a left cofinal morphism of simplicial sets. Suppose we are given a diagram $f : B \to C$ and a natural transformation $\alpha : C \to f$, where $C \in \text{Fun}(B,\mathcal{C})$ denotes the constant diagram taking the value $C$. Then $\alpha$ exhibits $C$ as a limit of $f$ (in the sense of Definition \textit{7.1.1.1} if and only if the induced natural transformation $\alpha|_A : C|_A \to f|_A$ exhibits $C$ as a limit of the diagram $f|_A$.

Proof. By virtue of Remark \textit{7.1.1.7} we are free to modify the natural transformation $\alpha$ by a homotopy and may therefore assume that it corresponds to a morphism of simplicial sets $\Delta^0 \circ B \to \mathcal{C}$ which factors through the categorical equivalence $\Delta^0 \circ B \to \Delta^0 \star B$ of Theorem \textit{4.5.8.8}. In this case, the desired result follows from Corollary \textit{7.2.2.3} and Remark \textit{7.1.2.6}. □

\textbf{Corollary 7.2.2.8.} Let $e : A \to B$ be a morphism of simplicial sets and let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories. If $e$ is left cofinal and the functor $F$ preserves $A$-indexed limits, then $F$ preserves $B$-indexed limits. If $e$ is right cofinal and the functor $F$ preserves $A$-indexed colimits, then the functor $F$ preserves $B$-indexed colimits.

\textbf{Proposition 7.2.2.9.} Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
B & \xrightarrow{f} & C \\
\downarrow & & \downarrow U \\
B^a & \xrightarrow{\overline{g}} & D,
\end{array}
\]

where $U$ is an inner fibration of $\infty$-categories. Let $e : A \to B$ be a left cofinal morphism of simplicial sets. The following conditions are equivalent:

1. There exists a $U$-limit diagram $\overline{f} : B^a \to \mathcal{C}$ satisfying $\overline{f}|_B = f$ and $U \circ \overline{f} = \overline{g}$.
2. There exists a $U$-limit diagram $\overline{f}_0 : A^a \to \mathcal{C}$ satisfying $\overline{f}_0|_A = f \circ e$ and $U \circ \overline{f}_0 = \overline{g} \circ e^a$.

\textbf{Proof.} The implication (1) \Rightarrow (2) follows by observing that if $\overline{f} : B^a \to \mathcal{C}$ is a $U$-limit diagram, then the left cofinality of $e$ guarantees that $\overline{f} \circ e^a$ is also a $U$-limit diagram (Corollary \textit{7.2.2.2}). We will complete the proof by showing that (2) implies (1). By virtue of Corollary \textit{7.2.1.14} we can assume that the morphism $e$ is either left anodyne or a trivial Kan fibration. We first treat the case where $e$ is a trivial Kan fibration. Let $s : B \to A$ be a section of $e$, and let $\overline{f}_0 : A^a \to \mathcal{C}$ satisfy the requirements of (2). Let $\overline{f}$ denote the composite map

\[
B^a \xrightarrow{s^a} A^a \xrightarrow{\overline{f}_0} \mathcal{C}.
\]
It follows immediately from the construction that $\overline{f}|_{B} = f$ and $U \circ \overline{f} = \overline{g}$. Moreover, the composition $\overline{f} \circ e^{c}$ is isomorphic to $\overline{f}_{0}$ (as an object of the $\infty$-category $\text{Fun}(B^{d}, C)$), and is therefore also a $U$-limit diagram (Proposition 7.1.5.13). Since $e$ is left cofinal, it follows that $\overline{f}$ is also a $U$-limit diagram (Corollary 7.2.2.2).

We now treat the case where $e$ is left anodyne. In this case, the induced map $A^{c} \coprod_{A} B \hookrightarrow B^{c}$ is inner anodyne. Since $U$ is an inner fibration, we can extend $f$ to a morphism $\overline{f} : B^{c} \rightarrow C$ satisfying $U \circ \overline{f} = \overline{g}$ and $\overline{f} \circ e^{c} = \overline{f}_{0}$. Since $e$ is left cofinal, the morphism $\overline{f}$ is automatically a $U$-limit diagram (Corollary 7.2.2.2).

Corollary 7.2.2.10. Let $C$ be an $\infty$-category and let $e : A \rightarrow B$ be a left cofinal morphism of simplicial sets. Then a diagram $f : B \rightarrow C$ has a limit if and only if the composite diagram $(f \circ e) : A \rightarrow C$ has a limit.

Proof. If $\overline{f} : B^{c} \rightarrow C$ is a colimit diagram extending $f$, then Corollary 7.2.2.3 guarantees that $\overline{f} \circ e^{c} : A^{c} \rightarrow C$ is a colimit diagram extending $f \circ e$. Conversely, if $f \circ e$ can be extended to a colimit diagram, then Proposition 7.2.2.9 (applied in the special case $D = \Delta^{0}$) guarantees that $f$ can also be extended to a colimit diagram.

Corollary 7.2.2.11. Let $C$ be an $\infty$-category, let $e : A \rightarrow B$ be a left cofinal morphism of simplicial sets, and let $f : B \rightarrow C$ be a diagram. Then an object $X \in C$ is a limit of $f$ if and only if it is a limit of the diagram $(f \circ e) : A \rightarrow C$.

Proof. If an object $X \in C$ is a limit of $f$, then we can choose a limit diagram $\overline{f} : B^{c} \rightarrow C$ carrying the cone point of $f^{c}$ to the object $X$. Applying Corollary 7.2.2.10 we deduce that $\overline{f} \circ e^{c}$ exhibits $X$ as a limit of the diagram $f \circ e$. Conversely, if $X$ is a limit of the diagram $f \circ e$, then Corollary 7.2.2.10 guarantees that the diagram $f$ admits a limit $Y \in C$. The preceding argument shows that $Y$ is also a limit of the diagram $f \circ e$. Applying Proposition 7.1.1.12, we deduce that $Y$ is isomorphic to $X$, so that $X$ is also a limit of the diagram $f$.

Corollary 7.2.2.12. Let $e : A \rightarrow B$ be a morphism of simplicial sets and let $C$ be an $\infty$-category. If $e$ is left cofinal and $C$ admits $A$-indexed limits, then $C$ also admits $B$-indexed limits. If $e$ is right cofinal and $C$ admits $A$-indexed colimits, then $C$ also admits $B$-indexed colimits.

Corollary 7.2.2.13. Let $e : A \rightarrow B$ be a morphism of simplicial sets and let $F : C \rightarrow D$ be a functor of $\infty$-categories. If $e$ is left cofinal and the functor $F$ creates $A$-indexed limits, then $F$ creates $B$-indexed limits. If $e$ is right cofinal and the functor $F$ creates $A$-indexed colimits, then the functor $F$ creates $B$-indexed colimits.
Corollary 7.2.2.14. Suppose we are given lifting problem

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{f} & \mathcal{D} \\
\downarrow & & \downarrow \\
\mathcal{C}^\circ & \xleftarrow{\bar{f}} & \mathcal{E},
\end{array}
\]

(7.9)

where \( \mathcal{C} \) is an \( \infty \)-category and \( U \) is a cartesian fibration of \( \infty \)-categories. If \( \mathcal{C} \) has a final object \( C \), then (7.9) admits a solution \( \bar{f} : \mathcal{C}^\circ \to \mathcal{D} \) which is a \( U \)-limit diagram.

Proof. Using Proposition 7.2.2.9 and Corollary 4.6.6.25, we can replace \( \mathcal{C} \) by the simplicial set \( \{ C \} \simeq \Delta^0 \), in which case the desired result follows from our assumption that \( U \) is a cartesian fibration (see Example 7.1.5.9). \( \square \)

7.2.3 Quillen’s Theorem A for \( \infty \)-Categories

The following result provides a concrete criterion for establishing the cofinality of a functor between \( \infty \)-categories.

Theorem 7.2.3.1 (Joyal). Let \( F : \mathcal{C} \to \mathcal{D} \) be a morphism of simplicial sets, where \( \mathcal{D} \) is an \( \infty \)-category. Then:

1. The morphism \( F \) is left cofinal if and only if, for every object \( X \in \mathcal{D} \), the simplicial set \( \mathcal{C} \times_\mathcal{D} \mathcal{D}_{/X} \) is weakly contractible.
2. The morphism \( F \) is right cofinal if and only if, for every object \( X \in \mathcal{D} \), the simplicial set \( \mathcal{D}_{X/} \times_\mathcal{C} \) is weakly contractible.

Remark 7.2.3.2. Let \( F : \mathcal{C} \to \mathcal{D} \) be a morphism of simplicial sets, where \( \mathcal{D} \) is an \( \infty \)-category. For every object \( X \in \mathcal{D} \), the slice and coslice diagonal morphisms of Construction 4.6.4.13 induce categorical equivalences

\[
\mathcal{C} \times_\mathcal{D} \mathcal{D}_{/X} \simeq \mathcal{C} \times_\mathcal{D} \{ X \} \quad \mathcal{C} \times_\mathcal{D} \mathcal{D}_{X/} \simeq \{ X \} \times_\mathcal{D} \mathcal{C}
\]

(Example 5.1.6.7). We can therefore reformulate Theorem 7.2.3.1 as follows:

1’. The morphism \( F \) is left cofinal if and only if, for every object \( X \in \mathcal{D} \), the simplicial set \( \mathcal{C} \times_\mathcal{D} \{ X \} \) is weakly contractible.

2’. The morphism \( F \) is right cofinal if and only if, for every object \( X \in \mathcal{D} \), the simplicial set \( \{ X \} \times_\mathcal{C} \mathcal{D} \) is weakly contractible.
Example 7.2.3.3 (Quillen’s Theorem A). Let $F : C \to D$ be a functor between categories. Suppose that, for every object $X \in D$, the category $C \times_D D_{X/}$ has weakly contractible nerve. Applying Theorem 7.2.3.1, we deduce that the induced morphism of simplicial sets $N_\bullet(F) : N_\bullet(C) \to N_\bullet(D)$ is right cofinal. In particular, it is a weak homotopy equivalence (Proposition 7.2.1.5). This recovers a classical result of Quillen (see [44]).

Corollary 7.2.3.4. Let $(S, \leq)$ and $(T, \leq)$ be linearly ordered sets, and let $f : S \to T$ be a nondecreasing function. The following conditions are equivalent:

1. The function $f : S \to T$ is cofinal in the sense of Definition 5.4.1.26. That is, for every element $t \in T$, there exists an element $s \in S$ satisfying $t \leq f(s)$.

2. The induced morphism of simplicial sets $N_\bullet(S) \to N_\bullet(T)$ is right cofinal, in the sense of Definition 7.2.1.1.

Proof. For each $t \in T$, set $S_{\geq t} = \{ s \in S : t \leq f(s) \}$, which we regard as a linearly ordered subset of $S$. Using Theorem 7.2.3.1, we can rewrite conditions (1) and (2) as follows:

1’ For each element $t \in T$, the linearly ordered set $S_{\geq t}$ is nonempty.

2’ For each element $t \in T$, the linearly ordered set $S_{\geq t}$ has weakly contractible nerve.

The implication (2’) $\Rightarrow$ (1’) is immediate, and the reverse implication follows from Corollary 3.2.8.5. □

Corollary 7.2.3.5. Let $C$ be an $\infty$-category and let $\overline{f} : A^c \to C$ be a diagram, where $A$ is a weakly contractible simplicial set. The following conditions are equivalent:

1. The diagram $\overline{f}$ carries each edge of $A^c$ to an isomorphism in $C$.

2. The restriction $f = \overline{f}|_A$ carries each edge of $A$ to an isomorphism in $C$, and $\overline{f}$ is a limit diagram.

Proof. Without loss of generality, we may assume that $f$ carries each edge of $A$ to an isomorphism in $C$. Under this assumption, we can restate (1) and (2) as follows:

1’ For every vertex $a \in A$, the edge

$$\Delta^1 \simeq \{a\}^c \hookrightarrow A^c \xrightarrow{\overline{f}} C$$

is an isomorphism in the $\infty$-category $C$.

2’ The morphism $\overline{f}$ is a colimit diagram.
CHAPTER 7. LIMITS AND COLIMITS

Using Corollary 3.1.7.2, we can choose an anodyne morphism \( i : A \to B \), where \( B \) is a Kan complex. Note that \( f \) can be regarded as a morphism from \( A \) to the core \( C \cong \Delta \), which is also a Kan complex (Corollary 4.4.3.11). We can therefore extend \( f \) to a morphism of Kan complexes \( g : B \to C \cong \Delta \). Moreover, the morphism \( i \) is right cofinal (Proposition 7.2.1.5) and therefore right anodyne (Proposition 7.2.1.3). It follows that the induced map \( B \amalg A \to A \) is inner anodyne (Example 4.3.6.5), so that we can choose a functor \( g : B \to C \) satisfying \( g|_B = g \) and \( g|_A = f \).

It follows from Corollary 7.2.2.3 that \( f \) is a colimit diagram if and only if \( g \) is a colimit diagram. Since \( A \) is weakly contractible, the Kan complex \( B \) is contractible. In particular, every vertex \( a \in A \) can be regarded as a final object of \( B \). The equivalence of (1') and (2') now follows from Corollary 7.2.2.6.

Corollary 7.2.3.6. Let \( \mathcal{C} \) be an \( \infty \)-category and let \( U : \mathcal{D} \to \mathcal{E} \) be a functor of \( \infty \)-categories. Then:

- If \( \mathcal{C} \) has an initial object \( Y \) and \( \overline{F} : \mathcal{C}^\circ \to \mathcal{D} \) is a functor which carries \( \{Y\}^\circ \cong \Delta^1 \) to an isomorphism in \( \mathcal{D} \), then \( \overline{F} \) is a \( U \)-limit diagram.
- If \( \mathcal{C} \) has an initial object \( Y \) and \( \overline{F} : \mathcal{C}^\circ \to \mathcal{D} \) is a functor which carries \( \{Y\}^\circ \cong \Delta^1 \) to an isomorphism in \( \mathcal{D} \), then \( \overline{F} \) is a \( U \)-limit diagram.

Proof. Combine Corollary 7.2.2.6 with Proposition 7.1.5.14.

Corollary 7.2.3.7. Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories. Then:

1. If \( F \) is a left adjoint, then it is left cofinal.
2. If \( F \) is a right adjoint, then it is right cofinal.

Proof. We will prove (1); the proof of (2) is similar. Suppose that \( F \) admits a right \( G : \mathcal{D} \to \mathcal{C} \). For every object \( X \in \mathcal{D} \), Corollary 6.2.4.2 guarantees that the \( \infty \)-category \( \mathcal{C} \times_\mathcal{D} \mathcal{D}_/X \) has a final object. In particular, the \( \infty \)-category \( \mathcal{C} \times_\mathcal{D} \mathcal{D}_/X \) is weakly contractible (Corollary 4.6.6.26). Allowing \( X \) to vary and applying Theorem 7.2.3.1, we conclude that \( F \) is left cofinal.

Example 7.2.3.8. Let \( \mathcal{C} \) be an \( \infty \)-category. If \( \mathcal{C}_0 \subseteq \mathcal{C} \) is a reflective subcategory (Definition 6.2.2.1), then the inclusion map \( \iota : \mathcal{C}_0 \hookrightarrow \mathcal{C} \) is right cofinal (this is a special case of Corollary 7.2.3.7 since Proposition 6.2.2.7 guarantees that \( \iota \) has a left adjoint). Similarly, if \( \mathcal{C}_0 \) is a coreflective subcategory of \( \mathcal{C} \), then the inclusion \( \iota \) is left cofinal.

Corollary 7.2.3.9. Let \( \mathcal{C} \) be an \( \infty \)-category and let \( K \) be a simplicial set. The following conditions are equivalent:

1. The diagonal map \( \delta : \mathcal{C} \to \text{Fun}(K, \mathcal{C}) \) is right cofinal.
7.2. COFINALITY

(2) For every diagram \( f : K \to C \), the coslice \( \infty \)-category \( C_{f/} \) is weakly contractible.

Proof. By virtue of Remark 7.2.3.2, condition (1) is equivalent to the requirement that for every diagram \( f : K \to C \), the oriented fiber product \( \{ f \} \times_{\text{Fun}(K,C)} C \) is weakly contractible. The equivalence of (1) and (2) now follows from Theorem 4.6.4.17.

Corollary 7.2.3.10. Let \( \Delta \) denote the simplex category (Definition 1.1.1.2), and let \( \Delta_{\text{inj}} \subseteq \Delta \) denote the non-full subcategory whose morphisms are strictly increasing functions \([m] \to [n]\) (Variant 1.1.1.6). Then the inclusion of simplicial sets \( N_\bullet(\Delta_{\text{inj}}) \hookrightarrow N_\bullet(\Delta) \) is left cofinal.

Proof. By virtue of Theorem 7.2.3.1, it will suffice to show that for every integer \( n \geq 0 \), the category \( \mathcal{C} = \Delta_{\text{inj}} \times_\Delta \Delta/[n] \) has weakly contractible nerve. Let \( C_0 \in \mathcal{C} \) denote the object corresponding to the inclusion map \([0] \simeq \{0\} \hookrightarrow [n]\). For every object \( C \in \mathcal{C} \), given by a nondecreasing function \( \alpha : [m] \to [n] \), we let \( F(C) \in \mathcal{C} \) denote the object given by the nondecreasing function \( \alpha^+ : [m+1] \to [n] \) given by the formula

\[
\alpha^+(i) = \begin{cases} 
\alpha(i) & \text{if } 0 \leq i \leq m \\
n & \text{if } i = m+1.
\end{cases}
\]

Note that we have canonical maps \( C \xrightarrow{\beta} F(C) \xleftarrow{\beta^+} C_0 \), given by the inclusions

\[
\{0 < 1 < \cdots < m\} \hookrightarrow \{0 < 1 < \cdots < m+1\} \hookrightarrow \{m+1\}.
\]

These morphisms depend functorially on \( C \), and therefore furnish natural transformations of functors \( \text{id}_C \to F \leftarrow C_0 \), where \( C_0 : C \to \mathcal{C} \) denotes the constant functor taking the value \( C_0 \). It follows that the identity morphism of \( N_\bullet(\mathcal{C}) \) is homotopic to the constant morphism \( N_\bullet(\mathcal{C}) \to \{C_0\} \hookrightarrow N_\bullet(\mathcal{C}) \), so that the simplicial set \( N_\bullet(\mathcal{C}) \) is contractible (and, in particular, it is weakly contractible).

Our proof of Theorem 7.2.3.1 will require some preliminaries.

Lemma 7.2.3.11. Let \( \mathcal{C} \) be a category and let \( \mathcal{F} : \mathcal{C} \to \text{Set}_{\Delta} \) be a diagram of simplicial sets indexed by \( \mathcal{C} \). Suppose we are given morphisms of simplicial sets \( A \xrightarrow{f} B \xrightarrow{g} N_\bullet(\mathcal{C}) \), where \( f \) is right anodyne. Then the induced map \( A \times_{N_\bullet(\mathcal{C})} \text{holim}(\mathcal{F}) \to B \times_{N_\bullet(\mathcal{C})} \text{holim}(\mathcal{F}) \) is right anodyne.

Proof. Without loss of generality, we may assume that \( f \) is the inclusion map \( \Lambda^n_i \hookrightarrow \Delta^n \) for some \( 0 < i \leq n \). Using Remark 5.3.2.3, we can reduce to the case where \( \mathcal{C} \) is the linearly
ordered set $[n] = \{0 < 1 < \cdots < n\}$ and $g$ is the identity map. In this case, Remark 5.3.2.12 supplies a pushout diagram of simplicial sets

\[
\begin{array}{ccc}
\Lambda_n^0 \times \mathcal{F}(0) & \rightarrow & \Lambda_n^0 \times \text{holim}(\mathcal{F}) \\
\downarrow & & \downarrow \\
\Delta^n \times \mathcal{F}(0) & \rightarrow & \text{holim}(\mathcal{F}).
\end{array}
\]

It will therefore suffice to show that the left vertical map is right anodyne, which follows from Proposition 4.2.5.3. \qed

**Example 7.2.3.12.** Let $\mathcal{F} : C \to \Delta$ be a diagram of simplicial sets, and suppose that the category $C$ contains a final object $C$. Combining Lemma 7.2.3.11 with Corollary 4.6.6.25, we deduce that the inclusion map

\[
\mathcal{F}(C) \simeq \{C\} \times_{\Delta} \text{holim}(\mathcal{F}) \hookrightarrow \text{holim}(\mathcal{F})
\]

is right anodyne.

**Proposition 7.2.3.13.** Suppose we are given a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
C' & \rightarrow & C \\
\downarrow F & & \downarrow \pi \\
D' & \rightarrow & D.
\end{array}
\]

If $\pi$ is a cocartesian fibration and $F$ is right cofinal, then $F$ is right cofinal.

**Proof.** By virtue of Corollary 7.2.1.14, it will suffice to prove Proposition 7.2.3.13 in the special case where $F$ is right anodyne. Let $S$ be the collection of all morphisms of simplicial sets $F : D' \to D$ having the property that, for every cocartesian fibration $\pi : C \to D$, the induced map $F : D' \times_D C \to C$ is right anodyne. We wish to show show that every right anodyne morphism belongs to $S$. It follows immediately from the definitions that $S$ is weakly saturated, in the sense of Definition 1.4.4.15. It will therefore suffice to show that $S$ contains every horn inclusion $\Lambda_i^n \hookrightarrow \Delta^n$ for $0 < i \leq n$. In other words, we are reduced to proving Proposition 7.2.3.13 in the special case where $D = \Delta^n$ is a standard simplex and $F$ is the inclusion of the horn $\Lambda_i^n \subseteq \Delta^n$. 

\[
\begin{array}{ccc}
\Lambda_i^n \times \mathcal{F}(0) & \rightarrow & \Lambda_i^n \times \text{holim}(\mathcal{F}) \\
\downarrow & & \downarrow \\
\Delta^n \times \mathcal{F}(0) & \rightarrow & \text{holim}(\mathcal{F}).
\end{array}
\]
7.2. COFINALITY

Applying Corollary 5.3.4.9, we deduce that there exists a diagram of ∞-categories \( G : [n] \to \text{QCat} \) and a scaffold \( \lambda : \text{holim}(G) \to C \) for the cocartesian fibration \( \pi \). We then have a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\Lambda^n \times \Delta^n & \xrightarrow{\lambda} & \Lambda^n \times \Delta^n C \\
\text{holim}(G) & \xrightarrow{\lambda} & C,
\end{array}
\]

where \( F' \) is right anodyne (Lemma 7.2.3.11) and therefore right cofinal (Proposition 7.2.1.3). Lemma 5.3.6.4 guarantees that horizontal maps are categorical equivalences, so that \( F \) is also right cofinal (Corollary 7.2.1.21).

\[\square\]

**Corollary 7.2.3.14.** Suppose we are given a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
C' & \xrightarrow{F} & C \\
\downarrow & & \downarrow \pi \\
D' & \xrightarrow{\mathbf{F}} & D.
\end{array}
\]

If \( \pi \) is a cocartesian fibration and \( \mathbf{F} \) is right anodyne, then \( F \) is right anodyne.

**Proof.** Combine Propositions 7.2.3.13 and 7.2.1.3. \[\square\]

**Example 7.2.3.15.** Let \( \pi : C \to D \) be a cocartesian fibration of ∞-categories, let \( X \) be an object of \( D \), and set \( C_X = \{X\} \times_D C \). If \( X \) is a final object of \( D \), then the inclusion map \( C_X \to C \) is right anodyne, and therefore right cofinal. This follows by combining Corollaries 7.2.3.11 and 4.6.6.25.

**Proof of Theorem 7.2.3.1.** Let \( F : C \to D \) be a morphism of simplicial sets, where \( D \) is an ∞-category. We will show that \( F \) is right cofinal if and only if, for every object \( X \in D \), the simplicial set \( C \times_D D_X \) is weakly contractible; the analogous characterization of left cofinal morphisms follows by a similar argument.

Suppose first that \( F \) is right cofinal. For every object \( X \in D \), the projection map \( D_X \to D \) is a left fibration (Proposition 4.3.6.1), and therefore a cocartesian fibration (Proposition 5.1.4.14). Applying Proposition 7.2.3.13, we conclude that the projection map \( C \times_D D_X \to D_X \) is also right cofinal. In particular, it is a weak homotopy equivalence.
(Proposition 7.2.1.5). Since the ∞-category \( D_{X/} \) has an initial object (Proposition 4.6.6.23), it is weakly contractible, so that the fiber product \( C \times_D D_{X/} \) is also weakly contractible.

We now prove the converse. Assume that, for every object \( X \in D \), the simplicial set \( C \times_D D_{X/} \) is weakly contractible. We wish to show that \( F \) is right cofinal. Using Proposition 4.1.3.2 we can factor \( F \) as a composition

\[
C \xrightarrow{F'} C' \xrightarrow{F''} D,
\]

where \( F' \) is inner anodyne and \( F'' \) is an inner fibration. Since \( F' \) is left cofinal (Proposition 7.2.1.3), it will suffice to show that \( F'' \) is right cofinal (Proposition 7.2.1.6). For every object \( X \in D \), Proposition 5.3.6.1 guarantees that the induced map \( C \times_D D_{X/} \to C' \times_D D_{X/} \) is a categorical equivalence. In particular, it is a weak homotopy equivalence (Remark 4.5.3.4), so that \( C' \times_D D_{X/} \) is also weakly contractible. We may therefore replace \( C \) by \( C' \) and thereby reduce to the case where \( F : C \to D \) is an inner fibration, so that \( C \) is also an ∞-category (Remark 4.1.1.9).

Let \( ev_0, ev_1 : Fun(\Delta^1, D) \to D \) denote the functors given by evaluation at the vertices 0,1 ∈ \( D \), and let \( \delta : D \hookrightarrow Fun(\Delta^1, D) \) be the diagonal map. Note that there is a unique natural transformation from \( id_{\Delta^1} \) to the constant map \( \Delta^1 \to \{1\} \hookrightarrow \Delta^1 \), which induces a natural transformation \( h : id_{Fun(\Delta^1, D)} \to \delta \circ ev_1 \). Let \( M \) denote the oriented fiber product \( D \times_D C = Fun(\Delta^1, D) \times_{Fun(\{1\}, D)} Fun(\{1\}, C) \) of Construction 4.6.4.1 so that \( ev_0 \) and \( ev_1 \) lift to functors

\[
D \xleftarrow{ev_0} M \xrightarrow{ev_1} C,
\]

the diagonal map \( \delta \) lifts to a functor \( \tilde{\delta} : C \hookrightarrow M \), and \( h \) lifts to a natural transformation \( \tilde{h} : id_M \to \delta \circ \tilde{ev}_1 \). Note that \( \tilde{h} \) can be identified with a morphism of simplicial sets \( \Delta^1 \times M \to M \) which fits into a commutative diagram

\[
\begin{array}{ccc}
\{0\} \times C & \to & (\Delta^1 \times C) \coprod_{\{1\} \times M}(\{1\} \times M) & \to & C \\
\downarrow_{\tilde{\delta}} & & \downarrow_{\iota} & & \downarrow_{\tilde{\delta}} \\
\{0\} \times M & \to & \Delta^1 \times M & \to & M,
\end{array}
\]

where the horizontal compositions are the identity. It follows that \( \tilde{\delta} \) is a retract of \( \iota \). Since \( \iota \) is right anodyne (Proposition 4.2.5.3), \( \tilde{\delta} \) is also right anodyne, and therefore right cofinal (Proposition 7.2.1.3).

The functor \( \tilde{ev}_0 : M \to D \) is a cartesian fibration (Proposition 5.3.7.1). Moreover, for each object \( X \in D \), the fiber \( \tilde{ev}_0^{-1}\{X\} \simeq \{X\} \times_D C \) is equivalent to the ∞-category \( C \times_D D_{X/} \) (Example 5.1.6.7), and is therefore weakly contractible. Applying Corollary 6.3.5.3 we deduce that the functor \( \tilde{ev}_1 \) exhibits \( D \) as a localization of \( D \times_D C \), and is therefore right
cofinal (Proposition 7.2.1.9). We now observe that the functor \( F : \mathcal{C} \to \mathcal{D} \) factors as a composition

\[
\mathcal{C} \xrightarrow{\bar{F}} \bar{\mathcal{M}} \xrightarrow{\bar{\sigma} \bar{v}} \mathcal{D},
\]

and is therefore also right cofinal (Proposition 7.2.1.6).

Combining Theorem 7.2.3.1 with Proposition 7.2.3.13, we obtain the following:

**Corollary 7.2.3.16 (Fiberwise Cofinality Criterion).** Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{E}' & \xrightarrow{F} & \mathcal{E} \\
\downarrow U' & & \downarrow U \\
\mathcal{C} & \xleftarrow{\bar{F}} & \bar{\mathcal{E}}
\end{array}
\]

where \( U \) and \( U' \) are cartesian fibrations, and the morphism \( F \) carries \( U' \)-cartesian edges of \( \mathcal{E}' \) to \( U \)-cartesian edges of \( \mathcal{E} \). The following conditions are equivalent:

1. The morphism \( F \) is right cofinal.
2. For every vertex \( C \in \mathcal{C} \), the induced map of fibers \( F_C : \mathcal{E}'_C \to \mathcal{E}_C \) is right cofinal.

**Proof.** We first reduce to the case where \( \mathcal{C} \) is an \( \infty \)-category. Using Corollary 4.1.3.3, we can choose an inner anodyne morphism \( \iota : \mathcal{C} \hookrightarrow \bar{\mathcal{C}} \), where \( \bar{\mathcal{C}} \) is an \( \infty \)-category. Using Proposition 5.7.7.2, we can extend \( U \) and \( U' \) to cocartesian fibrations of \( \infty \)-categories \( \bar{U} : \bar{\mathcal{E}} \to \bar{\mathcal{C}} \) and \( \bar{U}' : \bar{\mathcal{E}}' \to \bar{\mathcal{C}} \). Then the inclusion maps \( \mathcal{E} \hookrightarrow \bar{\mathcal{E}} \) and \( \mathcal{E}' \hookrightarrow \bar{\mathcal{E}}' \) are categorical equivalences (Lemma 5.3.6.5). Since \( \bar{U} \) is an isofibration (Proposition 5.1.4.8), we can extend \( F \) to a functor \( \bar{F} : \bar{\mathcal{E}}' \to \bar{\mathcal{E}} \) satisfying \( \bar{U} \circ \bar{F} = \bar{U}' \) (Proposition 4.5.5.1). It follows from Remark 5.3.1.12 that the functor \( \bar{F} \) carries \( \bar{U}' \)-cartesian morphisms of \( \bar{\mathcal{E}}' \) to \( \bar{U} \)-cartesian morphisms of \( \bar{\mathcal{E}} \). Moreover, the morphism \( F \) is right cofinal if and only if \( \bar{F} \) is right cofinal (Corollary 7.2.1.21). Consequently, we can replace \( \mathcal{C} \) by \( \bar{\mathcal{C}} \) and thereby reduce to proving Corollary 7.2.3.16 in the case where \( \mathcal{C} \) is an \( \infty \)-category.

Fix an object \( X \in \mathcal{E} \), let \( C = U(X) \) denote its image in \( \mathcal{C} \), and write \( \mathcal{E}_C \) and \( \mathcal{E}'_C \) denote the fibers \( \{C\} \times_{\mathcal{C}} \mathcal{E} \) and \( \{C\} \times_{\mathcal{C}} \mathcal{E}' \), respectively. We will prove that the following conditions are equivalent:

1. The \( \infty \)-category \( \mathcal{E}' \times_{\mathcal{E}} \mathcal{E}_X \) is weakly contractible.
2. The \( \infty \)-category \( \mathcal{E}'_C \times_{\mathcal{E}_C} (\mathcal{E}_C)_X \) is weakly contractible.

Corollary 7.2.3.16 will then follow by allowing the object \( X \) to vary and applying the criterion of Theorem 7.2.3.1.
To complete the proof, it will suffice to show that the inclusion map
\[ \mathcal{E}'_C \times_{\mathcal{E}_C} (\mathcal{E}_C)_X / \rightarrow \mathcal{E}'_E \times_{\mathcal{E}_E} \mathcal{E}_X / \]
is a weak homotopy equivalence. In fact, we will show that it is left anodyne. Unwinding
the definitions, we have a pullback diagram
\[ \begin{array}{ccc}
\mathcal{E}'_C \times_{\mathcal{E}_C} (\mathcal{E}_C)_X / & \rightarrow & \mathcal{E}'_E \times_{\mathcal{E}_E} \mathcal{E}_X / \\
\downarrow & & \downarrow \\
\{\text{id}_C\} & \rightarrow & \mathcal{C}_C /
\end{array} \]
where the right vertical map is a cartesian fibration (Corollary 5.1.4.21). By virtue of
Proposition 7.2.3.13, we are reduced to showing that the inclusion map \( \{\text{id}_C\} \rightarrow \mathcal{C}_C / \) is left
anodyne, or equivalently that \( \{\text{id}_C\} \) is an initial object of the \( \infty \)-category \( \mathcal{C}_C / \) (Corollary
4.6.6.24). This is a special case of Proposition 4.6.6.23.

7.2.4 Filtered \( \infty \)-Categories

We begin by recalling the classical notion of a filtered category.

Definition 7.2.4.1. Let \( \mathcal{C} \) be a category. We say that \( \mathcal{C} \) is filtered if it satisfies the following conditions:

- The category \( \mathcal{C} \) is nonempty.
- For every pair of objects \( X, Y \in \mathcal{C} \), there exists an object \( Z \in \mathcal{C} \) and a pair of morphisms
  \( u : X \rightarrow Z \) and \( v : Y \rightarrow Z \).
- For every pair of objects \( X, Y \in \mathcal{C} \) and every pair of morphisms \( f_0, f_1 : X \rightarrow Y \), there
  exists a morphism \( v : Y \rightarrow Z \) in \( \mathcal{C} \) satisfying \( v \circ f_0 = v \circ f_1 \).

Exercise 7.2.4.2. We say that a partially ordered set \( (A, \leq) \) is directed if every finite subset
\( A_0 \subseteq A \) has an upper bound. Show that \( (A, \leq) \) is directed if and only if it is filtered, when
regarded as a category.

Our goal in this section is to introduce an \( \infty \)-categorical counterpart of Definition 7.2.4.1.

Definition 7.2.4.3. Let \( \mathcal{C} \) be an \( \infty \)-category. We say that \( \mathcal{C} \) is filtered if, for every finite
simplicial set \( K \), every diagram \( f : K \rightarrow \mathcal{C} \) admits an extension \( \overrightarrow{f} : K^\circ \rightarrow \mathcal{C} \).

In 7.2.5 we will show that Definition 7.2.4.3 is a generalization of Definition 7.2.4.1
that is, a category \( \mathcal{C} \) is filtered if and only if the \( \infty \)-category \( \mathbb{N}_\bullet (\mathcal{C}) \) is filtered (Corollary
7.2.5.8).
Variant 7.2.4.4. Let $C$ be an $\infty$-category. We say that $C$ is cofiltered if, for every finite simplicial set $K$, every diagram $f : K \to C$ admits an extension $\overline{f} : K^\triangleright \to C$. Equivalently, $C$ is cofiltered if the opposite $\infty$-category $C^\text{op}$ is filtered.

Example 7.2.4.5. Let $C$ be an $\infty$-category which contains a final object $X$. Then every morphism of simplicial sets $f : K \to C$ can be extended to a morphism $\overline{f} : K^\triangleright \to C$ which carries the cone point of $K^\triangleright$ to the object $X$. In particular, the $\infty$-category $C$ is filtered. For a more general statement, see Proposition 7.2.7.1.

Remark 7.2.4.6. Let $\{C_\alpha\}$ be a filtered diagram of simplicial sets, where each $C_\alpha$ is a filtered $\infty$-category. Then the colimit $C = \varinjlim_\alpha C_\alpha$ is also a filtered $\infty$-category. To prove this, we first observe that $C$ is an $\infty$-category (Remark 1.3.0.9). If $K$ is a finite simplicial set, then any morphism $f : K \to C$ factors through $f_\alpha : K \to C_\alpha$ for some index $\alpha$ (see Proposition 3.5.1.9). Our assumption that $C_\alpha$ is filtered guarantees that $f_\alpha$ extends to a diagram $\overline{f}_\alpha : K^\triangleright \to C_\alpha$, from which it follows that $f$ extends to a diagram $\overline{f} : K^\triangleright \to C$.

Remark 7.2.4.7. Let $C$ be an $\infty$-category. The following conditions are equivalent:

1. The $\infty$-category $C$ is filtered.

2. For every finite simplicial set $K$ and every diagram $f : K \to C$, the coslice $\infty$-category $C_{f/}$ is nonempty.

3. For every finite simplicial set $K$ and every diagram $f : K \to C$, the oriented fiber product $\{f\} \times_{\text{Fun}(K,C)} C$ is nonempty.

4. For every finite simplicial set $K$ and every diagram $f : K \to C$, there exists a morphism $f \to f'$ in the $\infty$-category $\text{Fun}(K,C)$, where $f' : K \to C$ is a constant diagram.

The equivalences $(1) \iff (2)$ and $(3) \iff (4)$ follow immediately from the definitions, and the equivalence $(2) \iff (3)$ follows from Theorem 4.6.4.17.

Proposition 7.2.4.8. Let $C$ be a filtered $\infty$-category and let $f : K \to C$ be a diagram, where $K$ is a finite simplicial set. Then the $\infty$-category $C_{f/}$ is also filtered.

Proof. By virtue of Remark 7.2.4.7, it will suffice to show that for every finite simplicial set $L$ and every morphism $g : L \to C_{f/}$, the $\infty$-category $(C_{f/})_{g/}$ is nonempty. Unwinding the definitions, we can identify $g$ with a morphism of simplicial sets $\overline{g} : K \star L \to C$ satisfying $\overline{g}|_K = f$. This identification supplies an isomorphism $(C_{f/})_{g/} \simeq C_{\overline{g}/}$. We are therefore reduced to showing that the coslice $\infty$-category $C_{\overline{g}/}$ is nonempty. This follows from Remark 7.2.4.7 since the simplicial set $K \star L$ is finite (Remark 4.3.3.16).

Proposition 7.2.4.9. Let $C$ be a filtered $\infty$-category. Then $C$ is weakly contractible.
Proof. By virtue of Proposition 3.1.7.1, there exists a functor \( Q : \text{Set}_\Delta \to \text{Set}_\Delta \) and a natural transformation \( u : \text{id}_{\text{Set}_\Delta} \to Q \) with the following properties:

- The functor \( Q \) commutes with filtered colimits.
- For every simplicial set \( X \), the simplicial set \( Q(X) \) is a Kan complex.
- For every simplicial set \( X \), the morphism \( u_X : X \to Q(X) \) is a weak homotopy equivalence.

To show that \( \mathcal{C} \) is weakly contractible, it will suffice to show that the Kan complex \( Q(\mathcal{C}) \) is contractible. Note that \( \mathcal{C} \) is nonempty, so that \( Q(\mathcal{C}) \) is also nonempty. It will therefore suffice to show that for every integer \( n \geq 0 \), every morphism of simplicial sets \( \sigma : \Delta^n/\partial \Delta^n \to Q(\mathcal{C}) \) is nullhomotopic (Proposition 3.2.6.14). Since the simplicial set \( \Delta^n/\partial \Delta^n \) is finite and the functor \( Q \) commutes with filtered colimits, the morphism \( \sigma \) factors as a composition \( \Delta^n/\partial \Delta^n \to Q(K) \xrightarrow{Q(\iota)} Q(\mathcal{C}) \), where \( K \) is a finite simplicial subset of \( \mathcal{C} \) and \( \iota : K \to \mathcal{C} \) denotes the inclusion map. We will complete the proof by showing that \( Q(\iota) \) is nullhomotopic. Since \( u_K : K \to Q(K) \) is a weak homotopy equivalence, this is equivalent to assertion that the composite morphism \( Q(\iota) \circ u_K = u_C \circ \iota \) is nullhomotopic. This is clear: our assumption that \( \mathcal{C} \) is filtered guarantees that there exists a natural transformation from \( \iota \) to a constant diagram \( K \to \mathcal{C} \) (Remark 7.2.4.7).

Proposition 7.2.4.10. Let \( \mathcal{C} \) be an \( \infty \)-category. The following conditions are equivalent:

1. The \( \infty \)-category \( \mathcal{C} \) is filtered.
2. For every finite simplicial set \( K \) and every morphism \( f : K \to \mathcal{C} \), the \( \infty \)-category \( \mathcal{C}_{f/} \) is filtered.
3. For every finite simplicial set \( K \) and every morphism \( f : K \to \mathcal{C} \), the \( \infty \)-category \( \mathcal{C}_{f/} \) is weakly contractible.
4. For every finite simplicial set \( K \), the diagonal map \( \delta : \mathcal{C} \to \text{Fun}(K, \mathcal{C}) \) is right cofinal.

Proof. The implication (1) \( \Rightarrow \) (2) follows from Proposition 7.2.4.8, the implication (2) \( \Rightarrow \) (3) from Proposition 7.2.4.9, and the implication (3) \( \Rightarrow \) (1) is immediate from the definitions (Remark 7.2.4.7). The equivalence (3) \( \Leftrightarrow \) (4) is a special case of Corollary 7.2.3.9.

Corollary 7.2.4.11. Let \( F : \mathcal{C} \to \mathcal{D} \) be an equivalence of \( \infty \)-categories. Then \( \mathcal{C} \) is filtered if and only if \( \mathcal{D} \) is filtered.

Proof. By virtue of Proposition 7.2.4.10, it will suffice to show that for every (finite) simplicial set \( K \), the diagonal map \( \delta_C : \mathcal{C} \to \text{Fun}(K, \mathcal{C}) \) is right cofinal if and only if the diagonal map
7.2. COFINALITY

\[ \delta_D : D \to \text{Fun}(K, D) \] is right cofinal. This follows by applying Corollary 7.2.1.21 to the commutative diagram of \( \infty \)-categories

\[ \begin{array}{ccc}
C & \xrightarrow{\delta_C} & \text{Fun}(K, C) \\
\downarrow F & & \downarrow F_0 \\
D & \xrightarrow{\delta_D} & \text{Fun}(K, D).
\end{array} \]

\[ \square \]

**Corollary 7.2.4.12.** Let \( C \) be a Kan complex. Then \( C \) is filtered if and only if it is contractible.

*Proof.* If \( C \) is a contractible Kan complex, then there exists a categorical equivalence \( C \to \Delta^0 \), so that \( C \) is filtered by virtue of Corollary 7.2.4.11. The converse is a special case of Proposition 7.2.4.9. \[ \square \]

### 7.2.5 Local Characterization of Filtered \( \infty \)-Categories

**Definition 7.2.5.1.** Let \( \text{hKan} \) denote the homotopy category of Kan complexes (Construction 7.2.1.21), and let \( C \) be a category which is enriched over \( \text{hKan} \). We will say that \( C \) is *homotopy filtered* if it is nonempty and satisfies the following condition for each \( n \geq 1 \):

\[ (\ast_n) \text{ For every pair of objects } X, Y \in C \text{ and for every morphism of simplicial sets } \sigma : \partial \Delta^{n-1} \to \text{Hom}_C(X, Y), \text{ there exists morphism } v : Y \to Z \text{ for which the composite morphism} \]

\[ \partial \Delta^{n-1} \xrightarrow{\sigma} \text{Hom}_C(X, Y) \xrightarrow{v} \text{Hom}_C(X, Z) \]

is nullhomotopic.

**Warning 7.2.5.2.** In the formulation of condition \((\ast_n)\) of Definition 7.2.5.1, postcomposition with \( v \) defines a map of Kan complexes \( V : \text{Hom}_C(X, Y) \to \text{Hom}_C(X, Z) \) which is only well-defined up to homotopy. However, the condition that \( V \circ \sigma \) is nullhomotopic depends only on the homotopy class of \( V \).
Let $\mathcal{C}$ be an ordinary category, which we regard as an h Kan-enriched category in which each of the Kan complexes $\text{Hom}_C(X,Y)$ is equal to $\text{Hom}_C(X,Y)$ (regarded as a constant simplicial set). In this case, condition $(\ast_n)$ of Definition 7.2.5.1 is automatically satisfied for $n \geq 3$. Moreover, we can state conditions $(\ast_1)$ and $(\ast_2)$ more concretely as follows:

$(\ast_1)$ For every pair of objects $X,Y \in \mathcal{C}$, there exists an object $Z \in \mathcal{C}$ equipped with morphisms $u : X \to Z$ and $v : Y \to Z$.

$(\ast_2)$ For every pair of objects $X,Y \in \mathcal{C}$ and every pair of morphisms $f_0, f_1 : X \to Y$, there exists a morphism $v : Y \to Z$ satisfying $v \circ f_0 = v \circ f_1$.

It follows that $\mathcal{C}$ is homotopy filtered (in the sense of Definition 7.2.5.1) if and only if is filtered (in the sense of Definition 7.2.4.1).

Remark 7.2.5.4. Let $\mathcal{C}$ be an h Kan-enriched category. If $\mathcal{C}$ is homotopy filtered (in the sense of Definition 7.2.5.1), then it is filtered when regarded as an ordinary category (in the sense of Definition 7.2.4.1). Beware that the converse is false in general (see Warning 7.2.5.7).

We can now state the main result of this section:

Theorem 7.2.5.5. Let $\mathcal{C}$ be an $\infty$-category. Then $\mathcal{C}$ is filtered (in the sense of Definition 7.2.4.3) if and only if the homotopy category $\text{h}\mathcal{C}$ is homotopy filtered (in the sense of Definition 7.2.5.1), when regarded as an h Kan-enriched category by means of Construction 4.6.8.13.

Before giving the proof of Theorem 7.2.5.5, let us note some of its consequences.

Corollary 7.2.5.6. Let $\mathcal{C}$ be a filtered $\infty$-category (in the sense of Definition 7.2.4.3). Then $\text{h}\mathcal{C}$ is a filtered category (in the sense of Definition 7.2.4.1).

Proof. Combine Theorem 7.2.5.5 with Remark 7.2.5.4.

Warning 7.2.5.7. The converse of Corollary 7.2.5.6 is false. For example, if $\mathcal{C}$ is a simply connected Kan complex, then the homotopy category $\text{h}\mathcal{C}$ is automatically filtered. However, $\mathcal{C}$ is filtered if and only if it is contractible (Corollary 7.2.4.12).

Corollary 7.2.5.8. Let $\mathcal{C}$ be a category. Then the category $\mathcal{C}$ is filtered (in the sense of Definition 7.2.4.1) if and only if the $\infty$-category $\text{N}_\bullet(\mathcal{C})$ is filtered (in the sense of Definition 7.2.4.3).

Proof. Combine Theorem 7.2.5.5 with Example 7.2.5.3.
Example 7.2.5.9. Let \((A, \leq)\) be a partially ordered set. Combining Exercise 7.2.4.2 with Corollary 7.2.5.8, we see that the \(\infty\)-category \(\mathbf{N}_\bullet(A)\) is filtered if and only if the partially ordered set \((A, \leq)\) is directed.

Corollary 7.2.5.10. Let \(\mathcal{C}\) be a locally Kan simplicial category. Then the \(\infty\)-category \(\mathbf{N}^{hc}_\bullet(\mathcal{C})\) is filtered if and only if the homotopy category \(\mathbf{h}\mathcal{C}\) is homotopy filtered, when regarded as an hKan-enriched category.

Proof. Combine Theorem 7.2.5.5 with Corollary 4.6.8.20.

Exercise 7.2.5.11. Let \(\mathcal{C}\) be a \((2,1)\)-category (Definition 2.2.8.5). Show that the Duskin nerve \(\mathbf{N}_\bullet^{D}(\mathcal{C})\) is a filtered \(\infty\)-category if and only if \(\mathcal{C}\) satisfies the following conditions:

- The 2-category \(\mathcal{C}\) is nonempty.
- For every pair of objects \(X, Y \in \mathcal{C}\), there exists an object \(Z \in \mathcal{C}\) and a pair of 1-morphisms \(f : X \to Z\) and \(g : Y \to Z\).
- For every pair of objects \(X, Y \in \mathcal{C}\) and every pair of 1-morphisms \(f, g : X \to Y\), there exists a 1-morphism \(h : Y \to Z\) such that the 1-morphisms \(h \circ f\) and \(h \circ g\) are isomorphic (when viewed as objects of the category \(\text{Hom}_{\mathcal{C}}(X, Z)\)).
- For every 1-morphism \(f : X \to Y\) in \(\mathcal{C}\) and every 2-morphism \(\gamma : f \Rightarrow f\), there exists a 1-morphism \(g : Y \to Z\) for which the horizontal composition \(\text{id}_g \circ \gamma\) is equal to the identity 2-morphism \(\text{id}_{g \circ f}\).

We now turn to the proof of Theorem 7.2.5.5. The easy part is to show that if \(\mathcal{C}\) is a filtered \(\infty\)-category, then the homotopy category \(\mathbf{h}\mathcal{C}\) is homotopy filtered. Condition \((\ast_n)\) of Definition 7.2.5.1 is a special case of the following assertion:

Lemma 7.2.5.12. Let \(\mathcal{C}\) be a filtered \(\infty\)-category containing objects \(X\) and \(Y\), and let \(K\) be a finite simplicial set equipped with a morphism \(f : K \to \text{Hom}_{\mathcal{C}}(X,Y)\). Then there exists a morphism \(v : Y \to Z\) of \(\mathcal{C}\) for which the composition \(K \xrightarrow{f} \text{Hom}_{\mathcal{C}}(X,Y) \xrightarrow{v} \text{Hom}_{\mathcal{C}}(X,Z)\) is nullhomotopic.

Proof. Let \(\Sigma(K)\) denote the iterated coproduct

\[
\begin{align*}
\{x\} & \coprod_{(0) \times K} (\Delta^1 \times K) \coprod_{(1) \times K} \{y\},
\end{align*}
\]

so that we can identify \(f\) with a morphism of simplicial sets \(F : \Sigma(K) \to \mathcal{C}\) satisfying \(F(x) = X\) and \(F(y) = Y\). Our assumption that \(\mathcal{C}\) is filtered guarantees that we can extend \(F\) to a morphism of simplicial set \(\overline{F} : \Sigma(K) \ast \{z\} \to \mathcal{C}\). Set \(Z = \overline{F}(z)\). Then \(\overline{F}\) carries \(\{x\} \ast \{z\}\) and \(\{y\} \ast \{z\}\) to morphisms \(u : X \to Z\) and \(v : Y \to Z\) in \(\mathcal{C}\). Moreover, the natural
map \( \Delta^1 \times K \to \Sigma(K) \) admits a unique extension \( q : \Delta^2 \times K \to \Sigma(K) \ast \{z\} \) carrying \( \{2\} \times K \) to the vertex \( z \), and the composition

\[
\Delta^2 \times K \xrightarrow{q} \Sigma(K) \ast \{z\} \xrightarrow{p} C
\]

determines a morphism of simplicial sets \( g : K \to \text{Hom}_C(X,Y,Z) \). Unwinding the definitions, we see that the diagram of simplicial sets

\[
\begin{array}{ccc}
K & \xrightarrow{(v,f)} & \text{Hom}_C(Y,Z) \times \text{Hom}_C(X,Y) \\
\downarrow{g} & & \downarrow{g} \\
\text{Hom}_C(X,Y,Z) & \xrightarrow{u} & \text{Hom}_C(X,Z)
\end{array}
\]

is strictly commutative, from which we immediately deduce (from the definition of the composition law on \( C \)) that the composition \( K \xrightarrow{f} \text{Hom}_C(X,Y) \to v \circ \text{Hom}_C(X,Z) \) is homotopic to the constant map taking the value \( u \).

The difficult half of Theorem 7.2.5.5 will require some further preliminaries. We first note that, to verify that an \( \infty \)-category \( C \) is filtered, it suffices to verify the extension condition of Definition 7.2.4.3 in the special case where \( K = \partial \Delta^n \) is the boundary of a simplex.

**Lemma 7.2.5.13.** An \( \infty \)-category \( C \) is filtered if and only if it satisfies the following condition for every integer \( n \geq 0 \):

\((*')_n \) Every morphism of simplicial sets \( \partial \Delta^n \to C \) can be extended to a morphism \( (\partial \Delta^n)^{\triangleright} \to C \).

**Proof.** The necessity of condition \((*')_n \) is clear. For the converse, suppose that \( C \) satisfies \((*')_n \) for each \( n \geq 0 \). We wish to prove that \( C \) is filtered. Let \( f : K \to C \) be a diagram where \( K \) is a finite simplicial set; we wish to show that the \( \infty \)-category \( C_f \) is nonempty. If \( K = \emptyset \), then this follows immediately from assumption \((*')_0 \). Otherwise, the simplicial set \( K \) has dimension \( m \) for some integer \( m \geq 0 \). We proceed by induction on \( m \) and on the number of nondegenerate \( m \)-simplices of \( K \). Choose a nondegenerate \( m \)-simplex \( \sigma : \Delta^m \to K \). Using
Proposition 1.1.3.13, we can choose a pushout diagram

\[
\begin{array}{ccc}
\partial \Delta^m & \rightarrow & \Delta^m \\
\downarrow \sigma & & \downarrow \\
K' & \rightarrow & K
\end{array}
\]

where \( K' \subseteq K \) is a simplicial subset having a smaller number of nondegenerate \( m \)-simplices.

Set \( f' = f|_{K'} \), \( f_0 = f \circ \sigma \), and \( f_0' = f \circ \sigma|_{\partial \Delta^m} \), so that we have a pullback diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\mathcal{C}_{f/} & \rightarrow & \mathcal{C}_{f'/} \\
\downarrow \Phi & & \downarrow \\
\mathcal{C}_{f_0/} & \rightarrow & \mathcal{C}_{f_0'/}.
\end{array}
\]

Applying our inductive hypothesis, we deduce that the \( \infty \)-category \( \mathcal{C}_{f'/} \) is nonempty. Choose an object \( X \) of \( \mathcal{C}_{f'/} \), so that \( \Phi(X) \in \mathcal{C}_{f_0\Delta/} \) can be identified with a morphism of simplicial sets \( g : (\partial \Delta^m)^{\circ} \rightarrow \mathcal{C} \). Amalgamating \( f \circ \sigma \) with \( g \), we obtain a morphism of simplicial sets

\[
\bar{g} : \partial \Delta^{m+1} \simeq (\partial \Delta^m)^{\circ} \coprod_{\partial \Delta^m} \Delta^m \rightarrow \mathcal{C}.
\]

Invoking \((m+1)^*\), we conclude that \( \bar{g} \) can be extended to a morphism of simplicial sets \( (\partial \Delta^{m+1})^{\circ} \rightarrow \mathcal{C} \). Unwinding the definitions, we see that this extension supplies an object \( Y \in \mathcal{C}_{f_0/} \) together with a morphism \( u : \Phi(X) \rightarrow \Psi(Y) \) in the \( \infty \)-category \( \mathcal{C}_{f_0'/} \).

Note that the projection maps \( \mathcal{C}_{f'/} \rightarrow \mathcal{C} \leftarrow \mathcal{C}_{f_0'/} \) are left fibrations (Proposition 4.3.6.1). Let \( \mathbf{X} \) denote the image of \( X \) in the \( \infty \)-category \( \mathcal{C} \), so that Corollary 4.3.7.13 guarantees that the vertical maps in the diagram

\[
\begin{array}{ccc}
(\mathcal{C}_{f'/})_{X/} & \rightarrow & (\mathcal{C}_{f_0'/})_{U(X)/} \\
\downarrow \Phi_{X/} & & \downarrow \\
\mathcal{C}_{\mathbf{X}/}
\end{array}
\]

are trivial Kan fibrations. In particular, they are equivalences of \( \infty \)-categories, so that the functor \( \Phi_{X/} \) is also an equivalence of \( \infty \)-categories. It follows that we can choose a morphism
$w : X \to Z$ in the $\infty$-category $C_{\mathcal{f}/}$ and a 2-simplex

\[
\begin{array}{ccc}
\Phi(X) & \xrightarrow{\Phi(w)} & \Phi(Z) \\
\Phi(Y) & \xleftarrow{\Psi(Y)} & \\
\downarrow{u} & & \downarrow{v} \\
\downarrow{\Psi(X)} & & \downarrow{\Psi(Z)} \\
\end{array}
\]

in the $\infty$-category $C_{\mathcal{f}_{0}/}$, where $v$ is an isomorphism. Since $\Psi$ is a left fibration (Corollary 4.3.6.11), we can lift $v$ to a morphism $\tilde{v} : Y \to \tilde{Z}$ of the $\infty$-category $C_{\mathcal{f}_{0}/}$. The pair $(Z, \tilde{Z})$ can then be regarded as an object of the $\infty$-category $\mathcal{C}_{\mathcal{f}/} = C_{\mathcal{f}/} \times C_{\mathcal{f}_{0}/} \mathcal{C}_{\mathcal{f}_{0}/}$.

**Remark 7.2.5.14.** Let $\mathcal{C}$ be an $\infty$-category and let $n \geq 0$ be a nonnegative integer. Condition $(\ast'_n)$ of Lemma 7.2.5.13 is equivalent to the assertion that, for every morphism of simplicial sets $f : \partial \Delta^n \to \mathcal{C}$, the coslice $\infty$-category $\mathcal{C}_{\mathcal{f}/}$ is nonempty. By virtue of Theorem 4.6.4.17, this is equivalent to the requirement that the oriented fiber product $\{f\} \times_{\text{Fun}(\partial \Delta^n, \mathcal{C})} \mathcal{C}$ is nonempty. We can therefore reformulate $(\ast'_n)$ as follows:

$(\ast'_n)$ For every diagram $f : \partial \Delta^n \to \mathcal{C}$, there exists an object $C \in \mathcal{C}$ and a natural transformation $f \to C$, where $C : \partial \Delta^n \to \mathcal{C}$ is the constant morphism taking the value $C$.

For each integer $n \geq 1$, let us identify the standard simplex $\Delta^{n-1}$ with its image in $\partial \Delta^n \subset \Delta^n$ (given by the face opposite the $n$th vertex).

**Lemma 7.2.5.15.** Let $\mathcal{C}$ be an $\infty$-category and let $n \geq 1$ be an integer. Then condition $(\ast''_n)$ of Lemma 7.2.5.13 is equivalent to the following:

$(\ast''_n)$ Let $f : \partial \Delta^n \to \mathcal{C}$ be a morphism of simplicial sets for which the restriction $f|_{\Delta^{n-1}}$ is constant. Then $f$ can be extended to a morphism $\tilde{f} : (\partial \Delta^n)^{\circ} \to \mathcal{C}$.

**Proof.** The implication $(\ast'_n) \Rightarrow (\ast''_n)$ is immediate. We will prove the converse. Assume that $(\ast''_n)$ is satisfied, and let $g : \partial \Delta^n \to \mathcal{C}$ be an arbitrary morphism of simplicial sets; we wish to show that $g$ can be extended to a morphism $\tilde{g} : (\partial \Delta^n)^{\circ} \to \mathcal{C}$. If $n = 1$, this follows immediately form $(\ast''_n)$; we will therefore assume that $n \geq 2$. Note that we can write $\partial \Delta^n$ as the union of $\Delta^{n-1}$ and the horn $\Lambda^n_2$, whose intersection is the simplicial subset $\partial \Delta^{n-1} \subset \Delta^{n-1}$. Set

$$g_- = g|_{\Delta^{n-1}} \quad g_\pm = g|_{\partial \Delta^{n-1}} \quad g_+ = g|_{\Lambda^n_2}. $$

Let $X = g(0)$ and $Y = g(n)$ and let $\pi : \mathcal{C}_{/Y} \to \mathcal{C}$ denote the projection map, so that we can identify $g_+$ with a morphism $\tilde{g}_+ : \partial \Delta^{n-1} \to \mathcal{C}_{/Y}$ satisfying $\pi \circ \tilde{g}_+ = g_+$. 

Let $f_- : \Delta^{n-1} \to C$ be the constant morphism taking the value $X$, and let $h_- : f_- \to g_-$ be the natural transformation given by the composite map

$$\Delta^1 \times \Delta^{n-1} \xrightarrow{(i,j) \mapsto j} \Delta^{n-1} \xrightarrow{g_-} C.$$ 

Set $f_\pm = f_-|_{\partial \Delta^{n-1}}$ and $h_\pm = h_-|_{\Delta^1 \times \partial \Delta^{n-1}}$, so that $h_\pm$ can be regarded as a natural transformation from $f_\pm$ to $g_\pm$. Since $\pi$ is a right fibration, we can lift $h_\pm$ to a natural transformation $\tilde{h}_\pm : f_\pm \to g_\pm$ in the $\infty$-category $\text{Fun}(\partial \Delta^{n-1}, C)$. Let us identify $\tilde{f}_\pm$ with a morphism of simplicial sets $f_\pm : \Lambda_n^a \to C$ satisfying $f_\pm(n) = Y$. Then $\tilde{h}_\pm$ determines a natural transformation $h_+ : f_+ \to g_+$, given by the composition

$$\Delta^1 \times \Lambda_n^a \simeq \Delta^1 \times (\partial \Delta^{n-1})^\circ \to (\Delta^1 \times \partial \Delta^{n-1})^\circ \xrightarrow{\tilde{h}_\pm^\circ} (C/Y)^\circ \to C.$$ 

Note that $f_-$ and $f_+$ can be amalgamated to a morphism $f : \partial \Delta^n \to C$, and that $h_-$ and $h_+$ can be amalgamated to a natural transformation $h : f \to g$ in $\text{Fun}(\partial \Delta^n, C)$.

Invoking hypothesis $(x''_n)$, we see that $f$ can be extended to a morphism $\tilde{f} : (\partial \Delta^n)^\circ \to C$. Let $Z \in C$ denote the image under $\tilde{f}$ of the cone point and let $\varphi : C/Z \to C$ denote the projection map, so that $\tilde{f}$ can be identified with a morphism of simplicial sets $f' : \partial \Delta^n \to C/Z$ satisfying $\varphi \circ f' = f$. Let us identify the vertex $f'(n) \in C/Z$ with a morphism $v : Y \to Z$ in the $\infty$-category $C$, so that we have a commutative diagram

$$\begin{array}{ccc}
C/C & \xrightarrow{\varphi'} & C/Y \\
\downarrow{\pi'} & & \downarrow{\pi} \\
C/Z & \xrightarrow{\varphi} & C. \\
\end{array}$$

Set $f'_\pm = f'|_{\Lambda_n^a}$ and $f'_\pm = f'|_{\partial \Delta^{n-1}}$, so that we can identify $f'_\pm$ with a morphism $\tilde{f}'_\pm : \partial \Delta^{n-1} \to C/v$, satisfying $\pi' \circ \tilde{f}'_\pm = f'_\pm$. Since the inclusion $\{0\} \to \Delta^1$ is left anodyne, the morphism $\varphi' : C/v \to C/Y$ is a trivial Kan fibration (Corollary 4.3.6.13). We can therefore lift $\tilde{h}_\pm$ to a natural transformation $\tilde{h}'_\pm : f'_\pm \to g'_\pm$ for some morphism $g'_\pm : \partial \Delta^{n-1} \to C/v$. Let us identify $g'_\pm$ with a morphism $g'_\pm : \Lambda_n^a \to C/Z$ satisfying $\varphi \circ g'_\pm = g_+$. Then $\tilde{h}'_\pm$ determines a natural transformation $h'_+ : f'_+ \to g'_+$, given by the composition

$$\Delta^1 \times \Lambda_n^a \simeq \Delta^1 \times (\partial \Delta^{n-1})^\circ \to (\Delta^1 \times \partial \Delta^{n-1})^\circ \xrightarrow{\tilde{h}'_\pm^\circ} (C/v)^\circ \to C/Z.$$ 

Let $e$ denote the restriction $h'_+|_{\Delta^1 \times \{0\}}$, which we regard as an edge of the simplicial set $C/Z$. By construction, $\varphi(e)$ is the degenerate edge $\text{id}_X$ of $C$. Since $\varphi$ is a right fibration
(Proposition 4.3.6.1), it follows that $e$ is an isomorphism in $\mathcal{C}/\mathcal{Z}$ (Proposition 4.4.2.11). Applying Proposition 4.4.5.8 we deduce that the lifting problem

$$
(\Delta^1 \times \Lambda^n)_n \coprod \left( \left\{ 0 \right\} \times \Lambda^n \right) \xrightarrow{(h',f')} \mathcal{C}/\mathcal{Z}
$$

admits a solution. The morphism $h'$ is then a natural transformation from $f'$ to a morphism $g' : \partial \Delta^n \to \mathcal{C}/\mathcal{Z}$, which we can identify with a map $\bar{g} : (\partial \Delta^n)^0 \to \mathcal{C}$ satisfying $\bar{g}|_{\partial \Delta^n} = g$. \(\square\)

**Proof of Theorem 7.2.5.5.** Let $\mathcal{C}$ be an $\infty$-category and suppose that the homotopy category $\text{h}\mathcal{C}$ is homotopy filtered; we wish to show that $\mathcal{C}$ is filtered (the reverse implication follows from Lemma 7.2.5.12). By virtue of Lemma 7.2.5.13 it will suffice to show that for every integer $n \geq 0$, every morphism of simplicial sets $f : \partial \Delta^n \to \mathcal{C}$ can be extended to a morphism $\bar{f} : (\partial \Delta^n)^0 \to \mathcal{C}$. For $n = 0$, this follows from our assumption that $\text{h}\mathcal{C}$ is nonempty. We will therefore assume that $n > 0$. By virtue of Lemma 7.2.5.15 we may assume without loss of generality that the restriction $f_{-} = f|_{\Delta^{n-1}}$ is the constant map taking the value $X$ for some object $X \in \mathcal{C}$. Set $Y = f(n)$ and let $\text{Hom}_\mathcal{C}^{R}(X,Y) = \{X\} \times_{\mathcal{C}} \mathcal{C}/Y$ denote the right-pinched morphism space of Construction 4.6.5.1 so that we can identify $f|_{\Lambda^n}$ with a morphism of simplicial sets $\bar{g} : \partial \Delta^n \to \text{Hom}_\mathcal{C}^{R}(X,Y)$. Invoking assumption ($\ast_n$) of Definition 7.2.5.1 we deduce that there exists a morphism $v : Y \to Z$ in $\mathcal{C}$ for which the composite map

$$
\partial \Delta^n \xrightarrow{\bar{g}} \text{Hom}_\mathcal{C}^{R}(X,Y) \hookrightarrow \text{Hom}_\mathcal{C}(X,Y) \xrightarrow{[v] \circ} \text{Hom}_\mathcal{C}(X,Z)
$$

is nullhomotopic. Since the projection map $\mathcal{C}/f \to \mathcal{C}/Y$ is a trivial Kan fibration (Corollary 4.3.6.13), we can lift $g$ to a morphism $\bar{g} : \partial \Delta^{n-1} \to \{X\} \times_{\mathcal{C}} \mathcal{C}/f$. Combining Propositions 5.2.8.7 and 4.6.8.16 we deduce that the diagram of Kan complexes

$$
\begin{array}{ccc}
\{X\} \times_{\mathcal{C}} \mathcal{C}/Y & \xleftarrow{\iota_{X,Y}^R} & \{X\} \times_{\mathcal{C}} \mathcal{C}/f \\
\downarrow & & \downarrow \\
\text{Hom}_\mathcal{C}(X,Y) & \xrightarrow{[v] \circ} & \text{Hom}_\mathcal{C}(X,Z)
\end{array}
$$

commutes up to homotopy, where $\iota_{X,Y}^R$ and $\iota_{X,Z}^R$ are the right-pinch inclusion morphisms of Construction 4.6.5.6. Since $\iota_{X,Z}^R$ is a homotopy equivalence (Proposition 4.6.5.9), it follows that the composite map $\partial \Delta^{n-1} \xrightarrow{\bar{g}} \mathcal{C}/f \to \mathcal{C}/Z$ is nullhomotopic, and can therefore
be extended to an \((n - 1)\)-simplex \(g' : \Delta^{n-1} \to C/Z\) (Proposition 3.2.6.11). Unwinding the definitions, we can identify \(\tilde{g}\) and \(g'\) with morphisms \((\Lambda^n_0)^\triangleright \to C\) and \((\Delta^{n-1})^\triangleright \to C\), which can be amalgamated to a single morphism \(\tilde{f} : (\partial \Delta^n)^\triangleright \to C\) extending \(f\).

**Exercise 7.2.5.16.** Let \(C\) be an \(\infty\)-category and let \(n \geq 1\) be an integer. Show that the homotopy category \(hC\) satisfies condition \((\ast_n)\) of Definition 7.2.5.1 if and only if \(C\) satisfies condition \((\ast'_n)\) of Lemma 7.2.5.13.

### 7.2.6 Left Fibrations over Filtered \(\infty\)-Categories

**Theorem 7.2.6.1.** Let \(U : \tilde{C} \to C\) be a left fibration of \(\infty\)-categories, where the \(\infty\)-category \(C\) is filtered. For each object \(X \in C\), let \(\tilde{C}_X\) denote the fiber \(\{X\} \times_C \tilde{C}\). The following conditions are equivalent:

1. The \(\infty\)-category \(\tilde{C}\) is filtered.
2. The \(\infty\)-category \(\tilde{C}\) is weakly contractible.
3. For every object \(X \in C\) and every diagram \(e : K \to \tilde{C}_X\) where \(K\) is a finite simplicial set, there exists a morphism \(f : X \to Y\) in \(C\) for which the composite map \(K \overset{e}{\to} \tilde{C}_X \overset{f}{\to} \tilde{C}_Y\) is nullhomotopic; here \(f : \tilde{C}_X \to \tilde{C}_Y\) is given by covariant transport along \(f\) (see Notation 5.2.2.9).
4. For every object \(X \in C\), every integer \(n \geq 0\), and every diagram \(e : \partial \Delta^n \to \tilde{C}_X\), there exists a morphism \(f : X \to Y\) in \(C\) for which the composite map \(\partial \Delta^n \overset{e}{\to} \tilde{C}_X \overset{f}{\to} \tilde{C}_Y\) is nullhomotopic.

**Proof.** The implication \((1) \Rightarrow (2)\) follows from Proposition 7.2.4.9 and the implication \((3) \Rightarrow (4)\) is immediate. We next show that \((4)\) implies \((1)\). Assume that condition \((4)\) is satisfied; we wish to prove that \(\tilde{C}\) is filtered. By virtue of Lemma 7.2.5.13 (and Remark 7.2.5.14), it will suffice to show that for every integer \(n \geq 0\) and every diagram \(e : \partial \Delta^n \to \tilde{C}\), there exists a natural transformation from \(e\) to a constant diagram. Set \(\overline{e} = U \circ e\), which we regard as an object of the \(\infty\)-category \(\text{Fun}(\partial \Delta^n, C)\). Since \(C\) is filtered, there exists an object \(X \in C\) and a morphism \(\pi : \overline{e} \to X\) in the \(\infty\)-category \(\text{Fun}(\partial \Delta^n, C)\), where \(X : \partial \Delta^n \to C\) denotes the constant morphism taking the value \(X\). Since \(U\) is a left fibration, we can lift \(\overline{e}\) to a morphism \(\alpha : e \to e'\) in \(\text{Fun}(\partial \Delta^n, \tilde{C})\), where \(e'\) is a morphism from \(\partial \Delta^n\) to the Kan complex \(\tilde{C}_X\) (see Remark 4.2.6.3). Invoking assumption \((4)\), we can choose a morphism \(f : X \to Y\) in \(C\) and a covariant transport functor \(f_! : \tilde{C}_X \to \tilde{C}_Y\) for which the composite map \(f_1 \circ u'\) is nullhomotopic. It follows that there exists a natural transformation \(\beta : e' \to e''\)
in \( \text{Fun}(\partial\Delta^n, \tilde{C}) \), where \( e'' : \partial\Delta^n \to \tilde{C}_Y \) is a constant map. Any choice of composition of \( \alpha \) and \( \beta \) then determines a natural transformation from \( e' \) to the constant diagram \( e'' \).

We now complete the proof by showing that (2) implies (3). Assume that the \( \infty \)-category \( \tilde{C} \) is weakly contractible, and suppose that we are given an object \( X \in \mathcal{C} \) and a diagram \( e : K \to \tilde{C}_X \), where the simplicial set \( K \) is finite. We wish to show that there exists a morphism \( f : X \to Y \) in \( \mathcal{C} \) for which the composite map \( K \to \tilde{C}_X \xrightarrow{f} \tilde{C}_Y \) is nullhomotopic. Choose an embedding \( K \hookrightarrow L \), where \( L \) is another finite simplicial set which is weakly contractible (for example, we can take \( L = K^+ \)). Let \( \text{Ex}^\infty(\tilde{C}) \) be the simplicial set given by Construction [3.3.6.1] so that \( \text{Ex}^\infty(\tilde{C}) \) is a Kan complex (Proposition 3.3.6.9). Let \( \rho^\infty : \tilde{C} \to \text{Ex}^\infty(\tilde{C}) \) be the weak homotopy equivalence of Proposition 3.3.6.7. Since \( \tilde{C} \) is weakly contractible, the Kan complex \( \text{Ex}^\infty(\tilde{C}) \) is contractible. It follows that the composite map \( K \to \tilde{C}_X \xrightarrow{f} \text{Ex}^\infty(\tilde{C}) \) can be extended to a map \( e^+ : L \to \text{Ex}^\infty(\tilde{C}) \). Since the simplicial set \( L \) is finite, the morphism \( \bar{e} \) factors through \( \text{Ex}^m(\tilde{C}) \) for some \( m \geq 0 \) (see Proposition 3.5.1.9). By virtue of Proposition 3.3.4.8 we can replace \( K \) and \( L \) by the iterated subdivisions \( \text{Sd}^m(K) \) and \( \text{Sd}^m(L) \) (and \( e \) by the composite map \( \text{Sd}^m(K) \to K \to \tilde{C}_X \)) and thereby reduce to the case \( m = 0 \), so that \( e \) admits an extension \( e^+ : L \to \tilde{C} \).

Set \( \bar{e}^+ = U \circ e^+ \), which we regard as an object of the \( \infty \)-category \( \text{Fun}(L, \mathcal{C}) \). Since \( \mathcal{C} \) is filtered, there exists an object \( Y \in \mathcal{C} \) and a natural transformation \( \bar{\alpha} : \bar{e}^+ \to Y \), where \( Y \in \text{Fun}(L, \mathcal{C}) \) denotes the constant diagram taking the value \( Y \) (Remark 7.2.4.7). Let \( \bar{\alpha}_0 \) denote the image of \( \bar{\alpha} \) in \( \text{Fun}(K, \mathcal{C}) \). Then \( \bar{\alpha}_0 \) can be identified with a morphism from \( K \) to the morphism space \( \text{Hom}_\mathcal{C}(X, Y) \). Since \( \mathcal{C} \) is filtered, Theorem [7.2.5.5] guarantees the existence of a morphism \( g : Y \to Z \) of \( \mathcal{C} \) for which the composite map

\[
K \xrightarrow{\bar{\alpha}_0} \text{Hom}_\mathcal{C}(X, U) \xrightarrow{g_0} \text{Hom}_\mathcal{C}(X, Z)
\]

is nullhomotopic. Let \( Z : L \to \mathcal{C} \) denote the constant diagram taking the value \( Z \), so that \( g \) determines a morphism \( g : Y \to Z \) in the \( \infty \)-category \( \text{Fun}(L, \mathcal{C}) \). Replacing \( Y \) by \( Z \) and \( \bar{\alpha} \) by its composition with \( g \), we can reduce to the case where the morphism \( \bar{\alpha}_0 : K \to \text{Hom}_\mathcal{C}(X, Y) \) is nullhomotopic. Note that the restriction map \( \text{Fun}(L, \mathcal{C}) \to \text{Fun}(K, \mathcal{C}) \) is an isofibration of \( \infty \)-categories (Corollary [4.4.5.3]), and therefore induces a Kan fibration of morphism spaces \( \text{Hom}_{\text{Fun}(L, \mathcal{C})}(\bar{e}^+, Y) \to \text{Hom}_{\text{Fun}(K, \mathcal{C})}(\bar{e}^+, Y) \mid_K \) (Exercise [4.6.1.21]). We may therefore modify \( \bar{\alpha} \) by a homotopy and thereby reduce to the case where \( \bar{\alpha}_0 : K \to \text{Hom}_\mathcal{C}(X, Y) \) is the constant map taking some value \( f \in \text{Hom}_\mathcal{C}(X, Y) \). Since \( U \) is a left fibration, we can lift \( \bar{\alpha} \) to a natural transformation \( \alpha : e^+ \to e'^+ \), for some diagram \( e'^+ : L \to \tilde{C}_Y \subseteq \tilde{C} \). Set \( e' = e|_K \), so that \( \alpha \) restricts to a natural transformation \( \alpha_0 : e \to e' \) which witnesses \( e' \) as given by covariant transport along \( f \), in the sense of Definition [5.2.2.4]. To complete the proof, it will suffice to show that the morphism \( e'^+ : K \to \tilde{C}_Y \) is nullhomotopic. This is clear: already the morphism \( e'^+ : L \to \tilde{C}_Y \) is nullhomotopic, since \( L \) is weakly contractible and \( \tilde{C}_Y \) is a Kan complex (see Variant [3.2.6.10]).
Corollary 7.2.6.2. Suppose we are given a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{E}' & \rightarrow & \mathcal{E} \\
\downarrow & & \downarrow \\
\mathcal{C}' & \rightarrow & \mathcal{C},
\end{array}
\]

where \( U \) and \( V \) are left fibrations. If \( \mathcal{C}, \mathcal{C}' \), and \( \mathcal{E} \) are filtered \( \infty \)-categories, then \( \mathcal{E}' \) is also a filtered \( \infty \)-category.

Proof. Since \( U' : \mathcal{E}' \rightarrow \mathcal{C}' \) is a pullback of \( U \), it is a left fibration. It will therefore suffice to show that \( U' \) satisfies condition (4) of Theorem 7.2.6.1. Suppose we are given an object \( X' \in \mathcal{C}' \) and a morphism of simplicial sets \( e : \partial \Delta^n \rightarrow \mathcal{E}'_{X'} = \{X'\} \times_{\mathcal{C}'} \mathcal{E}' \). Set \( X = V(X') \), so that we can identify \( e \) with a morphism from \( \partial \Delta^n \) to the fiber \( \mathcal{E}_X = \{X\} \times_{\mathcal{C}} \mathcal{E} \). Since \( \mathcal{E} \) and \( \mathcal{C} \) are filtered, Theorem 7.2.6.1 guarantees that we can choose a morphism \( f : X \rightarrow Y \) in \( \mathcal{C} \) for which the composite map \( \partial \Delta^n \rightarrow \mathcal{E}_X \rightarrow \mathcal{E}_Y \) is nullhomotopic. Using Corollary 7.2.6.2, we obtain another characterization of the class of filtered \( \infty \)-categories:

Corollary 7.2.6.3. Let \( \mathcal{C} \) be an \( \infty \)-category. Then \( \mathcal{C} \) is filtered if and only if it satisfies the following pair of conditions:

(a) The \( \infty \)-category \( \mathcal{C} \) is weakly contractible.

(b) Let \( \tilde{\mathcal{C}} \rightarrow \mathcal{C} \), \( V_0 : \tilde{\mathcal{C}}_0 \rightarrow \tilde{\mathcal{C}} \), and \( V_1 : \tilde{\mathcal{C}}_1 \rightarrow \tilde{\mathcal{C}} \) be left fibrations of \( \infty \)-categories. If \( \tilde{\mathcal{C}}, \tilde{\mathcal{C}}_0, \) and \( \tilde{\mathcal{C}}_1 \) are weakly contractible, then the fiber product \( \tilde{\mathcal{C}}_0 \times_{\tilde{\mathcal{C}}} \tilde{\mathcal{C}}_1 \) is also weakly contractible.

Proof. Suppose first that \( \mathcal{C} \) is filtered. Assertion (a) follows from Proposition 7.2.4.9. To prove (b), suppose we are given left fibrations \( U : \tilde{\mathcal{C}} \rightarrow \mathcal{C} \), \( V_0 : \tilde{\mathcal{C}}_0 \rightarrow \tilde{\mathcal{C}} \), and \( V_1 : \tilde{\mathcal{C}}_1 \rightarrow \tilde{\mathcal{C}} \), where \( \tilde{\mathcal{C}}, \tilde{\mathcal{C}}_0, \) and \( \tilde{\mathcal{C}}_1 \) are weakly contractible. Applying Theorem 7.2.6.1, we deduce that the \( \infty \)-categories \( \tilde{\mathcal{C}}, \tilde{\mathcal{C}}_0, \) and \( \tilde{\mathcal{C}}_1 \) are filtered. Applying Corollary 7.2.6.2 to the diagram of left fibrations.
we conclude that the fiber product \( \tilde{\mathcal{C}}_0 \times_{\mathcal{C}} \tilde{\mathcal{C}}_1 \) is also filtered; in particular, it is weakly contractible (Proposition 7.2.4.9).

We now prove the converse. Assume that \( \mathcal{C} \) satisfies conditions \((a)\) and \((b)\); we wish to show that \( \mathcal{C} \) is filtered. We will prove this using the criterion of Lemma 7.2.5.13. Fix an integer \( n \geq 0 \) and a diagram \( e : \partial \Delta^n \to \mathcal{C} \); we wish to show that the coslice \( \infty \)-category \( \mathcal{C}_{e/} \) is nonempty. In fact, we will prove the following stronger assertion: for every simplicial subset \( K \subseteq \partial \Delta^n \), the coslice \( \infty \)-category \( \mathcal{C}_{eK/} \) is weakly contractible, where \( e_K \) denotes the restriction \( e|_K \). Our proof proceeds by induction on the number of nondegenerate simplices of \( K \). If \( K = \emptyset \), then the desired result follows from assumption \((a)\). If \( K \) is not isomorphic to a standard simplex, then we can use Proposition 1.1.3.13 to write \( K \) as a union \( K(0) \cup K(1) \), where \( K(0), K(1) \subseteq K \) are proper simplicial subsets. Setting \( K(01) = K(0) \cap K(1) \), we have a pullback diagram of left fibrations

\[
\begin{array}{ccc}
\mathcal{C}_{eK/} & \longrightarrow & \mathcal{C}_{eK(0)/} \\
\downarrow & & \downarrow \\
\mathcal{C}_{eK(1)/} & \longrightarrow & \mathcal{C}_{eK(01)/},
\end{array}
\]

where the \( \infty \)-categories \( \mathcal{C}_{eK(0)/}, \mathcal{C}_{eK(1)/}, \) and \( \mathcal{C}_{eK(01)/} \) are weakly contractible by virtue of our inductive hypothesis. Applying \((b)\), we deduce that \( \mathcal{C}_{eK/} \) is weakly contractible. We may therefore assume without loss of generality that \( K \approx \Delta^m \) is a standard simplex. In particular, \( K \) contains a final vertex \( v \) for which the inclusion \( \{v\} \to K \) is right anodyne (Example 4.3.7.11), so that the restriction map \( \mathcal{C}_{eK/} \to \mathcal{C}_{e(v)/} \) is a trivial Kan fibration (Corollary 4.3.6.13). It will therefore suffice to show that the \( \infty \)-category \( \mathcal{C}_{e(v)/} \) is weakly contractible. This follows from Corollary 4.6.6.26, since the \( \infty \)-category \( \mathcal{C}_{e(v)/} \) has an initial object (Proposition 4.6.6.23). \( \square \)

7.2.7 Cofinal Approximation
Let $\mathcal{C}$ be an $\infty$-category. Recall that an object $X \in \mathcal{C}$ is final if and only if the inclusion map $\{X\} \hookrightarrow \mathcal{C}$ is right cofinal (Corollary 4.6.6.25). If this condition is satisfied, then the $\infty$-category $\mathcal{C}$ is filtered (Example 7.2.4.5). We now establish a generalization:

**Proposition 7.2.7.1.** Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories. If $\mathcal{C}$ is filtered and $F$ is right cofinal, then $\mathcal{D}$ is filtered.

**Proof.** We will show that the $\infty$-category $\mathcal{D}$ satisfies conditions $(a)$ and $(b)$ of Corollary 7.2.6.3. Since $\mathcal{C}$ is weakly contractible (Proposition 7.2.4.9) and $F$ is a weak homotopy equivalence (Proposition 7.2.1.5), we deduce immediately that $\mathcal{D}$ is weakly contractible. Suppose we are given left fibrations $U : \tilde{\mathcal{D}} \to \mathcal{D}$, $V_0 : \tilde{\mathcal{D}}_0 \to \tilde{\mathcal{D}}$, and $V_1 : \tilde{\mathcal{D}}_1 \to \tilde{\mathcal{D}}$, where the $\infty$-categories $\tilde{\mathcal{D}}$, $\tilde{\mathcal{D}}_0$, and $\tilde{\mathcal{D}}_1$ are weakly contractible. We wish to show that the fiber product $\tilde{\mathcal{D}}_0 \times_{\tilde{\mathcal{D}}} \tilde{\mathcal{D}}_1$ is also weakly contractible. Set $\tilde{\mathcal{C}} = \mathcal{C} \times_{\mathcal{D}} \tilde{\mathcal{D}}$, and define $\tilde{\mathcal{C}}_0$ and $\tilde{\mathcal{C}}_1$ similarly. Applying Proposition 7.2.3.13 we deduce that the projection maps

$$\tilde{\mathcal{C}}_0 \to \tilde{\mathcal{D}}_0 \quad \tilde{\mathcal{C}} \to \tilde{\mathcal{D}} \quad \tilde{\mathcal{C}}_1 \to \tilde{\mathcal{D}}_1$$

are right cofinal; in particular, they are weak homotopy equivalences (Proposition 7.2.4.9). It follows that the $\infty$-categories $\tilde{\mathcal{C}}$, $\tilde{\mathcal{C}}_0$, and $\tilde{\mathcal{C}}_1$ are weakly contractible. Since $\mathcal{C}$ is filtered, Corollary 7.2.6.3 guarantees that the fiber product $\tilde{\mathcal{C}}_0 \times_{\tilde{\mathcal{C}}} \tilde{\mathcal{C}}_1$ is weakly contractible. The projection map

$$\tilde{\mathcal{C}}_0 \times_{\tilde{\mathcal{C}}} \tilde{\mathcal{C}}_1 \to \tilde{\mathcal{D}}_0 \times_{\tilde{\mathcal{D}}} \tilde{\mathcal{D}}_1$$

is also right cofinal (Proposition 7.2.3.13) and therefore a weak homotopy equivalence (Proposition 7.2.4.9). It follows that $\tilde{\mathcal{D}}_0 \times_{\tilde{\mathcal{D}}} \tilde{\mathcal{D}}_1$ is also weakly contractible, as desired. 

We now establish a partial converse of Proposition 7.2.7.1.

**Theorem 7.2.7.2.** Let $\mathcal{C}$ be an $\infty$-category. The following conditions are equivalent:

- The $\infty$-category $\mathcal{C}$ is filtered.
- There exists a directed partially ordered set $(A, \leq)$ and a right cofinal functor $F : N_\bullet(A) \to \mathcal{C}$.

We first prove the following:

**Lemma 7.2.7.3.** Let $\mathcal{C}$ be a filtered $\infty$-category. Then there exists a trivial Kan fibration of simplicial sets $\pi : \tilde{\mathcal{C}} \to \mathcal{C}$, where $\tilde{\mathcal{C}}$ is an $\infty$-category having the following property:

(*) For every finite simplicial subset $K \subseteq \tilde{\mathcal{C}}$, the inclusion map $K \hookrightarrow \tilde{\mathcal{C}}$ extends to a monomorphism $K^\circ \hookrightarrow \mathcal{C}$. 

Proof. Let $J$ be an infinite set, and let $\mathcal{J}$ be the corresponding indiscrete category (that is, the category having object set $\text{Ob}(\mathcal{J}) = J$ and $\text{Hom}_{\mathcal{J}}(j, j') = \ast$ for every pair of elements $j, j' \in J$). Then the nerve $N_{\bullet}(\mathcal{J})$ is a contractible Kan complex. Setting $\tilde{\mathcal{C}} = N_{\bullet}(\mathcal{J}) \times \mathcal{C}$, it follows that the projection map $\pi : \tilde{\mathcal{C}} \to \mathcal{C}$ is a trivial Kan fibration. We will complete the proof by showing that $\tilde{\mathcal{C}}$ satisfies condition ($\ast$). Let $K$ be a finite simplicial subset of $\tilde{\mathcal{C}}$, so that the inclusion map $K \hookrightarrow \tilde{\mathcal{C}}$ can be identified with a pair of diagrams $f : K \to N_{\bullet}(\mathcal{J}) \quad g : K \to \mathcal{C}$.

Since $J$ is infinite, we can choose an element $j \in J$ which is not of the form $f(x)$ for any vertex $x \in K$. It follows that $f$ admits a unique extension $\tilde{f} : K^\circ \to N_{\bullet}(\mathcal{J})$ which carries the cone point of $K^\circ$ to the element $j \in J$. Our assumption that $\mathcal{C}$ is filtered guarantees that $g$ admits an extension $\tilde{g} : K^\circ \to \mathcal{C}$. We complete the proof by observing that the pair $(\tilde{f}, \tilde{g})$ determines a monomorphism of simplicial sets $K \hookrightarrow \tilde{\mathcal{C}}$. 

Proof of Theorem 7.2.7.2. Let $\mathcal{C}$ be a filtered $\infty$-category; we wish to show that there exists a directed partially ordered set $(A, \leq)$ and a right cofinal functor $N_{\bullet}(A) \to \mathcal{C}$ (the reverse implication follows from Proposition 7.2.7.1 and Example 7.2.5.9). Choose a trivial Kan fibration $\pi : \tilde{\mathcal{C}} \to \mathcal{C}$ which satisfies condition ($\ast$) of Lemma 7.2.7.3. Then $\pi$ is right cofinal (Corollary 7.2.1.12). Since the collection of right cofinal morphisms is closed under composition (Proposition 7.2.1.6), we can replace $\mathcal{C}$ by $\tilde{\mathcal{C}}$ and thereby reduce to proving Theorem 7.2.1.6 in the special case where the $\infty$-category $\mathcal{C}$ satisfies condition ($\ast$) of Lemma 7.2.7.3.

Let $A$ be the collection of all simplicial subsets $L \subseteq \mathcal{C}$ which are isomorphic to $K^\circ$, for some finite simplicial set $K$. To avoid confusion, we use the symbol $\alpha$ to represent an element of $A$, and we will write $L_\alpha$ for the corresponding simplicial subset of $\mathcal{C}$. By assumption, we can write $L_\alpha$ as a join $K_\alpha \star \{C_\alpha\}$, where $K_\alpha$ is a finite simplicial subset of $\tilde{\mathcal{C}}$ and $C_\alpha$ is an object of $\mathcal{C}$.

Note that condition ($\ast$) of Lemma 7.2.7.3 can be restated as follows:

($\ast'$) Every finite simplicial subset $K \subseteq \mathcal{C}$ is equal to $K_\alpha$, for some element $\alpha \in A$.

Let us regard $A$ as a partially ordered set, where elements $\alpha, \beta \in A$ satisfy $\alpha \leq \beta$ if and only if $L_\alpha$ is contained in $L_\beta$ (as simplicial subsets of $\mathcal{C}$). If $A_0$ is any finite subset of $A$, it follows from ($\ast'$) that we have $\bigcup_{\alpha \in A_0} L_\alpha = K_\beta \subset L_\beta$ for some element $\beta \in A$. In particular, we have $\alpha < \beta$ for each $\alpha \in A_0$. Allowing $A_0$ to vary, we conclude that the partially ordered set $A$ is directed.

To every $n$-simplex $\sigma = (\alpha_0 \leq \cdots \leq \alpha_n)$ of $N_{\bullet}(A)$, we associate an $n$-simplex $F(\sigma)$ of $L_{\alpha_n} \subseteq \mathcal{C}$ by the following recursive procedure:

- If $n = 0$, so that $\sigma$ can be identified with an element $\alpha \in A$, then $F(\sigma)$ is the object $C_\alpha \in \mathcal{C}$. 

7.2. COFINALITY

- Suppose that $n > 0$, and let $\sigma' = d_n(\sigma)$ denote the $(n - 1)$-simplex $(\alpha_0 \leq \cdots \leq \alpha_{n-1})$ of $N_\bullet(A)$. Then $F(\sigma)$ is the unique $n$-simplex $\Delta^n \to L_{\alpha_n}$ whose restriction to $\Delta^{n-1}$ coincides with $F(\sigma')$ and which carries vertex $n \in \Delta^n$ to the cone point $C_{\alpha_n} \in L_{\alpha_n}$.

Regarding each $F(\sigma)$ as a simplex of the $\infty$-category $C$, we observe that the construction $\sigma \mapsto F(\sigma)$ is compatible with face and degeneracy operators and therefore determines a functor of $\infty$-categories $F : N_\bullet(A) \to C$.

We will complete the proof by showing that the functor $F$ is right cofinal. To verify this, we will use the criterion of Theorem 7.2.3.1. Let $C$ be an object of $C$; we wish to show that the $\infty$-category $N_\bullet(A) \times C_{C/}$ is weakly contractible. We will prove something a bit stronger: the $\infty$-category $N_\bullet(A) \times C_{C/}$ is filtered (this is sufficient, by virtue of Proposition 7.2.4.9). To prove this, let $S$ be any finite simplicial set and suppose that we are given a diagram $g : S \to N_\bullet(A) \times C_{C/}$; we wish to show that $g$ can be extended to a morphism $\overline{g} : S^\circ \to N_\bullet(A) \times C_{C/}$. Unwinding the definitions, we can identify $g$ with a pair of diagrams

$$g_0 : S \to N_\bullet(A) \quad g_1 : S^\circ \to C$$

satisfying $g_1|_S = F \circ g_0$, where $g_1$ carries the cone point of $S^\circ$ to the object $C \in C$. Note that the union $K = \text{im}(g_1) \cup \bigcup_{s \in S} L_{g_0(s)}$ is a finite simplicial subset of $C$. Since $C$ satisfies condition $(\ast)$ of Lemma 7.2.7.3, we can write $K = K_\alpha$ for some element $\alpha \in A$. Since the image of $g_1$ is contained in $K_\alpha$, it admits a canonical extension

$$\overline{g}_1 : (S^\circ)^p \to K_\alpha^p = L_\alpha \subseteq C.$$

Similarly, the inclusion $L_{g_0(s)} \subseteq K_\alpha \subseteq L_\alpha$ guarantees that $g_0$ can be extended uniquely to a morphism $\overline{g}_0 : S^\circ \to N_\bullet(A)$ carrying the cone point of $S^\circ$ to the element $\alpha \in A$. We conclude by observing that the pair $(\overline{g}_0, \overline{g}_1)$ determines a diagram $\overline{g} : S^\circ \to N_\bullet(A) \times C_{C/}$ satisfying $\overline{g}|_S = g$. □

**Definition 7.2.7.4.** Let $C$ be an $\infty$-category. We say that $C$ admits small filtered colimits if it admits $K$-indexed colimits, for every small filtered $\infty$-category $K$. We say that a functor $F : C \to D$ preserves small filtered colimits if it preserves $K$-indexed colimits, for every small filtered $\infty$-category $K$.

**Corollary 7.2.7.5.** Let $C$ be an $\infty$-category. The following conditions are equivalent:

1. The $\infty$-category $C$ admits small filtered colimits.
2. For every small filtered category $K$, the $\infty$-category $C$ admits $N_\bullet(K)$-indexed colimits.
3. For every directed partially ordered set $(A, \leq)$, the $\infty$-category $C$ admits $N_\bullet(A)$-indexed colimits.
CHAPTER 7. LIMITS AND COLIMITS

Proof. The implication (1) ⇒ (2) follows from Corollary 7.2.5.8 and the implication (2) ⇒ (3) follows from Exercise 7.2.4.2. The implication (3) ⇒ (1) follows from Theorem 7.2.7.2 and Corollary 7.2.2.3.

Variant 7.2.7.6. Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories. The following conditions are equivalent:

1. The functor \( F \) preserves small filtered colimits.
2. For every small filtered category \( \mathcal{K} \), the functor \( F \) preserves \( \mathcal{N}_\bullet(\mathcal{K}) \)-indexed colimits.
3. For every directed partially ordered set \((A, \leq)\), the functor \( F \) preserves \( \mathcal{N}_\bullet(A) \)-indexed colimits.

We close this section by recording another consequence of Lemma 7.2.7.3.

Proposition 7.2.7.7. Let \( \mathcal{C} \) be an \( \infty \)-category. The following conditions are equivalent:

1. There exists a filtered diagram of simplicial sets \( \{\mathcal{C}_\alpha\} \), where each \( \mathcal{C}_\alpha \) is an \( \infty \)-category with a final object, and an equivalence of \( \infty \)-categories \( F : \mathcal{C} \to \lim_{\alpha \in A} \mathcal{C}_\alpha \).
2. There exists a filtered diagram of simplicial sets \( \{\mathcal{C}_\alpha\} \), where each \( \mathcal{C}_\alpha \) is a filtered \( \infty \)-category, and an equivalence of \( \infty \)-categories \( F : \mathcal{C} \to \lim_{\alpha \in A} \mathcal{C}_\alpha \).
3. There exists an equivalence of \( \infty \)-categories \( F : \mathcal{C} \to \mathcal{C}' \), where \( \mathcal{C}' \) is filtered.
4. The \( \infty \)-category \( \mathcal{C} \) is filtered.

Proof. The implication (1) ⇒ (2) follows from Example 7.2.4.5, the implication (2) ⇒ (3) from Remark 7.2.4.6, and the implication (3) ⇒ (4) from Corollary 7.2.4.11. We will complete the proof by showing that every filtered \( \infty \)-category \( \mathcal{C} \) satisfies condition (1). Without loss of generality, we may assume that \( \mathcal{C} \) satisfies condition (\( \ast \)) of Lemma 7.2.7.3. Let \( A \) be the directed partially ordered set defined in the proof of Theorem 7.2.7.2. For each \( \alpha \in A \), let \( L_\alpha \subseteq \mathcal{C} \) denote the corresponding subset of \( \mathcal{C} \). By virtue of Corollary 4.1.3.3, we can choose an \( \infty \)-category \( \mathcal{C}_\alpha \) and an inner anodyne morphism \( F_\alpha : L_\alpha \hookrightarrow \mathcal{C}_\alpha \), which depend functorially on \( \alpha \). Applying Corollary 4.5.7.2, we see that the morphisms \( F_\alpha \) induce an equivalence of \( \infty \)-categories

\[
\mathcal{C} \simeq \lim_{\alpha \in A} L_\alpha \xrightarrow{(F_\alpha)_{\alpha \in A}} \lim_{\alpha \in A} \mathcal{C}_\alpha.
\]

To complete the proof, it will suffice to show that each of the \( \infty \)-categories \( \mathcal{C}_\alpha \) contains a final object. By construction, there exists an isomorphism of simplicial sets \( u : L_\alpha \simeq K^\circ \), for some finite simplicial set \( K \). Using Corollary 4.1.3.3, we can choose a categorical equivalence
7.2. COFINALITY

1271

$v : K \to D$, where $D$ is an $\infty$-category. Applying Corollary \ref{cor:cofinality}, we deduce that the map $v^p : K^p \to D^p$ is also a categorical equivalence of simplicial sets. Since $F_\alpha$ is inner anodyne, there exists a functor $G : C_\alpha \to D^p$ satisfying $G \circ F_\alpha = v^p \circ u$. Applying the two-out-of-three property (Remark \ref{rem:two-out-of-three}), we see that $G$ is an equivalence of $\infty$-categories. Since the $\infty$-category $D^p$ has a final object (given by the cone point; see Example \ref{ex:final-object}), it follows that $C_\alpha$ also has a final object (Corollary \ref{cor:final-object}). ∎

7.2.8 Sifted Simplicial Sets

We now introduce a useful enlargement of the class of filtered $\infty$-categories.

**Definition 7.2.8.1.** Let $K$ be a simplicial set. We say that $K$ is sifted if, for every finite set $I$, the diagonal map $K \to K^I$ is right cofinal. If $C$ is an $\infty$-category, we say that a diagram $K \to C$ is sifted if the simplicial set $K$ is sifted.

**Warning 7.2.8.2.** Definition 7.2.8.1 has a counterpart in classical category theory. In \cite{adamek2020}, Adámek and Rosický define a sifted category to be a nonempty category $C$ which satisfies the following condition:

$(\ast)$ For every pair of objects $X, Y \in C$, the nerve of the category $C_{X/} \times_C C_{Y/}$ is connected.

It follows from Corollary 7.2.8.9 below that if the simplicial set $N_\bullet(C)$ is sifted (in the sense of Definition 7.2.8.1), then the category $C$ satisfies condition $(\ast)$. Beware that the converse is false (see Exercise 7.2.8.11). In other words, Definition 7.2.8.1 is not a generalization of the classical notion of a sifted category (instead, it generalizes the notion of a homotopy sifted category, introduced by Rosický in \cite{rosicky2005}).

**Variant 7.2.8.3.** Let $K$ be a simplicial set. We say that $K$ is cosifted if, for every finite set $I$, the diagonal map $K \to K^I$ is left cofinal. Equivalently, $K$ is cosifted if and only if the opposite simplicial set $K^{op}$ is sifted.

**Example 7.2.8.4.** Every filtered $\infty$-category $C$ is sifted (see Proposition 7.2.4.10). In particular, if $C$ is an $\infty$-category which contains a final object, then $C$ is sifted (see Example 7.2.4.5).

**Proposition 7.2.8.5.** Let $f : K \to K'$ be a right cofinal morphism of simplicial sets. If $K$ is sifted, then $K'$ is also sifted.

**Proof.** Fix a finite set $I$. We have a commutative diagram of simplicial sets

$$
\begin{array}{ccc}
K & \xrightarrow{\delta_K} & K^I \\
\downarrow f & & \downarrow f \times f \\
K' & \xrightarrow{\delta_{K'}} & K''
\end{array}
$$

We need to show that $f : K \to K'$ is sifted. For any finite set $I$, the diagonal map $K \to K^I$ is right cofinal. Hence, $f \times f : K^I \to K'^I$ is also right cofinal. Since $K'^I$ is sifted (by the assumption), it follows that $K$ is sifted. Therefore, $K'$ is also sifted. ∎
where the vertical maps are right cofinal (Corollary \ref{cor:cofinality}). Our assumption that \( K \) is sifted guarantees that \( \delta_K \) is right cofinal, so that \( \delta_{K'} \) is also right cofinal (Proposition \ref{prop:cofinality}).

**Proposition 7.2.8.6.** Let \( f : K \to K' \) be a categorical equivalence of simplicial sets. Then \( K \) is sifted if and only if \( K' \) is sifted.

*Proof.* It will suffice to show that, for every finite set \( I \), the diagonal map \( \delta_K : K \to K^I \) is right cofinal if and only if the diagonal map \( \delta_{K'} : K \to K'^I \) is right cofinal. This follows by applying Corollary \ref{cor:cofinality} to the commutative diagram

\[
\begin{array}{ccc}
K & \xrightarrow{\delta_K} & K^I \\
\downarrow f & & \downarrow f^I \\
K' & \xrightarrow{\delta_{K'}} & K'^I.
\end{array}
\]

**Proposition 7.2.8.7.** Every sifted simplicial set is weakly contractible.

*Proof.* Let \( K \) be a sifted simplicial set. Taking \( I = \emptyset \) in Definition \ref{def:sifted} we conclude that the projection map \( K \to \Delta^0 \) is right cofinal, so that \( K \) is weakly contractible by virtue of Proposition \ref{prop:cofinality}.

**Proposition 7.2.8.8.** Let \( K \) be a simplicial set. Then \( K \) is sifted if and only if it is nonempty and the diagonal map \( \delta : K \hookrightarrow K \times K \) is right cofinal.

*Proof.* It follows immediately from the definition that if \( K \) is sifted, then the diagonal map \( \delta : K \hookrightarrow K \times K \) is right cofinal. Moreover, Proposition \ref{prop:cofinality} guarantees that \( K \) is weakly contractible, and therefore nonempty.

For the converse, assume that \( K \) is nonempty and that \( \delta \) is right cofinal. We wish to prove that, for every finite set \( I \), the map \( \delta_I : K \to K^I \) is right cofinal. The proof proceeds by induction on the cardinality of \( I \). We first treat the case where \( I = \emptyset \). Note that our assumption that \( \delta \) is right cofinal guarantees in particular that it is a weak homotopy equivalence (Proposition \ref{prop:cofinality}). Since \( K \) is nonempty, it follows that \( K \) is weakly contractible (Corollary \ref{cor:contractible}). Applying Proposition \ref{prop:cofinality} again, we deduce that the projection map \( K \to \Delta^0 \) is right cofinal, as desired.

We now carry out the inductive step. Assume that the set \( I \) is nonempty. Choose an element \( i \in I \), and set \( J = I \setminus \{i\} \). Unwinding the definitions, we see that \( \delta_I \) can be identified with the coposition

\[
K \xrightarrow{\delta} K \times K \xrightarrow{id_K \times \delta_i} K \times K^J.
\]
Our inductive hypothesis guarantees that $\delta J$ is right cofinal, so that the product map $\text{id}_K \times \delta J$ is also right cofinal (Corollary 7.2.1.18). Since the collection of right cofinal morphisms is closed under composition (Proposition 7.2.1.6).

**Corollary 7.2.8.9.** Let $C$ be an $\infty$-category. Then $C$ is sifted if and only if it is nonempty and, for every pair of objects $X, Y \in C$, the $\infty$-category $C_{X/} \times_C C_{Y/}$ is weakly contractible.

**Proof.** Combine Proposition 7.2.8.8 with Theorem 7.2.3.1.

We now consider an important example.

**Proposition 7.2.8.10.** Let $\Delta$ be the simplex category (Definition 1.1.1.2). Then the $\infty$-category $N_{\bullet}(\Delta)$ is cosifted.

**Proof.** We use the criterion of Corollary 7.2.8.9. Since the category $\Delta$ is nonempty, it will suffice to show that for every pair of nonnegative integers $m, n \geq 0$, the simplicial set

$$N(\Delta)/[m] \times N(\Delta)/[n] \simeq N(\Delta)/[m] \times \Delta \Delta/[n]$$

is weakly contractible. Unwinding the definitions, we can identify $\Delta/[m] \times \Delta \Delta/[n]$ with the category of simplices $\Delta_S$ of Construction 1.1.8.19, where $S$ is the product $\Delta^m \times \Delta^n$. Note that $S$ can be identified with the nerve of a partially ordered set, and is therefore a braced simplicial set (Exercise 3.3.1.2). Let $\Delta^{\text{nd}}_S$ denote the full subcategory of $\Delta_S$ spanned by the nondegenerate simplices of $S$ (Notation 3.3.3.9), so that the inclusion $\Delta^{\text{nd}}_S \hookrightarrow \Delta_S$ admits a left adjoint (Exercise 3.3.3.12). It follows that the inclusion map $N_{\bullet}(\Delta^{\text{nd}}_S) \hookrightarrow N_{\bullet}(\Delta_S)$ is a homotopy equivalence of simplicial sets (Proposition 3.1.6.9). It will therefore suffice to show that the nerve $N_{\bullet}(\Delta^{\text{nd}}_S)$ is weakly contractible. Using Proposition 3.3.3.15, we can identify $N_{\bullet}(\Delta^{\text{nd}}_S)$ with the subdivision $Sd(S)$, so that Construction 3.3.4.3 supplies a weak homotopy equivalence $\lambda_S : N_{\bullet}(\Delta^{\text{nd}}_S) \rightarrow S$. We conclude by observing that the simplicial set $S = \Delta^m \times \Delta^n$ is weakly contractible (in fact, it is contractible, since it is the nerve of a partially ordered set having a smallest element).

**Exercise 7.2.8.11.** Let $\Delta_{\leq 1}$ denote the full subcategory of $\Delta$ spanned by the objects $[0]$ and $[1]$, which we depict informally as a diagram

$$[0] \longrightarrow [1].$$

Show that:

- The opposite category $\Delta_{\leq 1}^{\text{op}}$ satisfies condition $(\ast)$ of Warning 7.2.8.2 (that is, it is a sifted category in the sense of [1]).
- The simplicial set $N_{\bullet}(\Delta_{\leq 1}^{\text{op}})$ is not sifted.
7.3 Kan Extensions

Let $F : C \to D$ be a functor between categories. In practice, it is often possible to reconstruct the functor $F$ (at least up to isomorphism) from its restriction to a full subcategory $C^0 \subseteq C$. To make this more precise, it will be convenient to introduce some terminology.

**Definition 7.3.0.1.** Let $F : C \to D$ be a functor between categories and let $C^0 \subseteq C$ be a full subcategory. We say that $F$ is left Kan extended from $C^0$ if, for every object $C \in C$, the collection of morphisms $\{F(u) : F(C^0) \to F(C)\}_{u : C^0 \to C}$ exhibits $F(C)$ as a colimit of the diagram

$$(C^0 \times_C C/C) \to C^0 \hookrightarrow C \xrightarrow{F} D.$$  

The central features of Definition 7.3.0.1 can be summarized as follows:

**Exercise 7.3.0.2 (Uniqueness of Kan Extensions).** Let $F, G : C \to D$ be functors between categories, and suppose that $F$ is left Kan extended from a full subcategory $C^0 \subseteq C$. Show that the restriction map

$$\{\text{Natural transformations from } F \text{ to } G\} \downarrow \downarrow \{\text{Natural transformations from } F|_{C^0} \text{ to } G|_{C^0}\}$$

is a bijection. In particular, the functor $F$ can be recovered (up to canonical isomorphism) from the restriction $F|_{C^0}$.

**Exercise 7.3.0.3 (Existence of Kan Extensions).** Let $C$ be a category, let $C^0 \subseteq C$ be a full subcategory, and let $F_0 : C^0 \to D$ be a functor between categories. Show that the following conditions are equivalent;

1. There exists a functor $F : C \to D$ which is left Kan extended from $C^0$ and satisfies $F|_{C^0} = F_0$.
2. For every object $C \in C$, the diagram

$$(C^0 \times_C C/C) \to C^0 \xrightarrow{F_0} D$$

has a colimit in $D$.

Stated more informally, if the diagram (7.10) has a colimit in $D$, then that colimit depends functorially on the object $C \in C$. 

In this section, we adapt the theory of Kan extensions to the ∞-categorical setting. Let $F : C \to D$ be a functor of ∞-categories, and let $C^0 \subseteq C$ be a full subcategory. We will say that $F$ is left Kan extended from $C^0$ if it satisfies an ∞-categorical analogue of the condition appearing in Definition 7.3.0.1, which we formulate in §7.3.2 (see Definition 7.3.2.1). Our main results are ∞-categorical counterparts of Exercises 7.3.0.2 and 7.3.0.3, which we prove in §7.3.5 and §7.3.6 respectively (see Corollaries 7.3.6.9 and 7.3.5.6).

For many applications, it will be useful to consider a different generalization of Definition 7.3.0.1, where we replace the inclusion map $C^0 \to C$ by an arbitrary functor $\delta : \mathcal{K} \to C$. Suppose we are given functors $F : C \to D$, $\delta : \mathcal{K} \to C$, and $F_0 : \mathcal{K} \to D$, together with a natural transformation $\beta : F_0 \to F \circ \delta$, as indicated in the diagram

\[
\begin{array}{ccc}
\mathcal{K} & \xrightarrow{\beta} & \mathcal{C} \\
\delta \downarrow & & \downarrow F \\
\mathcal{K} & \xrightarrow{F_0} & \mathcal{D} \\
\end{array}
\]

We will say that $\beta$ exhibits $F$ as a left Kan extension of $F_0$ along $\delta$ if, for every object $C \in \mathcal{C}$, the collection of morphisms $\{(F(u) \circ \beta_X) : F_0(X) \to F(C)\}_{u: \delta(X) \to C}$ exhibits $F(C)$ as a colimit of the diagram $\mathcal{K} \times_C \mathcal{C} / C \to \mathcal{K} \xrightarrow{F_0} \mathcal{D}$. This notion also has an ∞-categorical generalization which we introduce in §7.3.1 (Variant 7.3.1.5), for which we have counterparts of Exercises 7.3.0.2 and 7.3.0.3 (see Propositions 7.3.6.1 and 7.3.5.1). In the special case where $\mathcal{K} = C^0$ is a full subcategory of $\mathcal{C}$ and $\delta$ is the inclusion map, the Kan extension condition guarantees that $\beta$ is an isomorphism, and therefore essentially reduces to the notion of Kan extension introduced in Definition 7.3.0.1 (see Corollary 7.3.2.6 for a precise statement). In §7.3.4 we study a different extreme, where the functor $\delta$ is assumed to be a cocartesian fibration: in this case, the left Kan extension $F$ of a functor $F_0 : \mathcal{K} \to \mathcal{D}$ along $\delta$ is given concretely by the formula

\[
F(C) = \lim_{\delta(X) = C} (F_0(X))
\]

where the colimit is taken over the fiber $\mathcal{K}_C = \mathcal{K} \times_C \{C\}$ (see Proposition 7.3.4.1 and Corollary 7.3.4.2).

In §7.3.3 we consider another variant of Definition 7.3.0.1 where we replace colimits in $\mathcal{D}$ by the more general notion of $U$-colimit for an auxiliary functor $U : \mathcal{D} \to \mathcal{E}$ (see §7.1.5). The extra generality afforded by the relative setting is quite convenient in practice: for example, relative Kan extensions satisfy a universal property (Proposition 7.3.6.7 analogous to Exercise 7.3.0.2) which can be formally deduced from an existence criterion (Proposition 7.3.5.5 analogous to Exercise 7.3.0.3).
In §7.3.7, we study the transitivity properties of Kan extensions. Let \( \mathcal{F} : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories, and suppose we are given full subcategories \( \mathcal{C}^0 \subseteq \mathcal{C} \subseteq \mathcal{C} \) such that \( F = \mathcal{F}|_\mathcal{C} \) is left Kan extended from \( \mathcal{C} \). We will show that \( \mathcal{F} \) is left Kan extended from \( \mathcal{C} \) if and only if it is left Kan extended from \( \mathcal{C}^0 \) (Corollary 7.3.7.8). Moreover, we prove analogous statements for relative left Kan extensions (Proposition 7.3.7.6) and for Kan extensions along more general functors (Proposition 7.3.7.18). In §7.3.8, we apply these ideas to give a characterization of \( \mathcal{U} \)-colimit diagrams in the special case where \( \mathcal{U} : \mathcal{D} \to \mathcal{E} \) is a cocartesian fibration of \( \infty \)-categories.

Remark 7.3.0.4. In the summary above, we considered only the notion of left Kan extensions. There is also a dual theory of right Kan extensions, which can be obtained from the theory of left Kan extensions by passing to opposite categories.

7.3.1 Kan Extensions along General Functors

We begin by introducing some notation.

Notation 7.3.1.1. Let \( \mathcal{C} \) be an \( \infty \)-category and let \( \delta : K \to \mathcal{C} \) be a diagram. For each object \( C \in \mathcal{C} \), we let \( K_C \) denote the fiber product \( K \times_C \mathcal{C}_C \). Note that the slice diagonal of Construction 4.6.4.13 determines a map \( K_C \to K \times_C \{ C \} \), which we can identify with a natural transformation of diagrams \( \gamma : \delta|_{K_C} \to C \); here \( \delta|_{K_C} \) denotes the composition \( K_C \to K \to \mathcal{C} \), while \( C \) denotes the constant diagram \( K_C \to \mathcal{C} \) taking the value \( C \).

Similarly, we let \( K_C \) denote the fiber product \( \mathcal{C}_C \times K \), so that the coslice diagonal of Construction 4.6.4.13 determines a natural transformation \( \gamma' : C \to \delta|_{K_C} \).

Definition 7.3.1.2 (Right Kan Extensions). Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories. Suppose we are given a simplicial set \( K \) together with diagrams \( \delta : K \to \mathcal{C} \) and \( F_0 : K \to \mathcal{D} \) and a natural transformation \( \alpha : F \circ \delta \to F_0 \), as indicated in the diagram

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{D} \\
\downarrow \alpha & & \downarrow \\
K & \xrightarrow{\delta} & \mathcal{D}.
\end{array}
\]

We will say that \( \alpha \) exhibits \( F \) as a right Kan extension of \( F_0 \) along \( \delta \) if, for every object \( C \in \mathcal{C} \), the following condition is satisfied:

\((\ast_C)\) Let \( \alpha_C \) denote a composition of the natural transformations

\[
F(C) \xrightarrow{F(\gamma')} (F \circ \delta)|_{K_C} \xrightarrow{\alpha} F_0|_{K_C}.
\]
7.3. KAN EXTENSIONS

(formed in the ∞-category Fun(K_{C/}, D)), where γ′ : C → δ|_{K_{C/}} is defined in Notation
7.3.1.1. Then α_C exhibits F(C) as a limit of the diagram

\[ K_{C/} = C_{C/} \times_K K \rightarrow K \xrightarrow{F_0} D, \]

in the sense of Definition 7.1.1.1.

Remark 7.3.1.3. Stated more informally, a diagram

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{\alpha} & \mathcal{D} \\
\downarrow^{\delta} & & \downarrow^{F} \\
K & \xrightarrow{F_0} & D.
\end{array}
\]

exhibits F as a right Kan extension of F_0 along δ if, for every object C ∈ C, we can calculate
the value F(C) ∈ D as a limit of the diagram

\[ K_{C/} = C_{C/} \times_K K \rightarrow K \xrightarrow{F_0} D. \]

Note that this requirement characterizes the object F(C) ∈ D up to isomorphism (see
Proposition 7.1.1.12). We will later prove a stronger assertion: if the diagrams δ : K → C
and F_0 : K → D are fixed, then a right Kan extension of F_0 along δ is uniquely determined
(up to isomorphism) as an object of the ∞-category Fun(C, D) (Remark 7.3.6.6).

Warning 7.3.1.4. In the situation of Definition 7.3.1.2, the natural transformation α_C
appearing in condition \((*)_C\) is defined as a composition of morphisms in the ∞-category
Fun(K_{C/}, D), which is only well-defined up to homotopy. However, the condition that β_C
exhibits F(C) as a colimit of the diagram F_0|_{K_{C/}} depends only on the homotopy class [β_C]
(Remark 7.1.1.7).

Variant 7.3.1.5 (Left Kan Extensions). Let F : C → D be a functor of ∞-categories.
Suppose we are given a simplicial set K together with diagrams δ : K → C and F_0 : K → D
and a natural transformation β : F_0 → F ∘ δ, as indicated in the diagram

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{\beta} & \mathcal{D} \\
\downarrow^{\delta} & & \\
K & \xrightarrow{F_0} & D.
\end{array}
\]

We will say that β exhibits F as a left Kan extension of F_0 along δ if, for every object C ∈ C,
the following condition is satisfied:
Let $\beta_C$ denote a composition of the natural transformations
\[
F_0|_{K/C} \xrightarrow{\beta} (F \circ \delta)|_{K/C} \xrightarrow{\gamma} F(C)
\]
(formed in the $\infty$-category $\text{Fun}(K/C, \mathcal{D})$), where $\gamma : \delta|_{K/C} \to C$ is defined in Notation 7.3.1.1. Then $\beta_C$ exhibits $F(C)$ as a colimit of the diagram
\[
K/C = K \times_C C/C \to K \xrightarrow{F_0} \mathcal{D},
\]
in the sense of Definition 7.1.1.1.

**Remark 7.3.1.6.** In the situation of Variant 7.3.1.5, the natural transformation $\beta : F_0 \to F \circ \delta$ exhibits $F$ as a left Kan extension of $F_0$ along $\delta$ if and only if it exhibits $F^{\text{op}}$ as a right Kan extension of $F_0^{\text{op}}$ along $\delta^{\text{op}}$, when regarded as a morphism in the $\infty$-category $\text{Fun}(K^{\text{op}}, \mathcal{D}^{\text{op}}) \simeq \text{Fun}(K, \mathcal{D})^{\text{op}}$.

**Example 7.3.1.7.** Let $\mathcal{D}$ be an $\infty$-category, let $F_0 : K \to \mathcal{D}$ be a diagram. Let $\delta : K \to \Delta^0$ be the projection map and let $F : \Delta^0 \to \mathcal{D}$ be the functor corresponding to an object $Y \in \mathcal{D}$. Then:

- A natural transformation $\alpha : Y = (F \circ \delta) \to F_0$ exhibits $Y$ as a limit of $F_0$ (in the sense of Definition 7.1.1.1) if and only if it exhibits $F$ as a right Kan extension of $F_0$ along $\delta$ (in the sense of Definition 7.3.1.2).

- A natural transformation $\beta : F_0 \to (F \circ \delta) = Y$ exhibits $Y$ as a colimit of $F_0$ (in the sense of Definition 7.1.1.1) if and only if it exhibits $F$ as a left Kan extension of $F_0$ along $\delta$ (in the sense of Variant 7.3.1.5).

**Example 7.3.1.8.** Let $\mathcal{C}$ and $\mathcal{D}$ be $\infty$-categories, and let $\alpha : F \to G$ be a morphism in the $\infty$-category $\text{Fun}(\mathcal{C}, \mathcal{D})$. The following conditions are equivalent:

1. The natural transformation $\alpha$ is an isomorphism in the $\infty$-category $\text{Fun}(\mathcal{C}, \mathcal{D})$.
2. The natural transformation $\alpha$ exhibits $F$ as a right Kan extension of $G$ along the identity functor $\text{id}_\mathcal{C} : \mathcal{C} \to \mathcal{C}$.
3. The natural transformation $\alpha$ exhibits $G$ as a left Kan extension of $F$ along the identity functor $\text{id}_\mathcal{C} : \mathcal{C} \to \mathcal{C}$.

To prove the equivalence of (1) and (2), fix an object $C \in \mathcal{C}$. Since the identity morphism $\text{id}_\mathcal{C}$ is an initial object of the $\infty$-category $\mathcal{C}/C$ (Proposition 4.6.6.23), the natural transformation $\alpha$ satisfies condition $(\ast_C)$ of Definition 7.3.1.2 if and only if the induced map $\alpha_C : F(C) \to G(C)$ is an isomorphism in $\mathcal{D}$ (Corollary 7.2.2.6). The equivalence (1) $\iff$ (2) now follows from the criterion of Theorem 4.4.4.4. The equivalence (1) $\iff$ (3) follows by a similar argument.
Remark 7.3.1.9. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories and let $\delta : K \to \mathcal{C}$ and $F_0 : K \to \mathcal{D}$ be diagrams. Then:

- The condition that a natural transformation $\alpha : F \circ \delta \to F_0$ exhibits $F$ as a right Kan extension of $F_0$ along $\delta$ depends only on the homotopy class $[\alpha]$ (as a morphism in the $\infty$-category Fun($K, \mathcal{D}$)).
- The condition that a natural transformation $\beta : F_0 \to F \circ \delta$ exhibits $F$ as a left Kan extension of $F_0$ along $\delta$ depends only on the homotopy class $[\beta]$ (as a morphism in the $\infty$-category Fun($K, \mathcal{D}$)).

See Remark 7.1.1.7.

Remark 7.3.1.10. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories, let $\delta : K \to \mathcal{C}$ be a diagram, and let $\rho : F_0 \to F'_0$ be an isomorphism in the $\infty$-category Fun($K, \mathcal{D}$). Then:

- A natural transformation $\alpha : F \circ \delta \to F_0$ exhibits $F$ as a right Kan extension of $F_0$ along $\delta$ if and only if the composite natural transformation
  \[ F \circ \delta \xrightarrow{\alpha} F_0 \xrightarrow{\rho} F'_0 \]
  exhibits $F$ as a right Kan extension of $F'_0$ along $\delta$ (note that this condition is independent of the composition chosen, by virtue of Remark 7.3.1.9).
- A natural transformation $\beta : F'_0 \to F \circ \delta$ exhibits $F$ as a left Kan extension of $F'_0$ along $\delta$ if and only if the composite natural transformation
  \[ F_0 \xrightarrow{\rho} F'_0 \xrightarrow{\beta} F \circ \delta \]
  exhibits $F$ as a left Kan extension of $F_0$ along $\delta$.

See Remark 7.1.1.8.

Remark 7.3.1.11. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories, let $F_0 : K \to \mathcal{D}$ be a diagram, and let $\rho : \delta' \to \delta$ be an isomorphism in the $\infty$-category Fun($K, \mathcal{C}$). Then:

- A natural transformation $\alpha : F \circ \delta \to F_0$ exhibits $F$ as a right Kan extension of $F_0$ along $\delta$ if and only if the composite natural transformation
  \[ F \circ \delta' \xrightarrow{\rho} F \circ \delta \xrightarrow{\alpha} F_0 \]
  exhibits $F$ as a right Kan extension of $F_0$ along $\delta'$ (note that this condition is independent of the composition chosen, by virtue of Remark 7.3.1.9).
• A natural transformation $\beta : F_0 \to F \circ \delta'$ exhibits $F$ as a left Kan extension of $F_0$ along $\delta'$ if and only if the composite natural transformation

$$F_0 \xrightarrow{\beta} F \circ \delta' \xrightarrow{\rho} F \circ \delta$$

exhibits $F$ as a left Kan extension of $F_0$ along $\delta$.

See Remark 7.1.1.8.

Remark 7.3.1.12. Suppose we are given a diagram

\[ \begin{array}{ccc}
  C & \xrightarrow{\delta} & F \\
  \Downarrow{\alpha} & & \Downarrow{F_0} \\
  K & \xrightarrow{\delta} & D
\end{array} \]

as in Definition 7.3.1.2. Let $\rho : F' \to F$ be a morphism in the $\infty$-category $\text{Fun}(C, D)$. Then any two of the following conditions imply the third:

- The natural transformation $\alpha$ exhibits $F$ as a right Kan extension of $F_0$ along $\delta$.
- The composite natural transformation

$$\delta \circ F' \xrightarrow{\rho} \delta \circ F \xrightarrow{\alpha} F_0$$

exhibits $F'$ as a right Kan extension of $F_0$ along $\delta$ (note that this condition does not depend on the composition chosen, by virtue of Remark 7.3.1.9).
- The morphism $\rho$ is an isomorphism in the $\infty$-category $\text{Fun}(C, D)$.

This follows by combining Remark 7.1.1.9 with Theorem 4.4.4.4.

Remark 7.3.1.13 (Change of Target). Suppose we are given a diagram

\[ \begin{array}{ccc}
  C & \xrightarrow{\delta} & F \\
  \Downarrow{\alpha} & & \Downarrow{F_0} \\
  K & \xrightarrow{\delta} & D
\end{array} \]

as in Definition 7.3.1.2 and let $G : D \to E$ be a functor of $\infty$-categories. Then:
7.3. KAN EXTENSIONS

- If $G$ is fully faithful and $G(\alpha) : (G \circ F) \circ \delta \to G \circ F_0$ exhibits $G \circ F$ as a right Kan extension of $G \circ F_0$ along $\delta$, then $\alpha$ exhibits $F$ as a right Kan extension of $F_0$ along $\delta$.

- If $G$ is an equivalence of $\infty$-categories and $\alpha$ exhibits $F$ as a right Kan extension of $F_0$ along $\delta$, then $G(\alpha)$ exhibits $G \circ F$ as a right Kan extension of $G \circ F_0$ along $\delta$.

See Remark 7.1.1.10.

**Proposition 7.3.1.14** (Change of Diagram). Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories, let $\delta : K \to \mathcal{C}$ and $F_0 : K \to \mathcal{D}$ be diagrams, and let $\epsilon : K' \to K$ be a categorical equivalence of simplicial sets. Then:

1. A natural transformation $\alpha : F \circ \delta \to F_0$ exhibits $F$ as a right Kan extension of $F_0$ along $\delta$ if and only if the induced transformation $\alpha' : F \circ (\delta \circ \epsilon) \to F_0 \circ \epsilon$ exhibits $F$ as a right Kan extension of $F_0 \circ \epsilon$ along $\delta \circ \epsilon$.

2. A natural transformation $\beta : F_0 \to F \circ \delta$ exhibits $F$ as a left Kan extension of $F_0$ along $\delta$ if and only if the induced transformation $\beta' : F_0 \circ \epsilon \to F \circ (\delta \circ \epsilon)$ exhibits $F$ as a left Kan extension of $F_0 \circ \epsilon$ along $\delta \circ \epsilon$.

**Proof.** We will prove (1); the proof of (2) is similar. Fix an object $C \in \mathcal{C}$. Since $\epsilon$ is a categorical equivalence and the projection map $C_{C/} \to \mathcal{C}$ is a left fibration (Proposition 4.3.6.1), it follows that the induced map $\epsilon_{C/} : K' \times_{\mathcal{C}} C_{C/} \to K \times_{\mathcal{C}} C_{C/}$ is also a categorical equivalence of simplicial sets (Corollary 5.7.7.6). In particular, $\epsilon$ is left cofinal (Corollary 7.2.1.12). Applying Corollary 7.2.2.3, we see that the natural transformation $\alpha$ satisfies condition $(\ast_C)$ of Definition 7.3.1.2 if and only if $\alpha'$ satisfies condition $(\ast_C)$. The desired result now follows by allowing the object $C \in \mathcal{C}$ to vary. \qed

**Proposition 7.3.1.15.** Suppose we are given a diagram

![Diagram](image)

as in Definition 7.3.1.2, where $\delta$ factors as a composition

$$K \xrightarrow{\delta_0} C^0 \xrightarrow{G} \mathcal{C}$$

for some $\infty$-category $C^0$. Then:
(1) If \( G \) is fully faithful and \( \alpha \) exhibits \( F \) as a right Kan extension of \( F_0 \) along \( \delta \), then it also exhibits \( F \circ G \) as a right Kan extension of \( F_0 \) along \( \delta^0 \).

(2) If \( G \) is an equivalence of \( \infty \)-categories and \( \alpha \) exhibits \( F \circ G \) as a right Kan extension of \( F_0 \) along \( \delta^0 \), then it exhibits \( F \) as a right Kan extension of \( F_0 \) along \( \delta \).

Proof. Assume that \( G \) is fully faithful. Then, for every pair of objects \( X, Y \in \mathcal{C}^0 \), the induced map of left-pinched morphism spaces

\[
\mathcal{C}_X^0 \times \mathcal{C}\{Y\} = \text{Hom}_{\mathcal{C}^0}(X,Y) \to \text{Hom}_{\mathcal{C}}^L(G(X),G(Y)) = \mathcal{C}_{G(X)/\mathcal{C}}(G(Y))
\]

is a homotopy equivalence. Allowing \( Y \) to vary and applying Corollary 5.1.6.15, we see that the natural map \( \mathcal{C}_X^0 \to \mathcal{C}_{G(X)/\mathcal{C}}^0 \) of left fibrations over \( \mathcal{C}^0 \). It follows that the induced map

\[
\mathcal{C}_{X/\mathcal{C}}^0 \times_{\mathcal{C}^0}\mathcal{K} \to \mathcal{C}_{G(X)/\mathcal{C}} \times_{\mathcal{C}}\mathcal{K}
\]

is an equivalence of left fibrations over \( K \). In particular it is a categorical equivalence of simplicial sets (Proposition 5.1.6.5) and therefore left cofinal (Corollary 7.2.1.12). Applying Corollary 7.2.2.3, we see that the natural transformation \( \alpha \) satisfies condition \((\ast_X)\) of Definition 7.3.1.2 if and only if it satisfies condition \((\ast_{G(X)})\). Assertion (1) now follows by allowing the object \( X \in \mathcal{C}^0 \) to vary.

We now prove (2). Assume that \( G \) is an equivalence of \( \infty \)-categories and that \( \alpha \) exhibits \( F \circ G \) as a right Kan extension of \( F_0 \) along \( \delta^0 \); we wish to show that \( \alpha \) exhibits \( F \) as a right Kan extension of \( F_0 \) along \( \delta \). Let \( H : \mathcal{C} \to \mathcal{C}^0 \) be a homotopy inverse of \( G \). Then \( H \) is left adjoint to \( G \), so we can choose natural transformations

\[
\eta : \text{id}_{\mathcal{C}} \to G \circ H \quad \epsilon : H \circ G \to \text{id}_{\mathcal{C}^0}
\]

which are compatible up to homotopy in the sense of Definition 6.2.1.1. Note that \( \eta \) and \( \epsilon \) are isomorphisms (Proposition 6.1.4.1). Let \( \alpha' \) denote a composition of the natural transformations

\[
F \circ G \circ H \circ G \circ \delta^0 \xrightarrow{\epsilon} F \circ G \circ \delta^0 \xrightarrow{\alpha} F_0.
\]

Using Remark 7.3.1.11 we see that \( \alpha' \) exhibits \( H \circ G \circ \delta^0 = H \circ \delta \) as a right Kan extension of \( F_0 \) along \( F \circ G \). Applying assertion (1) to the fully faithful functor \( H : \mathcal{C} \to \mathcal{C}^0 \), we deduce that \( \alpha' \) also exhibits \( \delta \) as a right Kan extension of \( F_0 \) along \( F \circ G \circ H \). The compatibility of \( \eta \) and \( \epsilon \) guarantees that \( \alpha \) is a composition of the natural transformations

\[
F \circ \delta \xrightarrow{\eta} F \circ G \circ H \circ \delta \xrightarrow{\alpha'} F_0.
\]

Applying Remark 7.3.1.12 we conclude that \( \alpha \) exhibits \( F \) as a right Kan extension of \( F_0 \) along \( \delta \), as desired. \( \square \)
Corollary 7.3.1.16. Let $G : C^0 \to C$, $F_0 : C^0 \to D$, and $F : C \to D$ be functors of $\infty$-categories, where $G$ is fully faithful. Then:

- If $\alpha : F \circ G \to F_0$ is a natural transformation which exhibits $F$ as a right Kan extension of $F_0$ along $G$, then $\alpha$ is an isomorphism in the $\infty$-category $\text{Fun}(C^0, D)$.

- If $\beta : F_0 \to F \circ G$ is a natural transformation which exhibits $F$ as a left Kan extension of $F_0$ along $G$, then $\beta$ is an isomorphism in the $\infty$-category $\text{Fun}(C^0, D)$.

Proof. Let $\alpha : F \circ G \to F_0$ be a natural transformation which exhibits $F$ as a right Kan extension of $F_0$ along $G$. Applying Proposition (in the special case where $K = C^0$), we deduce that $\alpha$ also exhibits $F \circ G$ as a right Kan extension of $F_0$ along the identity functor $id_{C^0} : C^0 \to C^0$. Invoking Example 7.3.1.8, we see that $\alpha$ is an isomorphism. This proves the first assertion; the second follows by a similar argument.

Proposition 7.3.1.17. Suppose we are given a diagram

```
\begin{tikzcd}
  C \ar{dr}{F_0} \ar{dr}{\alpha} \ar{d}{\delta} & \\
  K & F \ar{r} & D
\end{tikzcd}
```

as in Definition 7.3.1.2. Assume that $\delta$ exhibits $K$ as a localization of $K$ (with respect to some collection of edges of $K$) and that $\alpha$ is an isomorphism in the $\infty$-category $\text{Fun}(K, D)$. Then $\alpha$ exhibits $F$ as a right Kan extension of $F_0$ along $\delta$.

Proof. Fix an object $C \in C$. Since $\alpha$ is an isomorphism, it will suffice to show that the tautological map $F(C) \to (F \circ \delta)|_{K_{C'}}$ exhibits $F(C)$ as a limit of the diagram $(F \circ \delta)|_{K_{C'}}$. Since the projection map $\mathcal{C}_{C'} \to \mathcal{C}$ is a left fibration (Proposition 4.3.6.1), the map $\delta_{C'} : K_{C'} \to \mathcal{C}_{C'}$ exhibits the $\infty$-category $\mathcal{C}_{C'}$ as a localization of the simplicial set $K_{C'}$ (Corollary 6.3.5.5). In particular, $\delta_{C'}$ is left cofinal (Proposition 7.2.1.9). We can therefore replace $K$ by $\mathcal{C}$ (Corollary 7.2.2.7), in which case the desired result follows from the criterion of Corollary 7.2.2.5.

7.3.2 Kan Extensions along Inclusions

Let $\mathcal{C}$ be an $\infty$-category and let $\delta : K \to \mathcal{C}$ be a diagram. In §7.3.1, we introduced the notion of a functor $F : \mathcal{C} \to D$ being a left Kan extension of another diagram $F_0 : K \to D$ along $\delta$ (Variant 7.3.1.5). Beware that this terminology is potentially misleading: if $F$ is a left Kan extension of $F_0$ along $\delta$, then the composition $F \circ \delta$ need not be equal to $F_0$. Instead,
it is equipped with a natural transformation $\beta : F_0 \to F \circ \delta$ satisfying a certain universal property. In this section, we specialize to the case where $K = \mathcal{C}^0$ is a full subcategory of $\mathcal{C}$ and $\delta : \mathcal{C}^0 \to \mathcal{C}$ is the inclusion map. In this case, the natural transformation $\beta$ is necessarily an isomorphism (Corollary 7.3.1.16). Consequently, the Kan extension condition can be substantially simplified: it can be regarded as a property of the functor $F$, which can be formulated without reference to the diagram $F_0$ or the natural transformation $\beta$.

**Definition 7.3.2.1.** Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories and let $\mathcal{C}^0 \subseteq \mathcal{C}$ be a full subcategory. Fix an object $C \in \mathcal{C}$. We will say that $F$ is left Kan extended from $\mathcal{C}^0$ at $C$ if the composite map

$$(\mathcal{C}^0_C) \hookrightarrow (\mathcal{C}/C)^\circ \xrightarrow{\varepsilon} \mathcal{C} \xrightarrow{F} \mathcal{D}$$

is a colimit diagram in the $\infty$-category $\mathcal{D}$. Here $\mathcal{C}^0_C$ denotes the fiber product $\mathcal{C}^0 \times_{\mathcal{C}} \mathcal{C}/C$ (Notation 7.3.1.1), and $\varepsilon$ is the slice contraction morphism of Construction 4.3.5.12. Similarly, we say that $F$ is right Kan extended from $\mathcal{C}^0$ at $C$ if the composite map

$$(\mathcal{C}^0_C) \hookrightarrow (\mathcal{C}/C)^\circ \xleftarrow{\varepsilon} \mathcal{C} \xrightarrow{F} \mathcal{D}$$

is a limit diagram in $\mathcal{D}$. We say that $F$ is left Kan extended from $\mathcal{C}^0$ if it is left Kan extended from $\mathcal{C}^0$ at every object $C \in \mathcal{C}$. We say that $F$ is right Kan extended from $\mathcal{C}^0$ if it is right Kan extended from $\mathcal{C}^0$ at every object $C \in \mathcal{C}$.

**Remark 7.3.2.2.** Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories and let $\mathcal{C}^0 \subseteq \mathcal{C}$ be a full subcategory. Then $F$ is right Kan extended from $\mathcal{C}^0$ if and only if the opposite functor $F^{\text{op}} : \mathcal{C}^{\text{op}} \to \mathcal{D}^{\text{op}}$ is left Kan extended from $\mathcal{C}^0$.

**Exercise 7.3.2.3.** Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories and let $\mathcal{C}^0 \subseteq \mathcal{C}$ be a full subcategory. Show that, for every object $C \in \mathcal{C}$, the functor $F$ is both left and right Kan extended from $\mathcal{C}^0$ at $C$. For a more general statement, see Proposition 7.3.3.5.

**Example 7.3.2.4.** Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of ordinary categories, and let $\mathcal{C}^0 \subseteq \mathcal{C}$ be a full subcategory. Then $F$ is left Kan extended from $\mathcal{C}^0$ (in the sense of Definition 7.3.2.1) if and only if the induced functor of $\infty$-categories $N_* : N_*(\mathcal{C}) \to N_*(\mathcal{D})$ is left Kan extended from $N_*(\mathcal{C}^0)$ (in the sense of Definition 7.3.2.1).

We now show that Definition 7.3.2.1 can be regarded as a special case of the notions introduced in §7.3.1.

**Proposition 7.3.2.5.** Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories, let $F_0$ denote the restriction of $F$ to a full subcategory $\mathcal{C}^0 \subseteq \mathcal{C}$, and let $i : \mathcal{C}^0 \to \mathcal{C}$ denote the inclusion functor. Then:
7.3. KAN EXTENSIONS

- The functor $F$ is left Kan extended from $\mathcal{C}^0$ (in the sense of Definition 7.3.2.1) if and only if the identity transformation $\text{id} : F_0 \to F \circ \iota$ exhibits $F$ as a left Kan extension of $F_0$ along $\iota$ (in the sense of Variant 7.3.1.5).

- The functor $F$ is right Kan extended from $\mathcal{C}^0$ (in the sense of Definition 7.3.2.1) if and only if the identity transformation $\text{id} : F_0 \to F \circ \iota$ exhibits $F$ as a right Kan extension of $F_0$ along $\iota$ (in the sense of Definition 7.3.1.2).

Proof. Fix an object $C \in \mathcal{C}$. It follows from Remark 7.1.2.6 that the composition

$$(\mathcal{C}^0 / C)^\circ \hookrightarrow (\mathcal{C} / C)^\circ \to \mathcal{C} \xrightarrow{F} \mathcal{D}$$

is a colimit diagram in $\mathcal{D}$ if and only if the natural transformation $\text{id} : F_0 \to F$ satisfies condition $(\ast_C)$ of Variant 7.3.1.5. The first assertion follows by allowing the object $C$ to vary, and the second follows by a similar argument. □

Corollary 7.3.2.6. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories, let $\mathcal{C}^0 \subseteq \mathcal{C}$ be a full subcategory, and let $\beta : F_0 \to F |_{\mathcal{C}^0}$ be a natural transformation of functors from $\mathcal{C}^0$ to $\mathcal{D}$. Then $\beta$ exhibits $F$ as a left Kan extension of $F_0$ along the inclusion map $\iota : \mathcal{C}^0 \hookrightarrow \mathcal{C}$ (in the sense of Variant 7.3.1.5) if and only if the following pair of conditions is satisfied:

1. The functor $F$ is left Kan extended from $\mathcal{C}^0$ (in the sense of Definition 7.3.2.1).
2. The natural transformation $\beta$ is an isomorphism in the $\infty$-category $\text{Fun}(\mathcal{C}^0, \mathcal{D})$.

Proof. By virtue of Corollary 7.3.1.16, we may assume that condition (2) is satisfied. Using Remark 7.3.1.10, we can reduce further to the special case where $F_0 = F |_{\mathcal{C}^0}$ and $\beta$ is the identity transformation, in which case the desired result is a restatement of Proposition 7.3.2.5. □

Corollary 7.3.2.7. Let $\mathcal{C}$ be an $\infty$-category, let $\mathcal{C}^0 \subseteq \mathcal{C}$ be a full subcategory, and let $F_0 : \mathcal{C}^0 \to \mathcal{D}$ be a functor of $\infty$-categories. The following conditions are equivalent:

1. There exists a functor $F : \mathcal{C} \to \mathcal{D}$ and a natural transformation $\beta : F_0 \to F |_{\mathcal{C}^0}$ which exhibits $F$ as a left Kan extension of $F_0$ along the inclusion functor $\mathcal{C}^0 \hookrightarrow \mathcal{C}$.
2. There exists a functor $F : \mathcal{C} \to \mathcal{D}$ which is left Kan extended from $\mathcal{C}^0$ and satisfies $F_0 = F |_{\mathcal{C}^0}$.

Proof. We will show that (1) implies (2); the converse is an immediate consequence of Proposition 7.3.2.5. Let $\beta : F_0 \to F' |_{\mathcal{C}^0}$ exhibit $F'$ as a left Kan extension of $F_0$ along the inclusion functor $\mathcal{C}^0 \hookrightarrow \mathcal{C}$. Then $\beta$ is an isomorphism in the $\infty$-category $\text{Fun}(\mathcal{C}^0, \mathcal{D})$ (Corollary 7.3.1.16). Using Corollary 4.4.5.9, we can lift $\beta$ to an isomorphism $\tilde{\beta} : F \to F'$. Therefore, $\mathcal{C}^0 \subseteq \mathcal{C}$ be a full subcategory, and let $F_0 : \mathcal{C}^0 \to \mathcal{D}$ be a functor of $\infty$-categories. The following conditions are equivalent:

1. There exists a functor $F : \mathcal{C} \to \mathcal{D}$ and a natural transformation $\beta : F_0 \to F |_{\mathcal{C}^0}$ which exhibits $F$ as a left Kan extension of $F_0$ along the inclusion functor $\mathcal{C}^0 \hookrightarrow \mathcal{C}$.
2. There exists a functor $F : \mathcal{C} \to \mathcal{D}$ which is left Kan extended from $\mathcal{C}^0$ and satisfies $F_0 = F |_{\mathcal{C}^0}$.

Proof. We will show that (1) implies (2); the converse is an immediate consequence of Proposition 7.3.2.5. Let $\beta : F_0 \to F' |_{\mathcal{C}^0}$ exhibit $F'$ as a left Kan extension of $F_0$ along the inclusion functor $\mathcal{C}^0 \hookrightarrow \mathcal{C}$. Then $\beta$ is an isomorphism in the $\infty$-category $\text{Fun}(\mathcal{C}^0, \mathcal{D})$ (Corollary 7.3.1.16). Using Corollary 4.4.5.9, we can lift $\beta$ to an isomorphism $\tilde{\beta} : F \to F'$.
in the \(\infty\)-category \(\text{Fun}(C, D)\), where \(F\) satisfies \(F|_{C^0} = F_0\). Applying Remark \(7.3.1.12\) we deduce that the identity transformation \(\text{id}_{F_0}\) exhibits \(F\) as a left Kan extension of \(F_0\) along the inclusion map \(C^0 \hookrightarrow C\). Invoking Proposition \(7.3.2.5\), we conclude that \(F\) is left Kan extended from \(C^0\).

**Definition 7.3.2.8.** Let \(C\) be an \(\infty\)-category, let \(C^0 \subseteq C\) be a full subcategory, and suppose we are given functors \(F : C \rightarrow D\) and \(F_0 : C^0 \rightarrow D\). We will say that \(F\) is a left Kan extension of \(F_0\) if \(F\) is left Kan extended from \(C^0\) and satisfies \(F|_{C^0} = F_0\). We will say that \(F\) is a right Kan extension of \(F_0\) if \(F\) is right Kan extended from \(C^0\) and satisfies \(F|_{C^0} = F_0\).

**Warning 7.3.2.9.** Let \(C\) be an \(\infty\)-category, let \(\iota : C^0 \hookrightarrow C\) be the inclusion of a full subcategory, and let \(F_0 : C^0 \rightarrow D\) be a functor. We have given two definitions for the notion of Kan extension:

(a) A functor \(F : C \rightarrow D\) is a left Kan extension of \(F_0\) if it is left Kan extended from \(C^0\) and satisfies \(F|_{C^0} = F_0\) (Definition \(7.3.2.8\)).

(b) A functor \(F : C \rightarrow D\) is a left Kan extension of \(F_0\) along \(\iota\) if there exists a natural transformation \(\beta : F_0 \rightarrow F|_{C^0}\) which exhibits \(F\) as a left Kan extension of \(F_0\) along \(\iota\), in the sense of Variant \(7.3.1.5\).

These definitions are not quite equivalent. By virtue of Proposition \(7.3.2.5\), a functor \(F : C \rightarrow D\) satisfies condition \((a)\) if and only if it satisfies a stronger version of condition \((b)\), where \(\beta\) is required to be an identity natural transformation. In particular, condition \((a)\) implies condition \((b)\). However, the converse is false: if \(F\) is a left Kan extension of \(F_0\) along \(\iota\), then the restriction \(F|_{C^0}\) need not be equal to \(F_0\). However, it is necessarily isomorphic to \(F_0\), by virtue of Corollary \(7.3.2.6\).

Let \(\delta : \mathcal{K} \rightarrow \mathcal{C}\) be a functor of \(\infty\)-categories. The preceding results show that, if \(\delta\) is an isomorphism from \(\mathcal{K}\) to a full subcategory of \(\mathcal{C}\), then the theory of Kan extensions along \(\delta\) (in the sense of §7.3.1) can be reformulated in terms of Definition \(7.3.2.1\).

We now extend this observation to the case of a general functor, by identifying \(\mathcal{K}\) with a full subcategory of the relative join \(\mathcal{K} \star_{\mathcal{C}} \mathcal{C}\) of Construction \(5.2.3.1\).
(2) The natural transformation \( \beta \) exhibits \( F_1 \) as a left Kan extension of \( F_0 \) along \( \delta \) (in the sense of Variant 7.3.1.5).

Proof. By virtue of Exercise 7.3.2.3, it will suffice to show that for every object \( C \in \mathcal{C} \), the following conditions are equivalent:

(1\( C \)) The functor \( F \) is left Kan extended from \( \mathcal{K} \) at \( C \) (in the sense of Definition 7.3.2.1).

(2\( C \)) The natural transformation \( \beta \) satisfies condition \((\ast_C)\) of Variant 7.3.1.5.

For the remainder of the proof, let us regard the object \( C \in \mathcal{C} \) as fixed, and set \( \mathcal{K}/C = \mathcal{K} \times_{\mathcal{C}} \mathcal{C}/C \). Let \( \pi: \Delta^2 \times \mathcal{K}/C \to (\Delta^1 \times \mathcal{K}/C)^{\circ} \) be the functor which is the identity on \( \Delta^1 \times \mathcal{K}/C \) and carries \( \{2\} \times \mathcal{K}/C \) to the cone point of \((\Delta^1 \times \mathcal{K}/C)^{\circ} \). Let \( \sigma \) denote the composite map

\[
\Delta^2 \times \mathcal{K}/C \xrightarrow{\pi} (\Delta^1 \times \mathcal{K}/C)^{\circ} \\
\simeq ((\mathcal{K} \times \Delta^1) \times_{\mathcal{K} \times \mathcal{C}} (\mathcal{K} \ast_{\mathcal{C}} \mathcal{C}/C)^\circ) \\
\to \mathcal{K} \ast_{\mathcal{C}} \mathcal{C}/C \\
\xrightarrow{F} \mathcal{D}.
\]

We will regard \( \sigma \) as a 2-simplex in the \( \infty \)-category \( \text{Fun}(\mathcal{K}/C, \mathcal{D}) \), which we display as a diagram

\[
\begin{tikzcd}
(F_1 \circ \delta)_{|\mathcal{K}/C} \ar[dr] \ar[dr] & \\
F_0_{|\mathcal{K}/C} \ar[ur] \ar[ur] & \\
& F_1(C)
\end{tikzcd}
\]

which witnesses the bottom horizontal map as the natural transformation \( \beta_C \) appearing in condition \((\ast_C)\). By construction, this natural transformation \( \beta_C \) is given by the composite map

\[
N_{\ast}(\{0 < 2\}) \times \mathcal{K}/C \to (\mathcal{K}/C)^{\circ} \to \mathcal{K} \ast_{\mathcal{C}} \mathcal{C} \xrightarrow{F} \mathcal{D},
\]

so the equivalence \((1_C) \iff (2_C)\) is a special case of Remark 7.1.2.6. \( \Box \)

**Warning 7.3.2.11.** For a general diagram

\[
\begin{tikzcd}
\mathcal{C} \ar[dr, \beta] \ar[dr, \delta] & \\
\mathcal{K} \ar[ur, \beta] \ar[ur, F_0] & \\
& \mathcal{D}
\end{tikzcd}
\]
we cannot always arrange that there exists a functor $F : \mathcal{K} \ast \mathcal{C} \to \mathcal{D}$ satisfying the requirements of Proposition 7.3.2.10. However, we can always find a functor $F' : \mathcal{K} \ast \mathcal{C} \to \mathcal{D}$ which satisfies $F'|_{\mathcal{K}} = F_0$, $F'|_{\mathcal{C}} = F_1$, and the map

$$\Delta^1 \times \mathcal{K} \simeq \mathcal{K} \ast \mathcal{K} \to \mathcal{K} \ast \mathcal{C} \stackrel{F'}{\to} \mathcal{D}$$

determines a natural transformation $\beta' : F_0 \to F_1 \circ \delta$ which is homotopic to $\beta$. To see this, set $M = (\Delta^1 \times \mathcal{K}) \coprod_{\{1\} \times \mathcal{K}} \mathcal{C}$, so that the pair $(\beta, F_1)$ determines a morphism of simplicial sets $f : M \to \mathcal{D}$. Proposition 5.2.4.4 supplies a categorical equivalence of simplicial sets $\theta : M \to \mathcal{K} \ast \mathcal{C}$, so the induced map

$$\text{Fun}_{\mathcal{K} \coprod \mathcal{C}/(\mathcal{K} \ast \mathcal{C}, \mathcal{D})} \circ \theta \to \text{Fun}_{\mathcal{K} \coprod \mathcal{C}/(M, \mathcal{D})}$$

is an equivalence of $\infty$-categories (Corollary 4.5.4.5). It follows that there exists a functor $F' : \mathcal{K} \ast \mathcal{C} \to \mathcal{D}$ such that $F'|_{\mathcal{K}} = F_0$, $F'|_{\mathcal{C}} = F_1$, and $F' \circ \theta$ is isomorphic to $f$ as an object of the $\infty$-category $\text{Fun}_{\mathcal{K} \coprod \mathcal{C}/(M, \mathcal{D})}$. The last requirement is a reformulation of the condition that $\beta' = F'|_{\Delta^1 \times \mathcal{K}}$ is homotopic to $\beta$.

**Corollary 7.3.2.12.** Let $\delta : \mathcal{K} \to \mathcal{C}$, $F_0 : \mathcal{K} \to \mathcal{D}$, and $F_1 : \mathcal{C} \to \mathcal{D}$ be functors of $\infty$-categories. The following conditions are equivalent:

1. There exists a functor $F : \mathcal{K} \ast \mathcal{C} \to \mathcal{D}$ which is left Kan extended from $\mathcal{K}$ which satisfies $F_0 = F|_{\mathcal{K}}$ and $F_1 = F|_{\mathcal{C}}$.

2. There exists a natural transformation $\beta : F_0 \to F_1 \circ \delta$ which exhibits $F_1$ as a left Kan extension of $F_0$ along $\delta$.

**Proof.** The implication $(1) \iff (2)$ follows immediately from Proposition 7.3.2.10. Conversely, suppose that there exists a natural transformation $\beta : F_0 \to F_1 \circ \delta$ which exhibits $F_1$ as a left Kan extension of $F_0$ along $\delta$. By virtue of Remark 7.3.1.9, we can modify $\beta$ by a homotopy and thereby arrange that there exists a functor $F : \mathcal{K} \ast \mathcal{C} \to \mathcal{D}$ satisfying $F|_{\mathcal{K}} = F_0$, $F|_{\mathcal{C}} = F_1$ and for which the induced map

$$\Delta^1 \times \mathcal{K} \simeq \mathcal{K} \ast \mathcal{K} \to \mathcal{K} \ast \mathcal{C} \to \mathcal{D}$$

coincides with $\beta$ (Warning 7.3.2.11). Applying Proposition 7.3.2.10 we see that $F$ is left Kan extended from $\mathcal{K}$. \qed

For later use, we record a slightly more general version of Proposition 7.3.2.10.

**Corollary 7.3.2.13.** Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories, and let $U : \mathcal{C} \to \Delta^1$ be a cocartesian fibration having fibers $\mathcal{C}_0 = \{0\} \times_{\Delta^1} \mathcal{C}$ and $\mathcal{C}_1 = \{1\} \times_{\Delta^1} \mathcal{C}$. Choose a functor $G : \mathcal{C}_0 \to \mathcal{C}_1$ and a natural transformation $\beta : \text{id}_{\mathcal{C}_0} \to G$ which exhibits $G$ as given by covariant transport along the nondegenerate edge of $\Delta^1$ (see Definition 5.2.2.4). The following conditions are equivalent:
7.3. KAN EXTENSIONS

(1) The functor $F$ is left Kan extended from $C_0$.

(2) The natural transformation $F(\alpha) : F|_{C_0} \to F|_{C_1} \circ G$ exhibits $F|_{C_1}$ as a left Kan extension of $F|_{C_0}$ along $G$.

Proof. Let us regard the functor $G$ as fixed. Let $M = (\Delta^1 \times C_0) \coprod (\{1\} \times C_0) C_1$ be the mapping cylinder of $G$, and let us abuse notation by identifying $C_0 \simeq \{0\} \times C_0$ and $C_1$ with (disjoint) simplicial subsets of $M$. We can then identify $\alpha$ with a morphism of simplicial sets $\mu : M \to C$ which is the identity when restricted to $C_0$ and $C_1$.

Note that the tautological map

$$\Delta^1 \times C_0 \simeq C_0 \ast C_0 C_0 \to C_0 \ast C_1 C_1$$

extends to a morphism of simplicial sets $\lambda : M \to C_0 \ast C_1 C_1$ which is the identity on $C_1$; moreover, $\lambda$ is a categorical equivalence (Proposition 5.2.4.4). It follows that precomposition with $\lambda$ induces an equivalence of $\infty$-categories

$$\text{Fun}_{C_0 \coprod C_1 / (C_0 \ast C_1, C)} \to \text{Fun}_{C_0 \coprod C_1 / (M, C)}.$$ 

We can therefore choose a functor $G : C_0 \ast C_1 C_1 \to D$ satisfying $G|_{C_0} = \text{id}_{C_0}$ and $G|_{C_1} = \text{id}_{C_1}$, where $G \circ \lambda$ is isomorphic to $\mu$ as an object of the $\infty$-category $\text{Fun}_{C_0 \coprod C_1 / (M, C)}$. Since condition (2) depends only on the homotopy class of the natural transformation $\alpha$ (Remark 7.3.1.9), we are free to modify $\alpha$ and may therefore assume that $G \circ \lambda = \mu$. In this case, Proposition 7.3.3.14 allows us to reformulate condition (2) as follows:

(2') The functor $(F \circ G) : C_0 \ast C_1 C_1 \to D$ is left Kan extended from $C_0$.

Since $\lambda$ and $\mu$ are categorical equivalences of simplicial sets (Proposition 5.2.4.4), the functor $G$ is an equivalence of $\infty$-categories (Remark 4.5.3.5). The equivalence of (1) and (2') is now a special case of Proposition 7.3.3.14.

7.3.3 Relative Kan Extensions

For many applications, it will be convenient to work with a generalization of Definition 7.3.2.1. In what follows, we assume that the reader is familiar with the theory of relative (co)limit diagrams introduced in § 7.1.5.

Definition 7.3.3.1 (Relative Kan Extensions). Let $F : C \to D$ and $U : D \to E$ be functors of $\infty$-categories, let $C^0 \subseteq C$ be a full subcategory. For each object $C \in C$, we will say that $F$ is $U$-left Kan extended from $C^0$ at $C$ if the composite map

$$(C^0 / C)^\triangleright \hookrightarrow (C / C)^\triangleright \xrightarrow{\Delta} C \xrightarrow{F} D$$
CHAPTER 7. LIMITS AND COLIMITS

is a \( U \)-colimit diagram in the \( \infty \)-category \( D \). We say that \( F \) is \( U \)-right Kan extended from \( C^0 \) at \( C \) if the composite map
\[
(C^0_{C/X})^o \rightarrow (C_{C/X})^o \xrightarrow{C \rightarrow \mathcal{D}} \mathcal{D}
\]
is a \( U \)-limit diagram in \( D \). Here \( c \) and \( c' \) denote the slice and coslice contraction morphisms of Construction 4.3.5.12. We say that \( F \) is \( U \)-right Kan extended from \( C^0 \) if it is \( U \)-right Kan extended from \( C^0 \) at every object \( C \in \mathcal{C} \). We say that \( F \) is \( U \)-right Kan extended from \( C^0 \) if it is \( U \)-right Kan extended from \( C^0 \) at every object \( C \in \mathcal{C} \).

**Remark 7.3.3.2.** Let \( F : \mathcal{C} \rightarrow \mathcal{D} \) be a functor of \( \infty \)-categories and let \( C^0 \subseteq \mathcal{C} \) be a full subcategory. Then \( F \) is left Kan extended from \( C^0 \) (in the sense of Definition 7.3.2.1) if and only if it is \( U \)-left Kan extended from \( C^0 \) (in the sense of Definition 7.3.3.1), where \( U : \mathcal{D} \rightarrow \Delta^0 \) is the projection map. Similarly, \( F \) is right Kan extended from \( C^0 \) if and only if it is \( U \)-right Kan extended from \( C^0 \). See Example 7.1.5.3.

**Remark 7.3.3.3.** In the situation of Definition 7.3.3.1, the morphism \( F : \mathcal{C} \rightarrow \mathcal{D} \) is \( U \)-right Kan extended from \( C^0 \) if and only if the opposite functor \( F^\text{op} : \mathcal{C}^\text{op} \rightarrow \mathcal{D}^\text{op} \) is \( U^\text{op} \)-left Kan extended from \( (C^0)^\text{op} \).

**Example 7.3.3.4.** Let \( F : \mathcal{C} \rightarrow \mathcal{D} \) and \( U : \mathcal{D} \rightarrow \mathcal{E} \) be functors of \( \infty \)-categories. If \( U \) is fully faithful, then \( F \) is \( U \)-left Kan extended and \( U \)-right Kan extended from any full subcategory \( C^0 \subseteq \mathcal{C} \) (see Example 7.1.5.4).

To verify the Kan extension conditions of Definition 7.3.3.1 it suffices to consider objects \( C \) which do not belong to the full subcategory \( C^0 \subseteq \mathcal{C} \).

**Proposition 7.3.3.5.** Let \( F : \mathcal{C} \rightarrow \mathcal{D} \) and \( U : \mathcal{D} \rightarrow \mathcal{E} \) be functors of \( \infty \)-categories. Let \( C^0 \subseteq \mathcal{C} \) be a full subcategory and let \( C \in \mathcal{C} \) be an object which is isomorphic to an object of \( C^0 \). Then \( F \) is both \( U \)-left Kan extended from \( C^0 \) and \( U \)-right Kan extended from \( C^0 \) at \( C \).

**Proof.** We will show that \( F \) is \( U \)-left Kan extended from \( C^0 \) at \( C \); the analogous statement for the right Kan extension condition follows by a similar argument. Let \( c : (C^0_{C/X})^p \rightarrow \mathcal{C} \) be the slice contraction morphism; we wish to show that the composition \( (F \circ c) : (C^0_{C/X})^p \rightarrow \mathcal{D} \) is a \( U \)-colimit diagram. Choose an object \( C' \in C^0 \) and an isomorphism \( u : C' \rightarrow C \) in the \( \infty \)-category \( \mathcal{C} \). Our assumption that \( u \) is an isomorphism guarantees that it is final when viewed as an object of the slice \( \infty \)-category \( \mathcal{C}/C \) (Proposition 4.6.6.23), and therefore also when viewed as an object of the \( \infty \)-category \( (C^0)^p \). The desired result now follows from Corollary 7.2.3.6 since \( F(u) \) is an isomorphism in the \( \infty \)-category \( \mathcal{D} \).

**Example 7.3.3.6.** Let \( F : \mathcal{C} \rightarrow \mathcal{D} \) and \( U : \mathcal{D} \rightarrow \mathcal{E} \) be functors of \( \infty \)-categories. Then \( F \) is \( U \)-left Kan extended and \( U \)-right Kan extended from the full subcategory \( \mathcal{C} \subseteq \mathcal{C} \).
Example 7.3.3.7. Let $F : C \to D$ and $U : D \to E$ be functors of $\infty$-categories, and set $F = F|_C$. Then $F$ is $U$-left Kan extended from a full subcategory $C^0 \subseteq C$ if and only if $\overline{F}$ is $U$-left Kan extended from the cone $(C^0)^\circ \subseteq C^\circ$. To prove this, it suffices (by virtue of Proposition 7.3.3.5) to show that $F$ is $U$-left Kan extended from the cone $(C^0)^\circ$ at an object $C \in C$ if and only if $\overline{F}$ is $U$-left Kan extended from $(C^0)^\circ$ at $C$, which follows immediately from the definition.

Example 7.3.3.8. Let $C$ be an $\infty$-category and let $U : D \to E$ be a functor of $\infty$-categories. It follows from Proposition 7.3.3.5 that a functor $F : C \to D$ is a $U$-colimit diagram (in the sense of Definition 7.1.5.1) if and only if it is $U$-left Kan extended from $C$.

Proposition 7.3.3.9. Let $F : C \to D$ be a functor of $\infty$-categories, let $U : D \to E$ be an inner fibration of $\infty$-categories, and let $C^0 \subseteq C$ be a coreflective subcategory of $C$. The following conditions are equivalent:

1. The functor $F$ is $U$-left Kan extended from $C^0$.
2. Let $e : X \to Y$ be a morphism in $C$ which exhibits $X$ as a $C^0$-coreflection of $Y$ (Definition 6.2.2.1). Then $F(e)$ is a $U$-cocartesian morphism of $D$.
3. Let $T : C \to C^0$ be a right adjoint to the inclusion. If $e$ is a morphism in $C$ and $T(e)$ is an isomorphism in $C^0$, then $F(e)$ is a $U$-cocartesian morphism of $D$.

Proof. Let $Y$ be an object of $C$. By assumption, there exists an object $X \in C^0$ and a morphism $e : X \to Y$ which exhibits $X$ as a $C^0$-coreflection of $Y$. Then $e$ is final when viewed as an object of the $\infty$-category $C^0 \times C/Y$. It follows that $F$ is $U$-left Kan extended from $C^0$ at $Y$ if and only if $F(e)$ is $U$-cocartesian morphism of $D$; in particular, this condition is independent of the choice of $e$. Allowing the object $Y$ to vary, we deduce the equivalence $(1) \iff (2)$.

Using Lemma 6.2.2.10, we can choose a functor $T : C \to C^0$ and a natural transformation $\epsilon : T \to \text{id}_C$ which exhibits $T$ as a $C^0$-coreflection functor, so that $T$ is right adjoint to the inclusion of $C^0$ into $C$ (Proposition 6.2.2.11). Let $e : X \to Y$ be a morphism in $C$. If $e$ exhibits $X$ as a $C^0$-coreflection of $Y$, then $T(e)$ is an isomorphism in $C^0$, which shows immediately that $(3)$ implies $(2)$. Conversely, suppose that $(2)$ is satisfied and that $T(e)$ is an isomorphism in $C^0$. We then have a commutative diagram

$$
\begin{array}{ccc}
(F \circ T)(X) & \xrightarrow{(F \circ T)(e)} & (F \circ T)(Y) \\
\downarrow{F(e_X)} & & \downarrow{F(e_Y)} \\
F(X) & \xrightarrow{F(e)} & F(Y)
\end{array}
$$

in the $\infty$-category $D$, where the upper horizontal map is an isomorphism and the vertical maps are $U$-cocartesian. Using Corollary 5.1.2.4 we see that $F(e)$ is also $U$-cocartesian. \qed
Corollary 7.3.3.10. Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories and let \( \mathcal{C}_0 \subseteq \mathcal{C} \) be a coreflective subcategory. The following conditions are equivalent:

1. The functor \( F \) is left Kan extended from \( \mathcal{C}_0 \).
2. Let \( e : X \to Y \) be a morphism in \( \mathcal{C} \) which exhibits \( X \) as a \( \mathcal{C}_0 \)-coreflection of \( Y \) (Definition 6.2.2.7). Then \( F(e) \) is an isomorphism in \( \mathcal{D} \).
3. Let \( T : \mathcal{C} \to \mathcal{C}_0 \) be a right adjoint to the inclusion. If \( e \) is a morphism in \( \mathcal{C} \) and \( T(e) \) is an isomorphism in \( \mathcal{C}_0 \), then \( F(e) \) is an isomorphism in \( \mathcal{D} \).

Proof. Combine Proposition 7.3.3.9 with Example 5.1.1.4 (for a closely related statement, see Proposition 7.3.1.17).

We now record some basic stability properties enjoyed by the class of relative Kan extensions, which follow easily from the analogous stability properties of relative (co)limit diagrams.

Remark 7.3.3.11. Suppose we are given a commutative diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\mathcal{D} & \xrightarrow{G} & \mathcal{D}' \\
U \downarrow & & \downarrow U' \\
\mathcal{E} & \xrightarrow{} & \mathcal{E}'
\end{array}
\]

where the horizontal functors are equivalence of \( \infty \)-categories. Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor and let \( \mathcal{C}_0 \subseteq \mathcal{C} \) be a full subcategory. Then \( F \) is \( U \)-left Kan extended from \( \mathcal{C}_0 \) if and only if \( G \circ F \) is \( U' \)-left Kan extended from \( \mathcal{C}_0 \) (see Remark 7.1.5.6). Similarly, \( F \) is \( U \)-right Kan extended from \( \mathcal{C}_0 \) if and only if \( G \circ F \) is \( U' \)-right Kan extended from \( \mathcal{C}_0 \).

Remark 7.3.3.12. Let \( F : \mathcal{C} \to \mathcal{D} \) and \( U : \mathcal{D} \to \mathcal{E} \) be functors of \( \infty \)-categories, and let \( \mathcal{C}_0 \subseteq \mathcal{C} \) be a full subcategory. Let \( V : \mathcal{D} \to \mathcal{E} \) be a functor which is isomorphic to \( U \) (as an object of the \( \infty \)-category \( \text{Fun}(\mathcal{D}, \mathcal{E}) \)). Then \( F \) is \( U \)-left Kan extended from \( \mathcal{C}_0 \) if and only if it is \( V \)-left Kan extended from \( \mathcal{C}_0 \) (see Remark 7.1.5.7). Similarly, \( F \) is \( U \)-right Kan extended from \( \mathcal{C}_0 \) if and only if it is \( V \)-right Kan extended from \( \mathcal{C}_0 \).

Remark 7.3.3.13. Let \( F : \mathcal{C} \to \mathcal{D} \) and \( U : \mathcal{D} \to \mathcal{E} \) be functors of \( \infty \)-categories, let \( G : \mathcal{C} \to \mathcal{D} \) be a functor which is isomorphic to \( F \) (as an object of the \( \infty \)-category \( \text{Fun}(\mathcal{C}, \mathcal{D}) \)), and let \( \mathcal{C}_0 \subseteq \mathcal{C} \) be a full subcategory. Then \( F \) is \( U \)-left Kan extended from \( \mathcal{C}_0 \) if and only if \( G \) is \( U \)-left Kan extended from \( \mathcal{C}_0 \) (see Proposition 7.1.5.13). Similarly, \( F \) is \( U \)-right Kan extended from \( \mathcal{C}_0 \) if and only if \( G \) is \( U \)-right Kan extended from \( \mathcal{C}_0 \).
03U5 Proposition 7.3.3.14 (Change of Source). Let $F : \mathcal{C} \to \mathcal{D}$ and $U : \mathcal{D} \to \mathcal{E}$ be functors of ∞-categories and let $\mathcal{C}^0 \subseteq \mathcal{C}$ be a replete full subcategory. Let $G : \mathcal{B} \to \mathcal{C}$ be an equivalence of ∞-categories, and set $\mathcal{B}^0 = \mathcal{C}^0 \times_{\mathcal{C}} \mathcal{B}$. Then $F$ is $U$-left Kan extended from $\mathcal{C}^0$ if and only if $F \circ G$ is $U$-left Kan extended from $\mathcal{B}^0$.

Proof. Assume first that $F$ is $U$-left Kan extended from $\mathcal{C}^0$; we will show that $F \circ G$ is $U$-left Kan extended from $\mathcal{B}^0$. Fix an object $B \in \mathcal{B}$ and set $\mathcal{B}^0_B = \mathcal{B}^0 \times_B \mathcal{B}/_B$; we wish to show that the composite map

$$\theta : (\mathcal{B}^0_B)^\circ \hookrightarrow \mathcal{B}^0_B \to \mathcal{B} \xrightarrow{F \circ G} \mathcal{D}$$

is a $U$-colimit diagram. Set $C = G(B)$ and $\mathcal{C}^0_C = \mathcal{C}^0 \times_{\mathcal{C}} \mathcal{C}^0$. Since $G$ is an equivalence of ∞-categories, the induced map $G_B : \mathcal{B}/_B \to \mathcal{C}/_C$ is also an equivalence of ∞-categories (Corollary 4.6.4.19). Our assumption that $\mathcal{C}^0$ is a replete subcategory of $\mathcal{C}$ guarantees that $\mathcal{C}^0_C$ is a replete subcategory of $\mathcal{C}/_C$. In particular, the inclusion map $\mathcal{C}^0_C \hookrightarrow \mathcal{C}/_C$ is an isofibration, so that $G_B$ restricts to an equivalence of ∞-categories $G^0_B : \mathcal{B}^0_B \to \mathcal{C}^0_C$. By construction, the morphism $\theta$ is the composition of $(G^0_B)^\circ$ with the map

$$\theta' : (\mathcal{C}^0_C)^\circ \hookrightarrow \mathcal{C}^0_C \to \mathcal{C} \xrightarrow{F} \mathcal{D},$$

which is a $U$-colimit diagram by virtue of our assumption that $F$ is $U$-left Kan extended from $\mathcal{C}^0$. Applying Corollary 7.2.2.2 we deduce that $\theta$ is also a $U$-colimit diagram.

We now prove the converse. Assume that $F \circ G$ is $U$-left Kan extended from $\mathcal{B}^0$; we wish to show that $F$ is $U$-left Kan extended from $\mathcal{C}^0$. Let $H : \mathcal{C} \to \mathcal{B}$ be a homotopy inverse to $G$, so that $(G \circ H) : \mathcal{C} \to \mathcal{C}$ is isomorphic to the identity functor $\text{id}_C$. Since $\mathcal{C}^0 \subseteq \mathcal{C}$ is replete, it coincides with the inverse image $(G \circ H)^{-1} \mathcal{C}^0 = H^{-1} \mathcal{B}^0$. Applying the first part of the proof, we deduce that the functor $(F \circ G \circ H) : \mathcal{C} \to \mathcal{D}$ is $U$-left Kan extended from $\mathcal{C}^0$. The functor $F$ is isomorphic to $F \circ G \circ H$, and is therefore also $U$-left Kan extended from $\mathcal{C}^0$ (Remark 7.3.3.13). □

02ZE Remark 7.3.3.15 (Transitivity). Let $F : \mathcal{C} \to \mathcal{D}$, $U : \mathcal{D} \to \mathcal{E}$, and $V : \mathcal{E} \to \mathcal{E}'$ be functors of ∞-categories, and let $\mathcal{C}^0 \subseteq \mathcal{C}$ be a full subcategory. Suppose that $U \circ F$ is $V$-left Kan extended from $\mathcal{C}^0$. Then $F$ is $U$-left Kan extended from $\mathcal{C}^0$ if and only if it is $(V \circ U)$-left Kan extended from $\mathcal{C}^0$ (see Proposition 7.1.5.14). Similarly, if $U \circ F$ is $V$-right Kan extended from $\mathcal{C}^0$, then $F$ is $U$-right Kan extended from $\mathcal{C}^0$ if and only if it is $(V \circ U)$-right Kan extended from $\mathcal{C}^0$.

02ZF Remark 7.3.3.16. Let $F : \mathcal{C} \to \mathcal{D}$ and $U : \mathcal{D} \to \mathcal{E}$ be functors of ∞-categories, and let $\mathcal{C}^0 \subseteq \mathcal{C}$ be a full subcategory. Suppose that $U \circ F$ is left Kan extended from $\mathcal{C}^0$. Then $F$ is left Kan extended from $\mathcal{C}^0$ if and only if it is $U$-left Kan extended from $\mathcal{C}^0$; this follows by applying Remark 7.3.3.15 in the special case $\mathcal{E}' = \Delta^0$. Similarly, if $U \circ F$ is right Kan extended from $\mathcal{C}^0$, then $F$ is right Kan extended from $\mathcal{C}^0$ if and only if it is $U$-right Kan extended from $\mathcal{C}^0$. 
**Proposition 7.3.3.17** (Base Change). Suppose we are given a commutative diagram of ∞-categories

![Diagram](7.11)

where each square is a pullback and the diagonal maps are inner fibrations. Let $F : C \to D'$ be a functor of ∞-categories and $C^0 \subseteq C$ be a full subcategory. Then:

1. If $G \circ F$ is $H$-left Kan extended from $C^0$, then $F$ is $H'$-left Kan extended from $C^0$.

2. Assume that $U$ and $V$ are cartesian fibrations and that the functor $G$ carries $U$-cartesian morphisms of $D$ to $V$-cartesian morphisms of $E$. If $F$ is $H'$-left Kan extended from $C^0$, then $G \circ F$ is an $H$-left Kan extended from $C^0$.

**Proof.** Use Proposition 7.1.5.19.

**Corollary 7.3.3.18.** Suppose we are given a pullback diagram of ∞-categories

![Diagram](7.11)

where the vertical maps are inner fibrations. Let $F : C \to D'$ be a functor of ∞-categories and let $C^0 \subseteq C$ be a full subcategory. If $G \circ F$ is $U$-left Kan extended from $C^0$, then $F$ is $U'$-left Kan extended from $C^0$. The converse holds if $U$ is a cartesian fibration.

**Proof.** Apply Proposition 7.3.3.17 in the special case $B = E$. 

□
Corollary 7.3.3.19. Let $U : \mathcal{D} \to \mathcal{E}$ be an inner fibration of $\infty$-categories, let $\mathcal{D}_E = \{E\} \times_{\mathcal{E}} \mathcal{D}$ be the fiber of $U$ over an object $E \in \mathcal{E}$, let $F : \mathcal{C} \to \mathcal{D}_E$ be a functor of $\infty$-categories, and $\mathcal{C}^0 \subseteq \mathcal{C}$ be a full subcategory. If $F$ is $U$-left Kan extended from $\mathcal{C}^0$ (when regarded as a functor from $\mathcal{C}$ to $\mathcal{D}$), then it is left Kan extended from $\mathcal{C}^0$ (when regarded as a functor from $\mathcal{C}$ to $\mathcal{D}_E$). The converse holds if $U$ is a cartesian fibration.

Proof. Apply Corollary [7.3.3.18](#) in the special case $\mathcal{E}' = \{E\}$. 

### 7.3.4 Kan Extensions along Fibrations

In this section, we study the formation of left Kan extension along cocartesian fibrations. We can state a preliminary version of our main result as follows:

Proposition 7.3.4.1. Let $\delta : K \to C$ be a cocartesian fibration of $\infty$-categories. Suppose we are given functors of $\infty$-categories $F_0 : K \to \mathcal{D}$ and $F : C \to \mathcal{D}$ and a natural transformation $\beta : F_0 \to F \circ \delta$. The following conditions are equivalent:

1. The natural transformation $\beta$ exhibits $F$ as a left Kan extension of $F_0$ along $\delta$.

2. For each object $C \in C$, the restriction of $\beta$ to the fiber $K_C = \{C\} \times_C K$ determines a natural transformation $F_0|_{K_C} \to F(C)$ which exhibits $F(C)$ as a colimit of the diagram $F_0|_{K_C}$ in the $\infty$-category $\mathcal{D}$.

Proof. By virtue of Corollary [7.2.2.7](#) it will suffice to show that for each object $C \in C$, the tautological map

$$K_C = K \times_C \{C\} \hookrightarrow K \times_C C / C$$

is right cofinal. Since $\delta$ is a cocartesian fibration, it will suffice to show that the inclusion map $\{id_C\} \hookrightarrow C / C$ is right cofinal (Proposition [7.2.3.13](#)). This follows from Corollary [4.6.6.25](#) since $id_C$ is a final object of the $\infty$-category $C / C$ (Proposition [4.6.6.23](#)). 

Corollary 7.3.4.2. Let $\delta : K \to C$ be a cocartesian fibration of $\infty$-categories and let $F : K \star_C C \to \mathcal{D}$ be a functor of $\infty$-categories. The following conditions are equivalent:

1. The functor $F$ is left Kan extended from $K$.

2. For every object $C \in C$, the functor

$$F_C : K_C \simeq K \times_C \{C\} \hookrightarrow K \star_C C \xrightarrow{F} \mathcal{D}$$

is a colimit diagram.

Proof. Combine Propositions [7.3.4.1](#) and [7.3.2.10](#). 

Corollary [7.3.4.2](#) generalizes to the setting of relative Kan extensions:
Chapter 7. Limits and Colimits

Proposition 7.3.4.3. Let \( \delta : \mathcal{K} \to \mathcal{C} \) be a cocartesian fibration of \( \infty \)-categories and let \( F : \mathcal{K} \star_{\mathcal{C}} \mathcal{C} \to \mathcal{D} \) and \( U : \mathcal{D} \to \mathcal{E} \) be functors. The following conditions are equivalent:

1. The functor \( F \) is \( U \)-left Kan extended from \( \mathcal{K} \).

2. For every object \( C \in \mathcal{C} \), the functor

\[
F_C : \mathcal{K}^C \simeq \mathcal{K} \star_{\{C\}} \mathcal{C} \hookrightarrow \mathcal{K} \star_{\mathcal{C}} \mathcal{C} \xrightarrow{F} \mathcal{D}
\]

is a \( U \)-colimit diagram.

Proof. By virtue of Proposition 7.3.3.5, it will suffice to show that for each object \( C \in \mathcal{C} \), the following conditions are equivalent:

1. The functor \( F \) is \( U \)-left Kan extended from \( \mathcal{K} \) at \( C \).

2. The functor \( F_C \) is a \( U \)-colimit diagram.

This follows from Corollary 7.2.2.3, since the tautological map

\[
\mathcal{K}_C \simeq \{\text{id}_C\} \times_{\mathcal{C}/C} \mathcal{K}/C \hookrightarrow \mathcal{K}/C
\]

is right cofinal (as noted in the proof of Proposition 7.3.4.1).

Our next goal is to establish a companion to Proposition 7.3.4.1, which provides necessary and sufficient conditions for the existence of a left Kan extension.

Proposition 7.3.4.4. Let \( \delta : \mathcal{K} \to \mathcal{C} \) be a cocartesian fibration of \( \infty \)-categories and let \( F_0 : \mathcal{K} \to \mathcal{D} \) be a functor of \( \infty \)-categories. The following conditions are equivalent:

1. The functor \( F_0 \) admits a left Kan extension along \( \delta \).

2. For every object \( C \in \mathcal{C} \), the induced diagram

\[
\mathcal{K}_C = \{C\} \times_{\mathcal{C}} \mathcal{K} \hookrightarrow \mathcal{K} \xrightarrow{F_0} \mathcal{D}
\]

has a colimit in the \( \infty \)-category \( \mathcal{D} \).

Note that the implication \((1) \Rightarrow (2)\) of Proposition 7.3.4.4 follows immediately from Proposition 7.3.4.1. To prove the converse, it will be convenient to again translate to a question about the inclusion map \( \mathcal{K} \hookrightarrow \mathcal{K} \star_{\mathcal{C}} \mathcal{C} \), which we will address in a more general form. First, we need a variant of Corollary 7.1.6.6.
Lemma 7.3.4.5. Let $\delta : K \to C$ be a cocartesian fibration of simplicial sets, let $U : D \to E$ be an isofibration of $\infty$-categories, let $C_0 \subseteq C$ be a simplicial subset which contains every vertex of $C$, and set $K_0 = C_0 \times C K$. Suppose we are given a lifting problem

\[
\begin{array}{ccc}
K \amalg_{K_0} (K_0 \star_{C_0} C_0) & \to & D \\
\downarrow & & \downarrow U \\
K \star_{C} C & \to & E
\end{array}
\]

(7.12)

which satisfies the following condition:

(*) Let $\sigma : \Delta^n \to C$ be an $n$-simplex which is not contained in $C_0$ and set $C = \sigma(0)$. Then the composite map

\[
K_C \simeq K_C \star \{C\} \to K_0 \star_{C_0} C_0 \to D
\]

is a $U$-colimit diagram in the $\infty$-category $D$.

Then the lifting problem (7.12) admits a solution.

Proof. Without loss of generality, we may assume that $C$ is an $\infty$-category (working one simplex at a time, we could even assume that $C = \Delta^n$ is a standard simplex and that $C_0 = \partial \Delta^n$ is its boundary). Set $\overline{K} = K \star_{C} C$, so that $\delta$ extends to a map

\[
\delta : \overline{K} = K \star_{C} C \to C \star_{C} C \simeq \Delta^1 \times C \to C.
\]

Since $\delta$ is a cocartesian fibration, Lemma 5.2.3.17 guarantees that $\overline{\delta}$ is also a cocartesian fibration. Applying Proposition 5.3.6.6 we obtain a commutative diagram of $\infty$-categories

\[
\begin{array}{ccc}
\text{Res}_{\overline{K}/C}(D \times \overline{K}) & \to & \text{Res}_{K}/C(D \times K) \\
\downarrow T & & \downarrow U_0 \\
\text{Res}_{\overline{K}/C}(\overline{E} \times \overline{K}) & \to & \text{Res}_{K}/C(\overline{E} \times K)
\end{array}
\]

(7.13)

where the diagonal arrows are cartesian fibrations and the morphisms on the outside of the diagram preserve cartesian morphisms. Applying Proposition 5.1.4.20 we see that the induced map

\[
T' : \text{Res}_{\overline{K}/C}(D \times K) \times_{\text{Res}_{\overline{K}/C}(\overline{E} \times K)} \text{Res}_{\overline{K}/C}(\overline{E} \times \overline{K}) \to C
\]
is also a cartesian fibration, and that the outer square of the diagram (7.13) determines a functor
\[ V : \text{Res}_{\mathcal{K}/\mathcal{C}}(\mathcal{D} \times \mathcal{K}) \to \text{Res}_{\mathcal{K}/\mathcal{C}}(\mathcal{D} \times \mathcal{K}) \times_{\text{Res}_{\mathcal{K}/\mathcal{C}}(\mathcal{E} \times \mathcal{K})} \text{Res}_{\mathcal{K}/\mathcal{C}}(\mathcal{E} \times \mathcal{K}) \to \mathcal{C} \]
which carries \( T \)-cartesian morphisms to \( T' \)-cartesian morphisms. Moreover, the functor \( V \) is an isofibration (Proposition 4.5.9.17).

Unwinding the definitions, we can rewrite (7.12) as a lifting problem
\[
\begin{array}{ccc}
\mathcal{C}_0 & \xrightarrow{G_0} & \text{Res}_{\mathcal{K}/\mathcal{C}}(\mathcal{D} \times \mathcal{K}) \\
\downarrow & & \downarrow \text{V} \\
\mathcal{C} & \xrightarrow{\text{Res}_{\mathcal{K}/\mathcal{C}}(\mathcal{D} \times \mathcal{K}) \times_{\text{Res}_{\mathcal{K}/\mathcal{C}}(\mathcal{E} \times \mathcal{K})} \text{Res}_{\mathcal{K}/\mathcal{C}}(\mathcal{E} \times \mathcal{K})} \to \mathcal{C}
\end{array}
\]

By virtue of Corollary 7.1.6.6, to show that this lifting problem admits a solution, it will suffice to verify the following:

\((*)'\) Let \( \sigma : \Delta^n \to \mathcal{C} \) be an \( n \)-simplex which is not contained in \( \mathcal{C}_0 \) and set \( C = \sigma(0) \). Then \( G_0(C) \) is a \( V \)-initial object of the \( \infty \)-category \( \text{Res}_{\mathcal{K}/\mathcal{C}}(\mathcal{D} \times \mathcal{K}) \).

Unwinding the definitions, we see that the functor \( T^{-1}\{C\} \to T'^{-1}\{C\} \) induced by \( V \) can be identified with the restriction map
\[ V_C : \text{Fun}(\mathcal{K}_C, \mathcal{D}) \to \text{Fun}(\mathcal{K}_C, \mathcal{D}) \times_{\text{Fun}(\mathcal{K}_C, \mathcal{E})} \text{Fun}(\mathcal{K}_C, \mathcal{E}). \]

Combining assumption \((*)\) with Proposition 7.1.6.3, we see that \( G_0(C) \) is a \( V_C \)-initial object of the \( \infty \)-category \( \text{Fun}(\mathcal{K}_C, \mathcal{D}) \). Proposition 7.1.4.19 then guarantees that \( G_0(C) \) is also \( V \)-initial when regarded as an object of the \( \infty \)-category \( \text{Res}_{\mathcal{K}/\mathcal{C}}(\mathcal{D} \times \mathcal{K}) \).

\[ \square \]

**Lemma 7.3.4.6.** Let \( \delta : \mathcal{K} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets, let \( U : \mathcal{D} \to \mathcal{E} \) be an isofibration of \( \infty \)-categories, and suppose we are given a lifting problem
\[
\begin{array}{ccc}
\mathcal{K} & \xrightarrow{F_0} & \mathcal{D} \\
\downarrow \mathcal{K} \xrightarrow{F} \mathcal{E} \\
\mathcal{K} \times_{\mathcal{C}} \mathcal{C} & \xrightarrow{G} & \mathcal{E}
\end{array}
\]

with the following property:
(* For each vertex \( C \in \mathcal{C} \), the induced lifting problem

\[
\begin{array}{ccc}
\mathcal{K}_C & \xrightarrow{F_C} & \mathcal{D} \\
\downarrow & & \downarrow U \\
\mathcal{K}_C \star \{C\} & \xrightarrow{G} & \mathcal{E}
\end{array}
\]

admits a solution \( F_C : \mathcal{K}_C \to \mathcal{D} \) which is a \( U \)-colimit diagram.

Then (7.14) admits a solution \( F : \mathcal{K} \star_\mathcal{C} \mathcal{C} \to \mathcal{D} \) satisfying \( F|_{\mathcal{X}^C} = F_C \) for each vertex \( C \in \mathcal{C} \).

Proof. Let \( \mathcal{C}_0 = \text{sk}_0(\mathcal{C}) \) be the 0-skeleton of \( \mathcal{C} \) and set \( \mathcal{K}_0 = \mathcal{C}_0 \times \mathcal{K} = \coprod_{C \in \mathcal{C}} \mathcal{K}_C \), so that we can amalgamate \( F_0 \) with the morphisms \( \{F_C\}_{C \in \mathcal{C}} \) to obtain a map \( F_1 : \mathcal{K} \coprod_{\mathcal{K}_0} (\mathcal{K}_0 \star_0 \mathcal{C}_0) \to \mathcal{D} \). To prove Lemma 7.3.4.6 we must show that the lifting problem

\[
\begin{array}{ccc}
\mathcal{K} \coprod_{\mathcal{K}_0} (\mathcal{K}_0 \star_0 \mathcal{C}_0) & \xrightarrow{F_1} & \mathcal{D} \\
\downarrow & & \downarrow U \\
\mathcal{C} \star_\mathcal{C} \mathcal{C} & \xrightarrow{G} & \mathcal{E}
\end{array}
\]

has a solution, which is a special case of Lemma 7.3.4.5. \qed

**Proposition 7.3.4.7.** Let \( \delta : \mathcal{K} \to \mathcal{C} \) be a cocartesian fibration of \( \infty \)-categories, let \( U : \mathcal{D} \to \mathcal{E} \) be an isofibration of \( \infty \)-categories, and suppose we are given a lifting problem

\[
\begin{array}{ccc}
\mathcal{K} & \xrightarrow{F_0} & \mathcal{D} \\
\downarrow & \xrightarrow{F} & \downarrow U \\
\mathcal{K} \star_\mathcal{C} \mathcal{C} & \to & \mathcal{E}
\end{array}
\] (7.15)

The following conditions are equivalent:

(1) The lifting problem (7.15) has a solution \( F : \mathcal{K} \star_\mathcal{C} \mathcal{C} \to \mathcal{D} \) which is \( U \)-left Kan extended from \( \mathcal{K} \).
(2) For every object \( C \in \mathcal{C} \), the associated lifting problem

\[
\begin{array}{ccc}
\mathcal{K}_C & \to & \mathcal{D} \\
\downarrow & & \downarrow \mathcal{U} \\
\mathcal{K}_C & \to & \mathcal{E}
\end{array}
\]

has a solution \( \mathcal{K}_C^* \to \mathcal{D} \) which is a \( \mathcal{U} \)-colimit diagram.

**Proof.** Combine Lemma 7.3.4.6 with Proposition 7.3.4.3. \( \square \)

**Corollary 7.3.4.8.** Let \( \delta : \mathcal{K} \to \mathcal{C} \) be a cocartesian fibration of \( \infty \)-categories and let \( F_0 : \mathcal{K} \to \mathcal{D} \) be a functor of \( \infty \)-categories. The following conditions are equivalent:

1. There exists a functor \( F : \mathcal{K} \star \mathcal{C} \to \mathcal{D} \) which is left Kan extended from \( \mathcal{K} \) and satisfies \( F|_\mathcal{K} = F_0 \).

2. For every object \( C \in \mathcal{C} \), the diagram

\[
\mathcal{K}_C = \{C\} \times_\mathcal{C} \mathcal{K} \hookrightarrow \mathcal{K} \xrightarrow{F_0} \mathcal{D}
\]

admits a colimit in the \( \infty \)-category \( \mathcal{D} \).

**Proof of Proposition 7.3.4.4.** Let \( \delta : \mathcal{K} \to \mathcal{C} \) be a cocartesian fibration of \( \infty \)-categories and let \( F_0 : \mathcal{K} \to \mathcal{D} \) be a functor of \( \infty \)-categories. Suppose that, for every object \( C \in \mathcal{C} \), the diagram

\[
\mathcal{K}_C = \{C\} \times_\mathcal{C} \mathcal{K} \hookrightarrow \mathcal{K} \xrightarrow{F_0} \mathcal{D}
\]

has a colimit in the \( \infty \)-category \( \mathcal{D} \). Applying Corollary 7.3.4.8, we deduce that there exists a functor \( F : \mathcal{K} \star \mathcal{C} \to \mathcal{D} \) which is left Kan extended from \( \mathcal{K} \) and satisfies \( F|_\mathcal{K} = F_0 \). Applying Proposition 7.3.1.15, we see that the restriction \( F|_\mathcal{C} \) is a left Kan extension of \( F_0 \) along \( \delta \). \( \square \)

### 7.3.5 Existence of Kan Extensions

Our goal in this section is to establish the following existence criterion for Kan extensions:

**Proposition 7.3.5.1.** Let \( \mathcal{C} \) and \( \mathcal{D} \) be \( \infty \)-categories, and suppose we are given diagrams \( \delta : K \to \mathcal{C} \) and \( F_0 : K \to \mathcal{D} \). Then:

- The diagram \( F_0 \) admits a left Kan extension along \( \delta \) if and only if, for every object \( C \in \mathcal{C} \), the diagram

\[
K|_C = K \times_\mathcal{C} C|_C \to K \xrightarrow{F_0} \mathcal{D}
\]

has a colimit in the \( \infty \)-category \( \mathcal{D} \).
• The diagram $F_0$ admits a right Kan extension along $\delta$ if and only if, for every object $C \in \mathcal{C}$, the diagram

$$K_{C/} = K \times_{\mathcal{C}} K_{C/} \to K \xrightarrow{F_0} \mathcal{D}$$

has a limit in the $\infty$-category $\mathcal{D}$.

**Corollary 7.3.5.2.** Let $\mathcal{C}$ and $\mathcal{D}$ be $\infty$-categories and let $\delta : K \to \mathcal{C}$ be a diagram. Assume that, for every object $C \in \mathcal{C}$, the $\infty$-category $\mathcal{D}$ admits $K_{C/}$-indexed colimits. Then every diagram $F_0 : K \to \mathcal{D}$ admits a left Kan extension along $\delta$.

**Corollary 7.3.5.3.** Let $\mathcal{C}$ be a category, let $\mathcal{G} : \mathcal{C} \to \operatorname{Set}_\Delta$ be a diagram of simplicial sets, let $\mathcal{D}$ be an $\infty$-category, and let $F_0 : \operatorname{holim}(\mathcal{G}) \to \mathcal{D}$ be a diagram. The following conditions are equivalent:

1. The diagram $F_0$ admits a left Kan extension along the projection map $U : \operatorname{holim}(\mathcal{G}) \to \mathcal{C}$.

2. For every object $C \in \mathcal{C}$, the diagram

$$\mathcal{G}(C) \simeq \{C\} \times_{\mathcal{C}} \operatorname{holim}(\mathcal{G}) \to \operatorname{holim}(\mathcal{G}) \xrightarrow{F_0} \mathcal{D}$$

admits a colimit in the $\infty$-category $\mathcal{D}$.

**Proof.** For each object $C \in \mathcal{C}$, the inclusion map

$$\mathcal{G}(C) \hookrightarrow \mathcal{C} \times_{\mathcal{C}} \operatorname{holim}(\mathcal{G}) \simeq \operatorname{holim}(\mathcal{G})$$

is right anodyne (Example 7.2.3.12), and therefore right cofinal. The desired result now follows by combining Proposition 7.3.5.1 with Corollary 7.2.2.10. $\square$

**Remark 7.3.5.4.** In the situation of Corollary 7.3.5.3, suppose we are given a functor $F : \mathcal{C} \to \mathcal{D}$ and a natural transformation $\beta : F_0 \to F \circ U$. Then $\beta$ exhibits $F$ as a left Kan extension of $F$ along $U$ if and only if, for every object $C \in \mathcal{C}$, the induced natural transformation $\beta_C : F_0|_{\mathcal{G}(C)} \to F(C)$ exhibits $F(C)$ as a colimit of the diagram $F_0|_{\mathcal{G}(C)}$.

In the special case where $\delta$ is a cocartesian fibration, Proposition 7.3.5.1 is essentially a reformulation of Proposition 7.3.4.4. We will proceed in general by reducing to this special case (see [49] for a similar approach). With an eye toward future applications, we first consider a variant of Proposition 7.3.5.1 in the setting of relative Kan extensions.
Proposition 7.3.5.5. Let $C$ be an $\infty$-category, let $C^0 \subseteq C$ be a full subcategory, let $U : D \to E$ be an isofibration of $\infty$-categories, and suppose we are given a lifting problem

$$F_0 : C^0 \to D$$

Then (7.16) admits a solution $F : C \to D$ which is $U$-left Kan extended from $C^0$ if and only if, for every object $C \in C$, the following condition is satisfied:

$(\ast_C)$ The induced lifting problem

$$C^0_{/C} \to D$$

admits a solution $F_C : (C^0_{/C})^\circ \to D$ which is a $U$-colimit diagram.

Proof. Assume that condition $(\ast_C)$ is satisfied for every object $C \in C$; we will show that the lifting problem (7.16) admits a solution $F : C \to D$ which is $U$-left Kan extended from $C^0$ (the converse follows immediately from the definitions). Let $K$ denote the oriented fiber product $C^0 \times_C C$: that is, the full subcategory of $\text{Fun}(\Delta^1, C)$ spanned by those morphisms $e : X \to Y$ of $C$ such that $X$ belongs to the subcategory $C^0$. Let $\pi : K \to C$ and $\pi' : K \to C$ be the evaluation maps, given on objects by $\pi(e) = X$ and $\pi'(e) = Y$, respectively. We then have a natural transformation $\alpha : \pi \to \pi'$ (which carries each morphism $e : X \to Y$ to itself). Regarding $K$ as an object of $(\text{Set}_\Delta)_{/C}$ via the functor $\pi'$, let $K \star_C C$ denote the relative join of Construction [5.2.3.1]. We will write $\iota_K : K \hookrightarrow K \star_C C$ and $\iota_C : C \hookrightarrow K \star_C C$ for the inclusion maps, and $\iota_{C^0}$ for the restriction of $\iota_C$ to the full subcategory $C^0 \subseteq C$. The natural transformation $\alpha$ then determines a functor $S : K \star_C C \to C$ satisfying $S \circ \iota_K = \pi$ and $S \circ \iota_C = \text{id}_C$. Consider the lifting problem

$$K \star_C C \to C \to E.$$
For each object \( C \in \mathcal{C} \), write \( \mathcal{K}_C \) for the fiber \( \pi'^{-1}\{C\} \), so that (7.18) restricts to a lifting problem

\[
\begin{array}{ccc}
\mathcal{K}_C & \xrightarrow{\pi'} & \mathcal{D} \\
\mathcal{K}_C \times_{\{C\}} \{C\} & \xrightarrow{\pi'} & \mathcal{E}.
\end{array}
\]

(7.19)

Note that \( \mathcal{K}_C \) can be identified with the oriented fiber product \( C^0 \times_C \{C\} \). Moreover, after precomposing with the slice diagonal equivalence \( C^0/\mathcal{C} \to C^0 \times_C \{C\} \) of Theorem 4.6.4.17 and Proposition 7.3.4.3, we recover the lifting problem (7.17). Combining assumption \((\ast_C)\) with Proposition 7.2.2.9, we deduce that the lifting problem (7.19) admits a solution \( \overline{F}_C : \mathcal{K}_C \to \mathcal{D} \) which is a \( U \)-colimit diagram. Since \( \pi' : \mathcal{K} \to \mathcal{C} \) is a cocartesian fibration (Proposition 5.3.7.1), Proposition 7.3.4.7 guarantees that the lifting problem (7.18) admits a solution \( F : \mathcal{K} \times_C \mathcal{C} \to \mathcal{D} \) which is \( U \)-left Kan extended from \( \mathcal{K} \).

Note that the diagonal inclusion \( \mathcal{C} \hookrightarrow \text{Fun}(\Delta^1, \mathcal{C}) \) restricts to a map \( \delta : C^0 \hookrightarrow \mathcal{K} \). Let \( \beta \) denote the composite map

\[
\Delta^1 \times C^0 \simeq C^0 \times C^0 \xrightarrow{\delta \times \text{id}} \mathcal{K} \times_C \mathcal{C},
\]

which we regard as a natural transformation from \( \iota_{\mathcal{K}} \circ \delta \) to \( \iota_{C^0} \). This natural transformation carries each object \( X \in C^0 \) to a morphism \( \beta_X : \iota_{\mathcal{K}}(\text{id}_X) \to \iota_{C}(X) \) in the \( \infty \)-category \( \mathcal{K} \times_C \mathcal{C} \). Since \( \text{id}_X \) is a final object of the \( \infty \)-category \( \mathcal{K}_X \simeq C^0 \times_C \{X\} \) (Proposition 4.6.6.23) and \( \overline{F}|_{\mathcal{K}_X} \) is a \( U \)-colimit diagram (Proposition 7.3.4.3), the image \( \overline{F}(\beta_X) \) is a \( U \)-cocartesian morphism of \( \mathcal{D} \) (Corollary 7.2.2.5). Since \( U(\overline{F}(\beta_X)) = \text{id}_{\mathcal{K}_X} \) is an isomorphism in \( \mathcal{E} \), we conclude that \( \overline{F}(\beta_X) \) is an isomorphism in \( \mathcal{D} \). Applying Corollary 4.4.5.9, we deduce that \( \overline{F}(\beta) \) can be lifted to an isomorphism \( F \to \overline{F} \circ \iota_{C^0} \) in the \( \infty \)-category \( \text{Fun}(\mathcal{C}, \mathcal{D}) \), where \( F : \mathcal{C} \to \mathcal{D} \) is a solution to the lifting problem (7.16). We will show \( \overline{F} \circ \iota_{C^0} \) is \( U \)-left Kan extended from \( C^0 \), so that \( F \) is also \( U \)-left Kan extended from \( C^0 \) (Remark 7.3.3.13).

Fix an object \( C \in \mathcal{C} \), let \( c : (C^0/C)^\triangleright \to \mathcal{C} \) be the slice contraction map and set \( T^+ = \iota_{C^0} \circ c \); we wish to show that \( T^+ : (C^0/C)^\triangleright \to \mathcal{D} \) is a \( U \)-colimit diagram. Let \( \psi : \mathcal{C}/\mathcal{C} \hookrightarrow \mathcal{C} \times_C \{C\} \) be the slice diagonal of Construction 4.6.4.13. Note that \( \psi \) is an equivalence of right fibrations over \( \mathcal{C} \) (Theorem 4.6.4.17 and Proposition 5.1.6.5), and therefore restricts to an equivalence of full subcategories \( \psi_0 : C^0/C \to C^0 \times_C \{C\} = \mathcal{K}_C \). Let \( T^- \) denote the composite functor

\[
(C^0/C)^\triangleright \xrightarrow{\psi_0^\triangleright} \mathcal{K}_C^\triangleright = \mathcal{K}_C \times_{\{C\}} \{C\} \hookrightarrow \mathcal{K} \times_C \mathcal{C}.
\]

Because \( \overline{F} \) is \( U \)-left Kan extended from \( \mathcal{K} \), the \( \overline{F}|_{\mathcal{K}_C^\triangleright} \) is a \( U \)-colimit diagram in \( \mathcal{D} \) (Proposition 7.3.4.3). Since the functor \( \psi_0 \) is right cofinal (Corollary 7.2.1.12), the functor \( \overline{F} \circ T^- \) is also a \( U \)-colimit diagram (Corollary 7.2.2.2). Beware that the functors \( T^- , T^+ : (C^0/C)^\triangleright \to \mathcal{K} \times_C \mathcal{C} \)
are not isomorphic: if \( \tilde{X} \) is an object of the \( \infty \)-category \( \mathcal{C}/C \) given by a morphism \( e : X \to C \) in \( \mathcal{C} \), then we have \( T^+(\tilde{X}) = \iota_C(X) \) and \( T^-(\tilde{X}) = \iota_K(e) \). However, we will show that the functors \( \mathcal{F} \circ T^- \) and \( \mathcal{F} \circ T^+ \) are isomorphic when regarded as objects of the \( \infty \)-category \( \text{Fun}((\mathcal{C}/C)^\circ, \mathcal{D}) \), so that \( \mathcal{F} \circ G^+ \) a U-colimit diagram by virtue of Proposition 7.1.5.13.

Let \( b : (\mathcal{C}/C)^\circ \to \Delta^1 \) be the map carrying \( \mathcal{C}/C \) to the vertex 0 \( \in \Delta^1 \) and the cone point of \( (\mathcal{C}/C)^\circ \) to the vertex 1 \( \in \Delta^1 \). Note that the map \( (b,c) : (\mathcal{C}/C)^\circ \to \Delta_1 \times \mathcal{C} \) factors through the full subcategory \( \mathcal{C}^0 \subseteq \mathcal{C} \subseteq \Delta_1 \times \mathcal{C} \).

We let \( T : (\mathcal{C}/C)^\circ \to \mathcal{K} \ast \mathcal{C} \) denote the composite functor

\[
(\mathcal{C}/C)^\circ \xrightarrow{(b,c)} \mathcal{C}^0 \xrightarrow{\delta \ast \text{id}} \mathcal{K} \ast \mathcal{C}.
\]

Concretely, the functor \( T \) carries the cone point of \( (\mathcal{C}/C)^\circ \) to the object \( \iota_C(C) \in \mathcal{K} \ast \mathcal{C} \), and carries an object \((e : X \to C) \in \mathcal{C}/C \) to the object \( \iota_K(\text{id}_X) \in \mathcal{K} \ast \mathcal{C} \). We will complete the proof by verifying the following:

(a) There exists a natural transformation of functors \( \gamma^+ : T \to T^+ \), which carries the cone point of \( (\mathcal{C}/C)^\circ \) to the identity morphism \( \iota_C(\text{id}_C) \), and carries each object \((e : X \to C) \) to the morphism \( \beta_X \).

(b) There exists a natural transformation of functors \( \gamma^- : T \to T^- \), which carries the cone point of \( (\mathcal{C}/C)^\circ \) to the identity morphism \( \iota_C(\text{id}_C) \) and carries each object \((e : X \to C) \) to the morphism of \( \mathcal{K} \subseteq \text{Fun}(\Delta^1, \mathcal{C}) \) given by a commutative diagram

\[
\begin{array}{ccc}
X & \xrightarrow{\text{id}_X} & X \\
\downarrow \text{id}_X & & \downarrow e \\
X & \xrightarrow{e} & C \\
\end{array}
\]

in the \( \infty \)-category \( \mathcal{C} \).

Assuming this has been done, we observe that the natural transformations \( \mathcal{F}(\gamma^-) \) and \( \mathcal{F}(\gamma^+) \) carry each object of \( (\mathcal{C}/C)^\circ \) to an isomorphism in the \( \infty \)-category \( \mathcal{D} \) and therefore supply isomorphisms \( \mathcal{F} \circ T^- \cong \mathcal{F} \circ T^+ \) in the \( \infty \)-category \( \text{Fun}((\mathcal{C}/C)^\circ, \mathcal{D}) \).

We begin by constructing the natural transformation \( \gamma^+ \). Let \( b' : (\mathcal{C}/C)^\circ \to \Delta^1 \) be the constant map taking the value 1, so that there is a unique natural transformation \( \xi : b \to b' \). Note that \( \xi \) induces a natural transformation from \((b,c)\) to \((b',c)\) in the \( \infty \)-category \( \text{Fun}((\mathcal{C}/C)^\circ, \mathcal{K} \ast \mathcal{C}) \). Composing with the map \( (\delta \ast \text{id}) : \mathcal{C}^0 \ast \mathcal{C} \to \mathcal{K} \ast \mathcal{C} \), we obtain a natural transformation \( \gamma^+ : T \to T^+ \) satisfying the requirements of (a).
We now construct the natural transformation $\gamma^-$. Note that $T$ and $T^-$ both carry $\mathcal{C}_0/C$ into $\mathcal{K}$ and the cone point of $(\mathcal{C}_0/C)^0$ to the object $\iota_C(C)$ and can therefore be identified with functors $T_0, T^-_0 : \mathcal{C}_0/C \to \mathcal{K} \times \mathcal{C}_0/C$. Let $\sigma$ be an $n$-simplex of the product $\Delta^1 \times \mathcal{C}_0$, which we identify with a pair $(\epsilon, \tau)$ where $\epsilon : [n] \to [1]$ is a nondecreasing function and $\tau : \Delta^{n+1} \to \mathcal{C}$ has the property that $\tau|_{\Delta^n}$ factors through $\mathcal{C}_0$ and $\tau(n+1) = C$. Let $\rho : \Delta^1 \times \Delta^n \to \Delta^{n+1}$ denote the maps given on vertices by the formulae

$$
\rho(i, j) = \begin{cases} 
n + 1 & \text{if } i = 1 = \epsilon(j) \\
j & \text{otherwise}
\end{cases} \quad \rho'(j) = \begin{cases} 
j & \text{if } j \leq n \text{ and } \epsilon(j) = 0 \\
n + 1 & \text{otherwise}
\end{cases}
$$

Then $(\rho \circ \tau) : \Delta^1 \times \Delta^n \to \mathcal{C}$ can be identified with an $n$-simplex of the simplicial set $\mathcal{K} \subseteq \operatorname{Fun}(\Delta^1, \mathcal{C})$, so that $(\rho \circ \tau, \rho' \circ \tau)$ is an $n$-simplex of $\mathcal{K} \times \mathcal{C}_0/C$. The construction $\sigma \mapsto (\rho \circ \tau, \rho' \circ \tau)$ depends functorially on $[n]$, and therefore determines a morphism of simplicial sets

$$
\Delta^1 \times \mathcal{C}_0 \to \mathcal{K} \times \mathcal{C}_0/C,
$$

We can identify this map with a natural transformation $\gamma^-_0 : T_0 \to T^-$, which then determines a natural transformation $\gamma^- : T \to T^-$ satisfying the requirements of (b).

**Corollary 7.3.5.6.** Let $\mathcal{C}$ be an $\infty$-category, let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a full subcategory, let $F_0 : \mathcal{C}_0 \to \mathcal{D}$ be a functor of $\infty$-categories. Then:

- The functor $F_0$ admits a left Kan extension $F : \mathcal{C} \to \mathcal{D}$ if and only if, for every object $C \in \mathcal{C}$, the diagram

$$
\mathcal{C} \times \mathcal{C}_0/C \to \mathcal{C}_0^0 \xrightarrow{F_0} \mathcal{D}
$$

has a colimit in the $\infty$-category $\mathcal{D}$.

- The functor $F_0$ admits a right Kan extension $F : \mathcal{C} \to \mathcal{D}$ if and only if, for every object $C \in \mathcal{C}$, the diagram

$$
\mathcal{C} \times \mathcal{C}_C/C \to \mathcal{C} \xrightarrow{F_0} \mathcal{D}
$$

has a limit in the $\infty$-category $\mathcal{D}$.

**Proof.** The first assertion follows by applying the criterion of Proposition 7.3.5.5 in the special case $E = \Delta^0$, and the second assertion follows by a similar argument. \qed

**Corollary 7.3.5.7.** Let $\mathcal{C}$ be an $\infty$-category, let $\mathcal{C}_0 \subseteq \mathcal{C}$ be a coreflective full subcategory, let $U : \mathcal{D} \to \mathcal{E}$ be a cocartesian fibration of $\infty$-categories. Then every lifting problem

$$
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{G} & \mathcal{E} \\
\downarrow & & \downarrow \\
\mathcal{C} \times \mathcal{C}_0/C & \xrightarrow{F} & \mathcal{D} \\
\downarrow & & \downarrow \\
\mathcal{C} & \xrightarrow{F_0} & \mathcal{D}
\end{array}
$$

(7.20)
admits a solution $F : C \to D$ which is $U$-left Kan extended from $C^0$.

Proof. By virtue of Proposition 7.3.5.5 it will suffice to show that for every object $C \in C$, the associated lifting problem

$$
\begin{array}{ccc}
C^0 & \xrightarrow{F^0} & D \\
\downarrow \quad \quad \quad \quad \quad \downarrow U & & \downarrow U \\
(C^0)^{op} & \xrightarrow{G} & \mathcal{E}
\end{array}
$$

admits a solution which is a $U$-colimit diagram. Our assumption that $C^0$ is a coreflective subcategory of $C$ guarantees that the $\infty$-category $C^0_{/C}$ has a final object, so the desired result follows from Corollary 7.2.2.14. \qed

Proof of Proposition 7.3.5.1. Let $C$ and $D$ be $\infty$-categories, and suppose we are given diagrams $\delta : K \to C$ and $F_0 : K \to D$ with the property that, for every object $C \in C$, the composite map

$$K_{/C} = K \times_C C_{/C} \to K \xrightarrow{F_0} D$$

has a colimit in the $\infty$-category $D$. We wish to show that $F_0$ has a left Kan extension along $\delta$ (the converse assertion is immediate from the definitions, and the analogous assertion for right Kan extensions will follow by a similar argument). Using Corollary 4.1.3.3, we can choose an inner anodyne morphism $\iota : K \to K$, where $K$ is an $\infty$-category. Since $C$ and $D$ are $\infty$-categories, we can extend $\delta$ and $F_0$ to functors $\overline{\delta} : K \to C$ and $\overline{F_0} : K \to D$, respectively (Proposition 4.1.3.1). For every object $C \in C$, the induced map $K \times_C C_{/C} \hookrightarrow K \times_C C_{/C}$ is a categorical equivalence (Corollary 5.7.7.6), and therefore right cofinal (Corollary 7.2.1.12). Applying Proposition 7.2.2.9 we deduce that the composite map

$$K \times_C C_{/C} \to K \xrightarrow{\overline{F_0}} D$$

has a colimit in $D$. Corollary 7.3.5.6 now guarantees that the functor $\overline{F_0}$ admits a left Kan extension $\overline{F} : K \times_C C \to D$. Set $F = \overline{F}_{|C}$. Applying Proposition 7.3.2.10, we obtain a natural transformation $\overline{\beta} : \overline{F}_0 \to F \circ \overline{\delta}$ which exhibits $F$ as a left Kan extension of $\overline{F}_0$ along $\overline{\delta}$. Since $\iota$ is a categorical equivalence, it follows that $\overline{\beta}$ restricts to a natural transformation $F_0 \to F \circ \delta$ which exhibits $F$ as a left Kan extension of $F_0$ along $\delta$ (Proposition 7.3.1.14). \qed

7.3.6 The Universal Property of Kan Extensions

The goal of this section is to show that Kan extensions (when they exist) can be characterized by a universal mapping property.
Proposition 7.3.6.1. Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories, let \( \delta : K \to \mathcal{C} \) and \( F_0 : K \to \mathcal{D} \) be diagrams, and let \( \beta : F_0 \to F \circ \delta \) be a natural transformation which exhibits \( F \) as a left Kan extension of \( F_0 \) along \( \delta \). Then, for every functor \( G : \mathcal{C} \to \mathcal{D} \), the composite map

\[
\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(F, G) \to \text{Hom}_{\text{Fun}(K, \mathcal{D})}(F \circ \delta, G \circ \delta) \xrightarrow{\circ [\beta]} \text{Hom}_{\text{Fun}(K, \mathcal{D})}(F_0, G \circ \delta)
\]

is a homotopy equivalence of Kan complexes.

We will give the proof of Proposition 7.3.6.1 at the end of this section.

Warning 7.3.6.2. In classical category theory, some authors take the universal property of Proposition 7.3.6.1 as the definition of a Kan extension. Beware that this is a slightly different notion in general: it is possible for a natural transformation \( \beta : F_0 \to F \circ \delta \) to satisfy the universal property of Proposition 7.3.6.1 without exhibiting \( F \) as a left Kan extension of \( F_0 \) along \( \delta \) (in which case \( F_0 \) cannot admit any other left Kan extension along \( \delta \); see Corollary 7.3.6.5).

Corollary 7.3.6.3. Let \( \mathcal{C} \) and \( \mathcal{D} \) be \( \infty \)-categories, and let \( \delta : K \to \mathcal{C} \) be a diagram. Suppose that every diagram \( F_0 : K \to \mathcal{D} \) has a left Kan extension along \( \delta \). Then the restriction functor

\[
\text{Fun}(\mathcal{C}, \mathcal{D}) \xrightarrow{\circ \delta} \text{Fun}(K, \mathcal{D})
\]

has a left adjoint, which carries each diagram \( F_0 : K \to \mathcal{D} \) to a left Kan extension of \( F_0 \) along \( \delta \).

Proof. Combine Propositions 7.3.6.1 and 6.2.4.1.

Corollary 7.3.6.4. Let \( \mathcal{C} \) and \( \mathcal{D} \) be \( \infty \)-categories and let \( \delta : K \to \mathcal{C} \) be a diagram. Suppose that, for every object \( C \in \mathcal{C} \), the \( \infty \)-category \( \mathcal{D} \) admits colimits indexed by the simplicial set \( K/\mathcal{C} = K \times_{\mathcal{C}} \mathcal{C}/C \). Then the restriction functor

\[
\text{Fun}(\mathcal{C}, \mathcal{D}) \xrightarrow{\circ \delta} \text{Fun}(K, \mathcal{D})
\]

has a left adjoint, which carries each diagram \( F_0 : K \to \mathcal{D} \) to a left Kan extension of \( F_0 \) along \( \delta \).

Proof. Combine Corollaries 7.3.6.3 and 7.3.5.2.

Corollary 7.3.6.5. Let \( \mathcal{C} \) and \( \mathcal{D} \) be \( \infty \)-categories equipped with diagrams \( \delta : K \to \mathcal{C} \) and \( F_0 : K \to \mathcal{D} \), and suppose that \( F_0 \) admits a left Kan extension along \( \delta \). Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor and let \( \beta : F_0 \to F \circ \delta \) be a natural transformation. The following conditions are equivalent:
(1) The natural transformation $\beta$ exhibits $F$ as a left Kan extension of $F_0$ along $\delta$.

(2) For every functor $G : C \to D$, the composite map

$$\text{Hom}_{\text{Fun}(C, D)}(F, G) \to \text{Hom}_{\text{Fun}(K, D)}(F \circ \delta, G \circ \delta) \xrightarrow{\circ [\beta]} \text{Hom}_{\text{Fun}(K, D)}(F_0, G \circ \delta)$$

is a homotopy equivalence of Kan complexes.

(3) For every functor $G : C \to D$, the composite map

$$\text{Hom}_{\text{hFun}(C, D)}(F, G) \to \text{Hom}_{\text{hFun}(K, D)}(F \circ \delta, G \circ \delta) \xrightarrow{\circ [\beta]} \text{Hom}_{\text{hFun}(K, D)}(F_0, G \circ \delta)$$

is a bijection of sets.

Proof. The implication (1) $\Rightarrow$ (2) follows from Proposition 7.3.6.1 and the implication (2) $\Rightarrow$ (3) is immediate. We will complete the proof by showing that (3) $\Rightarrow$ (1). By assumption, there exists a functor $F' : C \to D$ and a natural transformation $\beta' : F_0 \to F' \circ \delta$ which exhibits $F'$ as a left Kan extension of $F$ along $\delta$. Applying Proposition 7.3.6.1, we deduce that there exists a natural transformation $\gamma : F' \to F$ for which $\beta$ is a composition of $\beta'$ with the induced transformation $\gamma|_K : (F' \circ \delta) \to (F \circ \delta)$. For each object $G \in \text{Fun}(C, D)$, we have a commutative diagram

$$\begin{array}{ccc}
\text{Hom}_{\text{hFun}(C, D)}(F, G) & \xrightarrow{\circ [\gamma]} & \text{Hom}_{\text{hFun}(C, D)}(F', G) \\
\downarrow \downarrow \downarrow & & \downarrow \downarrow \downarrow \\
\text{Hom}_{\text{hFun}(K, D)}(F_0, G \circ \delta), & & \text{Hom}_{\text{hFun}(K, D)}(F_0, G \circ \delta),
\end{array}$$

where the right vertical map is bijective. If condition (3) is satisfied, then the left vertical map is also bijective. Allowing the functor $G$ to vary, it follows that the homotopy class $[\gamma]$ is an isomorphism in the homotopy category $\text{hFun}(C, D)$, so that $\gamma$ is an isomorphism in $\text{Fun}(C, D)$. Invoking Remark 7.3.1.12 we conclude that $\beta$ exhibits $F$ as a left Kan extension of $F_0$ along $\delta$.

Remark 7.3.6.6. Let $C$ and $D$ be $\infty$-categories equipped with diagrams $\delta : K \to C$ and $F_0 : K \to D$. It follows from Corollary 7.3.6.5 that if $F_0$ admits a left Kan extension $F : C \to D$ along $\delta$, then the isomorphism class of the functor $F$ is uniquely determined: it is characterized by the requirement that it corepresents the functor

$$\text{hFun}(C, D) \to \text{Set} \quad G \mapsto \text{Hom}_{\text{hFun}(K, D)}(F_0, G \circ \delta).$$
We will deduce Proposition \ref{prop:Kan-extensions} from the following more general assertion about relative Kan extensions:

**Proposition 7.3.6.7.** Let $\mathcal{C}$ be an $\infty$-category, let $U : \mathcal{D} \to \mathcal{E}$ be a functor of $\infty$-categories, and let $\mathcal{C}^0 \subseteq \mathcal{C}$ be a full subcategory. Let $F, G : \mathcal{C} \to \mathcal{D}$ be functors having restrictions $F_0 = F|_{\mathcal{C}^0}$ and $G_0 = G|_{\mathcal{C}^0}$, so that we have a commutative diagram of Kan complexes

\[
\begin{array}{ccc}
\Hom_{\Fun(\mathcal{C}, \mathcal{D})}(F, G) & \rightarrow & \Hom_{\Fun(\mathcal{C}^0, \mathcal{D})}(F_0, G_0) \\
\downarrow & & \downarrow \\
\Hom_{\Fun(\mathcal{C}, \mathcal{E})}(U \circ F, U \circ G) & \rightarrow & \Hom_{\Fun(\mathcal{C}^0, \mathcal{E})}(U \circ F_0, U \circ G_0).
\end{array}
\]

(7.21)

If $F$ is $U$-left Kan extended from $\mathcal{C}^0$ or $G$ is $U$-right Kan extended from $\mathcal{C}^0$, then \ref{eq:7.21} is a homotopy pullback square.

**Remark 7.3.6.8.** In the situation of Proposition \ref{prop:Kan-extensions}, the horizontal maps in the diagram \ref{eq:7.21} are Kan fibrations (Corollary \ref{cor:Kan-fibrations} and Proposition \ref{prop:homotopy-pullback}). Consequently, the diagram \ref{eq:7.21} is a homotopy pullback square if and only if the induced map

\[
\Hom_{\Fun(\mathcal{C}, \mathcal{D})}(F, G) \\
\downarrow \theta \\
\Hom_{\Fun(\mathcal{C}^0, \mathcal{D})}(F_0, G_0) \times_{\Hom_{\Fun(\mathcal{C}^0, \mathcal{E})}(U F_0, U G_0)} \Hom_{\Fun(\mathcal{C}, \mathcal{E})}(U F, U G)
\]

is a homotopy equivalence (Example \ref{ex:homotopy-equivalence}). Writing $\mathcal{M}$ for the fiber product

\[
\Fun(\mathcal{C}^0, \mathcal{D}) \times_{\Fun(\mathcal{C}^0, \mathcal{E})} \Fun(\mathcal{C}, \mathcal{E})
\]

and $\mathcal{V} : \Fun(\mathcal{C}, \mathcal{D}) \to \mathcal{M}$ for the functor given by $\mathcal{V}(H) = (H|_{\mathcal{C}^0}, U \circ H)$, we can identify $\theta$ with the map $\Hom_{\Fun(\mathcal{C}, \mathcal{D})}(F, G) \to \Hom_{\mathcal{M}}(\mathcal{V}(F), \mathcal{V}(G))$ determined by $\mathcal{V}$. We can therefore restate Proposition \ref{prop:Kan-extensions} as follows:

- If the functor $F : \mathcal{C} \to \mathcal{D}$ is $U$-left Kan extended from $\mathcal{C}^0 \subseteq \mathcal{C}$, then it is $\mathcal{V}$-initial when viewed as an object of the $\infty$-category $\Fun(\mathcal{C}, \mathcal{D})$.

- If the functor $G : \mathcal{C} \to \mathcal{D}$ is $U$-right Kan extended from $\mathcal{C}^0 \subseteq \mathcal{C}$, then it is $\mathcal{V}$-final when viewed as an object of the $\infty$-category $\Fun(\mathcal{C}, \mathcal{D})$.

**Proof of Proposition \ref{prop:Kan-extensions}** We will assume that the functor $F$ is $U$-left Kan extended from $\mathcal{C}^0$ (the proof in the case where $G$ is $U$-right Kan extended from $\mathcal{C}^0$ is similar). Using
Corollary 5.3.7.5, we can factor the functor $U$ as a composition $D \xrightarrow{T} D' \xrightarrow{U'} E$, where $U'$ is an isofibration and $T$ is an equivalence of $\infty$-categories. Note that the functor $T \circ F$ is $U'$-left Kan extended from $C^0$ (Remark 7.3.3.11), and that the natural maps

$$\text{Hom}_{\text{Fun}(C, D)}(F, G) \to \text{Hom}_{\text{Fun}(C, D')}(T \circ F, T \circ G)$$

$$\text{Hom}_{\text{Fun}(C^0, D)}(F_0, G_0) \to \text{Hom}_{\text{Fun}(C, D')}(T \circ F_0, T \circ G_0)$$

are homotopy equivalences. Consequently, we can replace $D$ by $D'$ and thereby reduce to proving Proposition 7.3.6.7 in the special case where the functor $U : D \to E$ is an isofibration of $\infty$-categories.

Let $V : \text{Fun}(C, D) \to \text{Fun}(C^0, D) \times_{\text{Fun}(C^0, E)} \text{Fun}(C, E)$ be as in Remark 7.3.6.8; we wish to show that $F$ is a $V$-initial object of the $\infty$-category $\text{Fun}(C, D)$. Note that $V$ is also an isofibration (Proposition 4.4.5.1). By virtue of Corollary 7.1.4.17, it will suffice to show that every lifting problem

$$\begin{align*}
\partial \Delta^n & \xrightarrow{\sigma_0} \text{Fun}(C, D) \\
\Delta^n & \xrightarrow{F_0} \text{Fun}(C^0, D) \times_{\text{Fun}(C^0, E)} \text{Fun}(C, E)
\end{align*}
$$

has a solution, provided that $n \geq 0$ and $\sigma_0(0) = F$. Unwinding the definitions, we can rewrite (7.22) as a lifting problem

$$\begin{align*}
C^0 & \xrightarrow{G_0} \text{Fun}(\Delta^n, D) \\
C & \xrightarrow{F_0} \text{Fun}(\partial \Delta^n, D) \times_{\text{Fun}(\partial \Delta^n, E)} \text{Fun}(\Delta^n, E)
\end{align*}
$$

Note that $V'$ is also an isofibration of $\infty$-categories (Proposition 4.4.5.1).

We will complete the proof by showing that the lifting problem (7.23) admits a solution $G : C \to \text{Fun}(\Delta^n, D)$ which is $V'$-left Kan extended from $C^0$. By virtue of Proposition 7.3.5.5, it will suffice to show that for each object $C \in C$, the induced lifting problem

$$\begin{align*}
C^0_C & \xrightarrow{Q} \text{Fun}(\Delta^n, D) \\
(C^0_C)^\circ & \xrightarrow{Q} \text{Fun}(\partial \Delta^n, D) \times_{\text{Fun}(\partial \Delta^n, E)} \text{Fun}(\Delta^n, E)
\end{align*}
$$
admits a solution $Q : (\mathcal{C}^0)^\triangleright \to \text{Fun}(\Delta^n, D)$ which is a $V'$-colimit diagram. Our assumption that $\sigma_0(0) = F$ is $U$-left Kan extended from $\mathcal{C}^0$ guarantees that the composite map

$$(\mathcal{C}^0)^\triangleright \to \text{Fun}(\partial \Delta^n, D) \to \text{Fun}(\{0\}, D) = D$$

is a $U$-colimit diagram. Applying Corollary 7.1.6.6 we conclude that the lifting problem (7.24) admits a solution $Q$, and Proposition 7.1.6.9 guarantees that $Q$ is automatically a $V'$-colimit diagram.

**Corollary 7.3.6.9.** Let $F, G : \mathcal{C} \to \mathcal{D}$ be functors of $\infty$-categories and let $\mathcal{C}^0 \subseteq \mathcal{C}$ be a full subcategory. If $F$ is left Kan extended from $\mathcal{C}^0$ or $G$ is right Kan extended from $\mathcal{C}^0$, then the restriction map

$$\theta : \text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(F, G) \to \text{Hom}_{\text{Fun}(\mathcal{C}^0, \mathcal{D})}(F|_{\mathcal{C}^0}, G|_{\mathcal{C}^0})$$

is a trivial Kan fibration.

**Proof.** Applying Proposition 7.3.6.7 in the special case $\mathcal{E} = \Delta^0$, we deduce that $\theta$ is a homotopy equivalence. Since the restriction map $\text{Fun}(\mathcal{C}, \mathcal{D}) \to \text{Fun}(\mathcal{C}^0, \mathcal{D})$ is an inner fibration of $\infty$-categories (Corollary 4.1.4.2), the map $\theta$ is also a Kan fibration (Proposition 4.6.1.19), and therefore a trivial Kan fibration (Proposition 3.3.7.4).

Note that relative Kan extensions are characterized by the mapping property described in Proposition 7.3.6.7.

**Corollary 7.3.6.10.** Suppose we are given a commutative diagram of $\infty$-categories

$$\begin{array}{ccc}
\mathcal{C}^0 & \xrightarrow{F_0} & \mathcal{D} \\
\downarrow & & \downarrow U \\
\mathcal{C} & \xrightarrow{F} & \mathcal{E}
\end{array}$$

(7.25)

where $\mathcal{C}^0$ is a full subcategory of $\mathcal{C}$. Assume that the lifting problem (7.25) admits a solution given by a functor $\mathcal{C} \to \mathcal{D}$ which is $U$-left Kan extended from $\mathcal{C}^0$. Let $F : \mathcal{C} \to \mathcal{D}$ be an arbitrary solution to the lifting problem (7.25). Then the following conditions are equivalent:

1. The functor $F$ is $U$-left Kan extended from $\mathcal{C}^0$.
2. For every functor $G : \mathcal{C} \to \mathcal{D}$, the diagram of Kan complexes

$$\begin{array}{ccc}
\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(F, G) & \longrightarrow & \text{Hom}_{\text{Fun}(\mathcal{C}^0, \mathcal{D})}(F|_{\mathcal{C}^0}, G|_{\mathcal{C}^0}) \\
\downarrow & & \downarrow \\
\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{E})}(U \circ F, U \circ G) & \longrightarrow & \text{Hom}_{\text{Fun}(\mathcal{C}^0, \mathcal{E})}(U \circ F|_{\mathcal{C}^0}, U \circ G|_{\mathcal{C}^0}).
\end{array}$$
is a homotopy pullback square.

Proof. The implication (1) ⇒ (2) follows from Proposition 7.3.6.7. To prove the converse, let $F' : C \to D$ be a solution to the lifting problem (7.25) which is $U$-left Kan extended from $C^0$, and let $V : \text{Fun}(C, D) \to \text{Fun}(C^0, D) \times_{\text{Fun}(C^0, E)} \text{Fun}(C, E)$ be as in Remark 7.3.6.8. If condition (2) is satisfied, then $F$ and $F'$ are both $V$-initial objects of $\text{Fun}(C, D)$ satisfying $V(F) = V(F')$. Applying Corollary 7.1.4.12 we see that $F$ and $F'$ are isomorphic as objects of the $\infty$-category $\text{Fun}(C, D)$, so that $F$ is also $U$-left Kan extended from $C^0$ (Remark 7.3.3.13).

Corollary 7.3.6.11. Let $F : C \to D$ be a functor of $\infty$-categories, and let $F_0 = F|_{C^0}$ be the restriction of $F$ to a full subcategory $C^0 \subseteq C$. Suppose that the functor $F_0$ admits a left Kan extension to $C$. The following conditions are equivalent:

1. The functor $F$ is left Kan extended from $C^0$.

2. For every functor $G : C \to D$, the restriction map

$$\theta : \text{Hom}_{\text{Fun}(C, D)}(F, G) \to \text{Hom}_{\text{Fun}(C^0, D)}(F|_{C^0}, G|_{C^0})$$

is a homotopy equivalence of Kan complexes.

3. For every functor $G : C \to D$, the restriction map

$$\theta : \text{Hom}_{\text{Fun}(C, D)}(F, G) \to \text{Hom}_{\text{Fun}(C^0, D)}(F|_{C^0}, G|_{C^0})$$

is a trivial Kan fibration of simplicial sets.

Proof. The equivalence (1) ⇔ (2) follows by applying Corollary 7.3.6.10 in the special case $E = \Delta^0$. The equivalence (2) ⇔ (3) is a special case of Proposition 3.3.7.4 since the morphism $\theta$ is automatically a Kan fibration (see Corollary 4.1.4.2 and Proposition 4.6.1.19).

Combining Proposition 7.3.6.7 with the existence criterion of Proposition 7.3.5.5 we obtain the following:

Theorem 7.3.6.12. Let $C$ be an $\infty$-category, let $C^0 \subseteq C$ be a full subcategory, and let $U : D \to E$ be an isofibration of $\infty$-categories. Let $\text{Fun}'(C, D)$ denote the full subcategory of $\text{Fun}(C, D)$ spanned by those functors which are $U$-left Kan extended from $C^0$, and let $B$ denote the full subcategory of $\text{Fun}(C^0, D) \times_{\text{Fun}(C^0, E)} \text{Fun}(C, E)$ whose objects correspond to lifting problems.
with the following property:

(*) For every object \( C \in \mathcal{C} \), the induced lifting problem

\[
\begin{array}{ccc}
\mathcal{C}^0 & \longrightarrow & \mathcal{D} \\
\downarrow & & \downarrow \\
(\mathcal{C}^0)_{/C} & \longrightarrow & \mathcal{E}
\end{array}
\]

admits a solution which is a \( U \)-colimit diagram \((\mathcal{C}^0)^{\triangleright} \rightarrow \mathcal{D}\).

Then the restriction map

\[
V : \text{Fun}(\mathcal{C}, \mathcal{D}) \rightarrow \text{Fun}(\mathcal{C}^0, \mathcal{D}) \times_{\text{Fun}(\mathcal{C}^0, \mathcal{E})} \text{Fun}(\mathcal{C}, \mathcal{E})
\]

restricts to a trivial Kan fibration \( \text{Fun}'(\mathcal{C}, \mathcal{D}) \rightarrow \mathcal{B} \).

Stated more informally, Theorem 7.3.6.12 asserts that if we are given a lifting problem

\[
\begin{array}{ccc}
\mathcal{C}^0 & \longrightarrow & \mathcal{D} \\
\downarrow & & \downarrow \\
\mathcal{C} & \longrightarrow & \mathcal{E}
\end{array}
\]

which has a possibility to be solved by a functor \( F : \mathcal{C} \rightarrow \mathcal{D} \) which is \( U \)-left Kan extended from \( \mathcal{C}^0 \), then the functor \( F \) exists and is unique up to a contractible space of choices.

Proof of Theorem 7.3.6.12. Note that the functor \( V \) is an isofibration of \( \infty \)-categories (Proposition 4.4.5.1). It follows from Proposition 7.3.5.5 that \( \mathcal{B} \) is the essential image of the functor \( V|_{\text{Fun}'(\mathcal{C}, \mathcal{D})} \), and from Proposition 7.3.6.7 (together with Remark 7.3.6.8) that every object of \( \text{Fun}'(\mathcal{C}, \mathcal{D}) \) is \( V \)-initial when regarded as an object of \( \text{Fun}(\mathcal{C}, \mathcal{D}) \). Applying Corollary 7.1.4.18 we see that the functor \( V|_{\text{Fun}(\mathcal{C}, \mathcal{D})} : \text{Fun}'(\mathcal{C}, \mathcal{D}) \rightarrow \mathcal{B} \) is a trivial Kan fibration.

Corollary 7.3.6.13. Let \( \mathcal{C} \) and \( \mathcal{D} \) be \( \infty \)-categories and let \( \mathcal{C}^0 \subseteq \mathcal{C} \) be a full subcategory. Let \( \text{Fun}'(\mathcal{C}, \mathcal{D}) \) denote the full subcategory of \( \text{Fun}(\mathcal{C}, \mathcal{D}) \) spanned by those functors which are left Kan extended from \( \mathcal{C}^0 \), and let \( \text{Fun}'(\mathcal{C}^0, \mathcal{D}) \) denote the full subcategory of \( \text{Fun}(\mathcal{C}^0, \mathcal{D}) \) spanned by those functors \( F_0 \) which satisfy the following condition:

(*) For every object \( C \in \mathcal{C} \), the diagram

\[
\begin{array}{ccc}
\mathcal{C}^0_{/C} = \mathcal{C}^0 \times_{\mathcal{C}} \mathcal{C}/C & \longrightarrow & \mathcal{C}^0 \\
F_0 & \rightarrow & \mathcal{D}
\end{array}
\]

has a colimit in the \( \infty \)-category \( \mathcal{D} \).
Then the restriction map \( \text{Fun}^\prime(C, D) \rightarrow \text{Fun}^\prime(C^0, D) \) is a trivial Kan fibration of simplicial sets.

**Proof.** Apply Theorem 7.3.6.12 in the special case \( \mathcal{E} = \Delta^0 \).

We now return to the result promised at the beginning of this section.

**Proof of Proposition 7.3.6.1.** Let \( F, G : C \rightarrow D \) be functors of \( \infty \)-categories. Suppose we are given a simplicial set \( K \) equipped with diagrams \( \delta : K \rightarrow C \) and \( F_0 : K \rightarrow D \), together with a natural transformation \( \beta : F_0 \rightarrow F \circ \delta \) which exhibits \( F \) as a left Kan extension of \( F_0 \) along \( \delta \). Let \( \theta \) denote the composite map

\[
\text{Hom}_{\text{Fun}(C, D)}(F, G) \rightarrow \text{Hom}_{\text{Fun}(K, D)}(F \circ \delta, G \circ \delta) \xrightarrow{\circ [\beta]} \text{Hom}_{\text{Fun}(K, D)}(F_0, G \circ \delta).
\]

We wish to show that \( \theta \) is a homotopy equivalence.

It follows from Corollary 4.1.3.3 that there exists an inner anodyne morphism \( K \rightarrow K \), where \( K \) is an \( \infty \)-category. Since \( C \) and \( D \) are \( \infty \)-categories, we can extend \( \delta \) and \( F_0 \) to functors \( \delta' : K \rightarrow C \) and \( F_0' : K \rightarrow D \), respectively (Proposition 1.4.6.7). Moreover, the restriction functor \( \text{Fun}(K, D) \rightarrow \text{Fun}(K, D) \) is a trivial Kan fibration (Proposition 1.4.7.6). We can therefore extend \( \beta \) to a natural transformation \( \beta' : F_0' \rightarrow F \circ \delta' \), which induces a map of Kan complexes \( \theta' : \text{Hom}_{\text{Fun}(K, D)}(F_0', G \circ \delta') \rightarrow \text{Hom}_{\text{Fun}(K, D)}(F_0, G \circ \delta) \). By construction, the map \( \theta \) is obtained (up to homotopy) by composing \( \theta' \) with the restriction map \( \text{Hom}_{\text{Fun}(K, D)}(F_0', G \circ \delta') \rightarrow \text{Hom}_{\text{Fun}(K, D)}(F_0, G \circ \delta) \), which is a trivial Kan fibration. Consequently, to show that \( \theta \) is a homotopy equivalence, it will suffice to show that \( \theta' \) is a homotopy equivalence. We may therefore replace \( K \) by \( K \) and thereby reduce to proving Proposition 7.3.6.1 in the special case where \( K = K \) is an \( \infty \)-category.

Let \( \mathcal{C} \) denote the relative join \( K \star_C C \). Note that the definition of \( \theta \) (as a morphism in the homotopy category \( \text{hKan} \)) depends only on the homotopy class of \( \beta \). We may therefore assume without loss of generality that there exists a functor \( \mathcal{F} : \mathcal{C} \rightarrow D \) for which \( \mathcal{F}|_K = F_0 \), \( \mathcal{F}|_C = F \), and the natural transformation \( \beta \) is given by the composition

\[
\Delta^1 \times K \simeq K \star_K K \rightarrow K \star_C C \xrightarrow{\mathcal{F}} D.
\]

Let \( \mathcal{G} : \mathcal{C} \rightarrow D \) denote the functor given by the composition

\[
K \star_C C \rightarrow C \star_C C \simeq \Delta^1 \times C \rightarrow C \xrightarrow{\mathcal{G}} D.
\]

Our assumption on \( \beta \) guarantees that \( \mathcal{F} \) is left Kan extended from the full subcategory \( K \subseteq \mathcal{C} \) (Proposition 7.3.2.10). Applying Corollary 7.3.6.9, we deduce that precomposition with the inclusion \( K \hookrightarrow \mathcal{C} \) determines a trivial Kan fibration

\[
\varphi : \text{Hom}_{\text{Fun}(\mathcal{C}, D)}(\mathcal{F}, \mathcal{G}) \rightarrow \text{Hom}_{\text{Fun}(K, D)}(F_0, G \circ \delta).
\]
We claim that $\mathcal{G}$ is right Kan extended from the full subcategory $\mathcal{C} \subseteq \mathcal{C}$. To prove this, it will suffice to show that for every object $X \in \mathcal{K}$, the functor $\mathcal{G}$ is right Kan extended from $\mathcal{C}$ at $X$ (see Proposition 7.3.3.5). Let $e_X : X \to \delta(X)$ denote the morphism in $\mathcal{G}$ given by the edge

$$\Delta^1 \simeq \{X\} \ast_{\{\delta(X)\}} \{\delta(X)\} \hookrightarrow \mathcal{K} \ast_{\mathcal{C}} \mathcal{C} = \mathcal{C}.$$  

Note that $e_X$ is cocartesian with respect to the projection map $\mathcal{C} \to \Delta^1$ (Proposition 5.2.3.15), and therefore exhibits $\delta(X)$ as a $\mathcal{C}$-reflection of $X$ in the $\infty$-category $\mathcal{C}$ (Lemma 6.2.3.1). It will therefore suffice to show that $G$ carries $e_X$ to an isomorphism in the $\infty$-category $D$, which is clear (by construction, $G(e_X)$ is the identity morphism $\text{id}_D$ for $D = G(\delta(X))$).

Applying Corollary 7.3.6.9 again, we deduce that precomposition with the inclusion map $\mathcal{C} \to \mathcal{D}$ determines a trivial Kan fibration $\varphi^+ : \text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}((F, \mathcal{G}) \to \text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(F, G)$.

Let $\varphi^- : \text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}((F, \mathcal{G}) \to \text{Hom}_{\text{Fun}(\mathcal{K}, \mathcal{D})}(F \circ \delta, G \circ \delta)$ be given by precomposition with the functor $K \to \mathcal{C} \hookrightarrow \mathcal{C}$. Consider the diagram of Kan complexes

$$\begin{array}{ccc}
\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(F, \mathcal{G}) & \xrightarrow{\varphi^+} & \text{Hom}_{\text{Fun}(\mathcal{K}, \mathcal{D})}(F \circ \delta, G \circ \delta) \\
\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(F, G) & \xrightarrow{\varphi^-} & \text{Hom}_{\text{Fun}(\mathcal{K}, \mathcal{D})}(F_0, G \circ \delta) \\
\varphi^- & & \circ[\beta]
\end{array}$$

(7.26)

Note that the diagonal maps are homotopy equivalences, and the triangle on the left is commutative. Consequently, to show that $\theta$ is a homotopy equivalence, it will suffice to show that the triangle on the right commutes up to homotopy.

Let $\text{Hom}_{\text{Fun}(\mathcal{K}, \mathcal{D})}(F_0, F \circ \delta, G \circ \delta)$ be the Kan complex introduced in Notation 4.6.8.1. To verify the homotopy commutativity of the right triangle in the diagram (7.26), it will suffice to show that there is exists map of Kan complexes $\rho : \text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(F, G) \to \text{Hom}_{\text{Fun}(\mathcal{K}, \mathcal{D})}(F_0, F \circ \delta, G \circ \delta)$ satisfying the following conditions:

- The composition

$$\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(F, G) \xrightarrow{\rho} \text{Hom}_{\text{Fun}(\mathcal{K}, \mathcal{D})}(F_0, F \circ \delta, G \circ \delta) \to \text{Hom}_{\text{Fun}(\mathcal{K}, \mathcal{D})}(F_0, F \circ \delta)$$

is the constant map taking the value $\beta$.

- The composition

$$\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(F, G) \xrightarrow{\rho} \text{Hom}_{\text{Fun}(\mathcal{K}, \mathcal{D})}(F_0, F \circ \delta, G \circ \delta) \to \text{Hom}_{\text{Fun}(\mathcal{K}, \mathcal{D})}(F_0, G \circ \delta)$$

is equal to $\varphi_-$.
• The composition

\[ \text{Hom}_{\text{Fun}(\mathcal{C},\mathcal{D})}(F,G) \xrightarrow{\rho} \text{Hom}_{\text{Fun}(\mathcal{K},\mathcal{D})}(F_0, F \circ \delta, G \circ \delta) \rightarrow \text{Hom}_{\text{Fun}(\mathcal{K},\mathcal{D})}(F \circ \delta, G \circ \delta) \]

is equal to \( \varphi_\pm \).

Let \( \sigma \) denote the 2-simplex of \( \Delta^1 \times \Delta^1 \) given on vertices by the formulae

\[
\sigma(0) = (0, 0) \quad \sigma(1) = (0, 1) \quad \sigma(2) = (1, 1),
\]

and let \( T : \Delta^2 \times \mathcal{K} \rightarrow \Delta^1 \times \mathcal{T} \) be the functor given by the composition

\[
\Delta^2 \times \mathcal{K} \xrightarrow{\sigma \times \text{id}_\mathcal{K}} \Delta^1 \times \Delta^1 \times \mathcal{K} \\
\simeq \Delta^1 \times (\mathcal{K} \star \mathcal{K}) \\
\rightarrow \Delta^1 \times (\mathcal{K} \star \mathcal{C}) \\
= \Delta^1 \times \mathcal{T}.
\]

More concretely, the functor \( T \) is given on objects by the formulae

\[
T(0, X) = (0, X) \quad T(1, X) = (0, \delta(X)) \quad T(2, X) = (1, \delta(X)).
\]

We conclude by observing that precomposition with \( T \) induces a map of Kan complexes

\[
\rho : \text{Hom}_{\text{Fun}(\mathcal{C},\mathcal{D})}(F,G) \rightarrow \text{Hom}_{\text{Fun}(\mathcal{K},\mathcal{D})}(F_0, F \circ \delta, G \circ \delta)
\]

having the desired properties.

\[ \square \]

### 7.3.7 Transitivity of Kan Extensions

Let \( \mathcal{T} \) be an \( \infty \)-category equipped with full subcategories \( \mathcal{C}^0 \subseteq \mathcal{C} \subseteq \mathcal{T} \). Our goal in this section is to show that a functor of \( \infty \)-categories \( F : \mathcal{T} \rightarrow \mathcal{D} \) is left Kan extended from \( \mathcal{C}^0 \) if and only if it is left Kan extended from \( \mathcal{C} \) and \( F_\mathcal{C} \) is left Kan extended from \( \mathcal{C}^0 \) (Corollary 7.3.7.8). We begin by analyzing the case special case where the \( \infty \)-category \( \mathcal{T} \) has the form \( \mathcal{C}^\circ \).

**Proposition 7.3.7.1.** Let \( \mathcal{C} \) be an \( \infty \)-category, let \( F : \mathcal{C}^\circ \rightarrow \mathcal{D} \) be a functor of \( \infty \)-categories, and let \( U : \mathcal{D} \rightarrow \mathcal{E} \) be another functor of \( \infty \)-categories. Assume that \( F = F|_\mathcal{C} \) is \( U \)-left Kan extended from a full subcategory \( \mathcal{C}^0 \subseteq \mathcal{C} \). Then \( F \) is a \( U \)-colimit diagram if and only if the composite map

\[
(\mathcal{C}^0)^\circ \hookrightarrow \mathcal{C}^\circ \xrightarrow{F} \mathcal{D}
\]

is a \( U \)-colimit diagram.
7.3. KAN EXTENSIONS

Proof. For each object \( D \in \mathcal{D} \), let \( \mathcal{D} \in \text{Fun}(\mathcal{C}, \mathcal{D}) \) denote the constant functor taking the value \( D \). By virtue of Proposition 7.1.5.12, the functor \( F \) is a \( U \)-colimit diagram if and only if, for each \( D \in \mathcal{D} \), the upper half of the diagram

\[
\begin{array}{ccc}
\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(F, D) & \rightarrow & \text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{E})}(U \circ F, U \circ D) \\
\downarrow & & \downarrow \\
\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(F, D|_c) & \rightarrow & \text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{E})}(U \circ F, U \circ D|_c) \\
\downarrow & & \downarrow \\
\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(F|_{\mathcal{C}^0}, D|_{\mathcal{C}^0}) & \rightarrow & \text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{E})}(U \circ F|_{\mathcal{C}^0}, U \circ D|_{\mathcal{C}^0})
\end{array}
\]  

(7.27)

is a homotopy pullback square. Since \( F \) is \( U \)-left Kan extended from \( \mathcal{C}^0 \), Proposition 7.3.6.7 shows that the right half of the diagram is a homotopy pullback square. It follows that \( F \) is a \( U \)-colimit diagram if and only if the outer rectangle of (7.27) is a homotopy pullback square for each \( D \in \mathcal{D} \) (Proposition 3.4.1.11).

Let \( v \) denote the cone point of \( \mathcal{C}^0 \). Let \( \mathcal{C}^1 \) denote the cone \( (\mathcal{C}^0)^e \), which we regard as a full subcategory of \( \mathcal{C}^0 \). Note that the functors \( D, D|_{\mathcal{C}^1}, U \circ D \) and \( U \circ D|_{\mathcal{C}^1} \) are all right Kan extended from the cone point, so Corollary 7.3.6.9 implies that the restriction maps

\[
\begin{array}{ccc}
\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(F, D) & \rightarrow & \text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(F|_{\mathcal{C}^1}, D|_{\mathcal{C}^1}) \\
\downarrow & & \downarrow \\
\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{E})}(U \circ F, U \circ D) & \rightarrow & \text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{E})}(U \circ F|_{\mathcal{C}^1}, U \circ D|_{\mathcal{C}^1}) \\
\downarrow & & \downarrow \\
\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{E})}(U \circ F|_{\mathcal{C}^0}, U \circ D|_{\mathcal{C}^0}) & \rightarrow & \text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{E})}(U \circ F|_{\mathcal{C}^0}, U \circ D|_{\mathcal{C}^0})
\end{array}
\]  

(7.28)

are homotopy equivalences. It follows that the restriction map from the outer rectangle of (7.27) to the diagram

\[
\begin{array}{ccc}
\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(F|_{\mathcal{C}^1}, D|_{\mathcal{C}^1}) & \rightarrow & \text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(F|_{\mathcal{C}^0}, D|_{\mathcal{C}^0}) \\
\downarrow & & \downarrow \\
\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{E})}(U \circ F|_{\mathcal{C}^1}, U \circ D|_{\mathcal{C}^1}) & \rightarrow & \text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{E})}(U \circ F|_{\mathcal{C}^0}, U \circ D|_{\mathcal{C}^0})
\end{array}
\]  

(7.28)

is a levelwise homotopy equivalence. In particular, the outer rectangle of (7.27) is a homotopy pullback square if and only if (7.28) is a homotopy pullback square (Corollary 3.4.1.12). By virtue of Proposition 7.1.5.12, this is satisfied for every object \( D \in \mathcal{D} \) if and only if \( F^1 \) is a \( U \)-colimit diagram.  

\( \square \)
Corollary 7.3.7.2. Let \( C \) be an \( \infty \)-category and let \( F : C \to D \) be a functor of \( \infty \)-categories. Suppose that \( F = F|_C \) is left Kan extended from a full subcategory \( C^0 \subseteq C \). Then \( F \) is a colimit diagram if and only if the composite map

\[
(C^0) \to C^0 \xrightarrow{F} D
\]

is a \( U \)-colimit diagram.

Proof. Apply Proposition 7.3.7.1 in the special case \( E = \Delta^0 \).

Proposition 7.3.7.3. Let \( F : C \to D \) and \( U : D \to E \) be functors of \( \infty \)-categories and let \( C^0 \subseteq C \) be a full subcategory. Suppose we are given a right fibration of \( \infty \)-categories \( V : B \to C \) and set \( B^0 = C^0 \times_C B \). Then, for every object \( B \in B \), the functor \( F \circ V \) is \( U \)-left Kan extended from \( B^0 \) at \( B \) if and only if \( F \) is \( U \)-left extended from \( C^0 \) at \( V(B) \).

Proof. Set \( C = V(B) \), and let \( F_C \) denote the composite map

\[
(C^0 \times_C C/_{C}) \to C \xrightarrow{F} D
\]

We wish to show that \( F_C \) is a \( U \)-colimit diagram if the composite map

\[
(B^0 \times_B B/_{B}) \to (B/_{B}) \to B \xrightarrow{V} C \xrightarrow{F} D
\]

is a \( U \)-colimit diagram. By virtue of Corollary 7.2.2.2 it will suffice to show that the natural map

\[
\theta : B^0 \times_B B/_{B} \to C^0 \times_C C/_{C}
\]

is right cofinal. By construction, \( \theta \) is a pullback of the map \( V/_{B} : B/_{B} \to C/_{V(B)} \). Our assumption that \( V \) is a right fibration guarantees that \( V/_{B} \) is a trivial Kan fibration (Corollary 4.3.7.13). It follows that \( \theta \) is also a trivial Kan fibration, and therefore right cofinal by virtue of Corollary 7.2.1.12.

Corollary 7.3.7.4. Let \( F : C \to D \) and \( U : D \to E \) be functors of \( \infty \)-categories and let \( C^0 \subseteq C \) be a full subcategory. Suppose we are given a right fibration of \( \infty \)-categories \( V : B \to C \) and set \( B^0 = C^0 \times_C B \). If \( F \) is \( U \)-left Kan extended from \( C^0 \), then \( F \circ V \) is \( U \)-left Kan extended from \( B^0 \). The converse holds if every fiber of \( V \) is nonempty.

Proof. Apply Corollary 7.3.7.4 in the special case \( E = \Delta^0 \).

Corollary 7.3.7.5. Let \( F : C \to D \) be a functor of \( \infty \)-categories and let \( C^0 \subseteq C \) be a full subcategory. Suppose we are given a right fibration of \( \infty \)-categories \( V : B \to C \) and set \( B^0 = C^0 \times_C B \). If \( F \) is left Kan extended from \( C^0 \), then \( F \circ V \) is left Kan extended from \( B^0 \). The converse holds if every fiber of \( V \) is nonempty.

Proof. Apply Corollary 7.3.7.4 in the special case \( E = \Delta^0 \).
Proposition 7.3.7.6 (Transitivity for Kan Extensions). Let $F : \mathcal{C} \to \mathcal{D}$ and $U : \mathcal{D} \to \mathcal{E}$ be functors of $\infty$-categories. Let $\mathcal{C}^0 \subseteq \mathcal{C} \subseteq \mathcal{C}$ be full subcategories. Then $F$ is $U$-left Kan extended from $\mathcal{C}^0$ if and only if it satisfies the following pair of conditions:

1. The functor $F$ is $U$-left Kan extended from $\mathcal{C}$.
2. The restriction $F|_{\mathcal{C}}$ is $U$-left Kan extended from $\mathcal{C}^0$.

Remark 7.3.7.7. In the special case $\mathcal{C} = \mathcal{C}^0$, Proposition 7.3.7.6 is essentially a restatement of Proposition 7.3.7.1 (see Example 7.3.3.8).

Proof of Proposition 7.3.7.6. It follows immediately from the definitions that if $F$ is $U$-left Kan extended from $\mathcal{C}^0$, then the functor $F = F|_{\mathcal{C}}$ has the same property. We may therefore assume that condition (2) is satisfied. Fix an object $X \in \mathcal{C}$. We will complete the proof by showing that $F$ is $U$-left Kan extended from $\mathcal{C}^0$ at $X$ if and only if it is $U$-left Kan extended from $\mathcal{C}$ at $X$. Let $\mathcal{F}_X$ denote the composite map $(\mathcal{C} \times _{\mathcal{C}/X}\mathcal{C}/X)^\triangleright \to \mathcal{C} \xrightarrow{F} \mathcal{D}$.

We wish to show that $\mathcal{F}_X$ is a $U$-colimit diagram if and only if its restriction to $(\mathcal{C}^0 \times _{\mathcal{C}/X}\mathcal{C}/X)^\triangleright$ is a $U$-colimit diagram. Let $F_X$ denote the restriction of $\mathcal{F}_X$ to $\mathcal{C} \times _{\mathcal{C}/X}\mathcal{C}/X$. By virtue of Proposition 7.3.7.4, it will suffice to show that $F_X$ is $U$-left Kan extended from $\mathcal{C}^0 \times _{\mathcal{C}/X}\mathcal{C}/X$. This follows by applying Corollary 7.3.7.4 to the right fibration $\mathcal{C} \times _{\mathcal{C}/X}\mathcal{C}/X \to \mathcal{C}$.

Corollary 7.3.7.8. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories, and let $\mathcal{C}^0 \subseteq \mathcal{C} \subseteq \mathcal{C}$ be full subcategories. Then $F$ is left Kan extended from $\mathcal{C}^0$ if and only if it satisfies the following pair of conditions:

1. The functor $F$ is left Kan extended from $\mathcal{C}$.
2. The restriction $F|_{\mathcal{C}}$ is left Kan extended from $\mathcal{C}^0$.

Proof. Apply Proposition 7.3.7.6 in the special case $\mathcal{E} = \Delta^0$.

Corollary 7.3.7.9. Let $F : \mathcal{C} \to \mathcal{D}$ and $U : \mathcal{D} \to \mathcal{E}$ be functors of $\infty$-categories, let $\mathcal{C}^0 \subseteq \mathcal{C}$ be a full subcategory, and let $C, C' \in \mathcal{C}$ be objects which are isomorphic. If $F$ is $U$-left Kan extended from $\mathcal{C}^0$ at $C$, then it is $U$-left Kan extended from $\mathcal{C}^0$ at $C'$.

Proof. Let $\mathcal{C}^1 \subseteq \mathcal{C}$ be the full subcategory spanned by the objects of $\mathcal{C}^0$ together with the object $C$, and let $\mathcal{C}^2 \subseteq \mathcal{C}$ be the full subcategory spanned by the objects of $\mathcal{C}$ together with the objects $C$ and $C'$. If $F$ is $U$-left Kan extended from $\mathcal{C}^0$ at $C$, then the functor $F|_{\mathcal{C}^1}$ is $U$-left Kan extended from $\mathcal{C}^0$. Since every object of $\mathcal{C}^2$ is isomorphic to an object of $\mathcal{C}^1$, the functor $F|_{\mathcal{C}^2}$ is automatically $U$-left Kan extended from $\mathcal{C}^1$ (Proposition 7.3.3.5). Applying Proposition 7.3.7.6, we see that $F|_{\mathcal{C}^2}$ is also $U$-left Kan extended from $\mathcal{C}^0$. In particular, $F$ is $U$-left Kan extended from $\mathcal{C}^0$ at the object $C' \in \mathcal{C}^2$. 

We now prove a variant of Proposition 7.3.7.6, which gives a criterion for the existence of relative Kan extensions.

**Proposition 7.3.7.10.** Let \( F : \mathcal{C} \to \mathcal{D} \) and \( U : \mathcal{D} \to \mathcal{E} \) be functors of \( \infty \)-categories, and suppose that \( F \) is \( U \)-left Kan extended from a full subcategory \( \mathcal{C}^0 \subseteq \mathcal{C} \). Set \( F_0 = F|_{\mathcal{C}^0} \). Then the restriction map

\[
\theta : \mathcal{D}_F/ \to \mathcal{D}_{F_0}/ \times \mathcal{E}(U \circ F)/
\]

is an equivalence of \( \infty \)-categories.

**Proof.** Note that the restriction maps

\[
\mathcal{D}_F/ \to \mathcal{D}_{F_0}/ \quad \mathcal{D}_{F_0}/ \to \mathcal{D} \quad \mathcal{E}(U \circ F)/ \to \mathcal{E}(U \circ F_0)/
\]

are left fibrations of simplicial sets (Corollary 4.3.6.11). It follows that we can regard \( \theta \) as a functor of \( \infty \)-categories which are left-fibered over \( \mathcal{D} \). Consequently, to show that \( \theta \) is an equivalence of \( \infty \)-categories, it will suffice to show that for every object \( D \in \mathcal{D} \), the commutative diagram

\[
\begin{array}{ccc}
\mathcal{D}_F/ \times \mathcal{D}\{D\} & \to & \mathcal{D}_{F_0}/ \times \mathcal{D}\{D\} \\
\downarrow & & \downarrow \\
\mathcal{E}(U \circ F)/ \times \mathcal{E}\{U(D)\} & \to & \{U(D)\} \times \mathcal{E}(U \circ F_0)/ \times \mathcal{E}\{U(D)\}
\end{array}
\]  

(7.29)

induces a homotopy equivalence of Kan complexes

\[
\mathcal{D}_F/ \times \mathcal{D}\{D\} \to (\mathcal{D}_{F_0}/ \times \mathcal{E}(U \circ F_0)/) \times \mathcal{D}\{D\}.
\]

Note that the horizontal maps in the diagram (7.29) are left fibrations between Kan complexes (Corollary 4.3.6.11), and therefore Kan fibrations (Corollary 4.4.3.8). We are therefore reduced to showing that the diagram (7.29) is a homotopy pullback square (Example 3.4.1.3).

Let \( D \in \text{Fun}(\mathcal{C}, \mathcal{D}) \) denote the constant functor taking the value \( D \). Using Theorem 3.4.1.3, we obtain a (termwise) homotopy equivalence from (7.29) to the diagram of morphism spaces

\[
\begin{array}{ccc}
\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{D})}(F, D) & \to & \text{Hom}_{\text{Fun}(\mathcal{C}_0, \mathcal{E})}(F_0, D|_{\mathcal{C}^0}) \\
\downarrow & & \downarrow \\
\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{E})}(U \circ F, U \circ D) & \to & \text{Hom}_{\text{Fun}(\mathcal{C}_0, \mathcal{E})}(U \circ F_0, U \circ D|_{\mathcal{C}^0}).
\end{array}
\]  

(7.30)
Using Corollary 3.4.1.12, we are reduced to showing that the diagram (7.30) is a homotopy pullback square, which is a special case of Proposition 7.3.6.7.

**Corollary 7.3.7.11.** Let \( F : \mathcal{C} \to \mathcal{D} \) and \( U : \mathcal{D} \to \mathcal{E} \) be functors of \( \infty \)-categories, where \( U \) is an inner fibration and \( F \) is \( U \)-left Kan extended from a full subcategory \( \mathcal{C}^0 \subseteq \mathcal{C} \). Set \( F_0 = F|_{\mathcal{C}^0} \). Then the restriction map

\[
\theta : \mathcal{D}/_F \to \mathcal{D}/_{F_0} \times_{\mathcal{E}(U \circ F_0)/} \mathcal{E}(U \circ F)/
\]

is a trivial Kan fibration.

**Proof.** It follows from Proposition 4.3.6.8 that \( \theta \) is a left fibration, and therefore an isofibration (Example 4.4.1.10). By virtue of Proposition 4.5.5.20 it will suffice to show that \( \theta \) is an equivalence of \( \infty \)-categories, which follows from Proposition 7.3.7.10. \( \square \)

**Corollary 7.3.7.12.** Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories which is Kan extended from a full subcategory \( \mathcal{C}^0 \subseteq \mathcal{C} \), and set \( F_0 = F|_{\mathcal{C}^0} \). Then the restriction functor \( \theta : \mathcal{C}/_F \to \mathcal{C}/_{F_0} \) is a trivial Kan fibration.

**Proof.** Apply Corollary 7.3.7.11 in the special case \( \mathcal{E} = \Delta^0 \). \( \square \)

**Corollary 7.3.7.13.** Let \( \mathcal{C} \) be an \( \infty \)-category, let \( U : \mathcal{D} \to \mathcal{E} \) be an inner fibration of \( \infty \)-categories, and suppose we are given a lifting problem

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{D} \\
\downarrow & & \downarrow \mathcal{U} \\
\mathcal{C}^0 & \xrightarrow{F|_{\mathcal{C}^0}} & \mathcal{D} \\
\end{array}
\]

(7.31)

Assume that \( F \) is \( U \)-left Kan extended from a full subcategory \( \mathcal{C}^0 \subseteq \mathcal{C} \). The following conditions are equivalent:

1. The lifting problem (7.31) admits a solution \( \mathbf{F} : \mathcal{C}^0 \to \mathcal{D} \) which is a \( U \)-colimit diagram.
2. The induced lifting problem

\[
\begin{array}{ccc}
\mathcal{C}^0 & \xrightarrow{F|_{\mathcal{C}^0}} & \mathcal{D} \\
\downarrow \mathbf{F}_0 & & \downarrow \mathcal{U} \\
(\mathcal{C}^0)^\circ & \xrightarrow{F|_{(\mathcal{C}^0)^\circ}} & \mathcal{D} \\
\end{array}
\]

(7.32)

admits a solution \( \mathbf{F}_0 : (\mathcal{C}^0)^\circ \to \mathcal{D} \) which is a \( U \)-colimit diagram.
CHAPTER 7. LIMITS AND COLIMITS

Proof. The implication (1) ⇒ (2) follows immediately from Proposition 7.3.7.1. For the converse, suppose that \( F_0 : (\mathcal{C}^0)^{\circ} \to \mathcal{D} \) is a \( U \)-colimit diagram which solves the lifting problem (7.32). Applying Corollary 7.3.7.11, we see that \( F_0 \) can be extended to a functor \( \overline{F} : \mathcal{C}^{\circ} \to \mathcal{D} \) which solves the lifting problem (7.31). It then follows from Proposition 7.3.7.1 that \( \overline{F} \) is a \( U \)-colimit diagram. \( \square \)

Corollary 7.3.7.14. Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories which is left Kan extended from a full subcategory \( \mathcal{C}^0 \subseteq \mathcal{C} \). Then \( F \) has a colimit in \( \mathcal{D} \) if and only if the restriction \( F|_{\mathcal{C}^0} \) has a colimit in \( \mathcal{D} \).

Proof. Apply Corollary 7.3.7.13 in the special case \( \mathcal{E} = \Delta^0 \). \( \square \)

Remark 7.3.7.15. In the situation of Corollary 7.3.7.14, an object of \( \mathcal{D} \) is a colimit of the diagram \( F \) if and only if it is a colimit of the diagram \( F|_{\mathcal{C}^0} \). This follows by combining Corollaries 7.3.7.14 and 7.3.7.2.

Proposition 7.3.7.16. Let \( \mathcal{C} \) be an \( \infty \)-category, let \( \mathcal{C} \subseteq \mathcal{C} \) be a full subcategory, and let \( U : \mathcal{D} \to \mathcal{E} \) be an isofibration of \( \infty \)-categories. Suppose we are given a lifting problem

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{F} & \mathcal{D} \\
\downarrow & \nearrow \mathcal{F} \\
\mathcal{C} & \xrightarrow{U} & \mathcal{E}
\end{array}
\] (7.33)

where \( F \) is \( U \)-left Kan extended from a full subcategory \( \mathcal{C}^0 \subseteq \mathcal{C} \). The following conditions are equivalent:

(1) The lifting problem (7.33) admits a solution \( \overline{F} : \mathcal{C} \to \mathcal{D} \) which is \( U \)-left Kan extended from \( \mathcal{C} \).

(2) The induced lifting problem

\[
\begin{array}{ccc}
\mathcal{C}^0 & \xrightarrow{F|_{\mathcal{C}^0}} & \mathcal{D} \\
\downarrow & \nearrow \mathcal{F} \\
\mathcal{C} & \xrightarrow{U} & \mathcal{E}
\end{array}
\] (7.34)

admits a solution \( \overline{F} : \mathcal{C} \to \mathcal{D} \) which is \( U \)-left Kan extended from \( \mathcal{C}^0 \).
Proof. The implication (1) ⇒ (2) follows immediately from Proposition 7.3.7.6. For the converse, assume that (2) is satisfied. To prove (1), it will suffice to show that for each object \( C \in \overline{\mathcal{C}} \), the induced lifting problem

\[
\begin{array}{ccc}
\mathcal{C}/C & \xrightarrow{F_C} & \mathcal{D} \\
\downarrow \mathcal{T}_C & & \downarrow U \\\n(C/C) \cap & \xrightarrow{E} & \mathcal{E}
\end{array}
\]  

admits a solution \( \mathcal{T}_C : (C/C) \cap \to \mathcal{D} \) which is a \( \mathcal{U} \)-colimit diagram (Proposition 7.3.5.5). Arguing as in the proof of Proposition 7.3.7.6, we see that \( F_C \) is \( \mathcal{U} \)-left Kan extended from the full subcategory \( C_0 / \mathcal{C} \subseteq \mathcal{C} / \mathcal{C} \). Let \( F_0^C \) denote the restriction of \( F_C \) to the subcategory \( C_0 / \mathcal{C} \subseteq \mathcal{C} / \mathcal{C} \). By virtue of Corollary 7.3.7.13, it will suffice to show that the induced lifting problem

\[
\begin{array}{ccc}
C_0/C & \xrightarrow{F_0^C} & \mathcal{D} \\
\downarrow \mathcal{T}_0^C & & \downarrow U \\\n(C_0/C)/C & \xrightarrow{E} & \mathcal{E}
\end{array}
\]  

has a solution \( \mathcal{T}_0^C : (C_0/C)/C \to \mathcal{D} \) which is a \( \mathcal{U} \)-colimit diagram, which follows immediately from assumption (2).

\[\square\]

**Corollary 7.3.7.17.** Let \( \overline{\mathcal{C}} \) be an \( \infty \)-category, let \( \mathcal{C} \subseteq \overline{\mathcal{C}} \) be a full subcategory, and let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories which is left Kan extended from a full subcategory \( C_0 \subseteq \mathcal{C} \). Then \( F \) admits a left Kan extension \( \overline{\mathcal{C}} \to \mathcal{D} \) if and only if the restriction \( F_{|C_0} \) admits a left Kan extension \( \overline{\mathcal{C}} \to \mathcal{D} \).

**Proof.** Apply Proposition 7.3.7.16 in the special case \( \mathcal{E} = \Delta^0 \). \[\square\]

We close this section by establishing counterparts of Corollaries 7.3.7.8 and 7.3.7.14 for Kan extensions along more general functors.

**Proposition 7.3.7.18.** Let \( \mathcal{C}_0, \mathcal{C}_1, \mathcal{C}_2, \) and \( \mathcal{D} \) be \( \infty \)-categories. Suppose we are given functors \( F_i : \mathcal{C}_i \to \mathcal{D} \) for \( 0 \leq i \leq 2 \), functors \( G : \mathcal{C}_0 \to \mathcal{C}_1 \) and \( H : \mathcal{C}_1 \to \mathcal{C}_2 \), and natural transformations

\[
\alpha : F_0 \to F_1 \circ G \quad \beta : F_1 \to F_2 \circ H,
\]

where \( \alpha \) exhibits \( F_1 \) as a left Kan extension of \( F_0 \) along \( G \). The following conditions are equivalent:
(1) The natural transformation $\beta$ exhibits $F_2$ as a left Kan extension of $F_1$ along $H$.

(2) Let $\gamma : F_0 \to F_2 \circ H \circ G$ be a composition of $\alpha$ with $\beta|_{C_0}$ (formed in the $\infty$-category $\text{Fun}(C_0, \mathcal{D})$). Then $\gamma$ exhibits $F_2$ as a left Kan extension of $F_0$ along $H \circ G$.

**Proof.** Let $\mathcal{C}$ denote the iterated relative join $(C_0 \star C_1) \star C_2$, so that we have a cocartesian fibration of $\infty$-categories $\pi : \mathcal{C} \to \Delta^2$ having fibers $\pi^{-1}\{i\} = C_i$ for $0 \leq i \leq 2$ (see Lemma 5.2.3.17). For $0 \leq i < j \leq 2$, let $C_{ij}$ denote the fiber product $N_*(\{i < j\}) \times_{\Delta^2} \mathcal{C}$, which we will identify with $C_i \star C_j$. By virtue of Remark 7.3.1.9 we are free to replace $\alpha$ and $\beta$ by homotopic natural transformations. We can therefore assume that there exist functors

$$F_{01} : C_{01} \to \mathcal{D} \quad F_{12} : C_{12} \to \mathcal{D}$$

satisfying $F_{01}|_{C_0} = F_0$, $F_{01}|_{C_1} = F_1 = F_{12}|_{C_1}$, and $F_{12}|_{C_2} = F_2$, where $\alpha$ and $\beta$ are given by the composite maps

$$\Delta^1 \times C_0 \simeq C_0 \star C_0 C_0 \to C_0 \star C_1 C_1 \xrightarrow{F_{01}} \mathcal{D}$$

$$\Delta^1 \times C_1 \simeq C_1 \star C_1 C_1 \to C_1 \star C_2 C_2 \xrightarrow{F_{12}} \mathcal{D}$$

(see Warning 7.3.2.11). Note that $F_{01}$ and $F_{12}$ can be amalgamated to a morphism of simplicial sets $F' : \Lambda^1_2 \times \Delta^1 \mathcal{C} \to \mathcal{D}$. Since $\pi$ is a cocartesian fibration, the inclusion map $\Lambda^1_2 \times \Delta^1 \mathcal{C} \hookrightarrow \mathcal{C}$ is a categorical equivalence (Proposition 5.3.6.1). Applying Lemma 4.5.5.2 we can extend $F'$ to a functor $F : \mathcal{C} \to \mathcal{D}$.

Let $F_{02}$ denote the restriction of $F$ to $C_{02}$, and let $\gamma : F_0 \to F_2 \circ H \circ G$ denote the natural transformation given by the composite map

$$\Delta^1 \times C_0 \simeq C_0 \star C_0 C_0 \to C_0 \star C_2 C_2 \xrightarrow{F_{02}} \mathcal{D}.$$ 

Note that the composite map

$$\Delta^2 \times C_0 \simeq (C_0 \star C_0 C_0) \star C_0 C_0 \to (C_0 \star C_1 C_1) \star C_2 C_2 \xrightarrow{\text{Fun}} \mathcal{D}$$

can be regarded as a 2-simplex of the $\infty$-category $\text{Fun}(C_0, \mathcal{D})$, which witnesses $\gamma$ as a composition of $\alpha$ with $\beta|_{C_0}$. Applying Proposition 7.3.2.10 we see that (1) and (2) can be reformulated as follows:

$(1')$ The functor $F_{12} : C_{12} \to \mathcal{D}$ is left Kan extended from $C_1$.

$(2')$ The functor $F_{02} : C_{02} \to \mathcal{D}$ is left Kan extended from $C_0$.

By assumption, the natural transformation $\alpha$ exhibits $F_1$ as a left Kan extension of $F_0$ along $G$. Applying Proposition 7.3.2.10 we see that the functor $F_{01}$ is left Kan extended from $C_0$. In particular, $F$ is left Kan extended from $C_0$ at every object of the full subcategory $C_1 \subseteq \mathcal{C}$. It follows that $(2')$ is equivalent to the following:
(2′′) The functor \( F : \mathcal{C} \to \mathcal{D} \) is left Kan extended from \( \mathcal{C}_0 \).

Using Corollary 7.3.7.8, we see that (2′′) is equivalent to the following:

(1′′) The functor \( F : \mathcal{C} \to \mathcal{D} \) is left Kan extended from \( \mathcal{C}_{01} \).

To complete the proof, it will suffice to show that conditions (1′) and (1′′) are equivalent. We will prove something slightly more precise: for every object \( X \in \mathcal{C}_2 \), the conditions are equivalent:

(1′_X) The functor \( F_{12} : \mathcal{C}_{12} \to \mathcal{D} \) is left Kan extended from \( \mathcal{C}_1 \) at \( X \).

(1′′_X) The functor \( F : \mathcal{C} \to \mathcal{D} \) is left Kan extended from \( \mathcal{C}_{01} \) at \( X \).

Let us regard the object \( X \) as fixed, and let \( F_X \) denote the composite map

\[
(\mathcal{C}_{01} \times \mathcal{C}/X)^{\circ} \hookrightarrow (\mathcal{C}/X)^{\circ} \to \mathcal{C} \xrightarrow{F} \mathcal{D}.
\]

We wish to show that \( F_X \) is a colimit diagram in \( \mathcal{D} \) if and only if its restriction to \( (\mathcal{C}_1 \times \mathcal{C}/X)^{\circ} \) is a colimit diagram in \( \mathcal{D} \). By virtue of Corollary 7.2.2.3 it will suffice to show that the inclusion map \( \mathcal{C}_1 \times \mathcal{C}/X \hookrightarrow \mathcal{C}_{01} \times \mathcal{C}/X \) is right cofinal. This follows by applying Proposition 7.2.3.13 to the upper square of the pullback diagram

\[
\begin{array}{ccc}
\mathcal{C}_1 \times \mathcal{C}/X & \xrightarrow{\pi'} & \Delta^2 \\
\downarrow & & \downarrow \\
\mathcal{C}_{01} \times \mathcal{C}/X & \to & \Delta^1 \\
\downarrow & & \downarrow \\
\mathcal{C}/X & \to & \Delta^2,
\end{array}
\]

where \( \pi' \) denotes the composite map \( \mathcal{C}/X \to \mathcal{C} \to \Delta^2 \) (which is a cocartesian fibration by virtue of Proposition 5.1.4.19). \(\square\)

**Proposition 7.3.7.19.** Let \( \mathcal{C}_0, \mathcal{C}_1, \mathcal{C}_2, \) and \( \mathcal{D} \) be \( \infty \)-categories. Suppose we are given functors \( F_0 : \mathcal{C}_0 \to \mathcal{D} \), \( F_1 : \mathcal{C}_1 \to \mathcal{D} \), \( G : \mathcal{C}_0 \to \mathcal{C}_1 \), and \( H : \mathcal{C}_1 \to \mathcal{C}_2 \), where \( F_1 \) is a left Kan extension of \( F_0 \) along \( G \). The following conditions are equivalent:

1. The functor \( F_1 \) admits a left Kan extension along \( H \).
2. The functor \( F_0 \) admits a left Kan extension along \( H \circ G \).
Proof. The implication (1) \(\Rightarrow\) (2) is immediate from Proposition \[7.3.7.18\]. To prove the converse, assume that (2) is satisfied. Define \(C\) as in the proof of Proposition \[7.3.7.18\]. Using the criterion of Corollary \[7.3.5.6\], we see that \(F_0\) admits a left Kan extension \(F : C \to D\). It follows from Proposition \[7.3.2.10\] that \(F|_{C_1}\) is a left Kan extension of \(F_0\) along \(G\), and is therefore isomorphic to \(F_1\) (Remark \[7.3.6.6\]). We may therefore assume without loss of generality that \(F_1 = F|_{C_1}\) (Remark \[7.3.1.10\]). We will complete the proof by showing that \(F_1\) is left Kan extended from \(C_1\), and therefore exhibits \(F|_{C_2}\) as a left Kan extension of \(F_0\) along \(H\) (Proposition \[7.3.2.10\]).

Fix an object \(X \in C_2\), and let \(F_X\) denote the composite map

\[\langle C_0 \times C / X \rangle^\triangleright \hookrightarrow \langle C / X \rangle^\triangleright \to C \xrightarrow{F} D.\]

We wish to show that the composite map

\[\langle C_1 \times C / X \rangle^\triangleright \hookrightarrow \langle C_0 \times C / X \rangle^\triangleright \xrightarrow{F_X} D\]

is a colimit diagram in \(D\). As in the proof of Proposition \[7.3.7.18\], the inclusion map \(C_1 \times C / X \hookrightarrow C_0 \times C / X\) is right cofinal. It will therefore suffice to show that \(F_X\) is a colimit diagram in \(D\) (Corollary \[7.2.2.3\]). This is clear: by construction, the functor \(F\) is left Kan extended from the full subcategory \(C_0 \subseteq C\), and is therefore also left Kan extended from the larger subcategory \(C_0 \subseteq C\) (Proposition \[7.3.7.6\]).

Corollary \[7.3.7.20\]. Let \(F : C \to D\) be a functor of \(\infty\)-categories, let \(\delta : K \to C\) and \(F_0 : K \to D\) be diagrams, and let \(\alpha : F_0 \to F \circ \delta\) be a natural transformation which exhibits \(F\) as a left Kan extension of \(F_0\) along \(\delta\) (see Variant \[7.3.1.5\]). Then:

1. The diagram \(F\) admits a colimit in \(D\) if and only if \(F_0\) admits a colimit in \(D\).
2. Let \(X\) be an object of \(D\), let \(X : C \to D\) denote the constant functor taking the value \(X\). Then a natural transformation \(\beta : F \to X\) exhibits \(X\) as a colimit of the diagram \(F\) if and only if the composite natural transformation

\[F_0 \xrightarrow{\alpha} F \circ \delta \xrightarrow{\beta|_K} X|_K\]

exhibits \(X\) as a colimit of the diagram \(F_0\).

Proof. Using Corollary \[4.1.3.3\] we can choose an inner anodyne morphism \(i : K \hookrightarrow K\), where \(K\) is an \(\infty\)-category. Since \(C\) is an \(\infty\)-category, we extend \(\delta\) and \(F_0\) to functors \(\delta : K \to C\) and \(F_0 : K \to D\), respectively. Similarly, we can extend \(\alpha\) to a natural transformation \(\overline{\alpha} : F_0 \to F \circ \delta\). It follows from Proposition \[7.3.1.14\] that we \(\overline{\alpha}\) exhibits \(F\) as a left Kan extension of \(F_0\) along \(\delta\). We may therefore replace \(K\) by \(K\) and thereby reduce to proving Corollary \[7.3.7.20\] in the special case where \(K\) is an \(\infty\)-category. In this case, assertion (1) is a special case of Proposition \[7.3.7.19\] and assertion (2) is a special case of Proposition \[7.3.7.18\] (see Example \[7.3.1.7\]).
Exercise 7.3.7.21. Show that the conclusions of Propositions 7.3.7.18 and 7.3.7.19 hold if we drop the assumption that the simplicial set \( C_0 \) is an \( \infty \)-category.

7.3.8 Relative Colimits for Cocartesian Fibrations

Let \( U : \mathcal{C} \to \mathcal{D} \) be an inner fibration of \( \infty \)-categories, let \( D \in \mathcal{D} \) be an object, and suppose we are given a morphism \( f : \mathcal{K} \to \mathcal{C} \). If \( f \) is a \( U \)-colimit diagram in the \( \infty \)-category \( \mathcal{C} \), then it is a colimit diagram in the \( \infty \)-category \( \mathcal{C}_D \). The converse holds if \( U \) is a cartesian fibration (Corollary 7.1.5.20), but not in general. In this section, we study the dual situation where \( U \) is a cocartesian fibrations. Our main result asserts that \( f \) is a \( U \)-colimit diagram in \( \mathcal{C} \) if and only if it is a transport-stable colimit diagram in the \( \infty \)-category \( \mathcal{C}_D \): that is, for every morphism \( e : D \to D' \) in \( \mathcal{D} \), the covariant transport functor \( e^! : \mathcal{C}_D \to \mathcal{C}_{D'} \) carries \( f \) to a colimit diagram in the \( \infty \)-category \( \mathcal{C}_{D'} \) (Proposition 7.3.8.2). We begin by showing that the collection of \( U \)-colimit diagrams is stable under covariant transport.

Proposition 7.3.8.1. Let \( U : \mathcal{C} \to \mathcal{D} \) be an inner fibration of \( \infty \)-categories, let \( K \) be a simplicial set, and let \( \alpha : F_0 \to F_1 \) be a natural transformation between diagrams \( F_0, F_1 : \mathcal{K} \to \mathcal{C} \). Suppose that, for every vertex \( x \in \mathcal{K} \), the morphism \( \alpha_x : F_0(x) \to F_1(x) \) is \( U \)-cocartesian. Then:

1. If \( F_0 \) is a \( U \)-colimit diagram, then \( F_1 \) is also a \( U \)-colimit diagram.
2. If \( F_1 \) is a \( U \)-colimit diagram and the natural transformation \( \alpha \) carries the cone point \( v \in \mathcal{K} \) to an isomorphism \( \alpha_v : F_0(v) \to F_1(v) \), then \( F_0 \) is a \( U \)-colimit diagram.

Proof. Using Corollary 4.1.3.3 we can choose an inner anodyne morphism \( i : \mathcal{K} \to \mathcal{K} \), where \( \mathcal{K} \) is an \( \infty \)-category. It follows that the induced map \( \hat{\iota} : \mathcal{K} \to \mathcal{K} \) is also inner anodyne (Example 4.3.6.7), so that the restriction map \( \text{Fun}(\mathcal{K}, \mathcal{C}) \to \text{Fun}(\mathcal{K}, \mathcal{D}) \) is a trivial Kan fibration of simplicial sets (Proposition 1.4.7.6). We can therefore lift \( \alpha \) to a natural transformation \( \iota : \mathcal{F}_0 \to \mathcal{F}_1 \) between natural transformations \( \mathcal{F}_0, \mathcal{F}_1 : \mathcal{K} \to \mathcal{C} \). Since \( \mathcal{F} \) is bijective on vertices, the natural transformation \( \iota \) carries each object of \( \mathcal{K} \) to a \( \mathcal{K} \)-cocartesian morphism of \( \mathcal{C} \). The morphism \( \hat{\iota} \) is right cofinal (Corollary 7.2.1.12), so Corollary 7.2.2.2 guarantees that \( F_0 \) is a \( U \)-colimit diagram if and only if \( \mathcal{F}_0 \) is a \( U \)-colimit diagram. Similarly, \( F_1 \) is a \( U \)-colimit diagram if and only if \( \mathcal{F}_1 \) is a \( U \)-colimit diagram. We may therefore replace \( \alpha \) by \( \iota \) in the statement of Proposition 7.3.8.1 and thereby reduce to the case where \( K = \mathcal{K} \) is an \( \infty \)-category.

Let us identify \( \alpha \) with a functor of \( \infty \)-categories \( F : \Delta^1 \times \mathcal{K} \to \mathcal{C} \). For each object \( x \in \mathcal{K} \), let us write \( x_0 = (0, x) \) and \( x_1 = (1, x) \) for the corresponding objects of \( \Delta^1 \times \mathcal{K} \),
so that the inclusion map $\Delta^1 \times \{x\} \hookrightarrow \Delta^1 \times \mathcal{K}^\circ$ determines a morphism $e_x : x_0 \to x_1$. By construction, the functor $F$ carries each $e_x$ to the $U$-cocartesian morphism $\alpha_x$ of $\mathcal{C}$. By virtue of Proposition 4.6.6.23, $e_x$ is final when viewed as an object of the $\infty$-category

$$\{(0) \times \mathcal{K}^\circ\} \times_{(\Delta^1 \times \mathcal{K}^\circ)} (\Delta^1 \times \mathcal{K}^\circ)/(x_1) \simeq (\mathcal{K}^\circ)/_{x_1},$$

so that $F$ is $U$-left Kan extended from $(0) \times \mathcal{K}^\circ$ at $x_1$ (Corollary 7.2.2.5). Allowing the object $x$ to vary, we see that the functor $H$ is $U$-left Kan extended from $(0) \times \mathcal{K}^\circ$.

We now prove (1). Suppose that $F_0$ is a $U$-colimit diagram. Then $F_0$ is $U$-left Kan extended from $\mathcal{K}$ (Example 7.3.3.7). Applying Proposition 7.3.7.6, we see that the functor $F$ is $U$-left Kan extended from $(0) \times \mathcal{K}$, and therefore from the larger subcategory $\Delta^1 \times \mathcal{K} \subseteq \Delta^1 \times \mathcal{K}^\circ$. It follows that the composite map

$$(\Delta^1 \times \mathcal{K}) \star \{v_1\} \hookrightarrow \Delta^1 \times (\mathcal{K} \star \{v\}) \xrightarrow{F} \mathcal{C}$$

is a $U$-colimit diagram. Since the inclusion map $\{1\} \times \mathcal{K} \hookrightarrow \Delta^1 \times \mathcal{K}$ is right cofinal (Proposition 7.2.1.3), Corollary 7.2.2.2 guarantees that $F_1 = F|_{(\{1\} \times \mathcal{K}) \star \{v_1\}}$ is also a $U$-colimit diagram.

We now prove (2). Let $\pi : \mathcal{K}^\circ \to \Delta^1$ be the functor carrying $\mathcal{K}$ to the vertex $0 \in \Delta^1$ and the cone point $v \in \mathcal{K}^\circ$ to the vertex $1 \in \Delta^1$, and let $G : \mathcal{K}^\circ \to \mathcal{C}$ be the functor given by the composition

$$\mathcal{K}^\circ \xrightarrow{(\pi, \text{id})} \Delta^1 \times \mathcal{K}^\circ \xrightarrow{\beta} \Delta^1.$$

Note that there is a natural transformation $\beta : F_0 \to G$ which is the identity when restricted to $\mathcal{K}$ and which carries the cone point $v$ to the morphism $\alpha_v : F_0(v) \to F_1(v) = G(v)$. If $\alpha_v$ is an isomorphism, then the natural transformation $\beta$ is also an isomorphism (Theorem 4.4.4.4). Consequently, to show that $F_0$ is a $U$-colimit diagram, it will suffice to show that $G$ is a $U$-colimit diagram (Proposition 7.1.5.13). Arguing as above, we see that the functor $F|_{\Delta^1 \times \mathcal{K}}$ is $U$-left Kan extended from the full subcategory $(0) \times \mathcal{K} \subseteq \Delta^1 \times \mathcal{K}$. Applying Proposition 7.3.7.1, we see that $G$ is a $U$-colimit diagram if and only if the composite map

$$(\Delta^1 \times \mathcal{K}) \star \{v_1\} \hookrightarrow \Delta^1 \times (\mathcal{K} \star \{v\}) \xrightarrow{F} \mathcal{C}$$

is a $U$-colimit diagram. By virtue of Corollary 7.2.2.2, this is equivalent to the requirement that $F_1$ is a $U$-colimit diagram. \qed

**Proposition 7.3.8.2.** Let $U : \mathcal{C} \to \mathcal{D}$ be a cocartesian fibration of $\infty$-categories, let $D \in \mathcal{D}$ be an object, and let $f : \mathcal{K}^\circ \to \mathcal{C}_D = \{D\} \times_\mathcal{D} \mathcal{C}$ be a diagram. Then $f$ is a $U$-colimit diagram in the $\infty$-category $\mathcal{C}$ if and only if it satisfies the following condition:

$$(\ast) \text{ Let } e : D \to D' \text{ be a morphism in the } \infty\text{-category } \mathcal{D} \text{ and let } e_1 : \mathcal{C}_D \to \mathcal{C}_{D'} \text{ be the covariant transport functor of Notation 5.2.2.9. Then } (e_1 \circ f) : \mathcal{K}^\circ \to \mathcal{C}_{D'} \text{ is a colimit diagram in the } \infty\text{-category}$$
Example 7.3.8.3. In the situation of Proposition 7.3.8.2, suppose that the cocartesian fibration \( U \) is also a cartesian fibration. Then, for every morphism \( e : D \to D' \) of \( D \), the covariant transport functor \( e! \) has a right adjoint \( e^* \), given by contravariant transport along \( e \) (Proposition 6.2.3.4). In particular, the functor \( e! \) automatically preserves \( K \)-indexed colimits (Corollary 7.1.3.21). We therefore recover the criterion of Corollary 7.1.5.20: the morphism \( f \) is a \( U \)-colimit diagram in \( C \) if and only if it is a colimit diagram in the \( \infty \)-category \( C_D \).

Proof of Proposition 7.3.8.2. For every morphism \( e : D \to D' \) in \( D \), we can choose a natural transformation \( \alpha : f \to e! \circ f \) carrying each vertex of \( K^\circ \) to a \( U \)-cocartesian morphism of \( C \). It follows from Proposition 7.3.8.1 that if \( f \) is a \( U \)-colimit diagram, then \( e! \circ f \) is also a \( U \)-colimit diagram, and therefore a colimit diagram in the \( \infty \)-category \( C_D \) (Corollary 7.1.5.20). This proves the necessity of condition \((\ast)\). For the converse, suppose that \( f \) satisfies condition \((\ast)\); we wish to show that \( f \) is a \( U \)-colimit diagram. By virtue of Proposition 7.1.5.12, this is equivalent to the assertion that for every object \( C \in C \), the diagram of Kan complexes

\[
\begin{array}{ccc}
\text{Hom}_{\text{Fun}(K^\circ, C)}(f, C) & \xrightarrow{\text{Hom}_{\text{Fun}(K, C)}(f|_K, C|_K)} & \text{Hom}_{\text{Fun}(K^\circ, D)}(U \circ f, U \circ C) \\
\downarrow & & \downarrow \\
\text{Hom}_{\text{Fun}(K, D)}(U \circ f|_K, U \circ C|_K) & \xrightarrow{\text{Hom}_{\text{Fun}(K, C)}(f|_K, C|_K)} & \text{Hom}_{\text{Fun}(K^\circ, D)}(U \circ f|_K, U \circ C|_K)
\end{array}
\] (7.37)

is a homotopy pullback square, where \( C \in \text{Fun}(K^\circ, C) \) is the constant diagram taking the value \( C \). Since \( U \) is an inner fibration, the vertical maps in this diagram are Kan fibrations (Proposition 4.6.1.19). Using the criterion of Example 3.4.1.4, it will suffice to show that for every vertex \( u \in \text{Hom}_{\text{Fun}(K^\circ, D)}(U \circ f, U \circ C) \), the induced map

\[
\{u\} \times_{\text{Hom}_{\text{Fun}(K^\circ, C)}(f, C)} \text{Hom}_{\text{Fun}(K^\circ, D)}(U \circ f, U \circ C) \xrightarrow{\theta_u} \{u\} \times_{\text{Hom}_{\text{Fun}(K^\circ, C)}(U \circ f|_K, U \circ C|_K)} \text{Hom}_{\text{Fun}(K^\circ, C)}(f|_K, C|_K)
\]

is a homotopy equivalence of Kan complexes. Set \( D' = U(C) \), so that \( u \) can be identified with a morphism of simplicial sets \( K^\circ \to \text{Hom}_D(D, D') \), and that the condition that \( \theta_u \) is a homotopy equivalence depends only on the homotopy class of \( u \). Since the simplicial set \( K^\circ \) is weakly contractible (Example 4.3.7.11), we may assume without loss of generality that \( u : K^\circ \to \text{Hom}_D(D, D') \) is the constant map taking the value \( e \), for some morphism...
\( e : D \to D' \) in \( \mathcal{D} \). In this case, we can use Proposition 5.1.2.1 to identify \( \theta_u \) with the restriction map

\[
\text{Hom}_{\text{Fun}(\mathcal{K}, \mathcal{C})}(e_! \circ f, D) \to \text{Hom}_{\text{Fun}(\mathcal{K}, \mathcal{C}')}\big( e_! \circ f' \big|_K, D \big|_K \big),
\]

which is a homotopy equivalence by virtue of assumption (*) (see Proposition 7.1.5.12).

Using Proposition 7.3.8.2, we obtain a relative version of Corollary 7.2.3.5:

**Corollary 7.3.8.4.** Let \( U : \mathcal{C} \to \mathcal{D} \) be a cocartesian fibration of \( \infty \)-categories, let \( K \) be a weakly contractible simplicial set, and let \( \mathcal{T} : K^\circ \to \mathcal{C} \) be a diagram. The following conditions are equivalent:

1. The diagram \( \mathcal{T} \) carries each edge of \( K^\circ \) to a \( U \)-cocartesian morphism of \( \mathcal{C} \).
2. The restriction \( f = \mathcal{T} \mid_K \) carries each edge of \( K \) to a \( U \)-cocartesian morphism of \( \mathcal{C} \), and \( \mathcal{T} \) is a \( U \)-colimit diagram.

**Proof.** Without loss of generality, we may assume that \( f \) carries each edge of \( K \) to a \( U \)-cocartesian morphism of \( \mathcal{C} \). Let \( \pi : \Delta^1 \times K^\circ \to K^\circ \) be the morphism which is the identity on \( \{0\} \times K^\circ \) and which carries \( \{1\} \times K^\circ \) to the cone point \( v \in K^\circ \). Set \( C = f(v) \in \mathcal{C} \) and \( D = U(C) \in \mathcal{D} \). Proposition 5.2.1.3 guarantees that the lifting problem

\[
\begin{array}{ccc}
\{0\} \times K^\circ & \to & \mathcal{C} \\
\downarrow \downarrow & & \downarrow \downarrow \\
\Delta^1 \times K^\circ & \to & \mathcal{C}
\end{array}
\]

admits a solution \( \alpha : \Delta^1 \times K^\circ \to \mathcal{C} \) which carries \( \Delta^1 \times \{x\} \) to a \( U \)-cocartesian morphism of \( \mathcal{C} \), for each vertex \( x \in K^\circ \). Set \( \overline{\alpha} = \alpha \mid \{1\} \times K^\circ \), which we regard as a morphism from \( K^\circ \) to the \( \infty \)-category \( \mathcal{C}_D \), and let us identify \( \alpha \) with a natural transformation from \( \mathcal{T} \) to \( \overline{\alpha} \). Note that \( \alpha_v : \mathcal{T}(v) \to \overline{\alpha}(v) \) is a \( U \)-cocartesian morphism of \( \mathcal{C} \) satisfying \( U(\alpha_v) = \text{id}_D \), and is therefore an isomorphism (Proposition 5.1.1.8). Applying Proposition 7.3.8.1 we can reformulate (2) as follows:

(2') The morphism \( \overline{\alpha} : K^\circ \to \mathcal{C}_D \) is a \( U \)-colimit diagram in \( \mathcal{C} \).

Set \( g = \overline{\alpha} \mid_K \). For every edge \( u : x \to y \) of \( K \), we have a commutative diagram

\[
\begin{array}{ccc}
f(x) & \xrightarrow{f(u)} & f(y) \\
\downarrow \alpha_x & & \downarrow \alpha_y \\
g(x) & \xrightarrow{g(u)} & g(y)
\end{array}
\]
where \( f(u), \alpha_x, \) and \( \alpha_y \) are \( U \)-cocartesian. Applying Corollary 5.1.2.4, we deduce that \( g(u) \) is \( U \)-cocartesian when viewed as a morphism of \( \mathcal{C} \), and is therefore an isomorphism in the \( \infty \)-category \( \mathcal{C}_D \) (Proposition 5.1.1.8). Similarly, for every vertex \( x \in K \), the unique edge \( c_x : x \to v \) of \( K^\circ \) determines a commutative diagram

\[
\begin{array}{ccc}
f(x) & \xrightarrow{f(c_x)} & f(v) \\
\downarrow{\alpha_x} & & \downarrow{\alpha_v} \\
g(x) & \xrightarrow{g(c_x)} & g(v),
\end{array}
\]

where \( \alpha_x \) is \( U \)-cocartesian and \( \alpha_v \) is an isomorphism. Combining Corollary 5.1.2.4, Corollary 5.1.2.5, and Proposition 5.1.1.8, we see that \( f(c_x) \) is \( U \)-cocartesian if and only if \( g(c_x) \) is an isomorphism in the \( \infty \)-category \( \mathcal{C}_D \). We can therefore reformulate condition (1) as follows:

(1') The diagram \( g \) carries each edge of \( K^\circ \) to an isomorphism in the \( \infty \)-category \( \mathcal{C}_D \).

By virtue of Corollary 7.2.3.5 (1') is equivalent to the requirement that \( g \) is a colimit diagram in the \( \infty \)-category \( \mathcal{C}_D \). In particular, the implication (1') \( \Rightarrow \) (2') follows from Corollary 7.1.5.20. To prove the converse, it will suffice to show that condition (1') is satisfied, then for every morphism \( e : D \to D' \) in \( \mathcal{D} \), the covariant transport functor \( e_! : \mathcal{C}_D \to \mathcal{C}_{D'} \) carries \( g \) to a colimit diagram in the \( \infty \)-category \( \mathcal{C}_{D'} \) (Proposition 7.3.8.2). This follows immediately from Corollary 7.2.3.5 (applied to the composite diagram \( K^\circ \xrightarrow{\mathcal{F}_0} \mathcal{C}_D \xrightarrow{\alpha} \mathcal{C}_{D'} \)).

The criterion of Proposition 7.3.8.2 has a counterpart for the existence of \( U \)-colimit diagrams.

**Proposition 7.3.8.5.** Let \( U : \mathcal{C} \to \mathcal{D} \) be a cocartesian fibration of \( \infty \)-categories, and suppose we are given a lifting problem

\[
\begin{array}{ccc}
K & \xrightarrow{f_0} & \mathcal{C} \\
\downarrow{\mathcal{F}_0} & & \downarrow{U} \\
K^\circ & \xrightarrow{g} & \mathcal{D}
\end{array}
\]  

(7.38)

Let \( v \in K^\circ \) be the cone point and set \( D = g(v) \). Then there exists a diagram \( f_1 : K \to \mathcal{C}_D \subseteq \mathcal{C} \) and a natural transformation \( \alpha : f_0 \to f_1 \) which carries each vertex \( x \in K \) to a \( U \)-cocartesian morphism \( \alpha_x : f_0(x) \to f_1(x) \) of \( \mathcal{C} \), where \( U \circ \alpha \) is given by the composition \( \Delta^1 \times K \xrightarrow{\xi} K^\circ \xrightarrow{g} \mathcal{D} \). Moreover, the lifting problem (7.38) admits a solution \( \mathcal{F}_0 : K^\circ \to \mathcal{C} \) which is a \( U \)-colimit diagram if and only if the following pair of conditions is satisfied:
(1) The diagram \( f_1 \) admits a colimit \( \overline{f}_1 : K^\circ \to C_D \) in the ∞-category \( C_D \).

(2) Let \( e : D \to D' \) be a morphism in the ∞-category \( D \) and let \( e_1 : C_D \to C_{D'} \) be the covariant transport functor of Notation 5.2.2.9. Then \( (e_1 \circ \overline{f}_1) : K^\circ \to C_{D'} \) is a colimit diagram in the ∞-category \( C_{D'} \).

**Proof.** The existence (and essential uniqueness) of the diagram \( f_1 \) and the natural transformation \( \alpha : f_0 \to f_1 \) follow from Proposition 5.2.1.3. Let us first show that conditions (1) and (2) are necessary. Suppose that the lifting problem (7.38) admits a solution \( f_0 : K \to C \) which is a \( U \)-colimit diagram. Using Proposition 5.2.1.3, we can extend \( f_1 \) to a diagram \( \overline{f}_1 : K^\circ \to C_D \) and \( \alpha \) to a natural transformation \( \overline{f}_0 \to \overline{f}_1 \) which carries each vertex \( x \in K^\circ \) to a \( U \)-cocartesian morphism \( \overline{f}_x : \overline{f}_0(x) \to \overline{f}_1(x) \). Proposition 7.3.8.1 guarantees that \( \overline{f}_1 \) is a \( U \)-colimit diagram in the ∞-category \( C \), and therefore satisfies conditions (1) and (2) by virtue of Proposition 7.3.8.2.

Now suppose that conditions (1) and (2) are satisfied. Let \( \overline{f}_1 : K^\circ \to C_D \) be a colimit diagram extending \( f_1 \). It follows from (2) that \( \overline{f}_1 \) is a \( U \)-colimit diagram in the ∞-category \( C \). Let \( \pi : (\Delta^1 \times K)^\circ \to K^\circ \) denote the morphism which is the identity when restricted to \( \{0\} \times K \), and which carries \( \{1\} \times K^\circ \) to the cone point of \( K^\circ \). Since the inclusion map \( \{1\} \times K \hookrightarrow \Delta^1 \times K \) is right cofinal (Proposition 7.2.1.3), Proposition 7.2.2.9 guarantees that the lifting problem

\[
\begin{array}{ccc}
\Delta^1 \times K & \xrightarrow{\alpha} & C \\
\downarrow \pi & & \downarrow U \\
(\Delta^1 \times K)^\circ & \xrightarrow{g \circ \pi} & D
\end{array}
\]

admits a solution \( \overline{\pi} : (\Delta^1 \times K)^\circ \to C \) which is a \( U \)-colimit diagram. Note that in this case \( \overline{f}_1 = \overline{\pi}|_{\{0\} \times K} \) is also a \( U \)-colimit diagram (Corollary 7.2.2.2). Setting \( \overline{f}_0 = \overline{\pi}|_{\{0\} \times K} \), we note that \( \overline{\pi} \) determines a natural transformation of functors \( \overline{f}_0 \to \overline{f}_1 \) which carries each vertex of \( x \) to a \( U \)-cocartesian morphism of \( C \) and carries the cone point to an identity morphism of \( C \). Applying the criterion of Proposition 7.3.8.1, we conclude that \( \overline{f}_0 \) is a \( U \)-colimit diagram which solves the lifting problem (7.38).

**Corollary 7.3.8.6.** Let \( U : C \to D \) be a cocartesian fibration of ∞-categories and let \( K \) be a simplicial set. The following conditions are equivalent:

1. For every object \( D \in D \), the ∞-category \( C_D = \{D\} \times_D C \) admits \( K \)-indexed colimits.

Moreover, for every morphism \( e : D \to D' \) in \( D \), the covariant transport functor \( e_1 : C_D \to C_{D'} \) preserves \( K \)-indexed colimits.
(2) Every lifting problem

\[
K @>f>>& C \\
\downarrow\downarrow @>{\overline{f}}>>& \downarrow\downarrow \\
K^\circ @>>D>>& D
\]

admits a solution \( \overline{f} : K^\circ \to C \) which is a \( U \)-colimit diagram.

\textbf{Proof.} The implication (1) \( \Rightarrow \) (2) follows immediately from Proposition \( \ref{Kan-extensions-7.3.8.5} \). Conversely, suppose that (2) is satisfied. For each object \( D \in \mathcal{D} \), condition (2) guarantees that every diagram \( f : K \to \mathcal{C}_D \) admits an extension \( \overline{f} : K^\circ \to \mathcal{C}_D \) which is a \( U \)-colimit diagram in \( \mathcal{C} \). In particular, \( \overline{f} \) is a colimit diagram in \( \mathcal{C}_D \) (Corollary \( \ref{Kan-extensions-7.1.5.20} \)) having the property that for every morphism \( e : D \to D' \) in \( \mathcal{D} \), the composition \( e_! \circ \overline{f} \) is a colimit diagram in \( \mathcal{C}_{D'} \) (Proposition \( \ref{Kan-extensions-7.3.8.2} \)). To complete the proof, we observe that if \( \overline{f}' : K^\circ \to \mathcal{C}_D \) is any other colimit diagram satisfying \( \overline{f}'|_K = f \), then \( \overline{f}' \) is isomorphic to \( \overline{f} \) as an object of the \( \infty \)-category \( \text{Fun}(K^\circ, \mathcal{C}_D) \), so that \( e_! \circ \overline{f}' \) is also a colimit diagram in \( \mathcal{C}_{D'} \) (Corollary \( \ref{Kan-extensions-7.1.2.14} \)). \( \square \)

\textbf{Corollary 7.3.8.7.} Let \( U : \mathcal{D} \to \mathcal{E} \) be a cocartesian fibration of \( \infty \)-categories, let \( \mathcal{C} \) be an \( \infty \)-category, and let \( \mathcal{C}^0 \subseteq \mathcal{C} \) be a full subcategory. Suppose that the following conditions are satisfied:

- For every object \( C \in \mathcal{C} \) and every object \( E \in \mathcal{E} \), the \( \infty \)-category \( \mathcal{D}_E = \{ E \} \times_\mathcal{E} \mathcal{D} \) admits \( \mathcal{C}^0/C \)-indexed colimits.

- For every object \( C \in \mathcal{C} \) and every morphism \( e : E \to E' \) in \( \mathcal{E} \), the covariant transport functor \( e_! : \mathcal{D}_E \to \mathcal{D}_{E'} \) preserves \( \mathcal{C}^0/C \)-indexed colimits.

Then every lifting problem

\[
\mathcal{C}^0 @>F>>& \mathcal{D} \\
\downarrow\downarrow @>{\overline{F}}>>& \downarrow\downarrow \\
\mathcal{C} @>>U>>& \mathcal{E}
\]

admits a solution \( \overline{F} : \mathcal{C} \to \mathcal{D} \) which is \( U \)-left Kan extended from \( \mathcal{C}^0 \).

\textbf{Proof.} Combine Proposition \( \ref{Kan-extensions-7.3.5.5} \) with Corollary \( \ref{Kan-extensions-7.3.8.6} \) \( \square \)
CHAPTER 7. LIMITS AND COLIMITS

7.4 Limits and Colimits of ∞-Categories

Recall that the collection of (small) ∞-categories can be organized into a (large) ∞-category QC (see Construction 5.6.4.1). Our goal in this section is to study limits and colimits in the ∞-category QC. Fix a small ∞-category C, and suppose we are given a diagram \( F : C \to QC \). We will show that the diagram \( F \) admits both a limit \( \lim_{\leftarrow} (F) \) and a colimit \( \lim_{\rightarrow} (F) \), which can be described explicitly in terms of the ∞-category of elements \( \int C F \) introduced in Definition 5.7.2.1:

(1) Let \( U : \int C F \to C \) be the forgetful functor, and let \( \text{Fun}_{\text{Cart}}^C(C, \int C F) \) denote the full subcategory of \( \text{Fun}_{/C}(C, \int C F) \) spanned by those functors \( F : C \to \int C F \) which satisfy \( U \circ F = \text{id}_C \) and which carry each morphism of \( C \) to a \( U \)-cocartesian morphism of \( \int C F \). In §7.4.1, we show that the ∞-category \( \text{Fun}_{\text{Cart}}^C(C, \int C F) \) is a limit of the diagram \( F \) (Corollary 7.4.1.10).

(2) Let \( W \) be the collection of all \( U \)-cocartesian morphisms of \( \int C F \), and let \( (\int C F)[W^{-1}] \) denote a localization of \( \int C F \) with respect to \( W \) (Definition 6.3.1.9). In §7.4.3, we show that \( (\int C F)[W^{-1}] \) is a colimit of the diagram \( F \) (Corollary 7.4.3.12).

For many applications, it is not enough to describe the limit \( \lim_{\leftarrow} (F) \) and colimit \( \lim_{\rightarrow} (F) \) as abstract ∞-categories: we also need to understand their relationship to the diagram \( F : C \to QC \). In other words, we would like to have criteria which can be used to detect when an extension \( F : C \to \int C F \) is a limit diagram, and when an extension \( F : C \to QC \) is a colimit diagram. To formulate these criteria, it will be convenient to slightly shift our perspective. Fix a cocartesian fibration \( U : E \to C \) having covariant transport representation \( F \) (that is, a cocartesian fibration which is equivalent to the forgetful functor \( \int C F \to C \)).

- Suppose \( U \) is obtained as the pullback of a cocartesian fibration \( \overline{U} : \overline{E} \to C^\circ \), and let \( \overline{E}_0 \) denote the fiber of \( \overline{U} \) over the cone point \( 0 \in C^\circ \). In §7.4.1 we introduce a map

\[
Df : \overline{E}_0 \to \text{Fun}_{/C}(C, E),
\]

which we will refer to as the covariant diffraction functor (Construction 7.4.1.3). Roughly speaking, it is characterized by the requirement that for every object \( X \in \overline{E}_0 \) and every object \( C \in C \), there is a \( U \)-cocartesian morphism \( X \to Df(X)(C) \) (depending functorially on \( X \) and \( C \)).

- Suppose \( U \) is obtained as the pullback of a cocartesian fibration \( \overline{U} : \overline{E} \to C^\circ \), and let \( \overline{E}_1 \) denote the fiber of \( \overline{U} \) over the cone point \( 1 \in C^\circ \). In §7.4.3 we introduce a map

\[
Rf : E \to \overline{E}_1,
\]
which we will refer to as the covariant refraction functor (Definition 7.4.3.1). Roughly speaking, it is characterized by the requirement that for every object \( X \in \mathcal{E} \), there is a \( \mathcal{U} \)-cocartesian morphism \( X \to \text{Rf}(X) \) (depending functorially on \( X \)).

We will deduce (1) and (2) from the following more precise assertions:

**Diffraction Criterion:** Suppose we are given a pullback diagram

\[
\begin{array}{ccc}
\mathcal{E} & \rightarrow & \mathcal{Y} \\
\downarrow & & \downarrow \\
\mathcal{C} & \rightarrow & \mathcal{C}^\circ,
\end{array}
\]

where \( U \) and \( \mathcal{U} \) are cocartesian fibrations. Then the covariant transport representation \( \text{Tr}_{\mathcal{E}/\mathcal{C}} : \mathcal{C}^{\circ} \to \mathcal{Q}\mathcal{C} \) is a limit diagram (in the \( \infty \)-category \( \mathcal{Q}\mathcal{C} \)) if and only if the covariant diffraction functor \( \text{Df} : \mathcal{E}_0 \to \text{Fun}_{/\mathcal{C}}^{/\mathcal{C}\text{art}}(\mathcal{C}, \mathcal{E}) \) is a fully faithful embedding, whose essential image is the the \( \infty \)-category \( \text{Fun}_{/\mathcal{C}}^{/\mathcal{C}\text{art}}(\mathcal{C}, \mathcal{E}) \) of cocartesian sections of \( U \) (see Theorem 7.4.1.1 and Remark 7.4.1.5).

**Refraction Criterion:** Suppose we are given a pullback diagram

\[
\begin{array}{ccc}
\mathcal{E} & \rightarrow & \mathcal{Y} \\
\downarrow & & \downarrow \\
\mathcal{C} & \rightarrow & \mathcal{C}^\circ,
\end{array}
\]

where \( U \) and \( \mathcal{U} \) are cocartesian fibrations. Then the covariant transport representation \( \text{Tr}_{\mathcal{E}/\mathcal{C}} : \mathcal{C}^{\circ} \to \mathcal{Q}\mathcal{C} \) is a colimit diagram (in the \( \infty \)-category \( \mathcal{Q}\mathcal{C} \)) if and only if the covariant refraction functor \( \text{Rf} : \mathcal{E} \to \mathcal{Y}_1 \) exhibits \( \mathcal{Y}_1 \) as a localization of \( \mathcal{E} \) with respect to the collection of \( U \)-cocartesian morphisms (Theorem 7.4.3.6).

We will establish the diffraction and refraction criteria in §7.4.2 and §7.4.3, respectively. In §7.4.5, we restrict our attention to the special case where \( U : \mathcal{E} \to \mathcal{C} \) is a left fibration, and apply the results described above to describe limits and colimits in the \( \infty \)-category \( \mathcal{S} \) of spaces.

**Remark 7.4.0.1.** In the outline above, we have implicitly suggested that \( \mathcal{C} \) is an \( \infty \)-category. This is not important: all of the results of this section can be applied to diagrams \( \mathcal{F} : \mathcal{C} \to \mathcal{Q}\mathcal{C} \) indexed by an arbitrary (small) simplicial set \( \mathcal{C} \).
Remark 7.4.0.2. For any cocartesian fibration $U : \mathcal{E} \to \mathcal{C}$, the associated covariant diffraction functor $Df : \mathcal{E}_0 \to \text{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ automatically factors through the full subcategory $\text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{C}, \mathcal{E})$ (see Construction 7.4.1.3). Similarly, for any cocartesian fibration $\overline{U} : \overline{\mathcal{E}} \to \overline{\mathcal{C}}$, the covariant refraction functor $Rf : \mathcal{E} \to \mathcal{E}_1$ automatically carries $U$-cocartesian edges of $\mathcal{E}$ to isomorphisms in the $\infty$-category $\mathcal{E}_1$ (Remark 7.4.3.5).

7.4.1 Limits of $\infty$-Categories

Let $\mathcal{QC}$ denote the $\infty$-category of (small) $\infty$-categories (Construction 5.6.4.1). Our goal in this section (and § 7.4.2) is to show that the $\infty$-category $\mathcal{QC}$ admits small limits (Corollary 7.4.1.11). In fact, we will prove something more precise: if $\mathcal{C}$ is a small $\infty$-category, then the limit of any diagram $F : \mathcal{C} \to \mathcal{QC}$ can be realized as explicitly as a full subcategory of the $\infty$-category of sections of the cocartesian fibration $U : \int_{\mathcal{C}} F \to \mathcal{C}$ of Proposition 5.7.2.2 (Corollary 7.4.1.10).

Recall that, if $U : \mathcal{E} \to \mathcal{C}$ and $U' : \mathcal{E}' \to \mathcal{C}$ are cocartesian fibrations of simplicial sets, then $\text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{E}, \mathcal{E}')$ denotes the full subcategory of $\text{Fun}_{/\mathcal{C}}(\mathcal{E}, \mathcal{E}')$ spanned by those functors $F : \mathcal{E} \to \mathcal{E}'$ which carry $U$-cocartesian edges of $\mathcal{E}$ to $U'$-cocartesian edges of $\mathcal{E}'$ (Notation 5.3.1.10). Our main result can be stated as follows:

Theorem 7.4.1.1 (Diffraction Criterion). Suppose we are given a pullback diagram of small simplicial sets

$$
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{U} & \mathcal{E}' \\
\mathcal{C} & \xrightarrow{\overline{U}} & \mathcal{C}'
\end{array}
$$

where $U$ and $\overline{U}$ are cocartesian fibrations. The following conditions are equivalent:

1. The restriction map

$$
\text{Fun}_{/\mathcal{C}^2}^{\text{Cart}}(\mathcal{C}, \mathcal{E}) \to \text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{C}, \mathcal{E})
$$

is an equivalence of $\infty$-categories.

2. The covariant transport representation

$$
\text{Tr}_{\mathcal{E}/\mathcal{C}^2} : \mathcal{C} \to \mathcal{QC}
$$

of Notation 5.7.5.14 is a limit diagram in the $\infty$-category $\mathcal{QC}$.

Remark 7.4.1.2. In the situation of Theorem 7.4.1.1, the restriction map $\text{Fun}_{/\mathcal{C}^2}^{\text{Cart}}(\mathcal{C}, \mathcal{E}) \to \text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{C}, \mathcal{E})$ is automatically an isofibration of $\infty$-categories (Remark 5.3.1.18). Using Proposition 4.5.5.20, we see that condition (1) of Theorem 7.4.1.1 is equivalent to the following a priori stronger condition:
The restriction map
\[ \text{Fun}_{\mathcal{C}}^{\mathbf{Cart}}(\mathcal{C}, \mathcal{E}) \to \text{Fun}_{\mathcal{C}}^{\mathbf{Cart}}(\mathcal{C}, \mathcal{E}) \]
is a trivial Kan fibration of simplicial sets.

**Construction 7.4.1.3 (Covariant Diffraction).** Suppose we are given a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{E} & \longrightarrow & \mathcal{E} \\
\downarrow U & & \downarrow \mathcal{U} \\
\mathcal{C} & \longrightarrow & \mathcal{C}^a,
\end{array}
\]

where \( U \) and \( \mathcal{U} \) are cocartesian fibrations. Let \( \mathcal{E}_0 \) denote the fiber of \( \mathcal{U} \) over the cone point \( 0 \in \mathcal{C}^a \). We then have restriction maps

\[
\begin{array}{c}
\mathcal{E}_0 \xleftarrow{ev} \text{Fun}_{\mathcal{C}}^{\mathbf{Cart}}(\mathcal{C}^a, \mathcal{E}) \xrightarrow{\theta} \text{Fun}_{\mathcal{C}}^{\mathbf{Cart}}(\mathcal{C}, \mathcal{E}),
\end{array}
\]

where \( ev \) is a trivial Kan fibration (Corollary 5.3.1.23). Composing \( \theta \) with a section of \( ev \), we obtain a functor of \( \infty \)-categories \( Df : \mathcal{E}_0 \to \text{Fun}_{\mathcal{C}}^{\mathbf{Cart}}(\mathcal{C}, \mathcal{E}) \) which is well-defined up to isomorphism. We will refer to \( Df \) as the **covariant diffraction functor** associated to the cocartesian fibration \( \mathcal{U} \).

**Remark 7.4.1.4.** In the situation of Construction 7.4.1.3, let \( C \in \mathcal{C} \) be a vertex and let \( ev_C : \text{Fun}_{\mathcal{C}}^{\mathbf{Cart}}(\mathcal{C}, \mathcal{E}) \to \mathcal{E}_C \) be the evaluation functor, given on objects by \( ev_C(F) = F(C) \). Then the composition

\[
\begin{array}{ccc}
\mathcal{E}_0 & \xrightarrow{Df} & \text{Fun}_{\mathcal{C}}^{\mathbf{Cart}}(\mathcal{C}, \mathcal{E}) \\
& \xrightarrow{ev_C} & \mathcal{E}_C
\end{array}
\]
is given by covariant transport along the unique edge \( 0 \to C \) of \( \mathcal{C}^a \).

**Remark 7.4.1.5.** Suppose we are given a pullback diagram of small simplicial sets

\[
\begin{array}{ccc}
\mathcal{E} & \longrightarrow & \mathcal{E} \\
\downarrow U & & \downarrow \mathcal{U} \\
\mathcal{C} & \longrightarrow & \mathcal{C}^a.
\end{array}
\]

Then the covariant diffraction functor \( Df : \mathcal{E}_0 \to \text{Fun}_{\mathcal{C}}^{\mathbf{Cart}}(\mathcal{C}, \mathcal{E}) \) of Construction 7.4.1.3 is an equivalence of \( \infty \)-categories if and only if the covariant transport representation \( Tr_{\mathcal{C}^a} : \mathcal{C}^a \to \mathcal{QC} \) is a limit diagram in the \( \infty \)-category \( \mathcal{QC} \) (this is a restatement of Theorem 7.4.1.1).
We now show that there exists a good supply of cocartesian fibrations which satisfy the hypotheses of Theorem 7.4.1.1.

**Proposition 7.4.1.6.** Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets. Then there exists a pullback diagram

\[
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{U} & \mathcal{E} \\
\downarrow & & \downarrow \\
\mathcal{C} & \xrightarrow{\mathcal{C}} & \mathcal{C} \end{array}
\]

where \( U \) is a cocartesian fibration and the restriction map

\[
\text{Fun}_{\mathcal{C}\text{Cart}}(\mathcal{C}^\Delta \times \mathcal{E}) \to \text{Fun}_{\mathcal{C}\text{Cart}}(\mathcal{C}, \mathcal{E})
\]

is an equivalence of \( \infty \)-categories.

**Proof.** Let \( \text{ev} : \text{Fun}_{\mathcal{C}\text{Cart}}(\mathcal{C}, \mathcal{E}) \times \mathcal{C} \to \mathcal{E} \) denote the evaluation morphism (given on vertices by the formula \( \text{ev}(F, C) = F(C) \)), and let

\[
\mathcal{E}' = (\text{Fun}_{\mathcal{C}\text{Cart}}(\mathcal{C}, \mathcal{E}) \times \mathcal{C}) \ast_{\mathcal{E}} \mathcal{E}
\]

denote the relative join of Construction 5.2.3.1. Note that we have a canonical map

\[
U' : \mathcal{E}' = (\text{Fun}_{\mathcal{C}\text{Cart}}(\mathcal{C}, \mathcal{E}) \times \mathcal{C}) \ast_{\mathcal{E}} \mathcal{E} \to \mathcal{C} \ast_{\mathcal{C}} \mathcal{C} \simeq \Delta^1 \times \mathcal{C}.
\]

Let \( \pi : \text{Fun}_{\mathcal{C}\text{Cart}}(\mathcal{C}, \mathcal{E}) \times \mathcal{C} \to \mathcal{C} \) be given by projection onto the second factor. Note that \( \pi \) is a cocartesian fibration, and that an edge of the product \( \text{Fun}_{\mathcal{C}\text{Cart}}(\mathcal{C}, \mathcal{E}) \times \mathcal{C} \) is \( \pi \)-cocartesian if and only if its image in \( \text{Fun}_{\mathcal{C}\text{Cart}}(\mathcal{C}, \mathcal{E}) \) is an isomorphism. It follows that the \( \text{ev} \) carries \( \pi \)-cocartesian edges of \( \text{Fun}_{\mathcal{C}\text{Cart}}(\mathcal{C}, \mathcal{E}) \times \mathcal{C} \) to \( U \)-cocartesian edges of \( \mathcal{E} \). Applying Lemma 5.2.3.17, we deduce that \( U' \) is a cocartesian fibration. By construction, we can identify \( \mathcal{E} \) with the inverse image of \( \{1\} \times \mathcal{C} \) under \( U' \).

Let \( \mathcal{E}'' \) denote the pushout

\[
(\text{Fun}_{\mathcal{C}\text{Cart}}(\mathcal{C}, \mathcal{E}) \times \mathcal{C}^\Delta) \coprod_{(\text{Fun}_{\mathcal{C}\text{Cart}}(\mathcal{C}, \mathcal{E}) \times \mathcal{C}^\Delta)} \mathcal{E}'
\]

Amalgamating \( U' \) with the projection map \( \text{Fun}_{\mathcal{C}\text{Cart}}(\mathcal{C}, \mathcal{E}) \times \mathcal{C}^\Delta \to \mathcal{C}^\Delta \), we obtain a morphism of simplicial sets \( U'' : \mathcal{E}'' \to K \), where \( K \) denotes the pushout \( (\{0\} \times \mathcal{C}) \coprod (\Delta^1 \times \mathcal{C}) \). It follows from Proposition 5.1.4.7 that \( U'' \) is also a cocartesian fibration.

Let us abuse notation by identifying \( K \) with its image in the simplicial set \( (\Delta^1 \times \mathcal{C})^\Delta \). Since the inclusion map \( \{0\} \times \mathcal{C} \hookrightarrow \Delta^1 \times \mathcal{C} \) is left anodyne (Proposition 4.2.5.3), the inclusion
7.4. LIMITS AND COLIMITS OF $\infty$-CATEGORIES

$K \hookrightarrow (\Delta^1 \times \mathcal{C})^\circ$ is inner anodyne (Example 4.3.6.5). Applying Proposition 5.7.7.2, we can write $U''$ as the pullback of a cocartesian fibration $U''' : \mathcal{E}''' \to (\Delta^1 \times \mathcal{C})^\circ$. We then have a commutative diagram of simplicial sets

\[
\begin{array}{cccc}
\mathcal{E} & \rightarrow & \mathcal{E}' & \rightarrow & \mathcal{E}'' & \rightarrow & \mathcal{E}'''\\
\downarrow U & & \downarrow U'' & & \downarrow U''' & & \downarrow U'''\\
\{1\} \times \mathcal{C} & \rightarrow & \Delta^1 \times \mathcal{C} & \rightarrow & K & \rightarrow & (\Delta^1 \times \mathcal{C})^\circ,
\end{array}
\]

where each square is a pullback and each vertical map is a cocartesian fibration. Let $\mathcal{E}'$ denote the pullback $((\{1\} \times \mathcal{C})^\circ \times (\Delta^1 \times \mathcal{C})^\circ) \mathcal{E}'''$, so that $U'''$ restricts to a cocartesian fibration $U : \mathcal{E} \to (\{1\} \times \mathcal{C})^\circ$. We will complete the proof by showing that the commutative diagram

\[
\begin{array}{c}
\mathcal{E} \rightarrow \mathcal{E}' \\
\downarrow U & \downarrow U' \\
\{1\} \times \mathcal{C} \rightarrow (\{1\} \times \mathcal{C})^\circ
\end{array}
\]

satisfies the requirements of Proposition 7.4.1.6.

For every simplicial subset $A \subseteq (\Delta^1 \times \mathcal{C})^\circ$, let $\mathcal{D}(A)$ denote the $\infty$-category $\text{Fun}_{/A}^{\text{CCart}}(A, A \times (\Delta^1 \times \mathcal{C})^\circ \mathcal{E}''')$.

Let $0$ denote the cone point of $(\Delta^1 \times \mathcal{C})^\circ$. Note that we have a commutative diagram of restriction functors

\[
\begin{array}{ccc}
\mathcal{D}((\Delta^1 \times \mathcal{C})^\circ) & \xrightarrow{\alpha} & \mathcal{D}(\{1\} \times \mathcal{C})^\circ \\
\downarrow \beta & & \downarrow \alpha \\
\mathcal{D}(K) & \xrightarrow{\beta'} & \mathcal{D}(\{1\} \times \mathcal{C}) \\
\downarrow \gamma & & \\
\mathcal{D}(\{0\}).
\end{array}
\]

We wish to show that $\alpha$ is an equivalence of $\infty$-categories. Since the inclusion $K \hookrightarrow (\Delta^1 \times \mathcal{C})^\circ$ is inner anodyne (as noted above) and the inclusion $\{1\} \times \mathcal{C}^\circ \hookrightarrow (\Delta^1 \times \mathcal{C})^\circ$ is left anodyne
(Lemma 4.3.7.8), the morphisms $\alpha'$ and $\beta$ are trivial Kan fibrations (Proposition 5.3.1.21). It will therefore suffice to show that $\beta'$ is an equivalence of $\infty$-categories.

Amalgamating the map

$$\text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{C}, \mathcal{E}) \times \Delta^1 \times \mathcal{C} \simeq \left( \text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{C}, \mathcal{E}) \times \mathcal{C} \right) \star_{(\text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{C}, \mathcal{E}) \times \mathcal{C})} \left( \text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{C}, \mathcal{E}) \times \mathcal{C} \right)$$

with the identity on $\text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{C}, \mathcal{E}) \times \mathcal{C}$, we obtain a morphism of simplicial sets $F : \text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{C}, \mathcal{E}) \times K \to \mathcal{E}'$. If $e$ is an edge of the product $\text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{C}, \mathcal{E}) \times K$ whose image in $\text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{C}, \mathcal{E})$ is an isomorphism, then $F(e)$ is a $U''$-cartesian edge of $\mathcal{E}''$. We can therefore identify $F$ with a morphism of simplicial sets $f : \text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{C}, \mathcal{E}) \to D(K)$. Unwinding the definitions, we see that $\beta' \circ f$ is an isomorphism of simplicial sets. Consequently, to show that $\beta'$ is an equivalence of $\infty$-categories, it will suffice to show that $f$ is an equivalence of $\infty$-categories. Similarly, the composite map $\gamma \circ f$ is an isomorphism, so we are reduced to proving that $\gamma$ is an equivalence of $\infty$-categories. Since $\beta$ is a trivial Kan fibration, this is equivalent to the assertion that $\gamma \circ \beta$ is an equivalence of $\infty$-categories, which is a special case of Corollary 5.3.1.23.

**Remark 7.4.1.7.** If $U : \mathcal{E} \to \mathcal{C}$ is a cocartesian fibration of small simplicial sets, then the simplicial set $\mathcal{E}$ constructed in the proof of Proposition 7.4.1.6 will also be small.

**Remark 7.4.1.8.** In the situation of Proposition 7.4.1.6, suppose that $U : \mathcal{E} \to \mathcal{C}$ is a left fibration. Then the extension $\overline{U} : \mathcal{E} \to \mathcal{C}$ is also a left fibration. To prove this, it will suffice to show that the fiber $\mathcal{E}_0$ is a Kan complex (Proposition 5.1.4.14). This follows from the fact that the covariant diffraction functor

$$D_f : \mathcal{E}_0 \to \text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{C}, \mathcal{E}) = \text{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$$

is an equivalence of $\infty$-categories, since the simplicial set $\text{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ is a Kan complex by (Corollary 4.4.2.5).

**Corollary 7.4.1.9.** Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of small simplicial sets and let $\text{Tr}_{\mathcal{E}/\mathcal{C}} : \mathcal{C} \to QC$ be a covariant transport representation for $U$. Then the diagram $\text{Tr}_{\mathcal{E}/\mathcal{C}}$ has a limit in the $\infty$-category QC, given by the $\infty$-category $\text{Fun}_{/\mathcal{C}}^{\text{Cart}}(\mathcal{C}, \mathcal{E})$ of cocartesian sections of $U$.

**Proof.** Using Proposition 7.4.1.6 (and Remark 7.4.1.7), we see that there exists a pullback
diagram of small simplicial sets

\[
\begin{array}{ccc}
\mathcal{E} & \longrightarrow & \mathcal{E} \\
\downarrow^{U} & & \downarrow^{U} \\
\mathcal{C} & \longrightarrow & \mathcal{C}^0,
\end{array}
\]

where \( U \) is a cocartesian fibration and the restriction map \( \text{Fun}^\text{CCart}(\mathcal{C}^0, \mathcal{E}) \to \text{Fun}^\text{CCart}(\mathcal{C}, \mathcal{E}) \) is a trivial Kan fibration. Using Corollary 5.7.5.11, we can extend \( \text{Tr}_{\mathcal{E}/\mathcal{C}} \) to a diagram \( \text{Tr}_{\mathcal{E}/\mathcal{C}^0} : \mathcal{C}^0 \to \mathcal{QC} \) which is a covariant transport representation for \( U \). Let \( 0 \) denote the cone point of \( \mathcal{C}^0 \). It follows from Theorem 7.4.1.1 that \( \text{Tr}_{\mathcal{E}/\mathcal{C}^0} \) is a limit diagram in the \( \infty \)-category \( \mathcal{QC} \), and therefore exhibits the \( \infty \)-category \( \text{Tr}_{\mathcal{E}/\mathcal{C}^0}(0) \simeq \mathcal{E}_0 \) as a limit of the diagram \( \text{Tr}_{\mathcal{E}/\mathcal{C}} \) (Proposition 7.1.1.12).

**Corollary 7.4.1.10.** Let \( \mathcal{C} \) be a small simplicial set and let \( \mathcal{F} : \mathcal{C} \to \mathcal{QC} \) be a diagram in the \( \infty \)-category \( \mathcal{QC} \). Then the \( \infty \)-category of cocartesian sections \( \text{Fun}^\text{CCart}(\mathcal{C}, \int_{\mathcal{C}} \mathcal{F}) \) is a limit of the diagram \( \mathcal{F} \).

**Proof.** Apply Corollary 7.4.1.9 to the cocartesian fibration \( U : \int_{\mathcal{C}} \mathcal{F} \to \mathcal{C} \).

**Corollary 7.4.1.11.** The \( \infty \)-category \( \mathcal{QC} \) admits small limits.

By inspecting the proof of Corollary 7.4.1.11, we can obtain more precise information.

**Corollary 7.4.1.12.** Let \( \lambda \) be an uncountable cardinal and let \( \kappa = \text{ecf}(\lambda) \) be the exponential cofinality of \( \lambda \). Suppose we are given a diagram \( \mathcal{F} : \mathcal{C} \to \mathcal{QC} \), where \( \mathcal{C} \) is a \( \kappa \)-small simplicial set. If the \( \infty \)-category \( \mathcal{F}(\mathcal{C}) \) is essentially \( \lambda \)-small for each \( \mathcal{C} \in \mathcal{C} \), then the limit \( \varprojlim(\mathcal{F}) \) is also essentially \( \lambda \)-small.

**Proof.** Using Proposition 5.4.5.5 we can choose a categorical equivalence \( G : \mathcal{C} \to \mathcal{D} \), where \( \mathcal{D} \) is a \( \lambda \)-small \( \infty \)-category (if \( \kappa \) is uncountable, we can even arrange that \( \mathcal{D} \) is \( \kappa \)-small). Without loss of generality, we may assume that \( \mathcal{F} \) is obtained as the restriction of the covariant transport representation of some cocartesian fibration \( U : \mathcal{E} \to \mathcal{D} \). Using Corollary 7.4.1.9, we can identify \( \varprojlim(\mathcal{F}) \) with a full subcategory of the \( \infty \)-category \( \text{Fun}_{/\mathcal{D}}(\mathcal{C}, \mathcal{E}) \). It will therefore suffice to show that the \( \infty \)-category \( \text{Fun}_{/\mathcal{D}}(\mathcal{C}, \mathcal{E}) \) is essentially \( \lambda \)-small (Corollary 5.4.5.13). By construction, we have a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
\text{Fun}_{/\mathcal{D}}(\mathcal{C}, \mathcal{E}) & \longrightarrow & \text{Fun}(\mathcal{C}, \mathcal{E}) \\
\downarrow & & \downarrow^{U_{\circ}} \\
\{G\} & \longrightarrow & \text{Fun}(\mathcal{C}, \mathcal{D})
\end{array}
\]
where the vertical maps are cocartesian fibrations (Theorem 5.2.1.1), and therefore isofibrations (Proposition 5.1.4.8). It follows that (7.40) is also a categorical pullback square (Corollary 4.5.2.21). Using Corollary 5.4.5.16 we are reduced to proving that the ∞-categories Fun(C, E) and Fun(C, D) are essentially λ-small, which follows from Remark 5.4.5.10.

7.4.2 Proof of the Diffraction Criterion

The goal of this section is to prove Theorem 7.4.1.1. We begin by treating a special case (which is already sufficient for most applications).

Proposition 7.4.2.1. Suppose we are given a pullback diagram of small ∞-categories

\[
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{F} & \mathcal{E} \\
\downarrow U & & \downarrow U \\
C & \xrightarrow{} & C^a,
\end{array}
\]

where U and U are cocartesian fibrations and the restriction map Fun_{C^a/C}(C^a, \mathcal{E}) \rightarrow Fun_{C/C}(C, \mathcal{E}) is an equivalence of ∞-categories. Then the covariant transport representation

\[\text{Tr}_{\mathcal{E}/C^a} : C^a \rightarrow \mathcal{QC}\]

is a limit diagram in the ∞-category \mathcal{QC}.

Proof. Suppose we are given an integer \(n \geq 1\) and a diagram \(\mathcal{F}_0 : \partial \Delta^n \ast C \rightarrow \mathcal{QC}\) with the property that \(\mathcal{F}_0|_{\{n\} \ast C} : \{n\} \ast C \rightarrow \mathcal{QC}\) is a covariant transport representation for the cocartesian fibration \(U\); here we abuse notation by identifying \(\{n\} \ast C\) with the cone \(C^a\). We wish to show that \(\mathcal{F}_0\) can be extended to a diagram \(\mathcal{F} : \Delta^n \ast C \rightarrow \mathcal{QC}\). Using Lemma 5.7.7.1 we can choose a pullback diagram

\[
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{F^+} & \mathcal{E}^+ \\
\downarrow U^+ & & \downarrow U^+ \\
\{n\} \ast C & \xrightarrow{} & \partial \Delta^n \ast C,
\end{array}
\]

where \(U^+\) is a cocartesian fibration having covariant transport representation \(\mathcal{F}_0\). Fix an auxiliary symbol c, so that the projection map C \rightarrow \{c\} induces a cartesian fibration of
Applying Corollary 5.7.5.11, we deduce that
\[ \pi \]

where
\[ u \]

\[ \{ \text{vertex} \} \subseteq T \]

fibration of Construction 5.2.3.1. Applying Lemma 5.2.3.17, we see that
\[ \partial \Delta^n \times \{ c \} \]

of \( (\partial \Delta^n \times \mathcal{C}) \) described in Construction 4.5.9.1. Note that \( ev \) carries
\[ G \]

that \( \partial \Delta^n \times \{ c \} \) is a cocartesian fibration of simplicial sets (Proposition 5.3.7.10).

Applying Corollary 5.7.5.12, we can choose a covariant transport representation
\[ G \]

is a pullback of \( T \), and is therefore also a cartesian fibration. Let \( D \) be the cocartesian direct image
\[ \text{Res}_{\partial \Delta^n \times \mathcal{C}} \mathcal{C} / \partial \Delta^n \times \{ c \} (\hat{\mathcal{E}}^+ ) \]

introduced in Notation 5.3.7.8 so that the projection map
\[ \pi : D \to \partial \Delta^n \times \{ c \} \]

Note that \( \text{ev} \) restricts to a to a morphism of simplicial sets
\[ G \]

that \( \partial \Delta^n \times \{ c \} \) is a cocartesian fibration of simplicial sets (Proposition 5.3.7.10).

Note that \( u \) is given by evaluation on the final vertex \( \{ c \} \subseteq e \), and \( s \) is a section of the
\[ \text{ev}_e^{\Delta^n} (e, e \times \partial \Delta^n \times \{ c \} D) \to \pi^{-1} \{ n \} \]

can be extended to a diagram \( \mathcal{G} : \Delta^n \times \{ c \} \to QC \) for the cocartesian fibration \( \pi \). Note that the value of \( \mathcal{G} \) on the edge
\[ e = \{ n \} \times \{ c \} \subseteq \partial \Delta^n \times \{ c \} \]

can be identified with the composition
\[ \mathcal{G}(\{ n \}) \simeq \pi^{-1} \{ n \} \]

\[ \longrightarrow \]

\[ \text{Fun}^{\mathcal{C} / \partial \Delta^n \times \{ c \} } (e, e \times \partial \Delta^n \times \{ c \} D) \]

\[ \longrightarrow \]

\[ \pi^{-1} \{ c \} \],

where \( u \) is given by evaluation on the final vertex \( \{ c \} \subseteq e \), and \( s \) is a section of the
\[ \text{ev}_e^{\Delta^n} \]

trivial Kan fibration \( \text{Fun}^{\Delta^n} (e, e \times \partial \Delta^n \times \{ c \} D) \to \pi^{-1} \{ n \} \) given by evaluation at the initial
\[ \{ n \} \subseteq e \). Using Proposition 5.3.7.11, we can identify \( u \) with the restriction map
\[ \text{Fun}^{\mathcal{C} / \partial \Delta^n \times \{ c \} } (\mathcal{C}, \mathcal{E}) \to \text{Fun}^{\mathcal{C} / \partial \Delta^n \times \mathcal{E} } (\mathcal{C}, \mathcal{E}) \]

which is an equivalence of \( \infty \)-categories (by assumption). It follows that the diagram \( \mathcal{G} \) carries the edge \( e \) to an isomorphism in the \( \infty \)-category \( QC \).

Identifying \( \partial \Delta^n \times \{ c \} \) with the outer horn \( \Lambda^{n+1}_n \) and applying Theorem 4.4.2.6, we deduce
\[ \mathcal{G} \]

that \( \mathcal{G} \) can be extended to a diagram \( \mathcal{H} : \Delta^n \times \{ c \} \to QC \).

Note that we have a commutative diagram of simplicial sets
\[ (\partial \Delta^n \times \mathcal{C}) \times (\partial \Delta^n \times \{ c \}) \]

\[ \longrightarrow \]

\[ \mathcal{E}^+ \]

\[ \pi' \]

\[ \partial \Delta^n \times \mathcal{C}, \]

where \( \pi' \) is given by projection onto the first factor and \( ev \) is the restriction of the
evaluation map described in Construction 4.5.9.1. Note that \( ev \) carries \( \pi' \)-cocartesian edges
\[ (\partial \Delta^n \times \mathcal{C}) \times (\partial \Delta^n \times \{ c \}) D \]

to \( \mathcal{U}^+ \)-cocartesian edges of \( \mathcal{E}^+ \). Let \( \mathcal{E}^+ \) denote the relative join
\[ (\partial \Delta^n \times \mathcal{C}) \times (\partial \Delta^n \times \{ c \}) D \]

of Construction 5.2.3.1. Applying Lemma 5.2.3.17, we see that \( \pi' \) and \( \mathcal{U}^+ \) induce a cocartesian
fibration
\[ \mathcal{U}^+ : \mathcal{E}^+ \to (\partial \Delta^n \times \mathcal{C}) \star (\partial \Delta^n \times \{ c \}) \simeq \Delta^1 \times (\partial \Delta^n \times \mathcal{C}). \]

Applying Corollary 5.7.5.11, we deduce that \( \mathcal{U}^+ \) admits a covariant transport representation
\[ \mathcal{H}_0 : \Delta^1 \times (\partial \Delta^n \times \mathcal{C}) \to QC \]

having the property that \( \mathcal{H}_0 \mid_{\{0\} \times (\partial \Delta^n \times \mathcal{C})} = \mathcal{G} \circ T_0 \) and
\( \mathcal{H}_0 \times (\partial \Delta^n \star \mathcal{C}) = \mathcal{F}_0 \). Note that, for \( 0 \leq i \leq n \), the evaluation map \( \text{ev} \) restricts to an isomorphism of \( \infty \)-categories \( \{i\} \times (\partial \Delta^n \star \mathcal{C}) \mathcal{D} \rightarrow \{i\} \times (\partial \Delta^n \star \mathcal{C}) \mathcal{E}^+ \), so that the diagram \( \mathcal{H}_0 \) carries the edge \( \Delta^1 \times \{i\} \) to an isomorphism in the \( \infty \)-category \( \mathcal{QC} \). Moreover, if \( \sigma : \Delta^m \rightarrow \Delta^n \star \mathcal{C} \) is any simplex which does not factor through \( \partial \Delta^n \star \mathcal{C} \), then the vertex \( \sigma(0) \) must belong to \( \partial \Delta^n \). Applying Proposition 4.4.5.8, we can extend \( H_0 \) to a diagram \( H : \Delta^1 \times (\Delta^n \star \mathcal{C}) \rightarrow \mathcal{QC} \) satisfying \( H\{0\} \times (\Delta^n \star \mathcal{C}) = \mathcal{G} \circ T \). We complete the proof by observing that the restriction \( F = H\{1\} \times (\Delta^n \star \mathcal{C}) \) provides the desired extension of the diagram \( \mathcal{F}_0 \).

**Proof of Theorem 7.4.1.1.** Suppose we are given a pullback diagram of small simplicial sets

\[
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{\gamma} & \mathcal{E} \\
\downarrow U & & \downarrow U \setlength{\unitlength}{1pt} \\
\mathcal{C} & \xrightarrow{\epsilon} & \mathcal{C} \setlength{\unitlength}{1pt}
\end{array}
\]

where \( U \) and \( U \) are cocartesian fibrations. Assume first that the restriction map

\[
\theta : \text{Fun}^{\mathcal{C}^\Delta}_{\mathcal{C}^\Delta / \mathcal{C}^\Delta / \mathcal{C}^\Delta}(\mathcal{C}^\Delta, \mathcal{E}) \rightarrow \text{Fun}^{\mathcal{C}^\Delta}_{\mathcal{C}^\Delta / \mathcal{C}^\Delta / \mathcal{C}^\Delta}(\mathcal{C}, \mathcal{E})
\]

is an equivalence of \( \infty \)-categories; we wish to show that the covariant transport representation \( \text{Tr}_{\mathcal{E} / \mathcal{C}^\Delta} : \mathcal{C}^\Delta \rightarrow \mathcal{QC} \) is a limit diagram in the \( \infty \)-category \( \mathcal{QC} \).

Using Corollary 4.1.3.3, we can choose an inner anodyne morphism \( \mathcal{C} \hookrightarrow \mathcal{C}^\Delta \), where \( \mathcal{C}^\Delta \) is an \( \infty \)-category. Note that the induced map \( \mathcal{C}^\Delta \hookrightarrow \mathcal{C}^\Delta \) is also inner anodyne (Proposition 4.3.6.4). Applying Corollary 5.7.7.3, we can realize \( U \) as the pullback of a cocartesian fibration of \( \infty \)-categories \( \overline{U} : \overline{\mathcal{E}} \rightarrow \mathcal{C}^\Delta \). Set \( \mathcal{E}' = \mathcal{C}' \times_{\mathcal{C}^\Delta} \overline{\mathcal{E}} \), so that we have a commutative diagram of restriction functors

\[
\begin{array}{ccc}
\text{Fun}^{\mathcal{C}^\Delta}_{\mathcal{C}^\Delta / \mathcal{C}^\Delta / \mathcal{C}^\Delta}(\mathcal{C}^\Delta, \mathcal{E}) & \xrightarrow{\theta'} & \text{Fun}^{\mathcal{C}^\Delta}_{\mathcal{C}^\Delta / \mathcal{C}^\Delta / \mathcal{C}^\Delta}(\mathcal{C}', \mathcal{E}') \\
\downarrow & & \downarrow \\
\text{Fun}^{\mathcal{C}^\Delta}_{\mathcal{C}^\Delta / \mathcal{C}^\Delta / \mathcal{C}^\Delta}(\mathcal{C}^\Delta, \mathcal{E}) & \xrightarrow{\theta} & \text{Fun}^{\mathcal{C}^\Delta}_{\mathcal{C}^\Delta / \mathcal{C}^\Delta / \mathcal{C}^\Delta}(\mathcal{C}, \mathcal{E}),
\end{array}
\]

where the vertical maps are trivial Kan fibrations (Proposition 5.3.1.21). It follows that \( \theta' \) is also an equivalence of \( \infty \)-categories.

Using Corollary 5.7.5.11, we can extend \( \text{Tr}_{\mathcal{E} / \mathcal{C}^\Delta} \) to a functor

\[
\text{Tr}_{\mathcal{E} / \mathcal{C}^\Delta} : \mathcal{C}^\Delta \rightarrow \mathcal{QC}
\]
which is a covariant transport representation for the cocartesian fibration $U'$. Since $C'$ is an $\infty$-category, Proposition 7.4.2.1 guarantees that $\text{Tr}_{E'/C'}$ is a limit diagram in the $\infty$-category $QC$. Since the inclusion map $C \hookrightarrow C'$ is left cofinal (Proposition 7.2.1.3), it follows that $\text{Tr}_{E/C}$ is also a limit diagram in $QC$.

We now prove the converse. Assume that the covariant transport representation $\text{Tr}_{E/C}$ is a limit diagram in the $\infty$-category $QC$; we wish to show that $\theta$ is an equivalence of $\infty$-categories. Using Proposition 7.4.1.6, we can choose another pullback diagram

\[
\begin{array}{ccc}
E & \rightarrow & E^+ \\
\downarrow & & \downarrow \\
C & \rightarrow & C^a,
\end{array}
\]

where $U^+$ is a cocartesian fibration for which the restriction map $\theta^+ : \text{Fun}_{C'}^{C^{\text{Cart}}}(C^a, E^+) \rightarrow \text{Fun}_{C}^{C^{\text{Cart}}}(C, E')$ is an equivalence of $\infty$-categories. Applying Corollary 5.7.5.11, we see that $U^+$ admits a covariant transport representation $\text{Tr}_{E^+/C^a} : C^a \rightarrow QC$ satisfying $(\text{Tr}_{E^+/C^a})|_C = (\text{Tr}_{E/C})|_C$. The first part of the proof shows that $\text{Tr}_{E^+/C^a}$ is also a limit diagram in the $\infty$-category $QC$, and is therefore isomorphic to $\text{Tr}_{E/C}$ as an object of the $\infty$-category $\text{Fun}(C^a, QC)$. Applying Theorem 5.7.0.2, we deduce that there exists a morphism $F : E \rightarrow E^+$ which is an equivalence of cocartesian fibrations over $C^a$. We have a commutative diagram of $\infty$-categories

\[
\begin{array}{ccc}
\text{Fun}_{C^a}^{C^{\text{Cart}}}(C^a, E^+) & \rightarrow & \text{Fun}_{C}^{C^{\text{Cart}}}(C, E') \\
\downarrow & & \downarrow \\
\text{Fun}_{C^a}^{C^{\text{Cart}}}(C^a, E) & \rightarrow & \text{Fun}_{C}^{C^{\text{Cart}}}(C, E),
\end{array}
\]

where the vertical maps are given by precomposition with $F$ and are therefore equivalences of $\infty$-categories. Since $\theta^+$ is an equivalence of $\infty$-categories, it follows that $\theta$ is also an equivalence of $\infty$-categories.

\section{Colimits of $\infty$-Categories}

Let $QC$ denote the $\infty$-category of (small) $\infty$-categories (Construction 5.6.4.1). Our goal in this section is to show that the $\infty$-category $QC$ admits small colimits (Corollary 7.4.3.13). In fact, we will prove something more precise: if $C$ is a small $\infty$-category, then the colimit of any diagram $\mathcal{F} : C \rightarrow QC$ can be described explicitly as the localization $(\int_C \mathcal{F})[W^{-1}]$, where
where \( \int_C \mathcal{F} \) denotes the \( \infty \)-category of elements of \( \mathcal{F} \) (Definition 5.7.2.4) and \( W \) is the collection of all morphisms of \( \int_C \mathcal{F} \) which are cocartesian with respect to the forgetful functor \( U : \int_C \mathcal{F} \to C \) (Corollary 7.4.3.12).

We begin with some general remarks. Let \( C \) denote the right cone on on a simplicial set \( C \) (Construction 4.3.3.25), and let \( \mathbf{1} \in C \) denote the cone point. For every vertex \( C \in C \), there is a unique edge \( e_C : C \to \mathbf{1} \) in \( C \). If \( U : \mathcal{E} \to \mathcal{C} \) is a cocartesian fibration of simplicial sets, then covariant transport along \( e_C \) determines a functor

\[
e_C! : \mathcal{E}_C = \{C\} \times_{\mathcal{C}} \mathcal{E} \to \{\mathbf{1}\} \times_{\mathcal{C}} \mathcal{E} = \mathcal{E}_1.
\]

In what follows, it will be convenient to amalgamate the functors \( \{e_C!\}_{C \in C} \) into a single morphism \( Rf : C \times_{\mathcal{C}} \mathcal{E} \to \mathcal{E}_1 \), which we will refer to as the covariant refraction diagram.

**Definition 7.4.3.1.** Let \( C \) be a simplicial set, and let \( \mathbf{1} \) denote the cone point of the simplicial set \( \mathcal{C} \simeq C \star \{\mathbf{1}\} \). Suppose that we are given a cocartesian fibration \( U : \mathcal{E} \to \mathcal{C} \), and set \( \mathcal{E} = C \times_{\mathcal{C}} \mathcal{E} \) and \( \mathcal{E}_1 = \{\mathbf{1}\} \times_{\mathcal{C}} \mathcal{E} \).

We will say that a morphism \( Rf : \mathcal{E} \to \mathcal{E}_1 \) is a **covariant refraction diagram** if there exists a morphism of simplicial sets \( H : \Delta^1 \times \mathcal{E} \to \mathcal{E} \) satisfying the following conditions:

- The restriction \( H|_{\{0\} \times \mathcal{E}} \) is the identity morphism from \( \mathcal{E} \) to itself.
- The restriction \( H|_{\{1\} \times \mathcal{E}} \) is equal to \( Rf \).
- For every vertex \( X \in \mathcal{E} \), the restriction \( H|_{\Delta^1 \times \{X\}} \) is a \( U \)-cocartesian edge of \( \mathcal{E} \).

**Remark 7.4.3.2.** In the situation of Definition 7.4.3.1, suppose that \( Rf : \mathcal{E} \to \mathcal{E}_1 \) is a covariant refraction diagram. Then, for every vertex \( C \in \mathcal{C} \), the restriction \( Rf|_{\mathcal{E}_C} : \mathcal{E}_C \to \mathcal{E}_1 \) is given by covariant transport along the unique edge \( e_C : C \to \mathbf{1} \) of \( \mathcal{C} \), in the sense of Definition 5.2.2.4.

**Proposition 7.4.3.3.** Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets, set \( \mathcal{E} = C \times_{\mathcal{C}} \mathcal{E} \), and let \( \mathbf{1} \) denote the cone point of \( \mathcal{C} \). Then:

1. There exists a covariant refraction diagram \( Rf : \mathcal{E} \to \mathcal{E}_1 \) (Definition 7.4.3.1).
2. Let \( F : \mathcal{E} \to \mathcal{E}_1 \) be any morphism of simplicial sets. Then \( F \) is a covariant refraction diagram if and only if it is isomorphic to \( Rf \) as an object of the \( \infty \)-category \( \operatorname{Fun}(\mathcal{E}, \mathcal{E}_1) \).

**Proof.** This is a special case of Lemma 5.2.2.13. \( \square \)
Example 7.4.3.4. Let $C$ be an $\infty$-category and let 1 denote the cone point of $C^\circ$. Using Example 5.2.3.18 we see that the tautological map $V : C^\circ \to (\Delta^0)^\circ \simeq \Delta^1$ is a cartesian fibration. If $U : E \to C^\circ$ is another cartesian fibration, then the $\infty$-categories $E = C \times_{C^\circ} \overline{E}$ and $\overline{E}_1 = \{1\} \times_{C^\circ} \overline{E}$ can be identified with the fibers of the composite map

$$(V \circ U) : \overline{E} \to \Delta^1,$$

which is also a cartesian fibration (Proposition 5.1.4.13). In this case, the covariant refraction diagram $Rf : E \to \overline{E}_1$ of Proposition 7.4.3.3 is given by covariant transport for the cartesian fibration $V \circ U$ (along the nondegenerate edge of $\Delta^1$).

Remark 7.4.3.5. Suppose we are given a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
E & \to & \overline{E} \\
\downarrow & & \downarrow \\
C & \to & C^\circ,
\end{array}
\]

where $U$ and $\overline{U}$ are cartesian fibrations. Let 1 denote the cone point of $C^\circ$ and let $Rf : E \to \overline{E}_1$ be a covariant refraction diagram. For every $U$-cartesian edge $e : X \to Y$ of $E$, the image $U(e)$ is an isomorphism in the $\infty$-category $\overline{E}_1$. To prove this, we observe that there is a morphism $\Delta^1 \times \Delta^1 \to \overline{E}$ as indicated in the diagram

\[
\begin{array}{ccc}
X & \to & Rf(X) \\
\downarrow & & \downarrow \\
Y & \to & Rf(Y),
\end{array}
\]

where the horizontal maps are $\overline{U}$-cartesian. Applying Proposition 5.1.4.12 we deduce that $Rf(e)$ is an $\overline{U}$-cartesian edge of $\overline{E}$, and therefore an isomorphism in the $\infty$-category $\overline{E}_1$ (Proposition 5.1.4.11).

Our study of colimits in the $\infty$-category $QC$ will make use of the following recognition principle for colimits in the $\infty$-category $QC$:

Theorem 7.4.3.6 (Refraction Criterion). Suppose we are given a pullback diagram of small
simplicial sets

\[ \begin{array}{ccc}
E & \longrightarrow & \mathcal{E} \\
\downarrow & & \downarrow \\
C & \longrightarrow & C^o,
\end{array} \]

where \( U \) and \( \overline{U} \) are cocartesian fibrations. Let \( 1 \) denote the cone point of \( C^o \) and let \( W \) be the collection of all \( U \)-cocartesian edges of \( E \). The following conditions are equivalent:

1. The covariant refraction diagram \( Rf : E \rightarrow \mathcal{E}_1 \) of Proposition 7.4.3.3 exhibits \( \mathcal{E}_1 \) as a localization of \( E \) with respect to \( W \).

2. The covariant transport representation \( \text{Tr}_{\mathcal{E}/C} : C^o \rightarrow QC \) of Notation 5.7.5.14 is a colimit diagram in the \( \infty \)-category \( QC \).

Remark 7.4.3.7. In the statement of Theorem 7.4.3.6, the covariant refraction diagram \( F : E \rightarrow \mathcal{E}_1 \) and the covariant transport representation \( \text{Tr}_{\mathcal{E}/C} : C^o \rightarrow QC \) are only well-defined up to isomorphism (as objects of the \( \infty \)-categories \( \text{Fun}(E, \mathcal{E}_1) \) and \( \text{Fun}(C^o, QC) \), respectively). However, conditions (1) and (2) depend only on their isomorphism classes (see Exercise 6.3.1.11 and Corollary 7.1.2.14).

Exercise 7.4.3.8. Let \( U : \mathcal{E} \rightarrow C^o \) and \( U' : \mathcal{E}' \rightarrow C^o \) be cocartesian fibrations of simplicial sets which are equivalent as inner fibrations over \( C^o \) (in the sense of Definition 5.1.6.1). Show that \( U \) satisfies condition (1) of Theorem 7.4.3.6 if and only if \( U' \) satisfies condition (1) of Theorem 7.4.3.6.

We will prove Theorem 7.4.3.6 in §7.4.4. The remainder of this section is devoted to explaining some of its consequences. We begin by showing that there is a good supply of cocartesian fibrations which satisfy the assumptions of Theorem 7.4.3.6.

Proposition 7.4.3.9. Let \( U : \mathcal{E} \rightarrow C \) be a cocartesian fibration of simplicial sets and let \( 1 \) denote the cone point of \( C^o \). Then there exists a pullback diagram

\[ \begin{array}{ccc}
\mathcal{E} & \longrightarrow & \mathcal{E} \\
\downarrow & & \downarrow \\
C & \longrightarrow & C^o,
\end{array} \]

where \( \overline{U} \) is a cocartesian fibration and a covariant refraction diagram \( Rf : E \rightarrow \mathcal{E}_1 \) which exhibits \( \mathcal{E}_1 \) as a localization of \( E \) with respect to the collection of all \( U \)-cocartesian edges of \( E \).
7.4. LIMITS AND COLIMITS OF $\infty$-CATEGORIES

Proof. Let $W$ be the collection of all $U$-cocartesian edges of $\mathcal{E}$. Applying Proposition 6.3.2.1, we deduce that there exists an $\infty$-category $\mathcal{E}[W^{-1}]$ and a diagram $Rf : \mathcal{E} \to \mathcal{E}[W^{-1}]$ which exhibits $\mathcal{E}[W^{-1}]$ as a localization of $\mathcal{E}$ with respect to $W$. In particular, the diagram $Rf$ carries each $U$-cocartesian edge of $\mathcal{E}$ to an isomorphism in $\mathcal{E}[W^{-1}]$. Let $\overline{\mathcal{E}}$ denote the relative join $\mathcal{E} \star \mathcal{E}[W^{-1}]$ (Construction 5.2.3.1). Applying Lemma 5.2.3.17 to the commutative diagram

\[
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{Rf} & \mathcal{E}[W^{-1}] \\
\downarrow & & \downarrow \\
\mathcal{C} & \xrightarrow{U} & \Delta^0,
\end{array}
\]

we deduce that vertical maps induce a cocartesian fibration

\[
\overline{U} : \overline{\mathcal{E}} = \mathcal{E} \star_{\mathcal{E}[W^{-1}]} \mathcal{E}[W^{-1}] \to \mathcal{C} \star_{\Delta^0} \Delta^0 \simeq \mathcal{C}^\circ.
\]

By construction, we have a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{U} & \mathcal{E} \star \mathcal{E}[W^{-1}] \\
\downarrow & & \downarrow \\
\mathcal{C} & \xrightarrow{V} & \mathcal{C}^\circ,
\end{array}
\]

and the fiber of $\overline{U}$ over the cone point $1 \in \mathcal{C}^\circ$ can be identified with the $\infty$-category $\mathcal{E}[W^{-1}]$. Moreover, $Rf$ induces a morphism of simplicial sets

\[
H : \Delta^1 \times \mathcal{E} \simeq \mathcal{E} \star_{\mathcal{E}[W^{-1}]} \mathcal{E}[W^{-1}] \to \mathcal{E} \star_{\mathcal{E}[W^{-1}]} \mathcal{E}[W^{-1}] = \overline{\mathcal{E}}
\]

for which $H|_{\{0\} \times \mathcal{E}}$ is the inclusion map $\mathcal{E} \hookrightarrow \overline{\mathcal{E}}$, and $H|_{\{1\} \times \mathcal{E}}$ is the diagram $Rf : \mathcal{E} \to \mathcal{E}[W^{-1}]$. For every vertex $X \in \mathcal{E}$, the criterion of Lemma 5.2.3.17 guarantees that $H|_{\Delta^1 \times \{X\}}$ is a $\overline{U}$-cocartesian edge of $\overline{\mathcal{E}}$, so that $H$ exhibits $Rf : \mathcal{E} \to \mathcal{E}[W^{-1}]$ as a covariant refraction diagram.

**Remark 7.4.3.10.** In the situation of Proposition 7.4.3.9, suppose that the simplicial sets $\mathcal{E}$ and $\mathcal{C}$ are small. Then the localization $\mathcal{E}[W^{-1}]$ supplied by Proposition 6.3.2.1 can also be chosen to be small. It follows that the simplicial set $\overline{\mathcal{E}}$ constructed in the proof is also small.

**Corollary 7.4.3.11.** Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration between small simplicial sets, and let $\mathcal{C} \to \mathcal{Q}\mathcal{C}$ be a covariant transport representation of $U$. Then the diagram $\mathcal{C} \to \mathcal{Q}\mathcal{C}$ admits a colimit in $\mathcal{Q}\mathcal{C}$. Moreover, an object $D \in \mathcal{Q}\mathcal{C}$ is a colimit of the diagram $\mathcal{C} \to \mathcal{Q}\mathcal{C}$ if and only if it is equivalent to the localization $\mathcal{E}[W^{-1}]$, where $W$ is the collection of all $U$-cocartesian morphisms of $\mathcal{E}$. 

Proof. Let 1 denote the cone point of $C^\circ$. By virtue of Proposition 7.4.3.9 (and Remark 7.4.3.10), there exists a pullback diagram of small simplicial sets

$$
\begin{array}{ccc}
E & \to & \bar{E} \\
\downarrow & & \downarrow \\
C & \to & C^\circ
\end{array}
$$

where $\bar{U}$ is a cocartesian fibration, and a covariant refraction diagram $Rf : E \to \bar{E}_1$ which exhibits $\bar{E}_1$ as a localization of $E$ with respect to $W$. Applying Corollary 5.7.5.11, we see that $\text{Tr}_{E/C}$ extends to a covariant transport representation $\text{Tr}_{E/C} : C^\circ \to QC$. By virtue of Theorem 7.4.3.6, this extension is a colimit diagram carrying $0$ to the $\infty$-category $\bar{E}_1 \simeq E[W^{-1}]$.

Corollary 7.4.3.12. Let $C$ be a small simplicial set, let $\mathcal{F} : C \to QC$ be a diagram, let $U : \int_C \mathcal{F} \to C$ denote the projection map, and let $W$ be the collection of all $U$-cocartesian morphisms of $\int_C \mathcal{F}$. Then the localization $(\int_C \mathcal{F})[W^{-1}]$ is a colimit of the diagram $\mathcal{F}$ in the $\infty$-category $QC$.

Proof. Apply Corollary 7.4.3.11 to the cocartesian fibration $\int_C \mathcal{F} \to C$.

Corollary 7.4.3.13. The $\infty$-category $QC$ admits small colimits.

By examining the proof of Corollary 7.4.3.13 we can obtain more precise information.

Corollary 7.4.3.14. Let $\kappa$ be an uncountable regular cardinal, let $C$ be a simplicial set which is essentially $\kappa$-small, and suppose we are given a diagram $\mathcal{F} : C \to QC$ with the property that, for each vertex $C \in C$, the $\infty$-category $\mathcal{F}(C)$ is essentially $\kappa$-small. Then the colimit $\lim_{\to} (\mathcal{F})$ (formed in the $\infty$-category $QC$) is essentially $\kappa$-small.

Proof. Without loss of generality, we may assume that $\mathcal{F}$ is a covariant transport representation for a cocartesian fibration $U : E \to C$, so that the colimit $\lim_{\to} (\mathcal{F})$ can be identified with the localization $E[W^{-1}]$, where $W$ is the collection of $U$-cocartesian morphisms of $E$ (Corollary 7.4.3.11). By virtue of Variant 6.3.2.6, it will suffice to show that the simplicial set $E$ is essentially $\kappa$-small, which follows from Corollary 5.4.8.11.

Corollary 7.4.3.15. Let $\lambda$ be an uncountable cardinal and let $\kappa = \text{cf}(\lambda)$ be the cofinality of $\lambda$. Let $C$ be a $\kappa$-small simplicial set and let $\mathcal{F} : C \to QC$ be a diagram. Suppose that, for each object $C \in C$, the $\infty$-category $\mathcal{F}(C)$ is essentially $\lambda$-small. Then the colimit $\lim_{\to} (\mathcal{F})$ is essentially $\lambda$-small.
7.4. LIMITS AND COLIMITS OF $\infty$-CATEGORIES

Proof. For each vertex $C \in \mathcal{C}$, the $\infty$-category $\mathcal{F}(C)$ is essentially $\lambda$-small, and is therefore essentially $\tau_C^+$-small for some infinite cardinal $\tau_C < \lambda$ (Corollary 5.4.6.14). Since $\lambda$ has cofinality $\kappa$, the supremum $\tau = \sup\{\tau_C\}_{C \in \mathcal{C}}$ satisfies $\tau < \lambda$. Replacing $\lambda$ by the cardinal $\sup\{\tau^+, \kappa\}$, we are reduced to proving Corollary 7.4.3.15 in the special case where $\lambda$ is regular. In this case, the desired result follows from Variant 7.4.3.14.

For strictly commutative diagrams, we can use the results of §5.3 to give an alternative description of the colimit.

Corollary 7.4.3.16. Let $\mathcal{C}$ be a small category and let $\mathcal{F} : \mathcal{C} \to \mathcal{QC}$ be a (strictly commutative) diagram of $\infty$-categories indexed by $\mathcal{C}$. Let $U : N^{\mathcal{F}}(\mathcal{C}) \to N_{\mathcal{C}}(\mathcal{C})$ be the cocartesian fibration of Definition 5.3.3.1, and let $W$ be the collection of $U$-cocartesian morphisms of $N^{\mathcal{F}}(\mathcal{C})$. Then the localization $N^{\mathcal{F}}(\mathcal{C})[W^{-1}]$ is a colimit of the diagram $N^{\mathcal{F}}(\mathcal{C}) : N_{\mathcal{C}}(\mathcal{C}) \to \mathcal{QC}$.

Proof. Combine Corollary 7.4.3.16 with Example 5.7.5.6.

Corollary 7.4.3.17. Let $\mathcal{C}$ be an $\infty$-category, let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration, and set $\mathcal{E} = \mathcal{C} \times_{\mathcal{C}^0} \mathcal{E}$. Let $F : \mathcal{E} \to \mathcal{D}$ be a functor of $\infty$-categories which carries $U$-cocartesian morphisms of $\mathcal{E}$ to isomorphisms in $\mathcal{D}$. If the covariant transport representation $\operatorname{Tr}_{\mathcal{E}/\mathcal{C}} : \mathcal{C}^0 \to \mathcal{QC}$ is a colimit diagram, then $F$ is left Kan extended from $\mathcal{E}$.

Proof. Let $Rf : \mathcal{E} \to \mathcal{E}_1$ be a covariant refraction diagram, so that there exists a natural transformation $h : \operatorname{id}_{\mathcal{E}} \to Rf$ (in the $\infty$-category $\operatorname{Fun}(\mathcal{E}, \mathcal{E})$) which carries each object $X \in \mathcal{E}$ to an $U$-cocartesian morphism $h_X : X \to \operatorname{Rf}(X)$. Our assumption that $\operatorname{Tr}_{\mathcal{E}/\mathcal{C}}$ is a colimit diagram guarantees that the functor $Rf$ exhibits $\mathcal{E}_1$ as a localization of $\mathcal{E}$ (Corollary 7.4.3.9). Moreover, for each object $X \in \mathcal{C}$, the functor $F$ carries $h_X$ to an isomorphism in the $\infty$-category $\mathcal{D}$. Set $F_0 = F|_{\mathcal{E}}$ and $F_1 = F|_{\mathcal{E}_1}$. Applying Proposition 7.3.1.17, we deduce that the natural transformation $F(h) : F_0 \to F_1 \circ \operatorname{Rf}$ exhibits the functor $F_1$ as a left Kan extension of $F_0$ along $\operatorname{Rf}$. By virtue of Example 7.4.3.4, the natural transformation $h$ exhibits $\operatorname{Rf}$ as a covariant transport functor for the cocartesian fibration

\[ \mathcal{E} \xrightarrow{U} \mathcal{C}^0 \to (\Delta^0)^\circ \simeq \Delta^1. \]

Applying Corollary 7.3.2.13, we conclude that the functor $F$ is left Kan extended from $\mathcal{E}$.

7.4.4 Proof of the Refraction Criterion

Our goal in this section is to prove Theorem 7.4.3.6. Our starting point is the following extension property for outer horns of the $\infty$-category $\mathcal{QC}$:

Lemma 7.4.4.1. Let $n \geq 2$, let $X : \Lambda^n_0 \to \mathcal{QC}$ be a diagram, and let $W$ be a collection of morphisms of the $\infty$-category $X(0)$ which satisfies the following pair of conditions:
(1) Let \(1 \leq i \leq n\), and let \(X(0 < i) : X(0) \to X(i)\) be the functor obtained by evaluating \(X\) on the edge \(N_\bullet(\{0 < i\}) \subseteq \Lambda^n_0\). Then \(X(0 < i)\) carries each element of \(W\) to an isomorphism in the \(\infty\)-category \(X(i)\).

(2) The functor \(X(0 < 1) : X(0) \to X(1)\) exhibits \(X(1)\) as a localization of \(X(0)\) with respect to \(W\). Then \(X\) can be extended to an \(n\)-simplex \(\Delta^n \to \mathcal{QC}\).

Proof. Set \(\mathcal{C} = X(0)\), \(\mathcal{D} = X(1)\), and let \(F : \mathcal{C} \to \mathcal{D}\) be the functor \(X(0 < 1)\). Using the isomorphism \(\Lambda^n_0 \simeq (\partial \Delta^{n-1})^a\), we can identify \(X\) with a diagram \(\sigma_0 : \partial \Delta^{n-1} \to \mathcal{QC}_{\mathcal{C}/}\). To complete the proof, it will suffice to show that \(\sigma_0\) can be extended to an \((n-1)\)-simplex of \(\mathcal{QC}_{\mathcal{C}/}\). Let us identify the objects of the \(\infty\)-category \(\mathcal{QC}_{\mathcal{C}/}\) with pairs \((\mathcal{E}, G)\), where \(\mathcal{E}\) is a small \(\infty\)-category and \(G : \mathcal{C} \to \mathcal{E}\) is a functor. Let \(\mathcal{QC}_{\mathcal{C}/}^W\) denote the full subcategory of \(\mathcal{QC}_{\mathcal{C}/}\) spanned by those pairs \((\mathcal{E}, G)\), where the functor \(G\) carries each element of \(W\) to an isomorphism in \(\mathcal{E}\). It follows from assumption (1) that the diagram \(\sigma_0\) factors through the subcategory \(\mathcal{QC}_{\mathcal{C}/}^W \subseteq \mathcal{QC}_{\mathcal{C}/}\). To prove the existence of \(\sigma\), it will suffice (by virtue of Corollary 4.6.6.14) to show that \(\sigma_0(0) = (\mathcal{D}, F)\) is an initial object of the \(\infty\)-category \(\mathcal{QC}_{\mathcal{C}/}^W\). Fix another object \((\mathcal{E}, G) \in \mathcal{QC}_{\mathcal{C}/}^W\); we wish to show that the morphism space \(\text{Hom}_{\mathcal{QC}_{\mathcal{C}/}^W}((\mathcal{D}, F), (\mathcal{E}, G)) = \text{Hom}_{\mathcal{QC}_{\mathcal{C}/}}((\mathcal{D}, F), (\mathcal{E}, G))\) is a contractible Kan complex. Using Corollary 4.6.8.18 and Remark 5.6.4.6, we can identify \(\text{Hom}_{\mathcal{QC}_{\mathcal{C}/}}((\mathcal{D}, F), (\mathcal{E}, G))\) with the homotopy fiber of the map of Kan complexes

\[
\text{Fun}(\mathcal{D}, \mathcal{E}) \simeq \circ F \to \text{Fun}(\mathcal{C}, \mathcal{E}) \simeq
\]

over the vertex \(G \in \text{Fun}(\mathcal{C}, \mathcal{E})\). Assumption (2) guarantees that this map is a homotopy equivalence onto the summand of \(\text{Fun}(\mathcal{C}, \mathcal{E})\) spanned by those functors \(\mathcal{C} \to \mathcal{E}\) which carry each element of \(W\) to an isomorphism in \(\mathcal{E}\). It will therefore suffice to show that this summand contains the functor \(G\), which follows from the definition of \(\mathcal{QC}_{\mathcal{C}/}^W\).

We now prove a weak form of Theorem 7.4.3.6 (which is already sufficient for most of our applications):

**Proposition 7.4.4.2.** Suppose we are given a pullback diagram of small \(\infty\)-categories

\[
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{U} & \mathcal{F} \\
\downarrow & & \downarrow \\
\mathcal{C} & \xrightarrow{V} & \mathcal{C}^o
\end{array}
\]
7.4. LIMITS AND COLIMITS OF $\infty$-CATEGORIES

where $U$ and $\overline{U}$ are cocartesian fibrations. Let $W$ be the collection of all $U$-cocartesian morphism of $E$, let $0$ denote the cone point of $C^0 \simeq C \ast \{0\}$, and assume that the covariant refraction diagram $Rf : E \to \overline{E}_0$ of Proposition 7.4.3.3 exhibits $\overline{E}_0$ as a localization of $E$ with respect to $W$. Then the covariant transport representation $\text{Tr}_{E/C^0} : C^0 \to QC$ is a colimit diagram in the $\infty$-category $QC$.

Proof. Fix an integer $n > 0$, and suppose we are given a diagram $\mathcal{F}_0 : C \ast \partial \Delta^n \to QC$ for which the restriction $\mathcal{F}_0|_{C \ast \{0\}}$ coincides with $\text{Tr}_{E/C^0}$. We wish to show that $\mathcal{F}_0$ can be extended to a functor $\mathcal{F} : C \ast \Delta^n \to QC$. Applying Lemma 5.7.7.1, we can choose a pullback diagram

$$
\begin{array}{ccc}
\mathcal{E} & \longrightarrow & \mathcal{E}^- \\
\downarrow \mathcal{U} & & \downarrow \mathcal{U}^- \\
C \ast \{0\} & \longrightarrow & C \ast \partial \Delta^n,
\end{array}
$$

where $\overline{U}^-$ is a cocartesian fibration having covariant transport representation $\mathcal{F}_0$. For $0 \leq i \leq n$, let us write $\mathcal{E}_i^-$ for the $\infty$-category given by the fiber of $\overline{U}^-$ on the vertex $i \in \partial \Delta^n$.

Fix an auxiliary symbol $c$, so that the projection map $C \to \{c\}$ induces a cocartesian fibration of $\infty$-categories $V^+ : C \ast \Delta^n \to \{c\} \ast \Delta^n$ (this follows by repeated application of Lemma 5.2.3.17). Note that $V^+$ restricts to a morphism of simplicial sets $V^- : C \ast \partial \Delta^n \to \{c\} \ast \Delta^n$ which is a pullback of $V^+$, and therefore also a cocartesian fibration (Remark 5.1.4.6). Applying Proposition 5.1.4.13 we deduce that the composite map $(V^- \circ \overline{U}^-) : \mathcal{E}^- \to \{c\} \ast \partial \Delta^n \simeq \Lambda^n_{0+1}$ is also a cocartesian fibration.

Let $\mathcal{G}_0 : \{c\} \ast \partial \Delta^n \to QC$ be a covariant transport representation for the cocartesian fibration $V^- \circ \overline{U}^-$. Let us identify $\mathcal{G}_0(c)$ with the $\infty$-category $\mathcal{E}_c$ for $0 \leq i \leq n$, and the restriction of $\mathcal{G}_0$ to the edge $\{c\} \ast \{i\}$ with a functor $G_i : E \to \mathcal{E}_i^-$. Applying Example 7.4.3.4 (and Remark 5.7.5.8), we see that $G_i$ is a covariant refraction diagram for the cocartesian fibration

$$(C \ast \{i\}) \times_{C \ast \partial \Delta^n} \mathcal{E}^- \rightarrow C \ast \{i\}.$$

In particular, each of the functors $G_i$ carries elements of $W$ to isomorphisms in the $\infty$-category $\mathcal{E}_i^-$ (Remark 7.4.3.5). Moreover, the functor $G_0$ is isomorphic to $Rf$ (Proposition 7.4.3.3), and therefore exhibits $\overline{E}_0 = \mathcal{E}_0$ as a localization of $E$ with respect to $W$ (Exercise 6.3.1.11). Applying Lemma 7.4.4.1 we can extend $\mathcal{G}_0$ to a diagram $\mathcal{G} : \{c\} \ast \Delta^n \to QC$. 

Using Lemma 5.7.7.1, we can choose a pullback diagram

\[
\begin{array}{ccc}
\xi^- & \to & \xi^+ \\
\downarrow & & \downarrow \\
C \times \partial \Delta^n & \to & C \times \Delta^n,
\end{array}
\]

where \( T \) is a cocartesian fibration having covariant transport representation \( \mathscr{G} \). Note that we can write \( T \) uniquely as a composition

\[
\xi^+ \xrightarrow{\xi^+} C \times \Delta^n \xrightarrow{V^+} \{c\} \times \Delta^n,
\]

where \( \xi^+ \) is a morphism of simplicial sets which fits into a pullback diagram

\[
\begin{array}{ccc}
\xi^- & \to & \xi^+ \\
\downarrow & & \downarrow \\
\xi & \to & \xi^+ \\
\downarrow & & \downarrow \\
C \times \partial \Delta^n & \to & C \times \Delta^n.
\end{array}
\]

We will show that the morphism \( \chi^+ \) is a cocartesian fibration. Assuming this, we can complete the proof by applying Corollary 5.7.5.11 to extend \( \mathscr{F}_0 \) to a diagram \( \mathscr{F} : C \times \Delta^n \to QC \) (which is a covariant transport representation for the cocartesian fibration \( \chi^+ \)).

We first prove that \( \chi^+ \) is an inner fibration of simplicial sets. Suppose we are given integers \( 0 < i < m \); we wish to show that every lifting problem

\[
\begin{array}{ccc}
\Delta^m_i & \xrightarrow{\sigma_0} & \xi^+ \\
\downarrow & & \downarrow \\
\Delta^m & \xrightarrow{\sigma} & C \times \Delta^n
\end{array}
\]

admits a solution. If \( \sigma \) factors through \( C \), then a solution exists by virtue of the fact that \( U \) is an inner fibration. Let us therefore assume that \( \sigma \) does not factor through \( C \). Since \( T \) is an inner fibration, we can extend \( \sigma_0 \) to an \( n \)-simplex \( \sigma \) of \( \xi^+ \) satisfying \( T \circ \sigma = V^+ \circ \sigma \). We claim that the \( n \)-simplex \( \sigma \) solves the lifting problem (7.41). Set \( \sigma' = U^+ \circ \sigma \); we wish to show that \( \sigma' \) coincides with \( \sigma \) (as \( m \)-simplices of the simplicial set \( C \times \Delta^n \)). Note that we have \( V^+ \circ \sigma = V^+ \circ \sigma' \). It follows that \( \sigma \) and \( \sigma' \) both carry the final vertex \( m \in \Delta^m \) to the
7.4. LIMITS AND COLIMITS OF ∞-CATEGORIES

same vertex of $\Delta^n \subseteq C \star \Delta^n$. Consequently, it will suffice to show that $\overline{\sigma}$ and $\overline{\sigma}'$ agree when restricted to the face $\Delta^{m-1} \subseteq \Delta^m$. This follows from the commutativity of the diagram (7.41), since $\Delta^{m-1}$ is contained in the horn $\Lambda^m_i \subseteq \Delta^m$.

Fix an object $X$ of the $\infty$-category $\mathcal{E}^+$ having image $X = U^+(X)$ and a morphism $\overline{\sigma} : \overline{X} \to \overline{Y}$ in the $\infty$-category $C \star \Delta^m$. We will complete the proof by showing that $\overline{\sigma}$ and $\overline{\sigma}'$ agree when restricted to the face $\Delta^{m-1} \subseteq \Delta^m$. This follows from the commutativity of the diagram (7.41), since $\Delta^{m-1}$ is contained in the horn $\Lambda^m_i \subseteq \Delta^m$.

Choose another object $Z \in \mathcal{E}^+$ having image $Z = U^+(Z)$; we wish to show that the diagram of Kan complexes

\[
\begin{array}{ccc}
\{c\} \times_{\Hom_{\mathcal{E}^+}(X,Y)} \Hom_{\mathcal{E}^+}(X,Y,Z) & \to & \Hom_{\mathcal{E}^+}(X,Z) \\
\downarrow & & \downarrow \\
\{c\} \times_{\Hom_{C^\star \Delta^n}(X,Y)} \Hom_{C^\star \Delta^n}(X,Y,Z) & \to & \Hom_{C^\star \Delta^n}(X,Z)
\end{array}
\]

is a homotopy pullback square. We consider several cases:

- Suppose first that the object $\overline{Z}$ belongs to $C$. If $\overline{X}$ and $\overline{Y}$ belong to $C$, then we deduce that (7.42) is a homotopy pullback square by applying Proposition 5.1.2.1 to the cocartesian fibration $U : \mathcal{E} \to C$ (since, by construction, the morphism $e$ is $U$-cocartesian). Otherwise, each of the Kan complexes appearing in the diagram (7.42) is empty, so there is nothing to prove.

- Suppose that the objects $\overline{Y}$ and $\overline{Z}$ belong to $\Delta^n$. In this case, we deduce that (7.42) is a homotopy pullback square by applying Proposition 5.1.2.1 to the cocartesian fibration $T : \mathcal{E}^+ \to \{c\} \star \Delta^n$ (since, by construction, the morphism $e$ is $T$-cocartesian).

- Suppose that the objects $\overline{X}$ and $\overline{Y}$ belong to $C$, but the object $\overline{Z}$ belongs to $\Delta^n$. In this case, the Kan complexes on the bottom row of (7.42) are contractible (see Example 4.6.1.5; in fact, they are both isomorphic to $\Delta^0$). In particular, the bottom horizontal map is a homotopy equivalence. To show that (7.42) is a homotopy pullback square, we must show that the upper horizontal map is also a homotopy equivalence (Corollary 3.4.1.5). In other words, we must show that composition with the homotopy class $[e]$ induces an isomorphism $\theta : \Hom_{\mathcal{E}^+}(Y,Z) \to \Hom_{\mathcal{E}^+}(X,Z)$ in the homotopy category $\text{hKan}$ (see Notation 4.6.8.15). Let $G : \mathcal{E} = \{c\} \times_{\{c\} \star \Delta^n} \mathcal{E}^+ \to \{\overline{Z}\} \times_{\{c\} \star \Delta^n} \mathcal{E}^+ = \mathcal{E}^+_Z$.

\[
G : \mathcal{E} = \{c\} \times_{\{c\} \star \Delta^n} \mathcal{E}^+ \to \{\overline{Z}\} \times_{\{c\} \star \Delta^n} \mathcal{E}^+ = \mathcal{E}^+_Z
\]
be given by covariant transport for the cocartesian fibration $T$. Using Corollary 5.1.2.3, we can identify $\theta$ with the morphism $\text{Hom}_{E^+Z}(G(Y), Z) \to \text{Hom}_{E^+Z}(G(X), Z)$ given by precomposition with the morphism $G(e) : G(X) \to G(Y)$. Since the morphism $e$ is $U$-cocartesian, its image $G(e)$ is an isomorphism in the $\infty$-category $E^+_Z$, so that $\theta$ is a homotopy equivalence as desired.

To extend Proposition 7.4.4.2 to the case where $\mathcal{C}$ is not assumed to be an $\infty$-category, we will need the following variant of Corollary 5.7.7.6:

**Lemma 7.4.4.3.** Suppose we are given a pullback diagram of simplicial sets

$$
\begin{array}{ccc}
\mathcal{E}_0 & \xrightarrow{\tilde{F}} & \mathcal{E} \\
\downarrow U_0 & & \downarrow U \\
\mathcal{C}_0 & \xrightarrow{F} & \mathcal{C},
\end{array}
$$

where $U_0$ and $U$ are cocartesian fibrations. Let $W_0$ denote the collection of all $U$-cocartesian edges of $\mathcal{E}_0$, and let $W$ denote the collection of all $U$-cocartesian morphisms of $\mathcal{E}$. If $F$ is inner anodyne, then $\tilde{F}$ induces an equivalence of $\infty$-categories $\mathcal{E}_0[W_0^{-1}] \to \mathcal{E}[W^{-1}]$.

**Remark 7.4.4.4.** Using Theorem 7.4.3.6, one can show that conclusion of Lemma 7.4.4.3 holds more generally under the assumption that $F : \mathcal{C}_0 \to \mathcal{C}$ is a left cofinal morphism of simplicial sets. For simplicity, let us assume that each of the simplicial sets appearing in the statement of Lemma 7.4.4.3 is small. Using Proposition 7.4.3.9, we can assume that $U$ is the pullback of a cocartesian fibration $\overline{U} : \overline{\mathcal{E}} \to \mathcal{C}^o$ for which the covariant refraction diagram $\text{Rf} : \mathcal{E} \to \overline{\mathcal{E}}_1$ exhibits the $\infty$-category $\overline{\mathcal{E}}_1$ as a localization of $\mathcal{E}$ with respect to $W$. Using Theorem 7.4.3.6, we deduce that the covariant transport representation $\text{Tr} = \text{Tr}_{\mathcal{E}/\mathcal{C}^o} : \mathcal{C}^o \to \mathcal{Q}\mathcal{C}$ is a colimit diagram. Since $F$ is right cofinal, it follows that the restriction $\text{Tr}|_{\mathcal{C}_0}$ is also a colimit diagram (Corollary 7.2.2.3). Applying Theorem 7.4.3.6 again, we conclude that $\text{Rf}|_{\mathcal{E}_0}$ exhibits $\overline{\mathcal{E}}_1$ as a localization of $\mathcal{E}_0$ with respect to $W_0$, so that $\tilde{F}$ induces an equivalence $\mathcal{E}_0[W_0^{-1}] \sim \mathcal{E}[W^{-1}]$.

**Proof of Lemma 7.4.4.3.** Fix an $\infty$-category $\mathcal{D}$; we wish to show that precomposition with $\tilde{F}$ induces an equivalence of $\infty$-categories $\text{Fun}(\mathcal{E}[W^{-1}], \mathcal{D}) \to \text{Fun}(\mathcal{E}_0[W_0^{-1}], \mathcal{D})$ (see Notation 6.3.1.1). Corollary 5.7.7.6 guarantees that $\tilde{F}$ is a categorical equivalence of simplicial sets, so that precomposition with $\tilde{F}$ induces an equivalence of $\infty$-categories $\text{Fun}(\mathcal{E}, \mathcal{D}) \to \text{Fun}(\mathcal{E}_0, \mathcal{D})$. It will therefore suffice to prove the following:
Let $G : \mathcal{E} \to \mathcal{D}$ be a morphism of simplicial sets with the property that $G \circ \tilde{F}$ carries every $U_0$-cocartesian edge of $\mathcal{E}_0$ to an isomorphism in $\mathcal{D}$. Then $G$ carries each $U$-cocartesian edge of $\mathcal{E}$ to an isomorphism in $\mathcal{D}$.

Let us henceforth regard the $\infty$-category $\mathcal{D}$ and the functor $G : \mathcal{E} \to \mathcal{D}$ as fixed. For every morphism of simplicial sets $K \to \mathcal{C}$, let $E_K$ denote the fiber product $K \times_\mathcal{C} \mathcal{E}$, let $U_K : E_K \to K$ be the projection map, and let $G_K$ denote the restriction of $G$ to $E_K$. Let us say that a monomorphism of simplicial sets $K' \hookrightarrow K$ is good if, for every morphism $K \to \mathcal{C}$ with the property that $G_K'$ carries $U_K'$-cocartesian morphisms of $E_K'$ to isomorphisms in $\mathcal{D}$, the morphism $G_K$ carries $U_K$-cocartesian morphisms of $E_K$ to isomorphisms in $\mathcal{D}$. To prove $(\ast)$, it will suffice to show that $F : \mathcal{C}_0 \to \mathcal{C}$ is weakly saturated. It is not difficult to see that the collection of good morphisms is weakly saturated, in the sense of Definition 1.4.4.15. It will therefore suffice to show that the horn inclusion $\Lambda^n_i \hookrightarrow \Delta^n$ is good for $0 < i < n$. In other words, it will suffice to prove $(\ast)$ in the special case where $\mathcal{C} = \Delta^n$ is a standard simplex and $F : \Lambda^n_i \hookrightarrow \Delta^n$ is the inclusion of an inner horn.

If $n \geq 3$, then every edge of $\mathcal{C} = \Delta^n$ is contained in the horn $\Lambda^n_i$; it follows that the morphism $\tilde{F} : \mathcal{E}_0 \to \mathcal{E}$ induces a bijection $W_0 \cong W$, so there is nothing to prove. We may therefore assume without loss of generality that $n = 2$. Let $w : X \to Z$ be a $U$-cocartesian of $\mathcal{E}$ which does not belong to the simplicial subset $\mathcal{E}_0 = \Lambda^2_1 \times_{\Delta^2} \mathcal{E}$, so that $U(X) = 0$ and $U(Z) = 2$. Since $U$ is a cocartesian fibration, we can choose a $U$-cocartesian morphism $u : X \to Y$ with $U(Y) = 1$. Our assumption that $u$ is $U$-cocartesian guarantees that there exists a 2-simplex of $\mathcal{E}'$ whose boundary is indicated in the diagram

\[
\begin{array}{ccc}
Y & \rightarrow & Z \\
\downarrow^u & & \downarrow^v \\
X & \rightarrow & Z.
\end{array}
\]

Invoking Corollary 5.1.2.4, we see that $v$ is also $U$-cocartesian, so that $u$ and $v$ can be regarded as elements of $W_0$. It now suffices to observe that if $G : \mathcal{E} \to \mathcal{D}$ is any functor which carries both $u$ and $v$ to isomorphisms in $\mathcal{D}$, then $G$ also carries $w$ to an isomorphism in $\mathcal{D}$. □
Proof of Theorem 7.4.3.6. Suppose we are given a pullback diagram of small simplicial sets

\[
\begin{array}{ccc}
E & \to & E_1 \\
\downarrow & & \downarrow \\
C & \to & C_1
\end{array}
\]

where \(U\) and \(\overline{U}\) are cocartesian fibrations. Let \(W\) denote the collection of all \(U\)-cocartesian edges of \(E\), let \(1\) denote the cone point of \(C_1\), let \(Rf : E \to E_1\) be a covariant refraction diagram (Definition 7.4.3.1). Assume first that \(Rf\) exhibits the \(\infty\)-category \(E_1\) as a localization of \(E\) with respect to \(W\). We wish to show that the covariant transport representation \(\text{Tr}_{E/C} : C_1 \to QC\) is a colimit diagram in the \(\infty\)-category \(QC\).

Using Corollary 4.1.3.3, we can choose an inner anodyne morphism \(C \hookrightarrow C'\), where \(C'\) is an \(\infty\)-category. Note that the induced map \(C_1 \hookrightarrow C_1\) is also inner anodyne (Proposition 4.3.6.4). Applying Corollary 5.7.7.3, we can realize \(\overline{U}\) as the pullback of a cocartesian fibration of \(\infty\)-categories \(U' : \overline{E} \to C_1\). Form a pullback diagram

\[
\begin{array}{ccc}
E' & \to & E_1 \\
\downarrow & & \downarrow \\
C' & \to & C_1
\end{array}
\]

and let \(W'\) denote the collection of all \(U'\)-cocartesian morphisms of \(E'\). Using Proposition 7.4.3.3, we can choose a covariant refraction diagram \(Rf' : E' \to E_1 = \overline{E}_1\) for the cocartesian fibration \(\overline{U}'\). Note that the restriction \(Rf|_E\) is a covariant refraction collapse diagram for the cocartesian fibration \(\overline{U}\), and is therefore isomorphic to \(Rf\) as an object of the \(\infty\)-category \(\text{Fun}(E, \overline{E}_1)\). It follows that \(Rf'|_E\) also exhibits the \(\infty\)-category \(\overline{E}_1\) as a localization of \(E\) with respect to \(W\) (Exercise 6.3.1.11). Applying Lemma 7.4.4.3, we see that \(Rf\) exhibits \(E_1\) as a localization of \(E'\) with respect to \(W\).

Using Corollary 5.7.5.11, we can extend \(\text{Tr}_{\overline{E}/C_1}\) to a functor

\[\text{Tr}_{\overline{E}/C_1} : C_1 \to QC\]

which is a covariant transport representation for \(\overline{U}'\). Applying Proposition 7.4.4.2 to the diagram of \(\infty\)-categories (7.43), we deduce that \(\text{Tr}_{\overline{E}/C_1}\) is a colimit diagram in the \(\infty\)-category \(QC\). Since the inclusion map \(C \hookrightarrow C'\) is right cofinal (Proposition 7.2.1.3), it follows that \(\text{Tr}_{\overline{E}/C_1}\) is also a colimit diagram in \(QC\), as desired.
We now prove the converse. Assume that the covariant transport representation $\text{Tr}_{\mathcal{E}/\mathcal{C}}$ is a colimit diagram in the $\infty$-category $\mathcal{QC}$; we wish to show that the covariant refraction diagram $\mathcal{R}_f$ exhibits $\mathcal{E}_1$ as a localization of $\mathcal{E}$ with respect to $W$. By virtue of Proposition 7.4.3.9 (and Remark 7.4.3.10), we can choose another pullback diagram

$$\begin{array}{ccc}
\mathcal{E} & \to & \mathcal{E}^+ \\
\downarrow & & \downarrow \\
\mathcal{C} & \to & \mathcal{C}^+, \\
\end{array}$$

where $\mathcal{U}^+$ is a cocartesian fibration for which the covariant refraction diagram $\mathcal{R}_f^+ : \mathcal{E} \to \mathcal{E}_1^+$ exhibits $\mathcal{E}_1^+$ as a localization of $\mathcal{E}$ with respect to $W$. Applying Corollary 5.7.5.11, we see that $\mathcal{U}^+$ admits a covariant transport representation $\text{Tr}_{\mathcal{E}^+/\mathcal{C}^+} : \mathcal{C}^+ \to \mathcal{QC}$ satisfying $(\text{Tr}_{\mathcal{E}^+/\mathcal{C}^+})|_{\mathcal{C}} = (\text{Tr}_{\mathcal{E}/\mathcal{C}})|_{\mathcal{C}}$. The first part of the proof shows that $\text{Tr}_{\mathcal{E}^+/\mathcal{C}^+}$ is also a colimit diagram in the $\infty$-category $\mathcal{QC}$, and is therefore isomorphic to $\text{Tr}_{\mathcal{E}/\mathcal{C}}$ as an object of the $\infty$-category $\text{Fun}(\mathcal{C}^+, \mathcal{QC})$. Applying Theorem 5.7.0.2, we see $\mathcal{U} : \mathcal{E} \to \mathcal{C}^+$ and $\mathcal{U}^+ : \mathcal{E}^+ \to \mathcal{C}^+$ are equivalent as cocartesian fibrations over $\mathcal{C}^+$. Applying Exercise 7.4.3.8, we conclude that $\mathcal{R}_f$ also exhibits $\mathcal{E}_1$ as a localization of $\mathcal{E}$ with respect to $W$, as desired.

\subsection{Limits and Colimits of Spaces}

Let $\mathcal{S}$ denote the $\infty$-category of spaces (Construction 5.6.1.1), which we regard as a full subcategory of the $\infty$-category $\mathcal{QC}$ (Remark 5.6.4.8). Our goal in this section is to describe limits and colimits in the $\infty$-category $\mathcal{S}$. Given the results of §7.4.1 and §7.4.3, this is a relatively formal exercise. We begin with an elementary observation:

\begin{proposition}
Let $f : K \to \mathcal{S}$ be a diagram. Then:

- An extension $\overline{f} : K^\circ \to \mathcal{S}$ is a limit diagram if and only if it is a limit diagram in the $\infty$-category $\mathcal{QC}$.
- An extension $\overline{f} : K^\circ \to \mathcal{S}$ is a colimit diagram if and only if it is a colimit diagram in the $\infty$-category $\mathcal{QC}$.

\end{proposition}

\begin{proof}
It follows immediately from the definitions that a diagram in $\mathcal{S}$ which is a limit (or colimit) diagram in the larger $\infty$-category $\mathcal{QC}$, then it is already a limit (or colimit) diagram in $\mathcal{S}$ (see Variant 7.1.3.10). To prove the converse implications, we must show that the inclusion functor $\mathcal{I} : \mathcal{S} \to \mathcal{QC}$ preserves all limits and colimits. This follows from Corollary 7.1.3.21 since the functor $\mathcal{I}$ admits both left and right adjoints (Example 5.2.2.12).
\end{proof}
Corollary 7.4.5.2. Let $U : \mathcal{E} \to \mathcal{C}$ be a left fibration between small simplicial sets and let $\operatorname{Tr}_{\mathcal{E}/\mathcal{C}} : \mathcal{C} \to \mathcal{S}$ be a covariant transport representation for $U$. Then the simplicial set $\operatorname{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ of sections of $U$ is a Kan complex, which is a limit of the diagram $\operatorname{Tr}_{\mathcal{E}/\mathcal{C}}$ in the $\infty$-category $\mathcal{S}$.

Proof. Since $U$ is a left fibration, Corollary 4.4.2.4 guarantees that the simplicial set $\operatorname{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ is a Kan complex. Note that every edge of $\mathcal{E}$ is $U$-cocartesian (Example 5.1.1.3), so that $\operatorname{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ coincides with the $\infty$-category $\operatorname{Fun}_{/\mathcal{C}}^{\operatorname{Cart}}(\mathcal{C}, \mathcal{E})$ of cocartesian sections of $U$. Applying Corollary 7.4.1.9, we see that the Kan complex $\operatorname{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})$ is a limit of the diagram $\operatorname{Tr}_{\mathcal{E}/\mathcal{C}}$ in the $\infty$-category $\mathcal{QC}$, and therefore also in the full subcategory $S \subseteq \mathcal{QC}$ (Proposition 7.4.5.1).

Corollary 7.4.5.3. Let $\mathcal{C}$ be a small simplicial set. Then any diagram $\mathcal{F} : \mathcal{C} \to \mathcal{S}$ admits a limit in the $\infty$-category $\mathcal{S}$, given by the $\infty$-category $\operatorname{Fun}_{/\mathcal{C}}(\mathcal{C}, \int_{\mathcal{C}} \mathcal{F})$.

Proof. Apply Corollary 7.4.5.2 to the left fibration $U : \int_{\mathcal{C}} \mathcal{F} \to \mathcal{C}$ of Example 5.7.2.9.

Corollary 7.4.5.4. Let $U : \mathcal{E} \to \mathcal{C}$ be a left fibration between small simplicial sets and let $\operatorname{Tr}_{\mathcal{E}/\mathcal{C}} : \mathcal{C} \to \mathcal{S}$ be a covariant transport representation for $U$. Then the diagram $\operatorname{Tr}_{\mathcal{E}/\mathcal{C}}$ admits a colimit in the $\infty$-category $\mathcal{S}$. Moreover, a Kan complex $X$ is a colimit of $\operatorname{Tr}_{\mathcal{E}/\mathcal{C}}$ if and only if there exists a weak homotopy equivalence $\mathcal{E} \to X$.

Proof. Since $U$ is a left fibration, every edge of $\mathcal{E}$ is $U$-cocartesian (Example 5.1.1.3). Let $W$ be the collection of all $U$-cocartesian edges of $\mathcal{E}$. By virtue of Corollary 7.4.3.11, an $\infty$-category $X$ is a colimit of $\operatorname{Tr}_{\mathcal{E}/\mathcal{C}}$ in the $\infty$-category $\mathcal{QC}$ if and only if there exists a functor $f : \mathcal{E} \to X$ which exhibits $X$ as a localization of $\mathcal{E}$ with respect to $W$. By virtue of Proposition 6.3.1.20, this is equivalent to the requirement that $X$ is a Kan complex and that $f$ is a weak homotopy equivalence. In this case, $X$ is also a colimit of the diagram $\operatorname{Tr}_{\mathcal{E}/\mathcal{C}}$ in the full subcategory $S \subseteq \mathcal{QC}$ (Proposition 7.4.5.1).

Corollary 7.4.5.5. Let $\mathcal{C}$ be a small simplicial set. Then any diagram $\mathcal{F} : \mathcal{C} \to \mathcal{S}$ admits a colimit in the $\infty$-category $\mathcal{S}$. Moreover, a Kan complex $X$ is a colimit of the diagram $\mathcal{F}$ if and only if there exists a weak homotopy equivalence $\int_{\mathcal{C}} \mathcal{F} \to X$.

Proof. Apply Corollary 7.4.5.4 to the left fibration $U : \int_{\mathcal{C}} \mathcal{F} \to \mathcal{C}$ of Example 5.7.2.9.

Corollary 7.4.5.6. The $\infty$-category $\mathcal{S}$ admits small limits and colimits.

Proof. Combine Corollaries 7.4.5.5 and 7.4.5.3.

Remark 7.4.5.7 (Size Estimates for Colimits). Let $\lambda$ be an uncountable cardinal and let $\kappa = \operatorname{cf}(\lambda)$ be its cofinality. Suppose we are given a diagram $\mathcal{F} : \mathcal{C} \to \mathcal{S}$, where $\mathcal{C}$ is a $\kappa$-small simplicial set, and that the Kan complex $\mathcal{F}(C)$ is essentially $\lambda$-small for each $C \in \mathcal{C}$. Then
the colimit \( \lim(\mathcal{F}) \) is also essentially \( \lambda \)-small. This follows from Corollary 7.4.3.15 and Proposition 7.4.5.1.

**Variant 7.4.5.8** (Size Estimates for Limits). Let \( \lambda \) be an uncountable cardinal and let \( \kappa = \text{ecf}(\lambda) \) be its exponential cofinality. Suppose we are given a diagram \( \mathcal{F} : \mathcal{C} \to \mathcal{S} \), where \( \mathcal{C} \) is a \( \kappa \)-small simplicial set, and that the Kan complex \( \mathcal{F}(C) \) is essentially \( \lambda \)-small for each \( C \in \mathcal{C} \). Then the limit \( \lim(\mathcal{F}) \) is also essentially \( \lambda \)-small. This follows from Corollary 7.4.1.12 and Proposition 7.4.5.1.

For strictly commutative diagrams, we can use the results of §5.3 to give an alternative construction.

**Corollary 7.4.5.9.** Let \( \mathcal{C} \) be a small category and let \( \mathcal{F} : \mathcal{C} \to \text{Kan} \) be a (strictly commutative) diagram of Kan complexes indexed by \( \mathcal{C} \). Then a Kan complex \( X \) is a colimit of the functor \( N_{\mathit{hc}}^\mathcal{C}(\mathcal{F}) : N_{\mathit{hc}}^\mathcal{C}(\mathcal{C}) \to \mathcal{S} \) if and only if it is weakly homotopy equivalent to the weighted nerve \( N^\mathcal{F}(\mathcal{C}) \) of Definition 5.3.3.1.

**Proof.** Combine Corollary 7.4.5.4 with Example 5.7.5.6. \( \square \)

For many applications, it will be useful to have more precise versions of the preceding results, which characterize limit and colimit diagrams in the \( \infty \)-category \( \mathcal{S} \).

**Corollary 7.4.5.10.** Suppose we are given a pullback diagram of small simplicial sets

\[
\begin{array}{ccc}
\mathcal{E} & \longrightarrow & \mathcal{E}' \\
\downarrow U & & \downarrow U' \\
\mathcal{C} & \longrightarrow & \mathcal{C}'
\end{array}
\]

where \( U \) and \( U' \) are left fibrations. The following conditions are equivalent:

1. The restriction map
   \[
   \text{Fun}_{/\mathcal{C}'}(\mathcal{C}', \mathcal{E}') \to \text{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E})
   \]
   is a homotopy equivalence of Kan complexes.

2. The covariant transport representation \( \text{Tr}_{\mathcal{E}/\mathcal{C}'} : \mathcal{C} \to \mathcal{S} \) is a limit diagram in the \( \infty \)-category \( \mathcal{S} \).

**Proof.** Since \( U' \) is a left fibration, every edge of \( \mathcal{E}' \) is \( U' \)-cocartesian (Example 5.1.1.3). We can therefore identify \( \text{Fun}_{/\mathcal{C}'}(\mathcal{C}', \mathcal{E}') \) and \( \text{Fun}_{/\mathcal{C}}(\mathcal{C}, \mathcal{E}) \) with the \( \infty \)-categories \( \text{Fun}_{/\mathcal{C}'}^\mathcal{C'}(\mathcal{C}', \mathcal{E}') \) and \( \text{Fun}_{/\mathcal{C}}^\mathcal{C}C(\mathcal{C}, \mathcal{E}) \), respectively. The desired result now follows by combining Theorem 7.4.1.1 with Proposition 7.4.5.1. \( \square \)
As an application, we prove a converse of Corollary 7.2.3.

**Corollary 7.4.5.11.** Let \( e : C' \to C \) be a morphism of simplicial sets. Then \( e \) is left cofinal if and only if it satisfies the following condition:

\( (*) \) For every limit diagram \( \mathcal{F} : C^\triangleright \to S \), the composition \( \mathcal{F} \circ e^\triangleright : C^\triangleright \to S \) is also a limit diagram.

**Proof.** Assume that condition \((*)\) is satisfied; we will show that \( e \) is left cofinal (the reverse implication is a special case of Corollary 7.2.3). Fix a left fibration \( U : \mathcal{E} \to C \); we wish to show that the restriction map

\[ e^* : \text{Fun}_{/C}(C, \mathcal{E}) \to \text{Fun}_{/C}(C', \mathcal{E}) \]

is a homotopy equivalence of Kan complexes. Using Proposition 7.4.1.6 (together with Remark 7.4.1.8), we can extend \( U \) to a left fibration \( \overline{U} : \overline{\mathcal{E}} \to C^\triangleright \) for which the restriction map

\[ T : \text{Fun}_{/C^\triangleright}(C^\triangleright, \overline{\mathcal{E}}) \to \text{Fun}_{/C}(C, \mathcal{E}) \]

is a homotopy equivalence.

Form a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
\overline{\mathcal{E}} & \to & \overline{\mathcal{E}} \\
\downarrow{\overline{U}} & & \downarrow{U} \\
C^\triangleright & \overset{e}{\to} & C^\triangleright.
\end{array}
\]

Let \( \mathcal{F} : C^\triangleright \to S \) be a covariant transport representation for the left fibration \( \overline{U} \), so that \( \mathcal{F} \circ e^\triangleright \) is a covariant transport representation for the left fibration \( \overline{U}' \). It follows from the criterion of Corollary 7.4.5.10 that \( \overline{\mathcal{F}} \) is a limit diagram in the \( \infty \)-category \( S \). Applying assumption \((*)\), we see that \( \overline{\mathcal{F}} \circ e^\triangleright \) is also a limit diagram in the \( \infty \)-category \( S \). We therefore have a commutative diagram of restriction maps

\[
\begin{array}{ccc}
\text{Fun}_{/C^\triangleright}(C^\triangleright, \overline{\mathcal{E}}) & \xrightarrow{T'} & \text{Fun}_{/C}(C', \mathcal{E}) \\
\downarrow{(e^\triangleright)^*} & & \downarrow{e^*} \\
\text{Fun}_{/C^\triangleright}(C^\triangleright, \overline{\mathcal{E}}) & \xrightarrow{T} & \text{Fun}_{/C}(C, \mathcal{E}),
\end{array}
\]

where the horizontal maps are homotopy equivalences (Corollary 7.4.5.10). Consequently, to show that \( e^* \) is a homotopy equivalence, it will suffice to show that \((e^\triangleright)^*\) is a homotopy equivalence.
equivalence. We now observe that \((e^\circ)^*\) fits into a commutative diagram

\[
\begin{array}{ccc}
\text{Fun}_{/C^\circ}(C'^{\circ}, \mathcal{E}) & \xrightarrow{(e^\circ)^*} & \{0\} \times_{C^\circ} \mathcal{E} \\
\downarrow & & \downarrow \\
\text{Fun}_{/C^\circ}(C^{\circ}, \mathcal{E}),
\end{array}
\]

where the horizontal maps are given by evaluation at the cone points of the simplicial sets \(C^\circ\) and \(C'^{\circ}\) are are therefore trivial Kan fibrations (Corollary 5.3.1.23).

\[\square\]

**Corollary 7.4.5.12.** Suppose we are given a pullback diagram of small simplicial sets

\[
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{U} & \mathcal{E} \\
\downarrow & & \downarrow \\
C & \xrightarrow{\iota} & C^\circ,
\end{array}
\]

where \(U\) and \(\iota\) are left fibrations. The following conditions are equivalent:

1. The inclusion map \(\mathcal{E} \hookrightarrow \mathcal{E}\) is a weak homotopy equivalence of simplicial sets.
2. The covariant transport representation \(\text{Tr}_{\mathcal{E}/C^\circ} : C^\circ \to S\) is a colimit diagram in the \(\infty\)-category \(S\).

**Proof.** Let \(\mathbf{1}\) denote the cone point of \(C^\circ\), and let \(\mathcal{E}_1 = \{\mathbf{1}\} \times_{C^\circ} \mathcal{E}\) denote the corresponding fiber of \(\mathcal{E}\). Since the inclusion map \(\{\mathbf{1}\} \hookrightarrow C^\circ\) is right anodyne (Example 4.3.7.11), the inclusion \(\iota : \mathcal{E}_1 \hookrightarrow \mathcal{E}\) is also right anodyne (Corollary 7.2.3.14). In particular, \(\iota\) is a weak homotopy equivalence of simplicial sets. Let \(Rf : \mathcal{E} \to \mathcal{E}_1\) be a covariant refraction diagram (Proposition 7.4.3.3), so that the inclusion map \(\mathcal{E} \hookrightarrow \mathcal{E}\) is homotopic to the composition \(\iota \circ Rf\). It follows that condition (1) can be reformulated as follows:

(1') The covariant refraction diagram \(Rf : \mathcal{E} \to \mathcal{E}_1\) is a weak homotopy equivalence.

The equivalence (1') \(\iff\) (2) follows by combining Proposition 7.4.5.1, Theorem 7.4.3.6, and Proposition 6.3.1.20. \(\square\)

We conclude this section with an application of Corollary 7.4.5.10.
Proposition 7.4.5.13. Let \( C \) be a locally small \( \infty \)-category and let \( K \) be a small simplicial set. Then a morphism \( F : K^\Delta \to C \) is a limit diagram if and only if, for every object \( X \in C \), the composition

\[
K^\Delta \xrightarrow{F} C \xrightarrow{h^X} S
\]

is a limit diagram in the \( \infty \)-category of spaces; here \( h^X \) denotes the functor corepresented by \( X \) (Notation 5.7.6.14).

Proof. Applying Proposition 7.1.5.12, we see that \( F \) is a limit diagram if and only if, for every object \( X \in C \), the restriction map

\[
\theta_X : \text{Hom}_{\text{Fun}(K^\Delta, C)}(X, F) \to \text{Hom}_{\text{Fun}(K, C)}(X|_K, F|_K)
\]

is a homotopy equivalence of Kan complexes. Let \( \mathcal{E} \) denote the oriented fiber product \( \{ X \}_C \times C \) and let \( U : \mathcal{E} \to C \) be given by projection onto the second factor. Note that \( U \) is a left fibration (Proposition 4.6.4.11) and that \( \theta_X \) can be identified with the restriction map

\[
\text{Fun}/C(K^\Delta, \mathcal{E}) \to \text{Fun}/C(K, \mathcal{E}).
\]

The identity morphism \( \text{id}_X \) can be viewed as an initial object of \( \mathcal{E} \) satisfying \( U(\text{id}_X) = X \) (Proposition 4.6.6.23), so the corepresentable functor \( h^X : C \to S \) is a covariant transport representation for \( U \) (Proposition 5.7.6.21). Applying Corollary 7.4.5.10 we see that \( \theta_X \) is a homotopy equivalence if and only if \( h^X \circ F \) is a limit diagram in the \( \infty \)-category \( S \).

Corollary 7.4.5.14. Let \( C \) be a locally small \( \infty \)-category. For every object \( X \in C \), the functors

\[
h^X : C \to S \quad h_X : C^{\text{op}} \to S
\]

preserve \( K \)-indexed limits, for every small simplicial set \( K \).

Remark 7.4.5.15. Let \( \lambda \) be an uncountable cardinal and let \( C \) be an \( \infty \)-category which is locally \( \lambda \)-small. Let \( \kappa = \text{ecf}(\lambda) \) be the exponential cofinality of \( \lambda \) and let \( K \) be a \( \kappa \)-small simplicial set. Then, in the statements of Proposition 7.4.5.13 and Corollary 7.4.5.14 we can replace \( S \) by the \( \infty \)-category \( S^{<\lambda} \) of \( \lambda \)-small spaces (see Variant 7.4.5.8).

7.5 Homotopy Limits and Colimits

Let \( C \) be a small category, and let \( \mathcal{F} : C \to \text{Kan} \) be a diagram of Kan complexes indexed by \( C \). Recall that the diagram \( \mathcal{F} \) has a limit \( \lim\left(\mathcal{F}\right) \) in the category of simplicial sets, given concretely by the formula

\[
\lim(\mathcal{F})(C)_n = \lim_{C \in C} \mathcal{F}(C)_n
\]

(Remark 1.1.1.13). However, from the perspective of homotopy theory, the construction \( \mathcal{F} \mapsto \lim(\mathcal{F}) \) is poorly behaved:
7.5. HOMOTOPY LIMITS AND COLIMITS

- Although each of the simplicial sets \(\{F(C)\}_{C \in C}\) is assumed to be a Kan complex, the inverse limit \(\lim_{\leftarrow}(F)\) need not be a Kan complex.

- If \(\alpha : F \to G\) is a natural transformation between diagrams \(F, G : C \to \text{Kan}\) which is a levelwise homotopy equivalence (Remark 4.5.6.2), then the induced map \(\lim_{\leftarrow}(F) \to \lim_{\leftarrow}(G)\) need not be a (weak) homotopy equivalence (see Warning 3.4.0.1).

These deficiencies can be remedied by working in the framework of \(\infty\)-categories. By passing to the homotopy coherent nerve, every functor of ordinary categories \(F : C \to \text{Kan}\) determines a functor of \(\infty\)-categories \(N^h_c(F) : N_\bullet(C) \to N^h_c(\text{Kan}) = S\). By virtue of Corollary 7.4.5.6, the \(\infty\)-category of spaces \(S\) admits all (small) limits and colimits. In particular, there exists a Kan complex \(X\) which is a limit of the diagram \(N^h_c(F)\). This construction has the advantage of being homotopy invariant: if \(\alpha : F \to G\) is a levelwise homotopy equivalence, then \(X\) is also a limit of the diagram \(N^h_c(G)\) (see Remark 7.1.1.8). However, it has the disadvantage of being somewhat inexplicit: the Kan complex \(X\) is \textit{a priori} well-defined only up to homotopy equivalence, rather than up to isomorphism.

By combining the results of 7.4 and 5.3, we can obtain a more direct description of the Kan complex \(X\). Let \(N^\varphi_\bullet(C)\) denote the \(\varphi\)-weighted nerve of \(C\) (Definition 5.3.3.1). It follows from Example 5.7.5.6 that \(N^\varphi_\bullet(C)\) is a covariant transport representation for the left fibration \(U : N^\varphi_\bullet(C) \to N_\bullet(C)\). By virtue of Corollary 7.4.5.2, the Kan complex \(\text{Fun}_{/N_\bullet(C)}(N_\bullet(C), N^\varphi_\bullet(C))\) is a limit of the diagram \(N^h_c(F)\). We will denote this Kan complex by \(\text{holim}(F)\) and refer to it as the \textit{homotopy limit} of the diagram \(F\) (Construction 7.5.1.1). In \(\text{§7.5.1}\), we give review some elementary properties of this construction (which goes back to the work of Bousfield and Kan; see [5]).

In \(\text{§7.5.2}\), we extend the definition of the homotopy limit \(\text{holim}(F)\) to the case where \(F : C \to \text{QCat}\) is a diagram of \(\infty\)-categories (rather than a diagram of Kan complexes). In this case, the projection map \(U : N^\varphi_\bullet(C) \to N_\bullet(C)\) is a cocartesian fibration (rather than a left fibration), and we define \(\text{holim}(F)\) to be the \(\infty\)-category of \textit{cocartesian} sections of \(U\) (that is, sections which carry each morphism of \(C\) to a \(U\)-cocartesian morphism of \(N^\varphi_\bullet(C)\); see Construction 7.5.2.1). It follows from the results of 7.4 that \(\text{holim}(F)\) is a limit of the diagram of \(\infty\)-categories \(N^h_c(F) : N_\bullet(C) \to \text{QCat}\) (Proposition 7.5.2.4).

In \(\text{§7.5.3}\), we consider another perspective on the homotopy limit construction \(F \mapsto \text{holim}(F)\): it can be viewed as a \textit{right derived functor} of the usual inverse limit \(F \mapsto \lim_{\leftarrow}(F)\). More precisely, for every diagram of \(\infty\)-categories \(F : C \to \text{QCat}\), there is a canonical isomorphism \(\text{holim}(F) \simeq \lim_{\leftarrow}(F^+)\), where \(F^+ : C \to \text{QCat}\) is an \textit{isofibrant replacement} for the diagram \(F\) (see Construction 7.5.3.3 and Proposition 7.5.3.7). In particular, there is a tautological map \(\lim_{\leftarrow}(F) \hookrightarrow \text{holim}(F)\) (see Remark 7.5.2.10), which is an equivalence of \(\infty\)-categories when the diagram \(F\) is already isofibrant (Proposition 7.5.3.12). This condition
is satisfied, for example, when the diagram \( \mathcal{F} \) corresponds to a tower of \( \infty \)-categories
\[
\cdots \to \mathcal{E}(3) \to \mathcal{E}(2) \to \mathcal{E}(1) \to \mathcal{E}(0)
\]
in which the transition functors are isofibrations (see Example 7.5.3.13).

Let \( \mathcal{F} : \mathcal{C} \to \text{Kan} \) be a diagram of Kan complexes and let \( \mathcal{F} : \mathcal{C}^\circ \to \text{Kan} \) be an extension of \( \mathcal{F} \), carrying the initial object of \( \mathcal{C}^\circ \) to a Kan complex \( X \). We say that \( \mathcal{F} \) is a \textit{homotopy limit diagram} if the composite map
\[
X \to \limleft( \mathcal{F} \right) \leftarrow \text{holim}(\mathcal{F})
\]
is a homotopy equivalence (Definition 7.5.4.1). In §7.5.4, we show that this condition is equivalent to the requirement that \( \text{N}^\text{hc}_{\bullet}(\mathcal{F}) \) is a limit diagram in the \( \infty \)-category \( \mathcal{S} \) (Proposition 7.5.4.5). Moreover, we extend the definition of homotopy limit diagram to the case where \( \mathcal{F} \) is an arbitrary diagram of simplicial sets (Definition 7.5.4.8), and show that it generalizes the notion of homotopy pullback diagram introduced in §3.4.1 (Proposition 7.5.4.13). In §7.5.5, we introduce the parallel (and closely related) notion of \textit{categorical limit diagram} (Definition 7.5.5.11), and show that it generalizes the notion of categorical pullback square introduced in §4.5.2 (Corollary 7.5.5.10).

There is a close relationship between the homotopy limit construction \( \mathcal{F} \mapsto \text{holim}(\mathcal{F}) \) of this section and the homotopy colimit construction \( \mathcal{F} \mapsto \text{holim}(\mathcal{F}) \) introduced in §5.3.2. If \( \mathcal{F} : \mathcal{C}^{\text{op}} \to \text{Set} \) is a diagram of simplicial sets and \( X \) is a Kan complex, then there is a canonical isomorphism of simplicial sets
\[
\text{holim}(X^{\mathcal{F}})^{\text{op}} \simeq \text{Fun}(\text{holim}(\mathcal{F}^{\text{op}}), X^{\text{op}}),
\]
where \( X^{\mathcal{F}} : \mathcal{C} \to \text{Kan} \) denotes the functor given by \( C \mapsto \text{Fun}(\mathcal{F}(C), X) \) (Example 7.5.1.7; see Example 7.5.2.9 for a generalization to the case where \( X \) is an \( \infty \)-category). Just as the homotopy limit construction can be viewed as a \textit{right} derived functor of the limit functor \( \lim : \text{Fun}(\mathcal{C}, \text{Set}_{\Delta}) \to \text{Set}_{\Delta} \), the homotopy colimit construction can be viewed as a \textit{left} derived functor of the colimit functor \( \text{colim} : \text{Fun}(\mathcal{C}, \text{Set}_{\Delta}) \to \text{Set}_{\Delta} \). More precisely, we show in §7.5.6 that the homotopy colimit of a diagram \( \mathcal{F} \) is isomorphic to the colimit \( \text{colim}(\mathcal{G}) \), where \( \mathcal{G} \) is a projectively cofibrant diagram of simplicial sets equipped with a levelwise weak homotopy equivalence \( \alpha : \mathcal{G} \to \mathcal{F} \) (Construction 7.5.6.8).

In §7.5.7, we show that the homotopy colimit construction has a close relationship with the formation of colimits in the \( \infty \)-category \( \mathcal{S} \). If \( \mathcal{F} : \mathcal{C} \to \text{Kan} \) is a diagram of Kan complexes, then a Kan complex is a colimit of the diagram \( \text{N}^\text{hc}_{\bullet}(\mathcal{F}) \) if and only if it is weakly homotopy equivalent to \( \text{holim}(\mathcal{F}) \) (Proposition 7.5.7.1). In fact, we can be more precise: if \( \mathcal{F} : \mathcal{C}^\circ \to \text{Kan} \) is a diagram extending \( \mathcal{F} \) which carries the final object of \( \mathcal{C}^\circ \) to a Kan complex \( X \), then \( \text{N}^\text{hc}_{\bullet}(\mathcal{F}) \) is a colimit diagram if and only if the composite map
holim(\mathcal{F}) \to \lim(\mathcal{F}) \to X is a weak homotopy equivalence (Corollary 7.5.7.7). If this condition is satisfied, we will say that \mathcal{F} is a homotopy colimit diagram (Definition 7.5.7.3). In §7.5.8 we introduce the parallel notion of categorical colimit diagram (Definition 7.5.8.2), which has a similar relationship with colimits in the \infty-category \mathcal{QC} (Corollary 7.5.8.9).

7.5.1 Homotopy Limits of Kan Complexes

In this section, we introduce the homotopy limit of a diagram of Kan complexes, following Bousfield and Kan (see [5]).

Construction 7.5.1.1 (Homotopy Limits of Kan Complexes). Let \mathcal{C} be a category, let \mathcal{F} : \mathcal{C} \to \text{Kan} be a diagram of Kan complexes indexed by \mathcal{C}, and \mathcal{N}^\mathcal{F}(\mathcal{C}) denote the weighted nerve of \mathcal{F} (Definition 5.3.3.1). We define

[holim(\mathcal{F}) = \text{Fun}_{\mathcal{N}^\mathcal{C}}(\mathcal{N}^\mathcal{F}(\mathcal{C}), \mathcal{N}^\mathcal{F}(\mathcal{C}))]

to be the simplicial set which parametrizes sections of the projection map \mathcal{N}^\mathcal{F}(\mathcal{C}) \to \mathcal{N}(\mathcal{C}). We will refer to holim(\mathcal{F}) as the homotopy limit of the diagram \mathcal{F}.

Proposition 7.5.1.2. Let \mathcal{F} : \mathcal{C} \to \text{Kan} be a diagram of Kan complexes. Then the homotopy limit \text{holim}(\mathcal{F}) is a Kan complex.

Proof. This is a special case of Corollary 4.4.2.5, since the projection map \mathcal{U} : \mathcal{N}^\mathcal{F}(\mathcal{C}) \to \mathcal{N}^\mathcal{F}(\mathcal{C}) is a left fibration (Corollary 5.3.3.16). \qed

Remark 7.5.1.3 (Homotopy Invariance). Let \mathcal{C} be a category and let \alpha : \mathcal{F} \to \mathcal{G} be a natural transformation between functors \mathcal{F}, \mathcal{G} : \mathcal{C} \to \text{Kan}. Then \alpha induces a morphism of weighted nerves \mathcal{T} : \mathcal{N}^\mathcal{F}(\mathcal{C}) \to \mathcal{N}^\mathcal{G}(\mathcal{C}), and therefore a morphism of Kan complexes \text{holim}(\alpha) : \text{holim}(\mathcal{F}) \to \text{holim}(\mathcal{G}). If \alpha is a levelwise homotopy equivalence, then \mathcal{T} is an equivalence of left fibrations over \mathcal{N}(\mathcal{C}) (Corollary 5.3.3.17), so \text{holim}(\alpha) is a homotopy equivalence.

Warning 7.5.1.4. In [5], Bousfield and Kan define the homotopy limit of an arbitrary diagram \mathcal{F} : \mathcal{C} \to \text{Set}_\Delta to be the simplicial set Fun_{\mathcal{N}(\mathcal{C})}(\mathcal{N}(\mathcal{C}), \mathcal{N}^\mathcal{F}(\mathcal{C})) appearing in Construction 7.5.1.1. We will avoid this convention for two reasons:

- Many important features of the Bousfield-Kan construction (such as the homotopy invariance property of Remark 7.5.1.3) are true for diagrams of Kan complexes, but not for general diagrams of simplicial sets.
- In the case where \mathcal{F} is a diagram of \infty-categories, it will be convenient to adopt a slightly different definition of homotopy limit (Construction 7.5.2.1), which generally does not agree with the Bousfield-Kan construction.
Note that every (strictly commutative) diagram of Kan complexes $\mathcal{F} : \mathcal{C} \to \text{Kan}$ determines a diagram

$N^\text{hc}_\bullet : N_\bullet(\mathcal{C}) \to N^\text{hc}_\bullet(\text{Kan}) = S$

in the $\infty$-category of spaces $S$.

**Proposition 7.5.1.5.** Let $\mathcal{F} : \mathcal{C} \to \text{Kan}$ be a diagram of Kan complexes. Then the Kan complex $\text{holim}(\mathcal{F})$ is a limit of the diagram

$N^\text{hc}_\bullet(\mathcal{F}) : N_\bullet(\mathcal{C}) \to N^\text{hc}_\bullet(\text{Kan}) = S$

in the $\infty$-category $S$.

**Proof.** This is a special case of Corollary 7.4.5.2, since the functor $N^\text{hc}_\bullet(\mathcal{F})$ is a covariant transport representation for the projection map $U : N^\bullet(\mathcal{C}) \to N^\bullet(\mathcal{C})$ (Example 5.7.5.6). \qed

We now give a more concrete description of the homotopy limit.

**Remark 7.5.1.6.** Let $\mathcal{C}$ be a category. For each object $C \in \mathcal{C}$, let $\mathcal{E}(C)$ denote the simplicial set $N_\bullet(\mathcal{C}/C)$. The construction $C \mapsto \mathcal{E}(C)$ determines a functor $\mathcal{E} : \mathcal{C} \to \text{Set}_\Delta$, which we view as an object of the functor category $\text{Fun}(\mathcal{C}, \text{Set}_\Delta)$. For every diagram of Kan complexes $\mathcal{F} : \mathcal{C} \to \text{Kan}$, Proposition 5.3.3.21 supplies a canonical isomorphism

$\text{holim}(\mathcal{F}) = \text{Hom}_{\text{Fun}(\mathcal{C}, \text{Set}_\Delta)}(\mathcal{E}, \mathcal{F})_\bullet,$

where the right hand side is defined using the simplicial enrichment of $\text{Fun}(\mathcal{C}, \text{Set}_\Delta)$ described in Example 2.4.2.2.

Stated more concretely, we can identify $\text{holim}(\mathcal{F})$ with a simplicial subset of the product $\prod_{C \in \mathcal{C}} \text{Fun}(N_\bullet(\mathcal{C}/C), \mathcal{F}(C))$, whose $n$-simplices are collections of maps $\{\sigma_C : \Delta^n \times N_\bullet(\mathcal{C}/C) \to \mathcal{F}(C)\}$ which satisfy the following condition:

\[ (\ast) \text{ For every morphism } f : C \to D \text{ in the category } \mathcal{C}, \text{ the diagram of simplicial sets} \]

\[
\begin{array}{ccc}
\Delta^n \times N_\bullet(\mathcal{C}/C) & \xrightarrow{\sigma_C} & \Delta^n \times N_\bullet(\mathcal{C}/D) \\
\downarrow^{\sigma_f} & & \downarrow^{\sigma_D} \\
\mathcal{F}(C) & \xrightarrow{\mathcal{F}(f)} & \mathcal{F}(D)
\end{array}
\]

is commutative.

In particular, we have an equalizer diagram of simplicial sets

$\text{holim}(\mathcal{F}) \to \prod_{C} \text{Fun}(N_\bullet(\mathcal{C}/C), \mathcal{F}(C)) \rightrightarrows \prod_{f : C \to D} \text{Fun}(N_\bullet(\mathcal{C}/C), \mathcal{F}(D)).$
Example 7.5.1.7 (Duality with Homotopy Colimits). Let \( \mathcal{F} : \mathcal{C}^{\text{op}} \to \text{Set}_\Delta \) be a diagram of simplicial sets, let \( X \) be a Kan complex, and let \( \mathcal{X}^{\mathcal{F}} : \mathcal{C} \to \text{Kan} \) be the diagram of Kan complexes given by the formula \( \mathcal{X}^{\mathcal{F}}(C) = \text{Fun}(\mathcal{F}(C), X) \). Let us write \( \mathcal{F}^{\text{op}} : \mathcal{C}^{\text{op}} \to \text{Set}_\Delta \) for the functor given by the formula \( \mathcal{F}^{\text{op}}(C) = \mathcal{F}(C)^{\text{op}} \), and let \( \mathcal{E} : \mathcal{C} \to \text{Set}_\Delta \) denote the functor given by \( \mathcal{E}(C) = N_*((\mathcal{C}/C)) \). Combining Remark 7.5.1.6 with Proposition 5.3.2.21, we obtain canonical isomorphisms

\[
\text{holim} \left( \mathcal{X}^{\mathcal{F}} \right)^{\text{op}} \cong \text{Hom}_{\text{Fun}(\mathcal{C}, \text{Set}_\Delta)}(\mathcal{E}, \mathcal{X}^{\mathcal{F}})^{\text{op}} \\
\cong \text{Hom}_{\text{Fun}(\mathcal{C}^{\text{op}}, \text{Set}_\Delta)}(\mathcal{F}^{\text{op}}, \mathcal{X}^{\mathcal{F}})^{\text{op}} \\
\cong \text{Fun}(\text{holim}(\mathcal{F}^{\text{op}}), X^{\text{op}}).
\]

7.5.2 Homotopy Limits of \( \infty \)-Categories

We now extend the definition of homotopy limit to diagrams taking values in the category \( \text{QCat} \).

Construction 7.5.2.1 (Homotopy Limits of \( \infty \)-Categories). Let \( \mathcal{F} : \mathcal{C} \to \text{QCat} \) be a (strictly commutative) diagram of \( \infty \)-categories, let \( N_*^{\mathcal{F}}(\mathcal{C}) \) denote the weighted nerve of \( \mathcal{F} \) (Definition 5.3.3.1), and let \( U : N_*^{\mathcal{F}}(\mathcal{C}) \to N_*(\mathcal{C}) \) the cocartesian fibration Proposition 5.3.3.15. We let \( \text{holim}(\mathcal{F}) \) denote the full subcategory

\[
\text{Fun}_{/N_*(\mathcal{C})}(N_*(\mathcal{C}), N_*^{\mathcal{F}}(\mathcal{C})) \subseteq \text{Fun}_{/N_*(\mathcal{C})}(N_*(\mathcal{C}), N_*(\mathcal{C}))
\]

whose objects are functors \( G : N_*(\mathcal{C}) \to N_*^{\mathcal{F}}(\mathcal{C}) \) which satisfy \( U \circ G = \text{id}_{N_*(\mathcal{C})} \) and which carry each morphism of \( \mathcal{C} \) to a \( U \)-cocartesian morphism of \( N_*^{\mathcal{F}}(\mathcal{C}) \) (see Notation 5.3.1.10). We will refer to \( \text{holim}(\mathcal{F}) \) as the homotopy limit of the diagram \( \mathcal{F} \).

Example 7.5.2.2 (Homotopy Limits of Kan Complexes). Let \( \mathcal{F} : \mathcal{C} \to \text{Kan} \) be a (strictly commutative) diagram of Kan complexes. Then the projection map \( U : N_*^{\mathcal{F}}(\mathcal{C}) \to N_*(\mathcal{C}) \) is a left fibration of simplicial sets (Corollary 5.3.3.16). It follows that every morphism of the \( \infty \)-category \( N_*^{\mathcal{F}}(\mathcal{C}) \) is \( U \)-cocartesian, so the homotopy limit \( \text{holim}(\mathcal{F}) \) of Construction 7.5.2.1 coincides with the homotopy limit \( \text{holim}(\mathcal{F}) \) of Construction 7.5.1.1.

Remark 7.5.2.3. Let \( \mathcal{F} : \mathcal{C} \to \text{QCat} \) be a (strictly commutative) diagram of \( \infty \)-categories, let \( K \) be a simplicial set, and let \( \mathcal{F}^K : \mathcal{C} \to \text{QCat} \) denote the functor given on objects by the formula \( \mathcal{F}^K(C) = \text{Fun}(K, \mathcal{F}(C)) \). Then there is a canonical isomorphism of simplicial sets \( \text{holim}(\mathcal{F}^K) \simeq \text{Fun}(K, \text{holim}(\mathcal{F})) \) (see Remarks 5.3.3.5 and 5.3.1.19).

Proposition 7.5.2.4. Let \( \mathcal{F} : \mathcal{C} \to \text{QCat} \) be a (strictly commutative) diagram of \( \infty \)-categories. Then the homotopy limit \( \text{holim}(\mathcal{F}) \) is an \( \infty \)-category. Moreover, \( \text{holim}(\mathcal{F}) \) can
be identified with a limit of the diagram

\[ N^\text{hc}(\mathcal{F}): N_\bullet(C) \to N^\text{hc}_{\infty}({\bf QCat}) = QC \]

in the \(\infty\)-category \(QC\).

**Proof.** By virtue of Example 5.7.5.6, the functor \(N^\text{hc}(\mathcal{F})\) is a covariant transport representation for the cocartesian fibration \(U: N^\text{\mathcal{F}}(C) \to N_\bullet(C)\). Proposition 7.5.2.4 is therefore a special case of Corollary 7.4.1.9. \(\square\)

**Remark 7.5.2.5** (Homotopy Invariance). Let \(C\) be a category and let \(\alpha: \mathcal{F} \to \mathcal{G}\) be a natural transformation between functors \(\mathcal{F}, \mathcal{G}: C \to \text{QCat}\). Then \(\alpha\) determines a commutative diagram of \(\infty\)-categories

\[
\begin{array}{ccc}
N^\mathcal{F}_\bullet(C) & \xrightarrow{T} & N^\mathcal{G}_\bullet(C) \\
\downarrow U & & \downarrow V \\
N_\bullet(C) & & N_\bullet(C)
\end{array}
\]

The functor \(T\) carries \(U\)-cocartesian morphisms of \(N^\mathcal{F}_\bullet(C)\) to \(V\)-cocartesian morphisms of \(N^\mathcal{G}_\bullet(C)\) (see Proposition 5.3.3.15), and therefore induces a functor of \(\infty\)-categories \(\text{holim}(\alpha): \text{holim}(\mathcal{F}) \to \text{holim}(\mathcal{G})\). If \(\alpha\) is a levelwise categorical equivalence, then \(T\) is an equivalence of cocartesian fibrations over \(N_\bullet(C)\) (Corollary 5.3.3.17), so \(\text{holim}(\alpha)\) is an equivalence of \(\infty\)-categories.

**Example 7.5.2.6** (Homotopy Limits of Cores). Let \(\mathcal{F}: C \to \text{QCat}\) be a diagram of \(\infty\)-categories, and let \(\mathcal{F}^\simeq: C \to \text{Kan}\) be the functor given on objects by the formula \(\mathcal{F}^\simeq(C) = \mathcal{F}(C)^\simeq\). Then the inclusion map \(\mathcal{F}^\simeq \to \mathcal{F}\) induces a monomorphism of simplicial sets \(\text{holim}(\mathcal{F}^\simeq) \to \text{holim}(\mathcal{F})\), whose image is the core of the \(\infty\)-category \(\text{holim}(\mathcal{F})\) (see Example 5.3.3.18 and Remark 5.3.1.20). In other words, there is a canonical isomorphism of Kan complexes \(\text{holim}(\mathcal{F}^\simeq) \simeq \text{holim}(\mathcal{F})^\simeq\).

**Remark 7.5.2.7.** Let \(\mathcal{F}: C \to \text{QCat}\) be a diagram of \(\infty\)-categories and let \(\mathcal{F}_0 = \mathcal{F}|_{C_0}\) be the restriction of \(\mathcal{F}\) to a subcategory \(C_0 \subseteq C\). Suppose that the inclusion \(N_\bullet(C_0) \hookrightarrow N_\bullet(C)\) is left anodyne (this condition is satisfied, for example, if the inclusion map \(C_0 \hookrightarrow C\) has a right adjoint: see Corollary 7.2.3.7). Then the restriction map \(\text{holim}(\mathcal{F}) \to \text{holim}(\mathcal{F}_0)\) is a trivial Kan fibration of \(\infty\)-categories (see Proposition 5.3.1.21).

**Remark 7.5.2.8.** Let \(\mathcal{F}: C \to \text{QCat}\) be a diagram of \(\infty\)-categories. Arguing as in Remark 7.5.1.6, we can identify the homotopy limit \(\text{holim}(\mathcal{F})\) with a simplicial subset of the product...
\[ \prod_{C \in C} \text{Fun}(N_\bullet(C/C), \mathcal{F}(C)), \]
whose \(n\)-simplices are collections of maps \( \{ \sigma_C : \Delta^n \times N_\bullet(C/C) \to \mathcal{F}(C) \} \) which satisfy the following pair of conditions:

\((\ast)\) For every morphism \( f : C \to D \) in the category \( C \), the diagram of simplicial sets

\[
\begin{array}{ccc}
\Delta^n \times N_\bullet(C/C) & \xrightarrow{\sigma_C} & \Delta^n \times N_\bullet(C/D) \\
\downarrow & & \downarrow \\
\mathcal{F}(C) & \xrightarrow{\mathcal{F}(f)} & \mathcal{F}(D)
\end{array}
\]

is commutative.

\((\ast')\) For every object \( C \in C \) and every integer \( 0 \leq i \leq n \), the composite map

\[
\{i\} \times N_\bullet(C/C) \hookrightarrow \Delta^n \times N_\bullet(C/C) \xrightarrow{\sigma_C} \mathcal{F}(C)
\]

carries every morphism in the category \( C/C \) to an isomorphism in the \( \infty \)-category \( \mathcal{F}(C) \).

**Example 7.5.2.9 (Duality with Homotopy Colimits).** Let \( C \) be a category, let \( \mathcal{F} : C^{\text{op}} \to \text{Set}_\Delta \) be a diagram of simplicial sets, and let \( W \) denote the collection of horizontal edges of the homotopy colimit \( \text{holim}(\mathcal{F}^{\text{op}}) \) (see Definition 5.3.4.1). Let \( D \) be an \( \infty \)-category and let \( D^\mathcal{F} : C \to \text{QCat} \) denote the functor given by the formula \( D^\mathcal{F}(C) = \text{Fun}(\mathcal{F}(C), D) \). Arguing as in Example 7.5.1.7, we obtain a canonical isomorphism

\[
\theta : \text{Fun}/N_\bullet(C)(N_\bullet(C), N_\bullet^D(C))^{\text{op}} \cong \text{Fun}(\text{holim}(\mathcal{F}^{\text{op}}), D^{\text{op}}).
\]

Unwinding the definitions, we see that \( \theta \) restricts to an isomorphism of \( \infty \)-categories

\[
\text{holim}(D^\mathcal{F})^{\text{op}} \cong \text{Fun}(\text{holim}(\mathcal{F}^{\text{op}})[W^{-1}], D^{\text{op}}).
\]

**Remark 7.5.2.10 (Comparison with the Limit).** Let \( \mathcal{F} : C \to \text{QCat} \) be a diagram of \( \infty \)-categories and let \( X = \text{lim}(\mathcal{F}) \) denote the limit of \( \mathcal{F} \), formed in the category of simplicial sets. Let \( X : C \to \text{Set}_\Delta \) denote the constant functor taking the value \( X \). We then have a tautological map \( X \to \mathcal{F} \). The induced morphism of simplicial sets

\[
X \times N_\bullet(C) \simeq N_\bullet^X(C) \to N_\bullet^\mathcal{F}(C)
\]
determines a comparison map \( \iota : X = \text{lim}(\mathcal{F}) \to \text{holim}(\mathcal{F}) \). Note that \( \iota \) is a monomorphism of simplicial sets (since each of the projection maps \( X = \text{lim}(\mathcal{F}) \to \mathcal{F}(C) \) factor through \( \iota \)).

**Proposition 7.5.2.11.** Let \( \mathcal{F} : C \to \text{QCat} \) be a diagram of \( \infty \)-categories, and suppose that the category \( C \) has an initial object. Then the comparison map \( \iota : \text{lim}(\mathcal{F}) \to \text{holim}(\mathcal{F}) \) of Remark 7.5.2.10 is an equivalence of \( \infty \)-categories.
Proof. Let $C \in \mathcal{C}$ be an initial object, so that the inclusion map $\{C\} \to N_\bullet(C)$ is left anodyne (Corollary 4.6.6.25). Applying Remark 7.5.2.7 we see that evaluation at $C$ induces an equivalence of $\infty$-categories $\text{ev}_C : \text{holim}(\mathcal{F}) \to \mathcal{F}(C)$. Our assumption that $C$ is initial also guarantees that the composition $(\text{ev}_C \circ \iota) : \lim(\mathcal{F}) \to \mathcal{F}(C)$ is an isomorphism of simplicial sets, so that $\lim(\mathcal{F})$ is an $\infty$-category and $\iota$ is an equivalence of $\infty$-categories. □

Example 7.5.2.12. Let $I$ be a set, which we regard as a category having only identity morphisms. Let $\mathcal{F} : I \to \mathcal{QC}$ be a diagram, which we view as a collection of $\infty$-categories $\{C_i\}_{i \in I}$ indexed by $I$. Then the comparison morphism

$$\prod_{i \in I} C_i = \lim(\mathcal{F}) \to \text{holim}(\mathcal{F})$$

of Remark 7.5.2.10 is an isomorphism.

Exercise 7.5.2.13 (Homotopy Limits of Sets). Let $\mathcal{C}$ be a category and let $\mathcal{F} : \mathcal{C} \to \text{Set}$ be a diagram in the category of sets. Let us abuse notation by identifying $\text{Set}$ with the full subcategory of Kan spanned by the constant simplicial sets. Show that the comparison map $\lim(\mathcal{F}) \to \text{holim}(\mathcal{F})$ of Remark 7.5.2.10 is an isomorphism.

Beware that the comparison morphism of Remark 7.5.2.10 is not an isomorphism in general.

Example 7.5.2.14. Let $[1]$ denote the linearly ordered set $\{0 < 1\}$ and let $\mathcal{F} : [1] \to \mathcal{QC}$ be a diagram, which we identify with a functor of $\infty$-categories $T : \mathcal{C} \to \mathcal{D}$. Then the homotopy limit $\text{holim}(\mathcal{F})$ of Construction 7.5.1.1 can be identified with the homotopy fiber product

$$\mathcal{C} \times^h_{\mathcal{D}} \mathcal{D} = \mathcal{C} \times_{\text{Fun}(\{0\}, \mathcal{D})} \text{Isom}(\mathcal{D})$$

of Construction 4.5.2.1. Under this identification, the comparison morphism $\lim(\mathcal{F}) \to \text{holim}(\mathcal{F})$ of Remark 7.5.2.10 corresponds to the monomorphism

$$\mathcal{C} \simeq \mathcal{C} \times_{\mathcal{D}} \mathcal{D} \hookrightarrow \mathcal{C} \times^h_{\mathcal{D}} \mathcal{D}$$

of Proposition 3.4.0.7. This morphism is usually not an isomorphism of simplicial sets, though it is always an equivalence of $\infty$-categories (Proposition 7.5.2.11).

Example 7.5.2.15. Let $\mathcal{K}$ be the partially ordered set depicted in the diagram

$$
\bullet \rightarrow \bullet \leftarrow \bullet
$$

and suppose we are given a functor $\mathcal{F} : \mathcal{K} \to \mathcal{QC}$, which we depict as a diagram of $\infty$-categories

$$
\mathcal{C}_0 \xrightarrow{T_0} \mathcal{C} \xleftarrow{T_1} \mathcal{C}_1.
$$
Then the homotopy limit \( \text{holim}(\mathcal{F}) \) can be identified with the iterated homotopy pullback \( \mathcal{C}_0 \times^h_{\mathcal{C}} (\mathcal{C}_1 \times^h_{\mathcal{C}} \mathcal{C}) \). Applying Corollary 4.5.2.18, we see that the equivalence \( \mathcal{C}_1 \leftrightarrow \mathcal{C}_0 \times^h_{\mathcal{C}} \mathcal{C} \) of Example 7.5.2.14 induces an equivalence of \( \infty \)-categories

\[
\mathcal{C}_0 \times^h_{\mathcal{C}} \mathcal{C}_1 \leftrightarrow \mathcal{C}_0 \times^h_{\mathcal{C}} (\mathcal{C}_1 \times^h_{\mathcal{C}} \mathcal{C}) \simeq \text{holim}(\mathcal{F}).
\]

In particular, the comparison map \( \lim_{\leftarrow} (\mathcal{F}) \to \text{holim}(\mathcal{F}) \) is a categorical equivalence of simplicial sets if and only if the inclusion \( \mathcal{C}_0 \times_{\mathcal{C}} \mathcal{C}_1 \hookrightarrow \mathcal{C}_0 \times^h_{\mathcal{C}} \mathcal{C}_1 \) is a categorical equivalence of simplicial sets. This condition is satisfied if either \( T_0 \) or \( T_1 \) is an isofibration of \( \infty \)-categories (Corollary 4.5.2.22), but not in general.

### 7.5.3 The Homotopy Limit as a Derived Functor

Let \( \mathcal{C} \) be a small category. In general, the inverse limit functor \( \lim_{\leftarrow} : \text{Fun}(\mathcal{C}, \mathcal{QCat}) \to \text{Set} \Delta \) does not respect categorical equivalence: that is, if \( \alpha : \mathcal{F} \to \mathcal{G} \) is a levelwise categorical equivalence of diagrams \( \mathcal{F}, \mathcal{G} : \mathcal{C} \to \mathcal{QCat} \), then the induced map \( \lim_{\leftarrow} (\alpha) : \lim_{\leftarrow} (\mathcal{F}) \to \lim_{\leftarrow} (\mathcal{G}) \) need not be a categorical equivalence of simplicial sets. In §7.5.2 and §4.5.6, we discussed two different ways of addressing this point:

- We can replace the limit \( \lim_{\leftarrow} (\mathcal{F}) \) by the homotopy limit \( \text{holim}(\mathcal{F}) \) of Construction 7.5.2.1. If \( \alpha : \mathcal{F} \to \mathcal{G} \) is a levelwise categorical equivalence of diagrams \( \mathcal{F}, \mathcal{G} \), then Remark 7.5.2.5 guarantees that the induced map \( \text{holim}(\alpha) : \text{holim}(\mathcal{F}) \to \text{holim}(\mathcal{G}) \) is an equivalence of \( \infty \)-categories.

- We can restrict our attention to isofibrant diagrams of \( \infty \)-categories (Definition 4.5.6.3). If \( \alpha : \mathcal{F} \to \mathcal{G} \) is a levelwise categorical equivalence between isofibrant diagrams, then Corollary 4.5.6.14 guarantees that the induced map \( \lim_{\leftarrow} (\alpha) : \lim_{\leftarrow} (\mathcal{F}) \to \lim_{\leftarrow} (\mathcal{G}) \) is an equivalence of \( \infty \)-categories.

In this section, we will show that these perspectives are closely related: if \( \mathcal{F} : \mathcal{C} \to \mathcal{QCat} \) is a diagram of \( \infty \)-categories, then the homotopy limit \( \text{holim}(\mathcal{F}) \) can be identified with the limit of an isofibrant replacement for \( \mathcal{F} \). More precisely, we show that there exists a canonical isomorphism \( \text{holim}(\mathcal{F}) \simeq \lim_{\leftarrow} (\mathcal{F}^+) \), where \( \mathcal{F}^+ : \mathcal{C} \to \mathcal{QCat} \) is an isofibrant diagram of simplicial sets equipped with a levelwise categorical equivalence \( \alpha : \mathcal{F} \leftrightarrow \mathcal{F}^+ \) (Construction 7.5.3.3 and Proposition 7.5.3.7). Moreover, we show that for any isofibrant diagram \( \mathcal{G} : \mathcal{C} \to \mathcal{QCat} \), the inclusion map \( \lim_{\leftarrow} (\mathcal{G}) \hookrightarrow \text{holim}(\mathcal{G}) \) is an equivalence of \( \infty \)-categories (Proposition 7.5.3.12). Consequently, if \( \beta : \mathcal{F} \to \mathcal{G} \) is any levelwise categorical equivalence from \( \mathcal{F} \) to an isofibrant diagram \( \mathcal{G} \), then the maps

\[
\begin{align*}
\text{holim}(\beta) : & \quad \text{holim}(\mathcal{F}) \to \text{holim}(\mathcal{G}) \\
\lim_{\leftarrow} (\beta) : & \quad \lim_{\leftarrow} (\mathcal{F}) \to \lim_{\leftarrow} (\mathcal{G})
\end{align*}
\]
are equivalences of ∞-categories; in particular, the ∞-categories \( \text{holim}(\mathcal{F}) \) and \( \text{lim}(\mathcal{G}) \) are equivalent (see Remark 7.5.3.15).

We begin with some elementary observations.

**Proposition 7.5.3.1.** Let \( \mathcal{C} \) be a small category and let \( U : \mathcal{E} \to \mathcal{N}_\bullet(\mathcal{C}) \) be an isofibration of ∞-categories. Then the weak transport representation

\[
\text{wTr}_{\mathcal{E}/\mathcal{C}} : \mathcal{C} \to \text{Set} \quad C \mapsto \text{Fun}_{/\mathcal{N}_\bullet(\mathcal{C})}(\mathcal{N}_\bullet(\mathcal{C}_C), \mathcal{E})
\]

of Construction 5.3.1.1 is an isofibrant diagram of simplicial sets.

**Proof.** Let \( \mathcal{F} : \mathcal{C} \to \text{Set}_\Delta \) be a functor and let \( \mathcal{F}_0 \subseteq \mathcal{F} \) be a subfunctor for which the inclusion \( \mathcal{F}_0 \to \mathcal{F} \) is a levelwise categorical equivalence. We wish to show that every natural transformation \( \alpha_0 : \mathcal{F}_0 \to \text{wTr}_{\mathcal{E}/\mathcal{C}} \) admits an extension \( \alpha : \mathcal{F} \to \text{wTr}_{\mathcal{E}/\mathcal{C}} \). Using Corollary 5.3.2.23, we can reformulate this as a lifting problem

\[
\begin{array}{ccc}
\text{holim}(\mathcal{F}_0) & \to & \mathcal{E} \\
\downarrow & & \downarrow \text{U} \\
\text{holim}(\mathcal{F}) & \to & \mathcal{N}_\bullet(\mathcal{C})
\end{array}
\]

in the category of simplicial sets. Since \( U \) is an isofibration, we are reduced to showing that the inclusion map \( \text{holim}(\mathcal{F}_0) \to \text{holim}(\mathcal{F}) \) is a categorical equivalence (Proposition 4.5.5.1), which is a special case of Variant 5.3.2.19.

**Corollary 7.5.3.2.** Let \( \mathcal{C} \) be a small category and let \( U : \mathcal{E} \to \mathcal{N}_\bullet(\mathcal{C}) \) be a cocartesian fibration of ∞-categories. Then the strict transport representation

\[
\text{sTr}_{\mathcal{E}/\mathcal{C}} : \mathcal{C} \to \text{Set} \quad C \mapsto \text{Fun}_{/\mathcal{N}_\bullet(\mathcal{C})}^{\text{CCart}}(\mathcal{N}_\bullet(\mathcal{C}_C), \mathcal{E})
\]

of Construction 5.3.1.5 is an isofibrant diagram of simplicial sets.

**Proof.** Let \( \mathcal{F} : \mathcal{C} \to \text{Set}_\Delta \) be a functor and let \( \mathcal{F}_0 \subseteq \mathcal{F} \) be a subfunctor for which the inclusion \( \mathcal{F}_0 \to \mathcal{F} \) is a levelwise categorical equivalence. Suppose we are given a natural transformation \( \alpha_0 : \mathcal{F}_0 \to \text{sTr}_{\mathcal{E}/\mathcal{C}} \). It follows from Proposition 7.5.3.1 that \( \alpha_0 \) can be extended to a natural transformation \( \alpha : \mathcal{F} \to \text{wTr}_{\mathcal{E}/\mathcal{C}} \). To complete the proof, it will suffice to show that \( \alpha \) factors through the subfunctor \( \text{sTr}_{\mathcal{E}/\mathcal{C}} \). Equivalently, we must show that for
each object $C \in \mathcal{C}$, the lifting problem

\[
\begin{array}{ccc}
\mathcal{F}_0(C) & \rightarrow & \text{sTr}_{\mathcal{E}/c}(C') \\
\downarrow & & \downarrow \\
\mathcal{F}(C) & \rightarrow & \text{wTr}_{\mathcal{E}/c}(C)
\end{array}
\]

admits a (unique) solution. This is clear, since the left vertical map is a categorical equivalence and $\text{sTr}_{\mathcal{E}/c}(C)$ is a replete subcategory of $\text{wTr}_{\mathcal{E}/c}(C)$ (see Remark 5.3.1.15).

**Construction 7.5.3.3 (Explicit Isofibrant Replacement).** Let $\mathcal{C}$ be a small category and let $\mathcal{F} : \mathcal{C} \rightarrow \text{QCat}$ be a (strictly commutative) diagram of $\infty$-categories. Let $N_\mathcal{F}(\mathcal{C})$ denote the $\mathcal{F}$-weighted nerve of $\mathcal{C}$ (Definition 5.3.3.1), and let $\mathcal{F}^+ = \text{sTr}_{N_\mathcal{F}(\mathcal{C})/c}$ denote the strict transport representation of the projection map $N_\mathcal{F}(\mathcal{C}) \rightarrow N_\mathcal{F}(c)$. It follows from Remark 5.3.4.10 that there is a unique natural transformation $\alpha : \mathcal{F} \rightarrow \mathcal{F}^+$ for which the diagram of simplicial sets

\[
\begin{array}{ccc}
\text{holim}(\mathcal{F}^+) & \xrightarrow{\text{holim}(\alpha)} & \text{holim}(\mathcal{F}) \\
\downarrow & & \downarrow \lambda_u \\
\lambda_t & & N_\mathcal{F}(c),
\end{array}
\]

is commutative, where $\lambda_u$ denotes the universal scaffold of Construction 5.3.4.7 and $\lambda_t$ denotes the taut scaffold of Construction 5.3.4.11. We will refer to $\mathcal{F}^+$ as the *isofibrant replacement* of $\mathcal{F}$.

**Proposition 7.5.3.4.** Let $\mathcal{C}$ be a small category, let $\mathcal{F} : \mathcal{C} \rightarrow \text{QCat}$ be a diagram of $\infty$-categories, and let $\alpha : \mathcal{F} \rightarrow \mathcal{F}^+$ be the natural transformation of Construction 7.5.3.3. Then $\mathcal{F}^+ : \mathcal{C} \rightarrow \text{QCat}$ is an isofibrant diagram, and $\alpha$ is a levelwise categorical equivalence. Moreover, $\alpha$ is also a monomorphism.

**Proof.** It follows from Corollary 7.5.3.2 that the diagram $\mathcal{F}^+$ is isofibrant. To see that $\alpha$ is a monomorphism, we observe that for each object $C \in \mathcal{C}$, the functor

$$\alpha_C : \mathcal{F}(C) \rightarrow \mathcal{F}^+(C) = \text{Fun}^{\mathcal{C}_{Cart}}_{N_\mathcal{F}(c)}(N_\mathcal{F}(\mathcal{C}), N_\mathcal{F}(C))$$

has a left inverse, given by the evaluation map

$$\text{ev}_C : \text{Fun}^{\mathcal{C}_{Cart}}_{N_\mathcal{F}(c)}(N_\mathcal{F}(\mathcal{C}), N_\mathcal{F}(C)) \rightarrow \{C\} \times_{N_\mathcal{F}(c)} N_\mathcal{F}(C) \simeq \mathcal{F}(C).$$
Since $ev_C$ is a trivial Kan fibration (Proposition 5.3.1.7), it follows that $\alpha_C$ is an equivalence of $\infty$-categories.

**Corollary 7.5.3.5** (Existence of Isofibrant Replacements). Let $\mathcal{F} : \mathcal{C} \to \operatorname{Set}_{\Delta}$ be a diagram of simplicial sets. Then there exists a monomorphism of diagrams $\alpha : \mathcal{F} \hookrightarrow \mathcal{I}$, where $\alpha$ is a levelwise categorical equivalence and $\mathcal{I} : \mathcal{C} \to \mathbf{QCat}$ is an isofibrant diagram of $\infty$-categories.

**Proof.** Using Proposition 4.1.3.2 we can reduce to the case where $\mathcal{F}$ is a diagram of $\infty$-categories. In this case, we can take $\alpha$ to be the natural transformation $\mathcal{F} \to \mathcal{F}^+$ of Construction 7.5.3.3 (Proposition 7.5.3.4).

**Variant 7.5.3.6.** Let $\mathcal{F} : \mathcal{C} \to \operatorname{Set}_{\Delta}$ be a diagram of simplicial sets. Then there exists a monomorphism of diagrams $\alpha : \mathcal{F} \hookrightarrow \mathcal{I}$, where $\alpha$ is a levelwise weak homotopy equivalence and $\mathcal{I} : \mathcal{C} \to \mathbf{Kan}$ is an isofibrant diagram of Kan complexes.

**Proof.** Using Proposition 3.1.7.1 we can reduce to the case where $\mathcal{F}$ is a diagram of Kan complexes. In this case, we can again take $\alpha$ to be the natural transformation $\mathcal{F} \to \mathcal{F}^+$ of Construction 7.5.3.3 (since $\alpha$ is a levelwise categorical equivalence, it follows that $\mathcal{F}^+$ is also a diagram of Kan complexes: see Remark 4.5.1.21).

**Proposition 7.5.3.7.** Let $\mathcal{C}$ be a small category, let $\mathcal{F} : \mathcal{C} \to \mathbf{QCat}$ be a diagram, and let $\mathcal{F}^+ : \mathcal{C} \to \mathbf{QCat}$ be the isofibrant replacement of Construction 7.5.3.3. Then there is a canonical isomorphism of simplicial sets $\theta : \operatorname{holim}(\mathcal{F}) \cong \lim(\mathcal{F}^+)$, which is characterized by the following requirement: for each object $C \in \mathcal{C}$, the composition

$$
\begin{align*}
\Fun_{/ \mathbf{N}(\mathcal{C})}(\mathbf{N}_{\bullet}(\mathcal{C}), \mathbf{N}_{\bullet}(\mathcal{C})) & = \operatorname{holim}(\mathcal{F}) \\
& \xrightarrow{\theta} \lim(\mathcal{F}^+) \\
& \to \mathcal{F}^+(C) \\
& = \Fun_{/ \mathbf{N}(\mathcal{C})}(\mathbf{N}_{\bullet}(\mathcal{C}), \mathbf{N}_{\bullet}(\mathcal{C}))
\end{align*}
$$

is given by precomposition with the projection map $\mathcal{C}_{C/} \to \mathcal{C}$.

**Proof.** Proposition 7.5.3.7 is a consequence of the following concrete assertion:

**Lemma 7.5.3.8.** Let $\mathcal{C}$ be a category. Then the collection of projection maps $\{\mathbf{N}_{\bullet}(\mathcal{C}_{C/}) \to \mathbf{N}_{\bullet}(\mathcal{C})\}_{C \in \mathcal{C}}$ exhibit $\mathbf{N}_{\bullet}(\mathcal{C})$ as the colimit of the diagram

$$
\mathcal{C}^{\operatorname{op}} \to \operatorname{Set}_{\Delta} \quad C \mapsto \mathbf{N}_{\bullet}(\mathcal{C}_{C/}).
$$

**Proof.** Fix an integer $n \geq 0$; we wish to show that the canonical map

$$
\rho : \lim_{C \in \mathcal{C}^{\operatorname{op}}} \mathbf{N}_n(\mathcal{C}_{C/}) \to \mathbf{N}_n(\mathcal{C})
$$
is an isomorphism in the category of sets. Let $\sigma$ be an $n$-simplex of $N_n(C)$, given by a diagram
\[ X_0 \to X_1 \to \cdots \to X_n \]
in the category $C$. Then the fiber $\rho^{-1}\{\sigma\}$ can be identified with the colimit
\[ \lim_{C \in C^{op}} \Hom_C(C, X_0), \]
formed in the category of sets. This colimit consists of a single element, represented by the identity morphism $\id_{X_0} \in \Hom_C(X_0, X_0)$.

**Remark 7.5.3.9.** Let $C$ be a category, let $U : E \to N_\bullet(C)$ be a morphism of simplicial sets, and let $w\Tr_{E/C} : C \to \Set_{\Delta}$ denote the weak transport representation of Construction 5.3.1.1, given on objects by the formula $w\Tr_{E/C}(C) = \Fun_{/N_\bullet(C)}(N_\bullet(C_{C/}), E)$. Then Lemma 7.5.3.8 supplies a canonical isomorphism of simplicial sets
\[ \Fun_{/N_\bullet(C)}(N_\bullet(C), E) \xrightarrow{\sim} \lim_{\leftarrow}(w\Tr_{E/C}). \]

**Variant 7.5.3.10.** Let $C$ be a category, let $U : E \to N_\bullet(C)$ be a cocartesian fibration of $\infty$-categories, and let $s\Tr_{E/C} : C \to \Set_{\Delta}$ denote the strict transport representation of Construction 5.3.1.5, given on objects by the formula $s\Tr_{E/C}(C) = \Fun_{/N_\bullet(C)}(N_\bullet(C_{C/}), E)$. Then the isomorphism of Remark 7.5.3.9 restricts to an isomorphism of simplicial sets
\[ \Fun_{/N_\bullet(C)}(N_\bullet(C), E) \xrightarrow{\sim} \lim_{\leftarrow}(s\Tr_{E/C}). \]

**Proof of Proposition 7.5.3.7.** Apply Variant 7.5.3.10 in the special case where $E = N^\mathcal{F}_\bullet(C)$ is the $\mathcal{F}$-weighted nerve of the category $C$.

**Remark 7.5.3.11.** In the situation of Proposition 7.5.3.7, the isomorphism $\theta : \holim(\mathcal{F}) \xrightarrow{\sim} \lim_{\leftarrow}(\mathcal{F}^+) \rightarrow \holim(\mathcal{F})$ fits into a commutative diagram
\[
\begin{array}{ccc}
\holim(\mathcal{F}) & \xrightarrow{\sim} & \lim_{\leftarrow}(\mathcal{F}^+) \\
\downarrow \theta & & \downarrow \lim_{\leftarrow}(\alpha) \\
\lim_{\leftarrow}(\mathcal{F}) & \xrightarrow{\sim} & \lim_{\leftarrow}(\mathcal{F}^+),
\end{array}
\]

where $\iota$ is the comparison map of Remark 7.5.2.10 and $\alpha : \mathcal{F} \leftrightarrow \mathcal{F}^+$ is the natural transformation appearing in Construction 7.5.3.3.

**Proposition 7.5.3.12.** Let $\mathcal{F} : C \to \QCat$ be an isofibrant diagram of $\infty$-categories. Then the inclusion map $\iota : \lim_{\leftarrow}(\mathcal{F}) \to \holim(\mathcal{F})$ is an equivalence of $\infty$-categories.
Proof. Let $\alpha : \mathcal{F} \hookrightarrow \mathcal{F}^+$ be the isofibrant replacement of Construction 7.5.3.3. By virtue of Proposition 7.5.3.7 (and Remark 7.5.3.11), it will suffice to show that the limit $\lim (\alpha) : \lim (\mathcal{F}) \hookrightarrow \lim (\mathcal{F}^+)$ is an equivalence of $\infty$-categories. This is a special case of Corollary 4.5.6.15 since $\alpha$ is a levelwise categorical equivalence between isofibrant diagrams (Proposition 7.5.3.4).

Example 7.5.3.13 (Towers of Isofibrations). Suppose we are given a tower of $\infty$-categories $\cdots \to C(3) \to C(2) \to C(1) \to C(0)$, which we identify with a functor $\mathcal{F} : \mathbb{Z}_{\geq 0}^{\text{op}} \to \mathbf{QCat}$. If each of the transition functors $C(n+1) \to C(n)$ is an isofibration, then the comparison map $\lim (\mathcal{F}(n)) \sim \to \lim (\mathcal{F}(n))$ is an equivalence of $\infty$-categories. This follows by combining Example 4.5.6.7 with Proposition 7.5.3.12.

Warning 7.5.3.14. Let $\mathcal{F} : \mathcal{C} \to \mathbf{QCat}$ be a strictly commutative diagram of $\infty$-categories and let $\alpha : \mathcal{F} \hookrightarrow \mathcal{F}^+$ denote the isofibrant replacement of Construction 7.5.3.3, and let $\theta : \text{holim}(\mathcal{F}) \sim \to \lim (\mathcal{F})$ be the isomorphism of Proposition 7.5.3.12. We then have a diagram of simplicial sets

$$
\begin{array}{ccc}
\lim (\mathcal{F}) & \xrightarrow{\lim (\alpha)} & \lim (\mathcal{F}^+) \\
\downarrow & & \downarrow \\
\text{holim}(\mathcal{F}) & \xleftarrow{\text{holim}(\alpha)} & \text{holim}(\mathcal{F}^+),
\end{array}
$$

where the outer square and the upper left triangle are commutative (Remark 7.5.3.11). Beware that the lower right triangle is usually not commutative. That is, $\text{holim}(\mathcal{F})$ and $\lim (\mathcal{F}^+)$ are isomorphic when viewed as abstract simplicial sets, but do not coincide when identified with simplicial subsets of $\text{holim}(\mathcal{F}^+)$. 

Remark 7.5.3.15 (The Homotopy Limit as a Right Derived Functor). The results of this section can be interpreted in the language of model categories. For every small category $\mathcal{C}$, the category $\text{Fun}(\mathcal{C}, \mathbf{Set}_{\Delta})$ can be equipped with a model structure in which the cofibrations are monomorphisms and the weak equivalences are levelwise categorical equivalences (see Example [??]). The inverse limit functor

$$
\lim : \text{Fun}(\mathcal{C}, \mathbf{Set}_{\Delta}) \to \mathbf{Set}_{\Delta}
$$

then admit a right derived functor $R\lim : \text{Fun}(\mathcal{C}, \mathbf{Set}_{\Delta}) \to \mathbf{Set}_{\Delta}$, which carries a diagram $\mathcal{F} : \mathcal{C} \to \mathbf{Set}_{\Delta}$ to the limit of a fibrant replacement of $\mathcal{F}$. It follows from Propositions 7.5.3.4 and
7.5. HOMOTOPY LIMITS AND COLIMITS

7.5.3.7 that, when restricted to the subcategory $\Fun(C, \QCat) \subset \Fun(C, \Set_\Delta)$, the functor $\mathbb{R}\lim$ is (categorically) equivalent to the homotopy limit functor $\text{holim} : \Fun(C, \QCat) \to \QCat$ of Construction 7.5.2.1. We will return to this point in §7[?].

7.5.4 Homotopy Limit Diagrams

Let $F : C \to \text{Kan}$ be a diagram in the category of Kan complexes, and let $N^\infty_\bullet(F) : N_\bullet(C) \to N^\infty_\bullet(\text{Kan}) = S$ be the induced functor of $\infty$-categories. Then the homotopy limit $\text{lim} \leftarrow F$ is a Kan complex, which can be regarded as a limit of the diagram $N^\infty_\bullet(F)$ in the $\infty$-category of spaces $S$ (Proposition 7.5.1.5). For many applications, this assertion is insufficiently precise: we would like to have not only a Kan complex $X$ which is known abstractly to be a limit of the diagram $N^\infty_\bullet(F)$, but also a diagram $N_\bullet(C^\square) \to S$ which exhibits $X$ as a limit of $N^\infty_\bullet(F)$.

Definition 7.5.4.1. Let $C$ be a category and let $F : C^\square \to \text{Kan}$ be a functor having restriction $F = F|_C$. We will say that $F$ is a homotopy limit diagram if the composite map $F(0) \to \text{lim}(F) \xrightarrow{\cong} \text{holim}(F)$ is a homotopy equivalence of Kan complexes; here $0$ denotes the initial object of the cone $C^\square \simeq \{0\} \star C$, and the morphism on the right is the comparison map of Remark 7.5.2.10.

Example 7.5.4.2 (Limits of Isofibrant Diagrams). Let $C$ be a small category and let $F : C^\square \to \text{Set}_\Delta$ be a limit diagram in the category of simplicial sets. Suppose that the diagram $F = F|_C$ is isofibrant (Definition 4.5.6.3) and that, for each object $C \in C$, the simplicial set $F(C)$ is a Kan complex. Then $F$ is a homotopy limit diagram of Kan complexes: this follows by combining Corollary 4.5.6.18 with Proposition 7.5.3.12.

Warning 7.5.4.3. For every diagram of Kan complexes $F : C \to \text{Kan}$, the homotopy limit $\text{holim}(F)$ of Construction 7.5.1.1 is well-defined. However, one cannot always extend $F$ to a homotopy limit diagram $F : C^\square \to \text{Kan}$ (see Warning 3.4.1.8). This is possible only if the tautological map $\lim(F) \xleftarrow{\cong} \text{holim}(F)$ has a left homotopy inverse. However, we can always choose a levelwise homotopy equivalence $\alpha : F \to F$, where $F$ is an isofibrant diagram of Kan complexes (Variant 7.5.3.6). We can then extend $F$ can be extended to a limit diagram $\tilde{F} : C^\square \to \text{Kan}$, which is also a homotopy limit diagram (Example 7.5.4.2). Moreover, if take $\tilde{F} = F^+$ to be the isofibrant replacement of Construction 7.5.3.3, then $\tilde{F}$ carries the initial object of $C^\square$ to the homotopy limit $\text{holim}(F)$ (Proposition 7.5.3.7).

Proposition 7.5.4.4 (Homotopy Invariance). Let $C$ be a category and let $\alpha : \mathcal{F} \to \mathcal{G}$ be a natural transformation between diagrams $\mathcal{F}, \mathcal{G} : C^\square \to \text{Kan}$. Assume that, for every object
$C \in \mathcal{C}$, the induced map $\alpha_C : \mathcal{F}(C) \to \mathcal{G}(C)$ is a homotopy equivalence of Kan complexes. Then any two of the following conditions imply the third:

1. The functor $\mathcal{F}$ is a homotopy limit diagram.
2. The functor $\mathcal{G}$ is a homotopy limit diagram.
3. The natural transformation $\alpha$ induces a homotopy equivalence $\mathcal{F}(0) \to \mathcal{G}(0)$, where $0$ denotes the cone point of $\mathcal{C}^a$.

Proof. Setting $\mathcal{F} = \mathcal{F}|_C$ and $\mathcal{G} = \mathcal{G}|_C$, we observe that $\alpha$ determines a commutative diagram of Kan complexes

$$
\begin{array}{ccc}
\mathcal{F}(0) & \to & \mathcal{G}(0) \\
\downarrow & & \downarrow \\
\operatorname{holim}(\mathcal{F}) & \to & \operatorname{holim}(\mathcal{G}),
\end{array}
$$

where the bottom horizontal map is a homotopy equivalence (Remark 7.5.1.3). The desired result now follows from the two-out-of-three property (Remark 3.1.6.7).

Proposition 7.5.4.5. Let $\mathcal{C}$ be a small category and let $\mathcal{F} : \mathcal{C}^a \to \operatorname{Kan}$ be a diagram of Kan complexes. Then $\mathcal{F}$ is a homotopy limit diagram (in the sense of Definition 7.5.4.1) if and only if the induced functor of $\infty$-categories $N^\text{hc}_\bullet(\mathcal{F}) : N^\bullet_\text{hc}(\mathcal{C}^a) \to N^\text{hc}_\bullet(\operatorname{Kan}) = \mathcal{S}$ is a limit diagram (in the sense of Definition 7.1.2.4).

Proof. Let $N^\text{hc}_\bullet(\mathcal{C}^a)$ be the weighted nerve of the functor $\mathcal{F}$ (Definition 5.3.3.1) and let $U : N^\text{hc}_\bullet(\mathcal{C}^a) \to N^\bullet_\text{hc}(\mathcal{C}^a)$ be the projection map. Then $U$ is a left fibration, and $N^\text{hc}_\bullet(\mathcal{F})$ is a covariant transport representation for $U$ (Example 5.7.5.6). Set $\mathcal{F} = \mathcal{F}|_C$. Applying Corollary 7.4.5.10, we deduce that $N^\text{hc}_\bullet(\mathcal{F})$ is a limit diagram in the $\infty$-category $\mathcal{S}$ if and only if the restriction map

$$
\rho : \operatorname{Fun}/_{N^\bullet_\text{hc}(\mathcal{C}^a)}(N^\bullet_\text{hc}(\mathcal{C}^a)) \to \simeq \operatorname{Fun}/_{N^\bullet_\text{hc}(\mathcal{C})}(N^\bullet_\text{hc}(\mathcal{C}), N^\text{hc}_\bullet(\mathcal{C}))
$$

is a homotopy equivalence of Kan complexes. We then have a commutative diagram $\rho$ fits
into a commutative diagram

\[
\begin{array}{ccc}
\lim(F) & \xrightarrow{\rho'} & \lim(F) \\
\downarrow{\tau} & & \downarrow{\iota} \\
\text{holim}(F) & \xrightarrow{\rho} & \text{holim}(F),
\end{array}
\]

where \(\iota\) and \(\iota\) are the comparison maps of Remark 7.5.2.10. Since the category \(C\) has an initial object, the morphism \(\iota\) is a homotopy equivalence (Proposition 7.5.2.11). It follows that \(\rho\) is a homotopy equivalence if and only if the composition \(\rho \circ \tau = \iota \circ \rho'\) is a homotopy equivalence. We conclude by observing that the composition \(\iota \circ \rho'\) can be identified with the map \(\mathcal{F}(0) \to \text{holim}(\mathcal{F})\) appearing in Definition 7.5.4.1.

**Corollary 7.5.4.6.** Let \(C\) be a small category, let \(D\) be a locally Kan simplicial category, and let \(\mathcal{F} : C^a \to D\) be a functor. The following conditions are equivalent:

1. The functor

\[
N_{hc}(\mathcal{F}) : N_*(C)^a \simeq N_*(C^a) \to N_{hc}(D)
\]

is a limit diagram in the \(\infty\)-category \(N_{hc}(D)\).

2. For every object \(D \in D\), the functor

\[
C^a \to \text{Kan} \quad C \mapsto \text{Hom}_D(D, \mathcal{F}(C))_.
\]

is a homotopy limit diagram of Kan complexes.

**Proof.** By virtue of Proposition 7.4.5.13, condition (1) is satisfied if and only if, for every object \(D \in D\), the composition \((h^D \circ N_{hc}(\mathcal{F})) : N_*(C)^a \to S\) is a limit diagram in the \(\infty\)-category \(S\), where \(h^D : N_{hc}(D) \to S\) denotes a functor corepresented by \(D\). Using Proposition 5.7.6.17, we can take \(h^D\) to be the homotopy coherent nerve of the simplicial functor \(\text{Hom}_D(D, \bullet) : D \to \text{Kan}\). In this case, \(h^D \circ N_{hc}(X)\) is the homotopy coherent nerve of the functor \(C \mapsto \text{Hom}_D(D, \mathcal{F}(C))_.\) The equivalence (1) \(\Leftrightarrow\) (2) now follows from the criterion of Proposition 7.5.4.5.

**Corollary 7.5.4.7.** Let \(C\) be a small category and let \(\mathcal{F} : C \to \text{Kan}\) be an isofibrant diagram of Kan complexes. Then \(\mathcal{F}\) has a limit in the category \(\text{Kan}\), which is preserved by the inclusion functor \(N_*(\text{Kan}) \hookrightarrow N_{hc}(\text{Kan}) = S\).

**Proof.** Combine Example 7.5.4.2 with Proposition 7.5.4.5.
For some applications, it is useful to extend Definition 7.5.4.1 to diagrams of simplicial sets which do not take values in the full subcategory $\text{Kan} \subset \text{Set}_\Delta$ of Kan complexes.

**Definition 7.5.4.8 (Homotopy Limit Diagrams of Simplicial Sets).** Let $\mathcal{C}$ be a small category. We say that a functor $\mathcal{F} : \mathcal{C}^\text{op} \to \text{Set}_\Delta$ is a homotopy limit diagram if there exists a levelwise weak homotopy equivalence $\alpha : \mathcal{F} \to \mathcal{G}$, where $\mathcal{G} : \mathcal{C}^\text{op} \to \text{Kan}$ is a homotopy limit diagram of Kan complexes (in the sense of Definition 7.5.4.1).

**Remark 7.5.4.9.** Let $\mathcal{C}$ be a small category and let $\mathcal{F} : \mathcal{C}^\text{op} \to \text{Kan}$ be a functor. The following conditions are equivalent:

1. The functor $\mathcal{F}$ is a homotopy limit diagram in the sense of Definition 7.5.4.1 (that is, it induces a homotopy equivalence $\mathcal{F}(0) \to \text{holim}(\mathcal{F}|_\mathcal{C})$, where 0 denotes the cone point of $\mathcal{C}^\text{op}$).

2. The functor $\mathcal{F}$ is a homotopy limit diagram in the sense of Definition 7.5.4.8 that is, there exists a homotopy limit diagram of Kan complexes $\mathcal{G} : \mathcal{C}^\text{op} \to \text{Kan}$ and a levelwise weak homotopy equivalence $\alpha : \mathcal{F} \to \mathcal{G}$.

The implication (1) $\Rightarrow$ (2) is immediate, and the reverse implication follows from Proposition 7.5.4.4.

**Proposition 7.5.4.10.** Let $\mathcal{C}$ be a small category and let $\mathcal{F} : \mathcal{C}^\text{op} \to \text{Set}_\Delta$ be a functor. The following conditions are equivalent:

1. The functor $\mathcal{F}$ is a homotopy limit diagram. That is, there exists a homotopy limit diagram $\mathcal{F}' : \mathcal{C}^\text{op} \to \text{Kan}$ and a levelwise weak homotopy equivalence $\alpha : \mathcal{F} \to \mathcal{F}'$.

2. Let $\mathcal{F}' : \mathcal{C}^\text{op} \to \text{Kan}$ be any functor. If there exists a levelwise weak homotopy equivalence $\alpha : \mathcal{F} \to \mathcal{F}'$, then $\mathcal{F}'$ is a homotopy limit diagram.

*Proof.* Using Proposition 3.1.7.1 we can choose a functor $\mathcal{G} : \mathcal{C}^\text{op} \to \text{Kan}$ and a natural transformation $\beta : \mathcal{F} \to \mathcal{G}$ which carries each object $C \in \mathcal{C}^\text{op}$ to an anodyne morphism of simplicial sets $\beta_C : \mathcal{F}(C) \to \mathcal{G}(C)$. We will show that (1) and (2) are equivalent to the following:

3. The functor $\mathcal{G}$ is a homotopy limit diagram.

The implications (2) $\Rightarrow$ (3) $\Rightarrow$ (1) are immediate. To prove the reverse implications, suppose we are given another functor $\mathcal{F}' : \mathcal{C}^\text{op} \to \text{Kan}$ and a levelwise weak homotopy equivalence $\alpha : \mathcal{F} \to \mathcal{F}'$. We will show that $\mathcal{F}'$ is a homotopy limit diagram if and only if $\mathcal{G}$ is a homotopy limit diagram.
Applying Proposition 3.1.7.1 again, we can choose a functor \( \mathcal{F}' : C^a \to \text{Kan} \) and a commutative diagram

\[
\begin{array}{ccc}
\mathcal{F} & \xrightarrow{\alpha} & \mathcal{F}' \\
\downarrow{\beta} & & \downarrow{\beta'} \\
\mathcal{G} & \xrightarrow{\alpha'} & \mathcal{G}'
\end{array}
\]

with the property that, for every object \( C \in C^a \), the induced map

\[
\mathcal{F}'(C) \coprod_{\mathcal{F}(C)} \mathcal{G}(C) \to \mathcal{G}'(C)
\]

is anodyne (and, in particular, a weak homotopy equivalence). Applying Proposition 3.4.2.11, we see that the diagram of simplicial sets

\[
\begin{array}{ccc}
\mathcal{F}(C) & \xrightarrow{\alpha_C} & \mathcal{F}'(C) \\
\downarrow{\beta_C} & & \downarrow{\beta'_C} \\
\mathcal{G}(C) & \xrightarrow{\alpha'_C} & \mathcal{G}'(C)
\end{array}
\]

is a homotopy pushout square. Since \( \alpha_C \) and \( \beta_C \) are weak homotopy equivalences, it follows that \( \alpha'_C \) and \( \beta'_C \) are also weak homotopy equivalences (Proposition 3.4.2.10). Applying Proposition 7.5.4.4, we see that \( \mathcal{F}' \) and \( \mathcal{G} \) are homotopy limit diagrams if and only if \( \mathcal{G}' \) is a homotopy limit diagram. \( \square \)

**Corollary 7.5.4.11 (Homotopy Invariance).** Let \( C \) be a category, let \( \mathcal{F}, \mathcal{G} : C^a \to \text{Set}_\Delta \) be functors, and let \( \alpha : \mathcal{F} \to \mathcal{G} \) be a natural transformation. Suppose that, for every object \( C \in C \), the induced map \( \alpha_C : \mathcal{F}(C) \to \mathcal{G}(C) \) is a weak homotopy equivalence. Then any two of the following conditions imply the third:

1. The functor \( \mathcal{F} \) is a homotopy limit diagram.
2. The functor \( \mathcal{G} \) is a homotopy limit diagram.
3. The natural transformation \( \alpha \) induces a weak homotopy equivalence \( \mathcal{F}(0) \to \mathcal{G}(0) \), where \( 0 \) denotes the cone point of \( C^a \).
**Proof.** Using Proposition \[3.1.7.1\] we can choose functors \(F', \mathcal{F} : C^\circ \to \text{Kan}\) and a commutative diagram

\[
\begin{array}{ccc}
\mathcal{F} & \xrightarrow{\alpha} & \mathcal{F} \\
\downarrow & & \downarrow \\
\mathcal{F}' & \xrightarrow{\alpha'} & \mathcal{F}',
\end{array}
\]

where the vertical maps are levelwise weak homotopy equivalences. Using Proposition \[7.5.4.10\] we can replace \(\alpha\) by the natural transformation \(\alpha' : \mathcal{F}' \to \mathcal{F}'\), in which case the desired result follows from Proposition \[7.5.4.4\]. \(\square\)

**Corollary 7.5.4.12.** Let \(C\) be a category and let \(\mathcal{F} : C^\circ \to \text{Set}_\Delta\) be a functor. Let

\[
\mathcal{F}^\text{op} : C^\circ \to \text{Set}_\Delta
\]

be the functor given on objects by \(\mathcal{F}^\text{op}(C) = \mathcal{F}(C)^\text{op}\). Then \(\mathcal{F}\) is a homotopy limit diagram if and only if \(\mathcal{F}^\text{op}\) is a homotopy limit diagram.

**Proof.** For each object \(C \in C^\circ\), let \(|\mathcal{F}(C)|\) denote the geometric realization of the simplicial set \(\mathcal{F}(C)\) (Definition \[1.1.8.1\]). Then the construction \(C \mapsto \text{Sing}_\bullet(|\mathcal{F}(C)|)\) determines a functor \(\mathcal{F} : C^\circ \to \text{Kan}\), and the unit maps \(\mathcal{F}(C) \to \text{Sing}_\bullet(|\mathcal{F}(C)|)\) determine a levelwise weak homotopy equivalence \(\alpha : \mathcal{F} \to \mathcal{F}\) (Theorem \[3.5.4.1\]). By virtue of Corollary \[7.5.4.11\] it will suffice to show that the functor \(\mathcal{F}\) is a homotopy limit diagram if and only if \(\mathcal{F}^\text{op}\) is a homotopy limit diagram. This is clear, since the functors \(\mathcal{F}\) and \(\mathcal{F}^\text{op}\) are isomorphic (see Example \[1.3.2.5\]). \(\square\)

The notion of homotopy pullback square (see §3.4.1) can be regarded as a special case of the notion of homotopy limit diagram:

**Proposition 7.5.4.13.** Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
X_0 & \xrightarrow{\alpha} & X_1 \\
\downarrow & & \downarrow \\
X_0 & \xrightarrow{\alpha} & X_1,
\end{array}
\]

which we identify with a functor \(\mathcal{F} : [1] \times [1] \to \text{Set}_\Delta\). Then \((7.44)\) is a homotopy pullback square (in the sense of Definition \[3.4.1.1\]) if and only if \(\mathcal{F}\) is a homotopy limit diagram (in the sense of Definition \[7.5.4.8\]).

**Proof.** Using Proposition \[3.1.7.1\] we can choose a levelwise weak homotopy equivalence \(\alpha : \mathcal{F} \to \mathcal{F}'\), where \(\mathcal{F}'\) is a diagram of Kan complexes. Using Corollaries \[3.4.1.12\] and
we can replace \( \mathcal{F} \) by \( \mathcal{F}' \) and thereby reduce to the case where (7.44) is a diagram of Kan complexes. By virtue of Corollary 3.4.1.6, the diagram (7.44) is a homotopy pullback square if and only if it induces a homotopy equivalence \( f : X_0 \rightarrow X_0 \times^h_X X_1 \), where \( X_0 \times^h_X X_1 \) is the homotopy fiber product of Construction 3.4.0.3. On the other hand, \( \mathcal{F} \) is a homotopy limit diagram if and only if the composition \( \iota \circ f \) is a homotopy equivalence, where

\[
\iota : X_0 \times^h_X X_1 \leftrightarrow X_0 \times^h_X (X_1 \times^h_X X) \simeq \text{holim}(F)
\]

is the comparison map described in Example 7.5.2.15. The desired result now follows from the observation that \( \iota \) is a homotopy equivalence (see Example 7.5.2.15).

### 7.5.5 Categorical Limit Diagrams

The theory of homotopy limit diagrams introduced in §7.5.4 should be regarded as belonging to the “classical” homotopy theory of simplicial sets: for example, it is invariant under weak homotopy equivalence (Corollary 7.5.4.11). When using simplicial sets to model higher category theory (rather than homotopy theory), it is useful to work with slightly different class of diagrams.

**Definition 7.5.5.1** (Categorical Limit Diagrams of \( \infty \)-Categories). Let \( \mathcal{C} \) be a small category and let \( \mathcal{F} : \mathcal{C}^\Delta \rightarrow \text{QCat} \) be a functor having restriction \( \mathcal{F} = \mathcal{F}|_\mathcal{C} \). We will say that \( \mathcal{F} \) is a **categorical limit diagram** if the composite map

\[
\mathcal{F}(0) \rightarrow \lim_{\leftarrow} (\mathcal{F}) \rightarrow \text{holim}(\mathcal{F})
\]

is an equivalence of \( \infty \)-categories; here \( 0 \) denotes the initial object of the cone \( \mathcal{C}^\Delta \simeq \{0\} \star \mathcal{C} \), and the morphism on the right is the comparison map of Remark 7.5.2.10.

**Example 7.5.5.2.** Let \( \mathcal{C} \) be a category. A diagram of Kan complexes \( \mathcal{F} : \mathcal{C}^\Delta \rightarrow \text{Kan} \) is a categorical limit diagram (in the sense of Definition 7.5.5.1) if and only if it is a homotopy limit diagram (in the sense of Definition 7.5.4.1).

**Example 7.5.5.3** (Limits of Isofibrant Diagrams). Let \( \mathcal{C} \) be a small category and let \( \overline{\mathcal{F}} : \mathcal{C}^\Delta \rightarrow \text{Set}_\Delta \) be a limit diagram in the category of simplicial sets. Suppose that the diagram \( \mathcal{F} = \overline{\mathcal{F}}|_\mathcal{C} \) is isofibrant (Definition 4.5.6.3). Then \( \mathcal{F} \) is a categorical limit diagram of \( \infty \)-categories: this follows by combining Corollary 4.5.6.11 with Proposition 7.5.3.12.

**Warning 7.5.5.4.** Let \( \mathcal{C} \) be a category and let \( \overline{\mathcal{F}} : \mathcal{C}^\Delta \rightarrow \text{QCat} \) be a diagram of \( \infty \)-categories. In general, the condition that \( \overline{\mathcal{F}} \) is a categorical limit diagram (in the sense of Definition 7.5.5.1) is independent of the condition that it is a homotopy limit diagram (in the sense of Definition 7.5.4.8): see Exercises 4.5.2.10 and 4.5.2.11.
Remark 7.5.5. Let $C$ be a category, let $\mathcal{F} : C^\triangleleft \to \mathbf{QCat}$ be a categorical limit diagram of $\infty$-categories, and define $\mathcal{F}^\leftarrow : C^\triangleleft \to \text{Kan}$ by the formula $\mathcal{F}^\leftarrow(C) = \mathcal{F}(C)^\simeq$. Then $\mathcal{F}^\leftarrow$ is a homotopy limit diagram. This follows by combining Example 7.5.2.6 with Remark 4.5.1.20.

Remark 7.5.5.6 (Homotopy Invariance). Let $C$ be a small category and let $\alpha : \mathcal{F} \to \mathcal{G}$ be a natural transformation between diagrams $\mathcal{F}, \mathcal{G} : C^\triangleleft \to \mathbf{QCat}$. Assume that, for every object $C \in C$, the induced map $\alpha_C : \mathcal{F}(C) \to \mathcal{G}(C)$ is an equivalence of $\infty$-categories. Then $\alpha$ determines a commutative diagram of $\infty$-categories

$$
\begin{array}{ccc}
\mathcal{F}(0) & \longrightarrow & \text{holim}(\mathcal{F}|_C) \\
\downarrow & & \downarrow \\
\mathcal{G}(0) & \longrightarrow & \text{holim}(\mathcal{G}|_C),
\end{array}
$$

where the right vertical map is an equivalence (Remark 7.5.2.5). It follows that any two of the following conditions imply the third:

(1) The functor $\mathcal{F}$ is a categorical limit diagram.

(2) The functor $\mathcal{G}$ is a categorical limit diagram.

(3) The natural transformation $\alpha$ induces an equivalence of $\infty$-categories $\mathcal{F}(0) \to \mathcal{G}(0)$, where $0$ denotes the cone point of $C^\triangleleft$.

Proposition 7.5.5.7. Let $C$ be a category and let $\mathcal{F} : C^\triangleleft \to \mathbf{QCat}$ be a functor. The following conditions are equivalent:

(1) The functor $\mathcal{F}$ is a categorical limit diagram, in the sense of Definition 7.5.5.1.

(2) For every simplicial set $K$, the functor

$$
\mathcal{F}^K : C^\triangleleft \to \mathbf{QCat} \\
C \mapsto \text{Fun}(K, \mathcal{F}(C))
$$

is a categorical limit diagram.

(3) For every simplicial set $K$, the functor

$$
(\mathcal{F}^K)^\simeq : C^\triangleleft \to \text{Kan} \\
C \mapsto \text{Fun}(K, \mathcal{F}(C))^\simeq
$$

is a homotopy limit diagram.

(4) The functor $(\mathcal{F}^\Delta^1)^\simeq : C^\triangleleft \to \text{Kan}$ is a homotopy limit diagram.
Proof. The implication \((1) \Rightarrow (2)\) follows from Remarks 7.5.2.3 and 4.5.1.16, the implication \((2) \Rightarrow (3)\) from Remark 7.5.5.5, and the implication \((3) \Rightarrow (4)\) is immediate. Set \(\mathcal{F} = \mathcal{F} |_{\mathcal{C}}\), and let \(0\) denote the initial object of \(\mathcal{C}^0\). Using Remark 7.5.2.3 and Example 7.5.2.6, we see that condition \((4)\) is equivalent to the requirement that the map \(\mathcal{F}(0) \to \operatorname{holim}(\mathcal{F})\) induces a homotopy equivalence of Kan complexes

\[
\operatorname{Fun}(\Delta^1, \mathcal{F}(0))^\sim \to \operatorname{Fun}(\Delta^1, \operatorname{holim}(\mathcal{F}))^\sim \simeq \operatorname{holim}(\mathcal{F}|_{\Delta^1})^\sim.
\]

The implication \((4) \Rightarrow (1)\) now follows from Theorem 4.5.7.1.\\

**Corollary 7.5.5.8.** Let \(\mathcal{C}\) be a category and let \(\mathcal{F} : \mathcal{C}^0 \to \text{QCat}\) be a functor. Then \(\mathcal{F}\) is a categorical limit diagram if and only if the induced functor of \(\infty\)-categories

\[
\mathbf{N}^\text{hc}(\mathcal{F}) : \mathbf{N}^\text{hc}(\mathcal{C}) \to \mathbf{N}^\text{hc}(\text{QCat}) = \mathbf{QC}
\]

is a limit diagram in the \(\infty\)-category \(\mathbf{QC}\) (in the sense of Definition 7.1.2.4).

**Proof.** By virtue of Corollary 7.5.4.6, the diagram \(\mathbf{N}^\text{hc}(\mathcal{F})\) is a limit diagram in the \(\infty\)-category \(\mathbf{QC}\) if and only if, for every \(\infty\)-category \(\mathcal{E}\), the diagram of Kan complexes

\[
\mathcal{C}^0 \to \mathbf{Kan} \quad C \mapsto \operatorname{Hom}_{\text{QCat}}(\mathcal{E}, \mathcal{F}(C))^\bullet = \operatorname{Fun}(\mathcal{E}, \mathcal{F}(C))^\sim
\]

is a homotopy limit diagram. Using Proposition 7.5.5.7, we see that this is equivalent to the requirement that \(\mathcal{F}\) is a categorical limit diagram.\\

**Corollary 7.5.5.9.** Let \(\mathcal{C}\) be a small category and let \(\mathcal{F} : \mathcal{C} \to \text{QCat}\) be an isofibrant diagram of \(\infty\)-categories Then \(\mathcal{F}\) has a limit in the category \(\text{QCat}\), which is preserved by the inclusion functor \(\mathbf{N}^\text{hc}(\text{QCat}) \hookrightarrow \mathbf{N}^\text{hc}(\text{QCat}) = \mathbf{QC}\).

**Proof.** Combine Example 7.5.5.3 with Corollary 7.5.5.8.\\

**Corollary 7.5.5.10.** Suppose we are given a commutative diagram of \(\infty\)-categories

\[
\begin{array}{ccc}
\mathcal{C}_0 & \to & \mathcal{C}_0 \\
\downarrow & & \downarrow \\
\mathcal{C}_1 & \to & \mathcal{C},
\end{array}
\]

which we identify with a functor \(\mathcal{F} : [1] \times [1] \to \mathbf{QC}\). The following conditions are equivalent:

1. The diagram (7.45) is a categorical pullback square, in the sense of Definition 4.5.2.7.
2. The functor \(\mathcal{F}\) is a categorical limit diagram, in the sense of Definition 7.5.5.4.
Proof. Using Proposition 4.5.2.12 we can restate (2) as follows:

\[(2')\] For every simplicial set \(K\), the diagram of Kan complexes

\[
\begin{array}{ccc}
\text{Fun}(K, \mathcal{C}_{01}) & \xrightarrow{\simeq} & \text{Fun}(K, \mathcal{C}_0) \\
\downarrow & & \downarrow \\
\text{Fun}(K, \mathcal{C}_1) & \xrightarrow{\simeq} & \text{Fun}(K, \mathcal{C})
\end{array}
\]

is a homotopy pullback square.

The equivalence \((1) \iff (2')\) follows by combining Propositions 7.5.4.13 and 7.5.5.7. \(\square\)

We now extend the scope of Definition 7.5.5.1 to arbitrary diagrams of simplicial sets.

**Definition 7.5.5.11** (Categorical Limit Diagrams of Simplicial Sets). Let \(\mathcal{C}\) be a category. We say that a functor \(\mathcal{F} : \mathcal{C} \to \text{Set}_\Delta\) is a categorical limit diagram if there exists a levelwise categorical equivalence \(\alpha : \mathcal{F} \to \mathcal{G}\), where \(\mathcal{G} : \mathcal{C} \to \text{QCat}\) is a categorical limit diagram (in the sense of Definition 7.5.5.1).

**Remark 7.5.5.12.** Let \(\mathcal{C}\) be a category and let \(\mathcal{F} : \mathcal{C} \to \text{QCat}\) be a functor. The following conditions are equivalent:

1. The functor \(\mathcal{F}\) is a categorical limit diagram in the sense of Definition 7.5.5.1, that is, it induces an equivalence of \(\infty\)-categories \(\mathcal{F}(0) \to \text{holim}(\mathcal{F}|_{\mathcal{C}})\).

2. The functor \(\mathcal{F}\) is a categorical limit diagram in the sense of Definition 7.5.5.11, that is, there exists a levelwise categorical equivalence \(\alpha : \mathcal{F} \to \mathcal{G}\), where \(\mathcal{G} : \mathcal{C} \to \text{QCat}\) induces an equivalence of \(\infty\)-categories \(\mathcal{G}(0) \to \text{holim}(\mathcal{G}|_{\mathcal{C}})\).

The implication \((1) \Rightarrow (2)\) is immediate, and the reverse implication follows from Remark 7.5.5.6.

**Proposition 7.5.5.13.** Let \(\mathcal{C}\) be a category and let \(\mathcal{F} : \mathcal{C} \to \text{Set}_\Delta\) be a functor. The following conditions are equivalent:

1. The functor \(\mathcal{F}\) is a categorical limit diagram. That is, there exists a categorical limit diagram \(\mathcal{F}' : \mathcal{C} \to \text{QCat}\) and a levelwise categorical equivalence \(\alpha : \mathcal{F} \to \mathcal{F}'\).

2. Let \(\mathcal{F}' : \mathcal{C} \to \text{QCat}\) be any functor. If there exists a levelwise categorical equivalence \(\alpha : \mathcal{F} \to \mathcal{F}'\), then \(\mathcal{F}'\) is a categorical limit diagram.
7.5. HOMOTOPY LIMITS AND COLIMITS

Proof. We proceed as in the proof of Proposition 7.5.4.10. Using Proposition 4.1.3.2 we can choose a functor $T : \mathcal{C} \to \mathbf{QCat}$ and a natural transformation $\beta : T \to T$ for which the morphism of simplicial sets $\beta_C : T(C) \to T(C)$ is inner anodyne for each object $C \in \mathcal{C}$. We will show that (1) and (2) are equivalent to the following:

(3) The functor $T$ is a categorical limit diagram.

The implications $(2) \Rightarrow (3) \Rightarrow (1)$ are immediate. To prove the reverse implications, suppose we are given another functor $T' : \mathcal{C} \to \mathbf{QCat}$ and a levelwise categorical equivalence $\alpha : T \to T'$. We will show that $T'$ is a categorical limit diagram if and only if $T$ is a categorical limit diagram.

Applying Proposition 4.1.3.2 again, we can choose a functor $T' : \mathcal{C} \to \mathbf{QCat}$ and a commutative diagram

$$
\begin{array}{ccc}
T & \xrightarrow{\alpha} & T' \\
\downarrow{\beta} & & \downarrow{\beta'} \\
T & \xrightarrow{\alpha'} & T'
\end{array}
$$

with the property that, for every object $C \in \mathcal{C}$, the induced morphism of simplicial sets $T'(C) \amalg_{\mathcal{T}(C)} T(C) \to T'(C)$ is inner anodyne (and, in particular, a categorical equivalence).

Applying Proposition 4.5.4.11, we see that the diagram of simplicial sets

$$
\begin{array}{ccc}
\mathcal{T}(C) & \xrightarrow{\mathcal{C}} & \mathcal{T}'(C) \\
\downarrow{\mathcal{B}_C} & & \downarrow{\mathcal{B}'_C} \\
\mathcal{T}(C) & \xrightarrow{\mathcal{C}'} & \mathcal{T}'(C)
\end{array}
$$

is a categorical pushout square. Since $\mathcal{C}_C$ and $\mathcal{B}_C$ are categorical equivalences, it follows that $\mathcal{C}'_C$ and $\mathcal{B}'_C$ are also categorical equivalences (Proposition 4.5.4.10). Applying Remark 7.5.5.6 we see that $T'$ and $T$ are categorical limit diagrams if and only if $T'$ is a categorical limit diagram.

\[\boxcheck\]

Corollary 7.5.5.14. Let $\mathcal{C}$ be a category, let $T, T' : \mathcal{C} \to \mathbf{Set}_\Delta$ be functors, and let $\alpha : T \to T'$ be a natural transformation. Suppose that, for every object $C \in \mathcal{C}$, the induced map $\alpha_C : T(C) \to T'(C)$ is a categorical equivalence of simplicial sets. Then any two of the following conditions imply the third:

(1) The functor $T$ is a categorical limit diagram.
(2) The functor $\mathcal{F}'$ is a categorical limit diagram.

(3) The natural transformation $\alpha$ induces a categorical equivalence of simplicial sets $\mathcal{F}(0) \to \mathcal{F}'(0)$, where $0$ denotes the initial object of $C$.  

**Proof.** Using Proposition 4.1.3.2, we can choose functors $\mathcal{F}, \mathcal{F}' : C^a \to \text{QCat}$ and a commutative diagram

\[
\begin{array}{ccc}
\mathcal{F} & \xrightarrow{\alpha} & \mathcal{F}' \\
\downarrow & & \downarrow \\
\mathcal{G} & \xrightarrow{\beta} & \mathcal{G}'
\end{array}
\]

where the vertical maps are levelwise categorical equivalences. By virtue of Proposition 7.5.5.13, we can replace $\alpha$ by the natural transformation $\beta : \mathcal{G} \to \mathcal{G}'$. In this case, the desired result follows from Remark 7.5.5.6.

**Corollary 7.5.5.15.** Let $C$ be a small category and let $\mathcal{F} : C^\circ \to \text{Set}_{\Delta}$ be a functor. Let $\mathcal{F}^{\text{op}} : C^a \to \text{Set}_{\Delta}$ be the functor given on objects by $\mathcal{F}^{\text{op}}(C) = \mathcal{F}(C)^{\text{op}}$. Then $\mathcal{F}$ is a categorical limit diagram if and only if $\mathcal{F}^{\text{op}}$ is a categorical limit diagram.

**Proof.** Using Proposition 4.1.3.2, we can choose a functor $\mathcal{G} : C^a \to \text{QCat}$ and a levelwise categorical equivalence $\alpha : \mathcal{F} \to \mathcal{G}$. By virtue of Corollary 7.5.5.14, it will suffice to show that $\mathcal{G}$ is a categorical limit diagram if and only if $\mathcal{G}^{\text{op}}$ is a categorical limit diagram. This follows by combining Proposition 7.5.5.7 with Corollary 7.5.4.12.

### 7.5.6 The Homotopy Colimit as a Derived Functor

Let $C$ be a small category and let $\mathcal{F} : C \to \text{QCat}$ be a diagram of $\infty$-categories. In §7.5.3, we showed that the homotopy limit $\text{holim}(\mathcal{F})$ can be identified with the limit of an isofibrant replacement for $\mathcal{F}$: that is, there exists an isomorphism $\text{holim}(\mathcal{F}) \simeq \text{lim}(\mathcal{F}^+) \simeq \text{lim}(\mathcal{F}_+)$, where $\mathcal{F}^+ : C \to \text{QCat}$ is an isofibrant diagram equipped with a levelwise categorical equivalence $\mathcal{F} \hookrightarrow \mathcal{F}^+$ (Construction 7.5.3.3 and Proposition 7.5.3.7). Our goal in this section is to present a parallel treatment of the homotopy colimit functor of Construction 5.3.2.1. More precisely, we show that the homotopy colimit of a diagram $\mathcal{F} : C \to \text{Set}_{\Delta}$ can be identified with the colimit of an auxiliary diagram $\mathcal{F}_+ : C \to \text{Set}_{\Delta}$ which is equipped with a levelwise weak homotopy equivalence $\mathcal{F}_+ \to \mathcal{F}$ (Proposition 7.5.6.12).

We begin by introducing some terminology. Recall that a natural transformation $\beta : \mathcal{G} \to \mathcal{F}$ is a levelwise trivial Kan fibration if, for each object $C \in C$, the morphism $\beta_C : \mathcal{G}(C) \to \mathcal{F}(C)$ is a trivial Kan fibration of simplicial sets.
Let \( \mathcal{C} \) be a small category. We say that a diagram of simplicial sets \( F : \mathcal{C} \to \text{Set}_\Delta \) is \textit{projectively cofibrant} if, for every levelwise trivial Kan fibration \( G' \to G \), the induced map

\[
\text{Hom}_{\text{Fun}(\mathcal{C}, \text{Set}_\Delta)}(F, G') \to \text{Hom}_{\text{Fun}(\mathcal{C}, \text{Set}_\Delta)}(F, G)
\]

is surjective. That is, every natural transformation \( \alpha : F \to G \) factors through \( \beta \).

\textbf{Example 7.5.6.2.} Let \( \mathcal{C} \) be a category and let \( U : \mathcal{E} \to N_\bullet(\mathcal{C}) \) be a morphism of simplicial sets. Then the diagram

\[
F_E : \mathcal{C} \to \text{Set}_\Delta \quad F_E(C) = N_\bullet(\mathcal{C}/_C) \times_{N_\bullet(\mathcal{C})} \mathcal{E}
\]

is projectively cofibrant, in the sense of Definition 7.5.6.1. To prove this, we must show that for every levelwise trivial Kan fibration \( G' \to G \) between functors \( G', G : \mathcal{C} \to \text{Set}_\Delta \), the induced map

\[
\theta : \text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{S})}(F_E, G') \to \text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{S})}(F_E, G)
\]

is surjective. Using Proposition 5.3.3.21, we can identify \( \theta \) with a pullback of the map \( \text{Hom}_{\text{Set}_\Delta}(E, N^\emptyset(\mathcal{C})) \to \text{Hom}_{\text{Set}_\Delta}(E, N^\emptyset(\mathcal{C})) \), which is surjective by virtue of Exercise 5.3.3.11.

\textbf{Exercise 7.5.6.3} (Well-Founded Diagrams). Let \( (Q, \leq) \) be a well-founded partially ordered set. Show that a diagram of simplicial sets \( \mathcal{F} : Q \to \text{Set}_\Delta \) is projectively cofibrant if and only if, for each element \( q \in Q \), the associated map \( \lim_{p<q} \mathcal{F}(p) \to \mathcal{F}(q) \) is a monomorphism of simplicial sets (compare with Proposition 4.5.6.6).

\textbf{Example 7.5.6.4} (Projectively Cofibrant Sequences). A sequential diagram of simplicial sets

\[
X(0) \to X(1) \to X(2) \to X(3) \to \cdots
\]

is projectively cofibrant (when regarded as a functor \( \mathbb{Z}_{\geq 0} \to \text{Set}_\Delta \)) if and only if each of the transition maps \( X(n) \to X(n + 1) \) is a monomorphism.

\textbf{Example 7.5.6.5} (Projectively Cofibrant Squares). A commutative diagram of simplicial sets

\[
\begin{array}{ccc}
A & \xrightarrow{f_0} & A_0 \\
\downarrow{f_1} & & \downarrow{f_1} \\
A_1 & \xrightarrow{f_0} & A_{01}
\end{array}
\quad \text{(7.46)}
\]

is projectively cofibrant (when regarded as a functor \( [1] \times [1] \to \text{Set}_\Delta \)) if and only if the morphisms

\[
f_0 : A \to A_0 \quad f_1 : A \to A_1 \quad (f_1', f_0') : A_0 \coprod_A A_1 \to A_{01}
\]

are monomorphisms of simplicial sets. Equivalently, (7.46) is projectively cofibrant if it is a pullback square consisting of monomorphisms.
Remark 7.5.6.6 (Relationship to Isofibrant Diagrams). Let $\mathcal{F} : \mathcal{C} \to \Delta$ be a diagram of simplicial sets, let $\mathcal{D}$ be an $\infty$-category, and let $\mathcal{D}^{\mathcal{F}} : \mathcal{C}^{\text{op}} \to \Delta$ denote the functor given by the construction $C \mapsto \text{Fun}(\mathcal{F}(C), \mathcal{D})$. If $\mathcal{F}$ is projectively cofibrant (in the sense of Definition 7.5.6.1), then $\mathcal{D}^{\mathcal{F}}$ is isofibrant (in the sense of Definition 4.5.6.3). That is, if $\mathcal{E} : \mathcal{C}^{\text{op}} \to \Delta$ is a diagram of simplicial sets and $\mathcal{E}_0 \subseteq \mathcal{E}$ is a subfunctor for which the equivalence $\mathcal{E}_0 \to \mathcal{E}$ is a levelwise categorical equivalence, then the restriction map
\[
\theta : \text{Hom}_{\text{Fun}(\mathcal{C}^{\text{op}}, \Delta)}(\mathcal{E}, \mathcal{D}^{\mathcal{F}}) \to \text{Hom}_{\text{Fun}(\mathcal{C}^{\text{op}}, \Delta)}(\mathcal{E}_0, \mathcal{D}^{\mathcal{F}})
\]
is surjective. This follows from the observation that $\theta$ can be identified with the map
\[
\text{Hom}_{\text{Fun}(\mathcal{C}^{\text{op}}, \Delta)}(\mathcal{F}, \mathcal{D}^{\mathcal{E}}) \to \text{Hom}_{\text{Fun}(\mathcal{C}^{\text{op}}, \Delta)}(\mathcal{F}, \mathcal{D}^{\mathcal{E}_0})
\]
given by composition with the restriction map $\mathcal{D}^{\mathcal{E}} \to \mathcal{D}^{\mathcal{E}_0}$, which is a levelwise trivial Kan fibration by virtue of Corollary 4.5.5.19.

Proposition 7.5.6.7. Let $\mathcal{C}$ be a small category and let $\alpha : \mathcal{F} \to \mathcal{G}$ be a natural transformation between projectively cofibrant diagrams $\mathcal{F}, \mathcal{G} : \mathcal{C} \to \Delta$. If $\alpha$ is a levelwise categorical equivalence, then the induced map $\lim\rightarrow(\alpha) : \lim\rightarrow(\mathcal{F}) \to \lim\rightarrow(\mathcal{G})$ is a categorical equivalence of simplicial sets. If $\alpha$ is a levelwise weak homotopy equivalence, then $\lim\rightarrow(\alpha)$ is a weak homotopy equivalence.

Proof. We will prove the first assertion; the second follows by a similar argument. Assume that $\alpha$ is levelwise categorical equivalence and let $\mathcal{D}$ be an $\infty$-category; we wish to show that precomposition with $\lim\rightarrow(\alpha)$ induces an equivalence of $\infty$-categories $\alpha^* : \text{Fun}(\lim\rightarrow(\mathcal{G}), \mathcal{D}) \to \text{Fun}(\lim\rightarrow(\mathcal{F}), \mathcal{D})$. $\alpha$ is a levelwise categorical equivalence, precomposition with $\alpha$ induces a levelwise categorical equivalence $\beta : \mathcal{D}^{\mathcal{G}} \to \mathcal{D}^{\mathcal{F}}$ in the category $\text{Fun}(\mathcal{C}^{\text{op}}, \Delta)$. Unwinding the definitions, we see that $\alpha^*$ can be identified with the limit $\lim(\beta)$. Since $\mathcal{D}^{\mathcal{G}}$ and $\mathcal{D}^{\mathcal{F}}$ are isofibrant diagrams (Remark 7.5.6.6), the functor $\lim(\beta)$ is an equivalence of $\infty$-categories (Corollary 4.5.5.19). \hfill \Box

We now show that every diagram of simplicial sets $\mathcal{F} : \mathcal{C} \to \Delta$ admits a weak homotopy equivalence from a projectively cofibrant diagram (for a stronger statement, see Proposition 7.5.9.7).

Construction 7.5.6.8 (Explicit Cofibrant Replacement). Let $\mathcal{C}$ be a small category, let $\mathcal{F} : \mathcal{C} \to \Delta$ be a diagram of simplicial sets, and let $\holim(\mathcal{F})$ denote the homotopy colimit of $\mathcal{F}$ (Construction 5.3.2.1). For each object $C \in \mathcal{C}$, we let $\mathcal{F}_+(C)$ denote the simplicial set given by the fiber product
\[
N^\bullet(C/C) \times_{N^\bullet(C)} \holim(\mathcal{F}) \setminus \holim(\mathcal{F}|_{C/C}).
\]
The construction \( C \mapsto F^+ : C \to \text{Set}_\Delta \) determines a diagram of simplicial sets \( F^+ : C \to \text{Set}_\Delta \). This diagram is equipped with a natural transformation \( \alpha : F^+ \to F \), which carries each object \( C \in C \) to the comparison map

\[
\holim(F|_{C/C}) \to \lim(F|_{C/C}) \simeq \mathcal{F}(C)
\]

of Remark 5.3.2.9.

**Proposition 7.5.6.9.** Let \( C \) be a small category and let \( \mathcal{F} : C \to \text{Set}_\Delta \) be a diagram of simplicial sets. Then the diagram \( F^+ : C \to \text{Set}_\Delta \) of Construction 7.5.6.8 is projectively cofibrant, and the natural transformation \( \alpha : F^+ \to F \) is a levelwise weak homotopy equivalence. Moreover, \( \alpha \) is also an epimorphism.

**Proof.** Example 7.5.6.2 shows that the diagram \( F^+ \) is projectively cofibrant and Remark 5.3.2.9 shows that \( \alpha \) is an epimorphism. To complete the proof, it will suffice to show that for each object \( C \in C \), the map \( \alpha_C : F^+(C) \to \mathcal{F}(C) \) is a weak homotopy equivalence of simplicial sets. Replacing \( C \) by the slice category \( C/C \), we can reduce to the case where \( C \) is a final object of \( C \); in this case, we wish to prove that the comparison map

\[
\holim(F) \to \lim(F) \simeq \mathcal{F}(C)
\]

is a weak homotopy equivalence. Note that this map admits a section, given by the inclusion map

\[
\iota : \mathcal{F}(C) \simeq \{C\} \times_{N(C)} \holim(F) \to \holim(F).
\]

We complete the proof by that our assumption that \( C \in C \) is a final object guarantees that \( \iota \) is right anodyne (Example 7.2.3.12). \(\square\)

**Warning 7.5.6.10.** In the situation of Proposition 7.5.6.9, the natural transformation \( \alpha : F^+ \to F \) is usually not a levelwise categorical equivalence. For example, if \( \mathcal{F} \) is the constant functor taking the value \( \Delta^0 \), then \( F^+ \) is given by the construction \( C \mapsto N(C/C) \).

**Remark 7.5.6.11.** Constructions 7.5.6.8 and 7.5.3.3 are closely related. Let \( \mathcal{C} \) be a small category, let \( \mathcal{F} : \mathcal{C} \to \text{Set}_\Delta \) be a diagram of simplicial sets, and let \( \mathcal{G} : \mathcal{C} \to \text{Kan} \) be a diagram of Kan complexes. Combining Corollary 5.3.2.24 with Proposition 5.3.3.21 we obtain canonical isomorphisms of Kan complexes

\[
\text{Hom}_{\text{Fun}(\mathcal{C},\text{Set}_\Delta)}(\mathcal{F},\mathcal{G}) \simeq \text{Hom}_{\text{Fun}(\mathcal{C},\text{Set}_\Delta)}(\mathcal{F},\text{Tr}_{N(C)} \mathcal{G})
\]

\[
\simeq \text{Fun}_{/N(C)}(\lim(\mathcal{F}), N(C))
\]

\[
\simeq \text{Hom}_{\text{Fun}(\mathcal{C},\text{Set}_\Delta)}(\mathcal{F}^+, \mathcal{G})^*.
\]
CHAPTER 7. LIMITS AND COLIMITS

More generally, if \( G \) is a diagram of \( \infty \)-categories, we can identify \( \text{Hom}_{\text{Fun}(C, \mathbf{Set}_\Delta)}(F, G^+) \) with the full subcategory of \( \text{Hom}_{\text{Fun}(C, \mathbf{Set}_\Delta)}(F_+, G^+) \) spanned by those natural transformations \( \alpha : F_+ \to G \) having the property that, for each object \( C \in C \), the diagram

\[
\alpha_C : F_+(C) = \text{holim}(F|_{C/C}) \to G(C)
\]
carries horizontal edges of \( \text{holim}(F|_{C/C}) \) to isomorphisms in the \( \infty \)-category \( G(C) \).

**Proposition 7.5.6.12.** Let \( C \) be a small category, let \( F : C \to \mathbf{Set}_\Delta \) be a diagram of simplicial sets, and let \( F_+ : C \to \mathbf{Set}_\Delta \) be the diagram of Construction 7.5.6.8. Then there is a canonical isomorphism of simplicial sets \( \lambda : \text{lim}(F_+) \to \text{holim}(F) \) which is characterized by the following requirement: for each object \( C \in C \), the composition

\[
N_\bullet(C/C) \times N_\bullet(C) \xrightarrow{\text{holim}(F)} = \text{F}_+(C) \\
\to \text{lim}(F_+) \\
\to \text{holim}(F)
\]
is given by projection onto the second factor.

**Proof.** It follows from the definition of the colimit that there is a unique morphism of simplicial sets \( \lambda : \text{lim}(F_+) \to \text{holim}(F) \) having the desired property. Using the dual of Lemma 7.5.3.8 we deduce that \( \lambda \) is an isomorphism. \( \square \)

**Remark 7.5.6.13.** Let \( F : C \to \mathbf{Set}_\Delta \) be a diagram of simplicial sets, let \( \theta : \text{holim}(F) \to \text{lim}(F) \) be the comparison map of Remark 5.3.2.9 and let \( \lambda : \text{lim}(F_+) \to \text{holim}(F) \) be the isomorphism of Proposition 7.5.6.12. Then the composition \( \theta \circ \lambda : \text{lim}(F_+) \to \text{lim}(F) \) is induced by the natural transformation \( \alpha : F_+ \to F \) appearing in Construction 7.5.6.8.

**Corollary 7.5.6.14.** Let \( C \) be a small category and let \( F : C \to \mathbf{Set}_\Delta \) be a projectively cofibrant diagram of simplicial sets. Then the comparison map \( \text{holim}(F) \to \text{lim}(F) \) of Remark 5.3.2.9 is a weak homotopy equivalence.

**Proof.** By virtue of Remark 7.5.6.13 it will suffice to show that the natural transformation \( \alpha : F_+ \to F \) of Construction 7.5.6.8 induces a weak homotopy equivalence \( \text{lim}(\alpha) : \text{lim}(F_+) \to \text{lim}(F) \). This is a special case of Proposition 7.5.6.7 since \( \alpha \) is a levelwise weak homotopy equivalence between projectively cofibrant diagrams (Proposition 7.5.6.9). \( \square \)

**Warning 7.5.6.15.** Let \( F : C \to \mathbf{QCat} \) be a diagram of simplicial sets, let \( \alpha : F_+ \to F \) be the natural transformation of Construction 7.5.6.8 and let \( \lambda : \text{lim}(F_+) \to \text{holim}(F) \) be the
isomorphism of Proposition 7.5.6.12. Then we have a diagram of simplicial sets

\[
\begin{array}{ccc}
\text{holim}(\mathcal{F}) & \xrightarrow{\text{holim}(\alpha)} & \text{holim}(\mathcal{F}) \\
\text{lim}(\mathcal{F}) & \xrightarrow{\text{lim}(\alpha)} & \text{lim}(\mathcal{F})
\end{array}
\]

where the outer square and the lower right triangle are commutative (Remark 7.5.6.13). Beware that the upper left triangle is usually not commutative. That is, \(\text{holim}(\mathcal{F})\) and \(\text{lim}(\mathcal{F})\) are isomorphic when viewed as abstract simplicial sets, but not when viewed as quotients of the simplicial set \(\text{holim}(\mathcal{F})\) (compare with Warning 7.5.3.14).

Remark 7.5.6.16 (The Homotopy Colimit as a Left Derived Functor). The preceding results can be interpreted in the language of model categories. For every small category \(\mathcal{C}\), the category \(\text{Fun}(\mathcal{C}, \text{Set}_\Delta)\) can be equipped with a model structure in which the fibrations are levelwise Kan fibrations and weak equivalences are levelwise weak homotopy equivalences (see Example [?]). Combining Propositions 7.5.6.9 and 7.5.6.12, we deduce that the homotopy colimit functor \(\text{holim}: \text{Fun}(\mathcal{C}, \text{Set}_\Delta) \to \text{Set}_\Delta\) can be viewed as a left derived functor of the usual colimit \(\lim: \text{Fun}(\mathcal{C}, \text{Set}_\Delta) \to \text{Set}_\Delta\) (see Definition [?]).

7.5.7 Homotopy Colimit Diagrams

Let \(\mathcal{C}\) be a (small) category and let \(\mathcal{F}: \mathcal{C} \to \text{Kan}\) be a (strictly commutative) diagram of Kan complexes indexed by \(\mathcal{C}\). Passing to the homotopy coherent nerve, we obtain a functor of \(\infty\)-categories

\[
N_{\text{hc}}(\mathcal{F}): N_{\bullet}(\mathcal{C}) \to N_{\text{hc}}(\text{Kan}) = \mathcal{S}.
\]

By virtue of Corollary 7.4.5.6, this functor admits a colimit in the \(\infty\)-category \(\mathcal{S}\). This colimit admits a classical description, using the homotopy colimit of Construction 5.3.2.1.

Proposition 7.5.7.1. Let \(\mathcal{C}\) be a small category and let \(\mathcal{F}: \mathcal{C} \to \text{QC\textit{at}}\) be a (strictly commutative) diagram of \(\infty\)-categories indexed by \(\mathcal{C}\). Then a Kan complex \(X\) is a colimit of the functor \(N_{\text{hc}}(\mathcal{F})\) if and only if it is weakly homotopy equivalent to the homotopy colimit \(\text{holim}(\mathcal{F})\).

Proof. Let \(\lambda_t: \text{holim}(\mathcal{F}) \to N_{\bullet}(\mathcal{C})\) be the taut scaffold of Construction 5.3.4.11. Then \(\lambda_t\) is a categorical equivalence of simplicial sets (Corollary 5.3.5.9), and therefore a weak homotopy equivalence (Remark 1.5.3.4). The desired result now follows from Corollary 7.4.5.9.

\[\square\]
**Example 7.5.7.2.** Let $C$ be a groupoid and let $\mathcal{F} : C \to \text{Kan}$ be a diagram of Kan complexes indexed by $C$. Then the homotopy colimit $\text{holim}(\mathcal{F})$ is a Kan complex (Corollary 5.3.4.23). In this case, Proposition 7.5.7.1 guarantees that $\text{holim}(\mathcal{F})$ is a colimit of the diagram $\text{N}^\circ\text{hc}(\mathcal{F})$ in the $\infty$-category $\text{S}$. For example, if $X$ is a Kan complex equipped with an action of a group $G$, then the homotopy quotient $X_{hG}$ is a colimit of the associated diagram $B\cdot G \to \text{S}$ (Example 5.3.4.24).

Our goal in this section is to formulate a companion to Proposition 7.5.7.1, which provides concrete models for colimit diagrams in the $\infty$-category $\text{S}$ (rather than colimits in the abstract).

**Definition 7.5.7.3.** Let $C$ be a category and let $\mathcal{F} : C \to \text{Set}$ be a diagram of simplicial sets restriction $\mathcal{F} = \mathcal{F}|_C$. We will say that $\mathcal{F}$ is a homotopy colimit diagram if the composite map

$$\text{holim}(\mathcal{F}) \to \lim_{\to} (\mathcal{F}) \to \mathcal{F}(1)$$

is a weak homotopy equivalence of simplicial sets. Here 1 denotes the final object of the cone $C^\circ \simeq C \ast \{1\}$, and the morphism on the left is the comparison map of Remark 5.3.2.9.

**Example 7.5.7.4.** Let $C$ be a small category and let $\mathcal{F} : C^{\circ} \to \text{Set}_\Delta$ be a colimit diagram in the category of simplicial sets. If the diagram $\mathcal{F} = \mathcal{F}|_C$ is projectively cofibrant, then $\mathcal{F}$ is a homotopy colimit diagram: this is a reformulation of Corollary 7.5.6.14 (for a stronger statement, see Corollary 7.5.8.7).

**Proposition 7.5.7.5 (Homotopy Invariance).** Let $C$ be a category and let $\alpha : \mathcal{F} \to \mathcal{G}$ be a natural transformation between diagrams $\mathcal{F}, \mathcal{G} : C^{\circ} \to \text{Set}_\Delta$. Assume that, for every object $C \in C$, the induced map $\alpha_C : \mathcal{F}(C) \to \mathcal{G}(C)$ is a weak homotopy equivalence of simplicial sets. Then any two of the following conditions imply the third:

1. The functor $\mathcal{F}$ is a homotopy colimit diagram.
2. The functor $\mathcal{G}$ is a homotopy colimit diagram.
3. The natural transformation $\alpha$ induces a weak homotopy equivalence $\mathcal{F}(1) \to \mathcal{G}(1)$, where 1 denotes the cone point of $C^{\circ}$.

**Proof.** Setting $\mathcal{F} = \mathcal{F}|_C$ and $\mathcal{G} = \mathcal{G}|_C$, we observe that $\alpha$ determines a commutative diagram of simplicial sets

$$\begin{array}{ccc}
\text{holim}(\mathcal{F}) & \longrightarrow & \text{holim}(\mathcal{G}) \\
\downarrow & & \downarrow \\
\mathcal{F}(1) & \longrightarrow & \mathcal{G}(1)
\end{array}$$
where the upper horizontal map is a weak homotopy equivalence (Proposition 5.3.2.18). The desired result now follows from the two-out-of-three property (Remark 3.1.6.16).

There is a close relationship between homotopy colimit diagrams (in the sense of Definition 7.5.7.3) and homotopy limit diagrams (in the sense of Definition 7.5.4.1).

**Proposition 7.5.7.6.** Let $\mathcal{C}$ be a category and let $\mathcal{F} : \mathcal{C}^\circ \to \text{Set}_\Delta$ be a diagram of simplicial sets. Then $\mathcal{F}$ is a homotopy colimit diagram if and only if, for every Kan complex $X$, the functor

$$X^\mathcal{F} : (\mathcal{C}^\circ)^{\text{op}} \to \text{Kan} \quad C \mapsto \text{Fun}(\mathcal{F}(C), X)$$

is a homotopy limit diagram.

**Proof.** Set $\mathcal{F} = \mathcal{F}|_C$, let $1$ denote the final object of $\mathcal{C}^\circ$, and let $\theta : \text{holim}(\mathcal{F}) \to \mathcal{F}(1)$ be the map appearing in Definition 7.5.7.3. Then $\mathcal{F}$ is a homotopy colimit diagram if and only if, for every Kan complex $X$, precomposition with $\theta$ induces a homotopy equivalence of Kan complexes

$$\theta^* : \text{Fun}(\mathcal{F}(1), X) \to \text{Fun}(\text{holim}(\mathcal{F}), X).$$

Setting $\mathcal{G} = \mathcal{F}^{\text{op}}$, $\mathcal{F} = \mathcal{F}^{\text{op}}$, and $Y = X^{\text{op}}$, Example 7.5.1.7 identifies $\theta^*$ with the opposite of the restriction map $Y^\mathcal{F}(1) \to \text{holim}(Y^\mathcal{F})$ appearing in Definition 7.5.4.1. In particular, $\theta^*$ is a homotopy equivalence if and only if $Y^\mathcal{F}$ is a homotopy limit diagram of Kan complexes. By virtue of Corollary 7.5.4.12, this is equivalent to the requirement that $X^\mathcal{F}$ is a homotopy limit diagram. \hfill $\Box$

**Corollary 7.5.7.7.** Let $\mathcal{C}$ be a small category and let $\mathcal{F} : \mathcal{C}^\circ \to \text{Kan}$ be a diagram of Kan complexes. Then $\mathcal{F}$ is a homotopy colimit diagram (in the sense of Definition 7.5.7.3) if and only if the induced functor of $\infty$-categories

$$N^\text{hc}_*(\mathcal{F}) : N_*(\mathcal{C}^\circ) \to N^\text{hc}_*(\text{Kan}) = S$$

is a colimit diagram (in the sense of Variant 7.1.2.5).

**Proof.** Combine Proposition 7.5.7.6 with Corollary 7.5.4.6 (applied to the simplicial category $\text{Kan}^{\text{op}}$). \hfill $\Box$

**Corollary 7.5.7.8.** Let $\mathcal{C}$ be a category and let $\mathcal{F} : \mathcal{C}^\circ \to \text{Set}_\Delta$ be a functor. Let $\mathcal{F}^{\text{op}} : \mathcal{C}^\circ \to \text{Set}_\Delta$ be the functor given on objects by $\mathcal{F}^{\text{op}}(C) = \mathcal{F}(C)^{\text{op}}$. Then $\mathcal{F}$ is a homotopy colimit diagram if and only if $\mathcal{F}^{\text{op}}$ is a homotopy colimit diagram.

**Proof.** Combine Proposition 7.5.7.6 with Corollary 7.5.7.8. \hfill $\Box$
Corollary 7.5.7.9. Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
A & \rightarrow & A_0 \\
\downarrow & & \downarrow \\
A_1 & \rightarrow & A_{01},
\end{array}
\]

which we identify with a functor \( \mathcal{F} : [1] \times [1] \rightarrow \text{Set}_\Delta \). Then (7.47) is a homotopy pushout square (in the sense of Definition 3.4.2.1) if and only if \( \mathcal{F} \) is a homotopy colimit diagram (in the sense of Definition 7.5.7.3).

Proof. Combine Propositions 7.5.7.6 and 7.5.4.13.

7.5.8 Categorical Colimit Diagrams

In \( \S 7.5.7 \) we introduced the notion of a homotopy colimit diagram (Definition 7.5.7.3), and showed that one can use homotopy colimit diagrams to compute colimits in the \( \infty \)-category \( \mathcal{S} \) of spaces (Corollary 7.5.7.7). In this section, we introduce the closely related notion of categorical colimit diagram, which can be used to compute colimits in the larger \( \infty \)-category \( \text{QC} \supset \mathcal{S} \).

Proposition 7.5.8.1. Let \( \mathcal{C} \) be a small category and let \( \mathcal{F} : \mathcal{C} \rightarrow \text{QCat} \) be a (strictly commutative) diagram of \( \infty \)-categories indexed by \( \mathcal{C} \), and let \( W \) denote the collection of horizontal edges of the homotopy colimit \( \text{holim}(\mathcal{F}) \) (Definition 5.3.4.1). Then an \( \infty \)-category \( \mathcal{D} \) is a colimit of the diagram \( N_{hc}(\mathcal{F}) : N_{\bullet}(\mathcal{C}) \rightarrow N_{hc}(\text{QCat}) = \text{QC} \) if and only if it is a localization of \( \text{holim}(\mathcal{F}) \) with respect to \( W \), in the sense of Remark 6.3.2.2.

Proof. Let \( U : N_{\bullet}(\mathcal{C}) \rightarrow N_{\bullet}(\mathcal{C}) \) be the projection map of Definition 5.3.3.1 and let \( W' \) denote the collection of all \( U \)-cocartesian morphisms of \( N_{\bullet}(\mathcal{C}) \). Choose a functor of \( \infty \)-categories \( T : N_{\bullet}(\mathcal{C}) \rightarrow \mathcal{D} \) which exhibits \( \mathcal{D} \) as a localization of \( N_{\bullet}(\mathcal{C}) \) with respect to \( W' \). Let \( \lambda_t : \text{holim}(\mathcal{F}) \rightarrow N_{\bullet}(\mathcal{C}) \) denote the taut scaffold of Construction 5.3.4.11. Then \( \lambda_t \) is a categorical equivalence of simplicial sets (Corollary 5.3.5.9). Moreover, a morphism of \( N_{\bullet}(\mathcal{C}) \) belongs to \( W' \) if and only if it is isomorphic (as an object of the \( \infty \)-category \( \text{Fun}(\Delta^1, N_{\bullet}(\mathcal{C})) \)) to an element of \( \lambda_t(W) \) (see Proposition 5.3.3.15). It follows that the composite map \( \text{holim}(\mathcal{F}) \overset{\lambda_t}{\rightarrow} N_{\bullet}(\mathcal{C}) \overset{T}{\rightarrow} \mathcal{D} \) exhibits \( \mathcal{D} \) as a localization of \( \text{holim}(\mathcal{F}) \) with respect to \( W \). We conclude by observing that \( \mathcal{D} \) is a colimit of the diagram \( N_{hc}(\mathcal{F}) \) (Corollary 7.4.3.16). \( \square \)
Motivated by Proposition 7.5.8.1, we introduce the following variant of Definition 7.5.7.3:

**Definition 7.5.8.2.** Let $\mathcal{C}$ be a category and let $\mathcal{F} : \mathcal{C} \to \text{Set}_{\Delta}$ be a diagram of simplicial sets. Set $\mathcal{F} = \mathcal{F}|_{\mathcal{C}}$, and let $W$ denote the collection of horizontal edges of $\text{holim}(\mathcal{F})$ (Definition 5.3.4.1). We will say that $\mathcal{F}$ is a **categorical colimit diagram** if the composite map

$$\text{holim}(\mathcal{F}) \to \text{lim}(\mathcal{F}) \to \mathcal{F}(1)$$

exhibits $\mathcal{F}(1)$ as a localization of $\text{holim}(\mathcal{F})$ with respect to $W$. (see Definition 6.3.1.9). Here $1$ denotes the final object of the cone $\mathcal{C} \simeq \mathcal{C} \ast \{1\}$, and the morphism on the left is the comparison map of Remark 5.3.2.9.

**Remark 7.5.8.3.** Let $\mathcal{F} : \mathcal{C} \to \text{Set}_{\Delta}$ be a categorical colimit diagram of simplicial sets. Then $\mathcal{F}$ is also a homotopy colimit diagram of simplicial sets, in the sense of Definition 7.5.7.3. This follows from the observation that every localization of simplicial sets is a weak homotopy equivalence (Remark 6.3.1.16).

**Proposition 7.5.8.4.** Let $\mathcal{C}$ be a category and let $\mathcal{F} : \mathcal{C} \to \text{Set}_{\Delta}$ be a diagram of simplicial sets. The following conditions are equivalent:

1. The diagram $\mathcal{F}$ is a categorical colimit diagram.
2. For every $\infty$-category $\mathcal{D}$, the diagram of $\infty$-categories

$$\left(\mathcal{C}^\circ\right)^{\text{op}} \to \text{QCat} \quad C \mapsto \text{Fun}(\mathcal{F}(C), \mathcal{D})$$

is a categorical limit diagram (Definition 7.5.5.1).
3. For every $\infty$-category $\mathcal{D}$, the diagram of Kan complexes

$$\left(\mathcal{C}^\circ\right)^{\text{op}} \to \text{Kan} \quad C \mapsto \text{Fun}(\mathcal{F}(C), \mathcal{D})^\simeq$$

is a homotopy limit diagram (Definition 7.5.4.1).

**Proof.** The equivalence of (1) and (2) follows by combining Example 7.5.2.9 with Corollary 7.5.5.15. The equivalence with (3) follows by combining the same results with Proposition 6.3.1.13 and Example 7.5.2.6. \qed

**Corollary 7.5.8.5.** Suppose we are given a commutative diagram of simplicial sets

\[ \begin{array}{ccc}
A & \to & A_0 \\
\downarrow & & \downarrow \\
A_1 & \to & A_{01}
\end{array} \]

(7.48)
which we identify with a functor $\mathcal{F} : [1] \times [1] \to \text{Set}_\Delta$. Then (7.48) is a categorical pushout square (in the sense of Definition 4.5.4.1) if and only if $\mathcal{F}$ is a categorical colimit diagram (in the sense of Definition 7.5.8.2).

**Corollary 7.5.8.6** (Homotopy Invariance). Let $\mathcal{C}$ be a category and let $\alpha : \mathcal{F} \to \mathcal{G}$ be a natural transformation between diagrams $\mathcal{F}, \mathcal{G} : \mathcal{C}^\circ \to \text{Set}_\Delta$. Assume that, for every object $C \in \mathcal{C}$, the induced map $\alpha_C : \mathcal{F}(C) \to \mathcal{G}(C)$ is a categorical equivalence of simplicial sets. Then any two of the following conditions imply the third:

1. The functor $\mathcal{F}$ is a categorical colimit diagram.
2. The functor $\mathcal{G}$ is a categorical colimit diagram.
3. The natural transformation $\alpha$ induces a categorical equivalence $\mathcal{F}(1) \to \mathcal{G}(1)$, where $1$ denotes the cone point of $\mathcal{C}^\circ$.

**Proof.** By virtue of Proposition 7.5.8.4 (and Proposition 4.5.3.8), it will suffice to show that for every $\infty$-category $\mathcal{D}$, any two of the following conditions imply the third:

1. $\mathcal{D}$ The functor $(\mathcal{C}^\circ)^{\text{op}} \to \text{QCat}$, $C \mapsto \text{Fun}(\mathcal{F}(C), \mathcal{D})$

   is a categorical limit diagram.

2. $(\mathcal{C}^\circ)^{\text{op}} \to \text{QCat}$, $C \mapsto \text{Fun}(\mathcal{G}(C), \mathcal{D})$

   is a categorical limit diagram.

3. $\mathcal{D}$ The natural transformation $\alpha$ induces an equivalence of $\infty$-categories $\text{Fun}(\mathcal{G}(1), \mathcal{D}) \to \text{Fun}(\mathcal{F}(1), \mathcal{D})$.

This follows from Remark 7.5.5.6.

**Corollary 7.5.8.7.** Let $\mathcal{C}$ be a small category and let $\mathcal{F} : \mathcal{C}^\circ \to \text{Set}_\Delta$ be a colimit diagram in the category of simplicial sets. If the diagram $\mathcal{F} = \mathcal{F}|_{\mathcal{C}}$ is projectively cofibrant, then $\mathcal{F}$ is a categorical colimit diagram.

**Proof.** Let $\mathcal{D}$ be an $\infty$-category and define $\mathcal{G} : (\mathcal{C}^\circ)^{\text{op}} \to \text{QCat}$ by the formula $\mathcal{G}(C) = \text{Fun}(\mathcal{F}(C), \mathcal{D})$. By virtue of Proposition 7.5.8.4, it will suffice to show that the diagram of Kan complexes $\mathcal{G}^\circ$ is a homotopy limit diagram. Setting $\mathcal{G} = \mathcal{F}|_{\mathcal{C}^\circ}$, our assumption that $\mathcal{F}$ is projectively cofibrant guarantees that the diagram $\mathcal{G}$ is isofibrant (Remark 7.5.6.6). It follows that the diagram of Kan complexes $\mathcal{G}^\circ$ is also isofibrant, and that $\mathcal{G}^\circ$ is a limit diagram (Corollary 4.5.6.19). The desired result now follows from Example 7.5.4.2.
Corollary 7.5.8.8. Let $F : C \to \text{Set}_\Delta$ be a diagram of simplicial sets, let $\theta : \text{holim}(F) \to \lim(F)$ be the comparison map of Remark 5.3.2.9, and let $W$ denote the collection of all horizontal edges of the homotopy colimit $\text{holim}(F)$ (Definition 5.3.4.1). If $F$ is projectively cofibrant (Definition 7.5.6.1), then $\theta$ exhibits $\lim(F)$ as a localization of $\text{holim}(F)$ with respect to $W$.

Proof. This is a restatement of Corollary 7.5.8.7.

Corollary 7.5.8.9. Let $C$ be a small category and let $F : C^\circ \to \text{QCat}$ be a diagram of $\infty$-categories. Then $F$ is a categorical colimit diagram (in the sense of Definition 7.5.7.3) if and only if the induced functor of $\infty$-categories $N_{\text{hc}}(F) : N_\bullet(C^\circ) \to N_{\text{hc}}(\text{QCat}) = \text{QC}$ is a colimit diagram (in the sense of Variant 7.1.2.5).

Proof. Combine Proposition 7.5.8.4 with Corollary 7.5.4.6 (applied to the simplicial category $\text{QCat}^{\text{op}}$).

Corollary 7.5.8.10. Let $C$ be a small category and let $F : C^\circ \to \text{Kan}$ be a diagram of Kan complexes. Then $F$ is a categorical colimit diagram if and only if it is a homotopy colimit diagram.

Proof. Combine Corollary 7.5.8.9, Corollary 7.5.7.7, and Proposition 7.4.5.1.

Corollary 7.5.8.11. Let $C$ be a category and let $F : C^\circ \to \text{Set}_\Delta$ be a functor. Let $F^{\text{op}} : C^\circ \to \text{Set}_\Delta$ be the functor given on objects by $F^{\text{op}}(C) = F(C)^{\text{op}}$. Then $F$ is a categorical colimit diagram if and only if $F^{\text{op}}$ is a categorical colimit diagram.

Proof. Combine Proposition 7.5.8.4 with Corollary 7.5.5.15.

We close this section with an application of the formalism of categorical colimit diagrams.

Proposition 7.5.8.12 (Rewriting Colimits). Let $C$ be a small category and let $F : C^\circ \to \text{Set}_\Delta$ be a categorical colimit diagram which carries the final object of $C^\circ$ to a simplicial set $K$. Let $D$ be an $\infty$-category equipped with a diagram $q : K \to D$ satisfying the following condition:

(*) For each object $C \in C$, the composite map $q_C : F(C) \to K \xrightarrow{q} D$ admits a colimit in the $\infty$-category $D$. 

Then there exists a functor $Q : N_{\bullet}(C) \to D$ with the following properties:

1. For each object $C \in \mathcal{C}$, the object $Q(C) \in \mathcal{D}$ is a colimit of the diagram $q_C$.

2. An object $X \in \mathcal{D}$ is a colimit of the diagram $q$ if and only if it is a colimit of $Q$. In particular, the diagram $q$ has a colimit in $\mathcal{D}$ if and only if the diagram $Q$ has a colimit in $\mathcal{D}$.

3. Let $G : \mathcal{D} \to \mathcal{E}$ be a functor of $\infty$-categories which preserves the colimit of each of the diagrams $q_C$, and suppose that the diagrams $q$ and $Q$ admit colimits in $\mathcal{D}$. Then $G$ preserves the colimit of $q$ if and only if it preserves the colimit of $Q$.

Proof. Set $\mathcal{F} = \mathcal{F}|_C$, let $U : \text{holim}(\mathcal{F}) \to N_{\bullet}(C)$ be the projection map, and let $W$ be the collection of all horizontal edges of $\text{holim}(\mathcal{F})$. The diagram $\mathcal{F}$ then determines a morphism of simplicial sets $T : \text{holim}(\mathcal{F}) \to K$ which exhibits $K$ as a localization of $\text{holim}(\mathcal{F})$ with respect to $W$. It follows from assumption ($\ast$) that for each object $C \in \mathcal{C}$, the composite map

$$\mathcal{F}(C) \simeq \{C \times N_{\bullet}(C) \to \text{holim}(\mathcal{F}) \to \text{holim}(\mathcal{F}) \to K \to D$$

admits a colimit in $\mathcal{D}$. Applying Corollary 7.3.5.3, we conclude that there is a functor $Q : N_{\bullet}(C) \to \mathcal{D}$ and a natural transformation $\beta : T \circ q \to Q \circ U$ which exhibits $Q$ as a left Kan extension of $T \circ q$ along $U$. We will complete the proof by showing that $Q$ satisfies conditions (1), (2), and (3) of Proposition 7.5.8.12. Condition (1) follows immediately from Remark 7.3.5.4.

We now prove (2). Assume first that $X \in \mathcal{D}$ is a colimit of the diagram $Q$. For every simplicial set $S$, we let $X_S$ denote the image of $X$ in the $\infty$-category $\text{Fun}(S, \mathcal{D})$. Choose a natural transformation $\alpha : Q \to X_{N_{\bullet}(C)}$ which exhibits $X \in \mathcal{D}$ as a colimit of the diagram $Q$, let $\tilde{\alpha} : Q \circ U \to X_{\text{holim}(\mathcal{F})}$ denote the image of $\alpha$ in $\text{Fun}(\text{holim}(\mathcal{F}), \mathcal{D})$, and let $\tilde{\gamma} : q \circ T \to X_{\text{holim}(\mathcal{F})} = X_K \circ T$ be a composition of $\beta$ with $\tilde{\alpha}$ in $\text{Fun}(\text{holim}(\mathcal{F}), \mathcal{D})$. Since precomposition with $T$ induces a fully faithful functor $\text{Fun}(K, \mathcal{D}) \to \text{Fun}(\text{holim}(\mathcal{F}), \mathcal{D})$, we may assume without loss of generality that $\tilde{\gamma}$ is the image of a natural transformation $\gamma : q \to X_K$. Note that $\tilde{\gamma}$ exhibits $X$ as a colimit of the diagram $q \circ T$ (Corollary 7.3.7.20). Since $T$ is right cofinal (Proposition 7.2.1.9), it follows that $\gamma$ exhibits $X$ as a colimit of the diagram $q$ (Corollary 7.2.2.7).

To prove the reverse implication, it will suffice to show that if the diagram $q : K \to \mathcal{D}$ admits a colimit, then $Q$ also admits a colimit. Since $T$ is right cofinal, the diagram $q \circ T$ also admits a colimit in $\mathcal{D}$ (Corollary 7.2.2.11), so the desired result is immediate from Corollary 7.3.7.20.

We now prove (3). Let $G : \mathcal{D} \to \mathcal{E}$ be a functor of $\infty$-categories which preserves the colimit of the diagram $q_C$, for each object $C \in \mathcal{C}$. Let $\alpha : Q \to X_{N_{\bullet}(C)}$ and $\gamma : q \to X_K$ be
7.5. HOMOTOPY LIMITS AND COLIMITS

defined as above; we wish to show that \(G(\alpha)\) exhibits \(G(X)\) as a colimit of the diagram \(G \circ Q\) if and only if \(G(\gamma)\) exhibits \(G(X)\) as a colimit of the diagram \(G \circ q\). Using Corollary 7.2.2.7 we see that latter condition is equivalent to the requirement that \(G(\tilde{\gamma})\) exhibits \(G(X)\) as a colimit of the diagram \(G \circ q \circ T\). By virtue of Corollary 7.3.7.20, we are reduced to showing that the natural transformation \(G(\beta)\) exhibits \(G \circ Q\) as a left Kan extension of \(G \circ q \circ T\) along \(U\). This follows from the criterion of Remark 7.3.5.4.

**Corollary 7.5.8.13.** Let \(\mathcal{C}\) be a small category and let \(\mathcal{F} : \mathcal{C}^\circ \to \text{Set}_{\Delta}\) be a categorical colimit diagram carrying the final object of \(\mathcal{C}^\circ\) to a simplicial set \(K\). Let \(\mathcal{D}\) be an \(\infty\)-category which admits \(N_\bullet(\mathcal{C})\)-indexed colimits and \(\mathcal{F}(\mathcal{C})\)-indexed colimits, for each object \(\mathcal{C} \in \mathcal{C}\). Then \(\mathcal{D}\) also admits \(K\)-indexed colimits. Moreover, if \(G : \mathcal{D} \to \mathcal{E}\) is a functor of \(\infty\)-categories which preserves \(N_\bullet(\mathcal{C})\)-indexed colimits and \(\mathcal{F}(\mathcal{C})\)-indexed colimits for each \(\mathcal{C} \in \mathcal{C}\), then \(G\) also preserves \(K\)-indexed colimits.

7.5.9 Application: Filtered Colimits of \(\infty\)-Categories

Let \(\mathcal{C}\) be a small filtered category, let \(\mathcal{F} : \mathcal{C} \to \text{Set}_{\Delta}\) be a diagram, and let \(\mathcal{E} = \lim_{\to}(\mathcal{F})\) denote the colimit of \(\mathcal{F}\) in the category of simplicial sets. If each of the simplicial sets \(\mathcal{F}(\mathcal{C})\) is an \(\infty\)-category, then the simplicial set \(\mathcal{E}\) is also an \(\infty\)-category (Remark 1.3.0.9). Our goal in this section is to show that, in this case, we can also regard \(\mathcal{E}\) as a colimit of the diagram \(N_{hc}(\mathcal{F}) : N_\bullet(\mathcal{C}) \to QC\). This is a consequence of the following more general result:

**Proposition 7.5.9.1.** Let \(\mathcal{C}\) be a small filtered category and let \(\mathcal{F} : \mathcal{C}^\circ \to \text{Set}_{\Delta}\) be a colimit diagram in the category of simplicial sets. Then \(\mathcal{F}\) is a categorical colimit diagram.

**Remark 7.5.9.2.** Let \(\mathcal{F} : \mathcal{C} \to \text{Set}_{\Delta}\) be a diagram of simplicial sets and let \(W\) denote the collection of horizontal edges of the homotopy colimit \(\text{holim}(\mathcal{F})\). Proposition 7.5.9.1 asserts that, if the category \(\mathcal{C}\) is filtered, then the comparison map \(\theta : \text{holim}(\mathcal{F}) \to \lim_{\to}(\mathcal{F})\) exhibits \(\lim_{\to}(\mathcal{F})\) as a localization of \(\text{holim}(\mathcal{F})\) with respect to \(W\). In particular, \(\theta\) is a weak homotopy equivalence.

Before giving the proof of Proposition 7.5.9.1, let us record some of its consequences.

**Corollary 7.5.9.3.** Let \(\mathcal{C}\) be a small filtered category. Then the inclusion map

\[
N_\bullet(Q\text{Cat}) \to N_{hc}(Q\text{Cat}) = QC
\]

preserves \(N_\bullet(\mathcal{C})\)-indexed colimits.

**Proof.** We first observe that the full subcategory \(Q\text{Cat} \subseteq \text{Set}_{\Delta}\) is closed under filtered colimits (Remark 1.3.0.9), so the category \(Q\text{Cat}\) admits \(\mathcal{C}\)-indexed colimits. Fix a colimit diagram \(\mathcal{F} : \mathcal{C}^\circ \to Q\text{Cat}\) in the ordinary category \(Q\text{Cat}\). We wish to show that the induced
map $N^\text{hc}(\mathcal{F}) : N_\bullet(C) \to QC$ is a colimit diagram in the $\infty$-category $QC$. By virtue of Corollary 7.5.8.9, this is equivalent to the requirement that $\mathcal{F}$ is a categorical colimit diagram, which follows from Proposition 7.5.9.1.

**Variant 7.5.9.4.** Let $C$ be a small filtered category. Then the inclusion map $N_\bullet(Kan) \hookrightarrow N^\text{hc}_\bullet(Kan) = S$ preserves $N_\bullet(C)$-indexed colimits.

**Corollary 7.5.9.5.** Let $C$ be a small filtered category and let $\mathcal{F} : C \to \text{Set}_\Delta$ be a diagram of simplicial sets having colimit $K = \lim (\mathcal{F})$. Let $D$ be an $\infty$-category which admits $N_\bullet(C)$-indexed colimits and which admits $\mathcal{F}(C)$-indexed colimits, for each $C \in C$. Then $D$ also admits $K$-indexed colimits. Moreover, if $G : D \to E$ is a functor which preserves both $N_\bullet(C)$-indexed colimits and $\mathcal{F}(C)$-indexed colimits for each $C \in C$, then $G$ also preserves $K$-indexed colimits.

**Proof.** Combine Proposition 7.5.9.1 with Corollary 7.5.8.13.

**Corollary 7.5.9.6.** Let $D$ be an $\infty$-category which admits finite colimits and small filtered colimits. Then $D$ admits all small colimits. Moreover, if $G : D \to E$ is a functor of $\infty$-categories which preserves finite colimits and small filtered colimits, then $G$ preserves all small colimits.

**Proof.** This is a special case of Corollary 7.5.9.5, since every small simplicial set $K$ can be realized as a (small) filtered colimit of finite simplicial sets. For example, we can write $K$ as the union of all finite simplicial subsets of itself.

Our proof of Proposition 7.5.9.1 will require a brief digression. Let $C$ be a small category and let $\mathcal{G} : C \to \text{Set}_\Delta$ be a diagram of simplicial sets. In §7.5.6, we showed that there exists a projectively cofibrant diagram $\mathcal{F} : C \to \text{Set}_\Delta$ equipped with a levelwise weak homotopy equivalence $\alpha : \mathcal{F} \to \mathcal{G}$ (Proposition 7.5.6.9). Using a somewhat less explicit construction, we can obtain a better approximation to $\mathcal{G}$:

**Proposition 7.5.9.7.** Let $C$ be a small category and let $\mathcal{G} : C \to \text{Set}_\Delta$ be a diagram of simplicial sets. Then there exists a projectively cofibrant diagram $\mathcal{F} : C \to \text{Set}_\Delta$ and a levelwise trivial Kan fibration $\alpha : \mathcal{F} \to \mathcal{G}$.

**Proof of Proposition 7.5.9.1 from Proposition 7.5.9.7.** Let $C$ be a small filtered category and let $\overline{\mathcal{F}} : C^\circ \to \text{Set}_\Delta$ be a colimit diagram in the category of simplicial sets; we wish to show that $\overline{\mathcal{F}}$ is a categorical colimit diagram. Set $\overline{\mathcal{F}} = \overline{\mathcal{F}}|_C$. Using Proposition 7.5.9.7, we can choose a levelwise categorical equivalence $\alpha : \mathcal{E} \to \overline{\mathcal{F}}$, where $\mathcal{E} : C \to \text{Set}_\Delta$ is projectively cofibrant. Let $\overline{\mathcal{E}} : C^\circ \to \text{Set}_\Delta$ be a colimit diagram extending $\mathcal{E}$, so that $\alpha$ extends uniquely...
to a natural transformation $\overline{\alpha} : \mathcal{E} \rightarrow \mathcal{F}$. Applying Corollary 4.5.7.2, we deduce that $\overline{\alpha}$ is also a levelwise categorical equivalence. Consequently, to show that $\mathcal{F}$ is a categorical colimit diagram, it will suffice to show that $\mathcal{E}$ is a categorical colimit diagram (Corollary 7.5.8.6). This follows from Corollary 7.5.8.7, since $\mathcal{E}$ is projectively cofibrant.

It will be useful to formulate a slightly stronger version of Proposition 7.5.9.7. First, we need some terminology.

**Definition 7.5.9.8.** Let $\mathcal{C}$ be a small category and let $\alpha : \mathcal{F}' \rightarrow \mathcal{F}$ be a natural transformation between diagrams $\mathcal{F}, \mathcal{F}' : \mathcal{C} \rightarrow \text{Set}_\Delta$. We say that $\alpha$ is a projective cofibration if it has the left lifting property with respect to all levelwise trivial Kan fibrations (see Remark 4.5.6.2). That is, $\alpha$ is a projective cofibration if every lifting problem

![Diagram](https://via.placeholder.com/150)

admits a solution, under the assumption that $\beta$ is a levelwise trivial Kan fibration between diagrams $\mathcal{G}, \mathcal{G}' : \mathcal{C} \rightarrow \text{Set}_\Delta$.

**Example 7.5.9.9.** Let $\mathcal{C}$ be a small category. Then a diagram of simplicial sets $\mathcal{F} : \mathcal{C} \rightarrow \text{Set}_\Delta$ is projectively cofibrant (in the sense of Definition 7.5.6.1) if and only if the unique natural transformation $\emptyset \rightarrow \mathcal{F}$ is a projective cofibration (in the sense of Definition 7.5.9.8). Here $\emptyset : \mathcal{C} \rightarrow \text{Set}_\Delta$ denotes the initial object of the category $\text{Fun}(\mathcal{C}, \text{Set}_\Delta)$, which carries every object of $\mathcal{C}$ to the empty simplicial set.

**Example 7.5.9.10.** Let $\mathcal{C}$ be a small category. For each object $C \in \mathcal{C}$, let $h^C : \mathcal{C} \rightarrow \text{Set}$ denote the functor corepresented by $C$ (given on objects by the formula $h^C(D) = \text{Hom}_\mathcal{C}(C, D)$). If $A \hookrightarrow B$ is a monomorphism of simplicial sets, then the natural transformation $A \times h^C \hookrightarrow B \times h^C$ is a projective cofibration in $\text{Fun}(\mathcal{C}, \text{Set}_\Delta)$; here $A$ and $B$ denote the constant simplicial sets taking the values $A$ and $B$, respectively.

**Remark 7.5.9.11.** Let $\mathcal{C}$ be a small category. Then the collection of projective cofibrations in $\text{Fun}(\mathcal{C}, \text{Set}_\Delta)$ is weakly saturated, in the sense of Definition 1.4.4.15. That is, it is closed under retracts, pushouts, and transfinite composition. See Proposition 1.4.4.16.

**Proposition 7.5.9.12.** Let $\mathcal{C}$ be a small category and let $\alpha_0 : \mathcal{F}_0 \rightarrow \mathcal{G}$ be a natural transformation between diagrams $\mathcal{F}_0, \mathcal{G} : \mathcal{C} \rightarrow \text{Set}_\Delta$. Then $\alpha_0$ factors as a composition

$$\mathcal{F}_0 \xrightarrow{\beta} \mathcal{F} \xrightarrow{\alpha} \mathcal{G},$$

where $\beta$ is a projective cofibration and $\alpha$ is a levelwise trivial Kan fibration.
Proof. We will construct $F$ as the colimit of a diagram of projective cofibrations
\[ F_0 \to F_1 \to F_2 \to F_3 \to \cdots \]
in the category $\text{Fun}(C, \text{Set}_{\Delta})_{/f}$. Fix $n \geq 0$, and suppose that we have constructed an object $F_n \in \text{Fun}(C, \text{Set}_{\Delta})_{/f}$, which we identify with a natural transformation $\alpha_n : F_n \to \mathcal{G}$. For each object $C \in C$, Exercise 3.1.7.10 guarantees that $\alpha_{n,C}$ factors as a composition
\[ F_n(C) \xrightarrow{\alpha'_{n,C}} F'_n(C) \xrightarrow{\alpha''_{n,C}} \mathcal{G}(C), \]
where $\alpha'_{n,C}$ is a monomorphism and $\alpha''_{n,C}$ is a trivial Kan fibration (beware that $F'_n(C)$ does not depend functorially on $C$). Form a pushout diagram
\[
\begin{array}{ccc}
\coprod_{C \in C} F_n(C) \times h^C & \xrightarrow{} & \coprod_{C \in C} F'_n(C) \times h^C \\
\downarrow & & \downarrow \\
F_n & \rightarrow & F_{n+1}
\end{array}
\]
in the category $\text{Fun}(C, \text{Set}_{\Delta})_{/f}$, where the upper horizontal map is the coproduct of the projective cofibrations described in Example 7.5.9.10. Using Remark 7.5.9.11, we see that each of the maps
\[ F_0 \to F_1 \to F_2 \to F_3 \to \cdots \]
is a projective cofibration. Setting $F = \lim_{\rightarrow n} F_n$, we obtain a factorization of $\alpha_0$ as a composition $F_0 \xrightarrow{\beta} F \xrightarrow{\alpha} \mathcal{G}$, where $\beta$ is a projective cofibration. We complete the proof by observing that for each object $C \in \mathcal{C}$, the morphism $\alpha_C : F(C) \to \mathcal{G}(C)$ is a trivial Kan fibration, since it can be written as a filtered colimit (in the arrow category $\text{Fun}([1], \text{Set}_{\Delta})$) of the trivial cofibrations $\alpha''_{n,C} : F'_n(C) \to \mathcal{G}(C)$ (see Remark 1.4.5.3).

Proof of Proposition 7.5.9.7. Apply Proposition 7.5.9.12 in the special case $F_0 = \emptyset$ (see Example 7.5.9.9).

Corollary 7.5.9.13. Let $C$ be a small category, and let $S$ be the collection of all projective cofibrations in the category $\text{Fun}(C, \text{Set}_{\Delta})$. Then $S$ is the smallest weakly saturated collection of morphisms which contains each of the inclusion maps $\iota_{n,C} : \partial \Delta^n \times h^C \hookrightarrow \Delta^n \times h^C$, for each $n \geq 0$ and each object $C \in \mathcal{C}$.

Proof. It follows from Remark 7.5.9.11 that $S$ is weakly saturated. Let $S'$ be the smallest weakly saturated collection of morphisms of $\text{Fun}(C, \text{Set}_{\Delta})$ which contains each $\iota_{n,C}$. Using Example 7.5.9.10, we see that $S'$ is contained in $S$. For every monomorphism of simplicial
sets $A \hookrightarrow B$ and every object $C \in C$, Proposition 1.4.5.13 guarantees that the projective cofibration $A \times h^C \hookrightarrow B \times h^C$ is contained in $S'$. It follows from the proof of Proposition 7.5.9.12 that every morphism $\alpha_0 : \mathcal{F}_0 \to \mathcal{G}$ in $\text{Fun}(C, \text{Set}_\Delta)$ factors as a composition $\mathcal{F}_0 \xrightarrow{\beta} \mathcal{F} \xrightarrow{\alpha} \mathcal{G}$, where $\beta$ belongs to $S'$ and $\alpha$ is a trivial Kan fibration. If $\alpha_0$ is projective cofibration, then the lifting problem

admits a solution. It follows that $\alpha_0$ is a retract of the morphism $\beta$, and therefore belongs to $S'$.

### 7.6 Examples of Limits and Colimits

Let $C$ be an $\infty$-category. In §7.1 we introduced the notion of limit and colimit for an arbitrary morphism of simplicial sets $\sigma : K \to C$. Our goal in this section is to make the general theory more explicit for some special classes of diagrams which arise frequently in practice.

We begin in §7.6.1 by considering the case where $K$ is a discrete simplicial set. In this case, specifying a functor $\sigma : K \to C$ is equivalent to specifying a collection of objects $\{Y_k \in C\}_{k \in K}$, indexed by the collection of vertices of $K$. We say that an object of $C$ is a product of the collection $\{Y_k\}_{k \in K}$ if it is a limit of the diagram $\sigma$, and a coproduct of the collection $\{Y_k\}_{k \in K}$ if it is a colimit of the diagram $\sigma$. These conditions can be formulated purely in terms of the homotopy category $hC$, provided that we regard $hC$ as enriched over the homotopy category of Kan complexes $h\text{Kan}$ (see Remark 7.6.1.5). In particular, the forgetful functor from $C$ to (the nerve of) its homotopy category $hC$ preserves products and coproducts (Warning 7.6.1.2).

In §7.6.2, we allow $K$ to be an arbitrary simplicial set, but require $\sigma : K \to C$ to be a constant diagram taking some value $Y \in C$. In this case, we will denote a limit of $\sigma$ (if it exists) by $Y^K$ and a colimit of $\sigma$ (if it exists) by $K \otimes Y$ (Notation 7.6.2.5). We refer to $Y^K$ as a power of $Y$ by $K$, and $K \otimes Y$ as a tensor product of $Y$ by $K$. These notions can again be formulated purely at the level of the homotopy category $hC$, regarded as an $h\text{Kan}$-enriched category (Definition 7.6.2.1 and Remark 7.6.2.6).

In §7.6.3, we study limit and colimit diagrams indexed by the simplicial set $K = \Delta^1 \times \Delta^1$. 
Let $\sigma : \Delta^1 \times \Delta^1 \to C$ be a functor of $\infty$-categories, which we depict as a diagram

$$
\begin{array}{ccc}
X_{01} & \longrightarrow & X_0 \\
\downarrow & & \downarrow f_0 \\
X_1 & \longrightarrow & X,
\end{array}
$$

We say that $\sigma$ is a pullback square if it is a limit diagram, and a pushout square if it is a colimit diagram (Definition 7.6.3.1). Beware that these conditions cannot be formulated at the level of the homotopy category $hC$, even if its $h$Kan-enrichment is accounted for: see Warning 7.6.3.3 Example 7.6.3.4.

It follows from Proposition 7.5.4.13 that a (strictly commutative) diagram of Kan complexes

$$
\begin{array}{ccc}
X_{01} & \longrightarrow & X_0 \\
\downarrow & & \downarrow \\
X_1 & \longrightarrow & X
\end{array}
$$

determines a pullback square in the $\infty$-category $S$ if and only if it is a homotopy pullback square. However, not every pullback square in the $\infty$-category $S$ arises in this way. In §7.6.4 we give a detailed classification of all pullback squares in the $\infty$-category $S$ (Corollary 7.6.4.10). In particular, for every pair of morphisms of Kan complexes $f_0 : X_0 \to X$ and $f_1 : X_1 \to X$, we construct a pullback diagram

$$
\begin{array}{ccc}
X_0 \times_X X_1 & \longrightarrow & X_0 \\
\downarrow & & \downarrow f_0 \\
X_1 & \longrightarrow & X \\
& & \downarrow f_1
\end{array}
$$

in the $\infty$-category $S$ (Example 7.6.4.11); beware that this diagram usually does not commute in the ordinary category of simplicial sets. Our analysis can be applied more generally to any $\infty$-category which arises as the homotopy coherent nerve of a locally Kan simplicial category (Corollary 7.6.4.12); in particular, it can be applied to the $\infty$-category $\mathcal{C} = QC$ of small $\infty$-categories (see Proposition 7.6.4.8 and Corollary 7.6.4.9).

Let $(\bullet \Rightarrow \bullet)$ denote the simplicial set given by the coproduct $\Delta^1 \coprod_{\partial \Delta^1} \Delta^1$ (Notation 7.6.5.1). In §7.6.5 we study limits and colimits of diagrams indexed by $(\bullet \Rightarrow \bullet)$. For any $\infty$-category $\mathcal{C}$, functors $\sigma : (\bullet \Rightarrow \bullet) \to \mathcal{C}$ can be identified with pairs $f_0, f_1 : Y \to X$ of
morphisms in $C$ having the same source and target. In this case, we denote a limit of $\sigma$ (if it exists) by $\text{Eq}(f_0, f_1)$, and a colimit of $\sigma$ (if it exists) by $\text{Coeq}(f_0, f_1)$ (Notation 7.6.5.5). We refer to $\text{Eq}(f_0, f_1)$ as an equalizer of the pair $(f_0, f_1)$, and to $\text{Coeq}(f_0, f_1)$ as a coequalizer of $(f_0, f_1)$ (Definition 7.6.5.4). Beware that, as with pullbacks and pushouts, the notions of equalizer and coequalizer cannot be formulated purely in terms of the homotopy category $hC$; in particular, the forgetful functor from $C$ to (the nerve of) its homotopy category need not preserve equalizers and coequalizers.

Let $\mathbb{Z}_{\geq 0}$ denote the set of nonnegative integers, endowed with its usual linear ordering. In §7.6.6, we study colimits of diagram $X : N_\bullet(\mathbb{Z}_{\geq 0}) \to C$, which we represent informally as

$$X(0) \overset{f_0}{\longrightarrow} X(1) \overset{f_1}{\longrightarrow} X(2) \overset{f_2}{\longrightarrow} X(3) \overset{f_3}{\longrightarrow} X(4) \to \cdots$$

In the special case where $C = S$ is the $\infty$-category of spaces, we show that the colimit $\varinjlim X(n)$ (formed in the ordinary category of simplicial sets, using the transition morphisms $f_i$) is also a colimit in the $\infty$-category $S$ (Variant 7.6.6.9). Similarly, if $Y : N_\bullet(\mathbb{Z}_{\geq 0}) \to S$ is a diagram which we depict informally as

$$\cdots \to Y(4) \overset{g_3}{\longrightarrow} Y(3) \overset{g_2}{\longrightarrow} Y(2) \overset{g_1}{\longrightarrow} Y(1) \overset{g_0}{\longrightarrow} Y(0),$$

then the usual inverse limit $\varprojlim Y(n)$ (formed in the category of simplicial sets, using the transition morphisms $g_n$) is also a limit in the $\infty$-category $S$, provided that each of the maps $g_n$ is a Kan fibration (Variant 7.6.6.11). These assertions have counterparts for sequential limits and colimits in the $\infty$-category $\mathcal{QC}$: see Examples 7.6.6.8 and 7.6.6.10.

Though the classes of diagrams we study in this section are of a very restricted type, they are nonetheless useful for analyzing limits and colimits in general. If $K$ is a complicated simplicial set which can be decomposed into simpler constituents, then we can often use Proposition 7.5.8.12 to reduce questions about $K$-indexed (co)limits to questions about (co)limits indexed by those constituents. We will consider several variants on this theme:

- If a simplicial set $K$ decomposes as a disjoint union $\coprod_{j \in J} K_j$, then we can often rewrite $K$-indexed limits as products; see Proposition 7.6.1.17.

- If a simplicial set $K$ fits into a categorical pushout diagram

$$\begin{tikzcd}
K_0 \arrow{r} & K_0 \\
K_1 \arrow{r} \arrow{u} & K \arrow{u}
\end{tikzcd}$$

then we can often rewrite $K$-indexed limits as pullbacks; see Proposition 7.6.3.17.
• If \( C \) is an \( \infty \)-category which admits finite products, then an equalizer of a pair of morphisms \( f_0, f_1 : Y \to X \) (if it exists) is characterized by the existence of a pullback diagram

\[
\begin{array}{ccc}
\text{Eq}(f_0, f_1) & \rightarrow & Y \\
\downarrow & & \downarrow (f_0, f_1) \\
X & \xrightarrow{\delta_X} & X \times X;
\end{array}
\]

see Proposition \ref{7.6.5.22}.

• If \( C \) is an \( \infty \)-category which admits finite products, then a pullback of a diagram \( X_0 \xrightarrow{f_0} X \leftarrow X_1 \) can be rewritten as the equalizer of a diagram \( X_0 \times X_1 \to X \) (Proposition \ref{7.6.5.23}).

• If \( C \) is an \( \infty \)-category which admits countable products, then the limit of a tower

\[
\cdots \to X(3) \xrightarrow{f_3} X(2) \xrightarrow{f_2} X(1) \xrightarrow{f_1} X(0)
\]

can be rewritten as an equalizer \( \text{Eq}(f, \text{id}_X) \), where \( X \) is the product \( \prod_{n \geq 0} X(n) \) and \( f : X \to X \) is the endomorphism of \( X \) determined by the sequence \( \{f_n\}_{n \geq 0} \); see Proposition \ref{7.6.6.16}.

• If \( K \) is a simplicial set which can be written as the colimit of a sequence \( K(0) \to K(1) \to K(2) \to K(3) \to \cdots \),

then we can often rewrite \( K \)-indexed limits as sequential limits (Corollary \ref{7.6.6.14}).

By applying these observations iteratively, one can build arbitrarily complicated limits (and colimits) out of the constructions studied in this section. For example, we show that an \( \infty \)-category \( C \) admits finite limits if and only if it admits pullbacks and has a final object (Corollary \ref{7.6.3.18}).

### 7.6.1 Products and Coproducts

We now study limits and colimits of diagrams which are indexed by discrete simplicial sets. In this case, the definitions of limit and colimit can be formulated entirely at the level of the (enriched) homotopy category.

**Definition 7.6.1.1.** Let \( \text{hKan} \) denote the homotopy category of Kan complexes and let \( C \) be an \( \text{hKan} \)-enriched category. We say that a collection of morphisms \( \{q_i : Y \to Y_i\}_{i \in I} \) of \( C \)
7.6. EXAMPLES OF LIMITS AND COLIMITS

exhibits \( Y \) as an hKan-enriched product of the collection \( \{Y_i\}_{i \in I} \) if, for every object \( X \in \mathcal{C} \), the collection of maps \( \text{Hom}_\mathcal{C}(X, Y) \xrightarrow{q_i} \text{Hom}_\mathcal{C}(X, Y_i) \) induces an isomorphism

\[
\text{Hom}_\mathcal{C}(X, Y) \to \prod_{i \in I} \text{Hom}_\mathcal{C}(X, Y_i)
\]

in the homotopy category hKan.

We say that a collection of morphisms \( \{e_i : Y_i \to Y\}_{i \in I} \) exhibits \( Y \) as an hKan-enriched coproduct of the collection \( \{Y_i\}_{i \in I} \) if, for every object \( Z \in \mathcal{C} \), the collection of maps \( \text{Hom}_\mathcal{C}(Y, Z) \xrightarrow{e_i} \text{Hom}_\mathcal{C}(Y_i, Z) \) induces an isomorphism

\[
\text{Hom}_\mathcal{C}(X, Y) \to \prod_{i \in I} \text{Hom}_\mathcal{C}(X, Y_i)
\]

**Warning 7.6.1.2.** Let \( \mathcal{C} \) be an hKan-enriched category, and let \( \{q_i : Y \to Y_i\}_{i \in I} \) be a collection of morphisms in \( \mathcal{C} \). If \( \{q_i\}_{i \in I} \) exhibits \( Y \) as an hKan-enriched product of \( \{Y_i\}_{i \in I} \), then it also exhibits \( Y \) as a product of the collection \( \{Y_i\}_{i \in I} \) in the underlying category \( \mathcal{C} \) (where we neglect its hKan-enrichment). Beware that the converse is false in general (see Warning 7.6.1.11).

**Definition 7.6.1.3.** Let \( \mathcal{C} \) be an \( \infty \)-category. We say that a collection of morphisms \( \{q_i : Y \to Y_i\}_{i \in I} \) in \( \mathcal{C} \) exhibits \( Y \) as a product of the collection \( \{Y_i\}_{i \in I} \) if the collection of homotopy classes \( \{[q_i] : Y \to Y_i\}_{i \in I} \) exhibits \( Y \) as an hKan-enriched product \( \{Y_i\}_{i \in I} \) in the homotopy category h\( \mathcal{C} \) (equipped with the hKan-enrichment described in Construction 4.6.8.13). In other words, the collection of morphisms \( \{q_i\}_{i \in I} \) exhibits \( Y \) as a product of the collection of objects \( \{Y_i\}_{i \in I} \) if, for every object \( X \in \mathcal{C} \), the induced map

\[
\text{Hom}_\mathcal{C}(X, Y) \to \prod_{i \in I} \text{Hom}_\mathcal{C}(X, Y_i)
\]

is a homotopy equivalence of Kan complexes. Similarly, we say that a collection of morphisms \( \{e_i : Y_i \to Y\}_{i \in I} \) of \( \mathcal{C} \) exhibits \( Y \) as a coproduct of the collection \( \{Y_i\}_{i \in I} \) if, for every object \( Z \in \mathcal{C} \), the induced map

\[
\text{Hom}_\mathcal{C}(Y, Z) \to \prod_{i \in I} \text{Hom}_\mathcal{C}(Y_i, Z)
\]

is a homotopy equivalence of Kan complexes.

**Remark 7.6.1.4.** Let \( \{f_i : Y \to Y_i\}_{i \in I} \) be a collection of morphisms in an \( \infty \)-category \( \mathcal{C} \). Then the collection \( \{q_i\}_{i \in I} \) exhibits \( Y \) as a product of the collection \( \{Y_i\}_{i \in I} \) in the category \( \mathcal{C} \) if and only if it exhibits \( Y \) as a coproduct of the collection \( \{Y_i\}_{i \in I} \) in the opposite \( \infty \)-category \( \mathcal{C}^{\text{op}} \).
Remark 7.6.1.5. Let $\mathcal{C}$ be an $\infty$-category and let $\{Y_i\}_{i \in I}$ be a collection of objects of $\mathcal{C}$, which we will identify with a diagram

$$F : I \to \mathcal{C} \quad F(i) = Y_i$$

indexed by the constant simplicial set associated to $I$ (Remark 1.1.4.3). Suppose we are given another object $Y \in \mathcal{C}$ together with a collection of morphisms $\{q_i : Y \to Y_i\}_{i \in I}$. The following conditions are equivalent:

1. The collection of morphisms $\{q_i\}_{i \in I}$ exhibits $Y$ as a product of the collection $\{Y_i\}_{i \in I}$, in the sense of Definition 7.6.1.3.

2. Let $Y : I \to \mathcal{C}$ denote the constant diagram taking the value $Y$, so that the collection $\{q_i\}_{i \in I}$ can be identified with a natural transformation $q : Y \to F$. Then $q$ exhibits $Y$ as a limit of the diagram $F$, in the sense of Definition 7.1.1.1.

3. Let $F : I^a \to \mathcal{C}$ be the diagram carrying each edge $\{i\}^a \subseteq I^a$ to the morphism $q_i$. Then $F$ is a limit diagram in $\mathcal{C}$, in the sense of Definition 7.1.2.4.

The equivalence (1) $\iff$ (2) is immediate from the definitions (see Remark 4.6.1.8) and the equivalence (2) $\iff$ (3) follows from Remark 7.1.2.6.

Remark 7.6.1.6. Let $\mathcal{C}$ be an ordinary category, and let $\{q_i : Y \to Y_i\}_{i \in I}$ be a collection of morphisms in $\mathcal{C}$. Then $\{q_i\}_{i \in I}$ exhibits $Y$ as a product of the collection $\{Y_i\}_{i \in I}$ in the category $\mathcal{C}$ (in the sense of classical category theory) if and only if it exhibits $Y$ as a product of the collection $\{Y_i\}_{i \in I}$ in the $\infty$-category $\mathcal{N}_\bullet(\mathcal{C})$ (in the sense of Definition 7.6.1.3).

Notation 7.6.1.7. Let $\mathcal{C}$ be an $\infty$-category and let $\{Y_i\}_{i \in I}$ be a collection of objects of $\mathcal{C}$. We will say that an object $Y \in \mathcal{C}$ is a product of the collection $\{Y_i\}_{i \in I}$ if there exists a collection of morphisms $\{q_i : Y \to Y_i\}$ which exhibits $Y$ as a product of the collection $\{Y_i\}_{i \in I}$. If this condition is satisfied, then the object $Y$ is uniquely determined up to isomorphism (see Proposition 7.1.1.12). To emphasize this uniqueness, we will sometimes denote the object $Y$ by $\prod_{i \in I} Y_i$, and refer to it as the product of the collection $\{Y_i\}_{i \in I}$. Similarly, we say that $Y$ is a coproduct of the collection $\{Y_i\}_{i \in I}$ if there exists a collection of morphisms $\{e_i : Y_i \to Y\}_{i \in I}$ which exhibits $Y$ as a coproduct of $\{Y_i\}_{i \in I}$. In this case, we sometimes denote the object $Y$ by $\coprod_{i \in I} Y_i$ and refer to it as the coproduct of the collection $\{Y_i\}_{i \in I}$.

Example 7.6.1.8 (Initial and Final Objects). Let $\mathcal{C}$ be an $\infty$-category. An object $Y \in \mathcal{C}$ is initial (in the sense of Definition 4.6.6.1) if and only if it is the coproduct of the empty collection of objects of $\mathcal{C}$ (see Example 7.1.1.6). Similarly, $Y$ is final if and only if it is a product of the empty collection of objects.

Example 7.6.1.9 (Isomorphisms). Let $f : X \to Y$ be a morphism in an $\infty$-category $\mathcal{C}$. The following conditions are equivalent:
(1) The morphism $f$ is an isomorphism.

(2) The morphism $f$ exhibits $X$ as a product of the one-element collection of objects $\{Y\}$.

(3) The morphism $f$ exhibits $Y$ as a coproduct of the one-element collection of objects $\{X\}$.

**Notation 7.6.1.10.** In practice, we will use Definition 7.6.1.3 most often in the case where the set $I$ has exactly two elements, so that the collection $\{Y_i\}_{i \in I}$ can be identified with an ordered pair $(Y_0, Y_1)$ of objects of $C$. In this case, we say that morphisms $q_0 : Y \to Y_0$ and $q_1 : Y \to Y_1$ exhibit $Y$ as a product of $Y_0$ with $Y_1$ if they satisfy the requirement of Definition 7.6.1.3; that is, for every object $X \in C$, the induced map

$$\text{Hom}_C(X, Y) \to \text{Hom}_C(X, Y_0) \times \text{Hom}_C(X, Y_1)$$

is a homotopy equivalence. If this condition is satisfied, then we will often denote the object $Y$ by $Y_0 \times Y_1$ and refer to it as the product of $Y_0$ with $Y_1$. Similarly, we say that a pair of morphisms $e_0 : Y_0 \to Y$ and $e_1 : Y_1 \to Y$ exhibit $Y$ as a coproduct of $Y_0$ with $Y_1$ if, for every object $Z \in C$, the induced map

$$\text{Hom}_C(Y, Z) \to \text{Hom}_C(Y_0, Z) \times \text{Hom}_C(Y_1, Z)$$

is a homotopy equivalence; in this case, we denote $Y$ by $Y_0 \coprod Y_1$ and refer to it as the coproduct of $Y_0$ with $Y_1$.

**Warning 7.6.1.11.** Let $C$ be an $\infty$-category. If $\{q_i : Y \to Y_i\}_{i \in I}$ is a collection of morphisms of $C$ which exhibits $Y$ as a product of the collection of objects $\{Y_i\}_{i \in I}$ in the $\infty$-category $C$, then the collection of homotopy classes $\{[q_i] : Y \to Y_i\}_{i \in I}$ exhibits $Y$ as a product of the collection $\{Y_i\}_{i \in I}$ in the ordinary category $\text{h}C$. The converse holds if the collection $\{Y_i\}_{i \in I}$ admits a products in the $\infty$-category $C$. However, the converse need not hold in general, even in the special case where the set $I$ is empty: see Warning 4.6.6.19.

**Example 7.6.1.12** (Homotopy Products). Let $C$ be a locally Kan simplicial category, and let $\{q_i : Y \to Y_i\}_{i \in I}$ be a collection of morphisms in $C$. By virtue of Theorem 4.6.7.5 (and Proposition 4.6.8.19), the following conditions are equivalent:

1. The morphisms $q_i$ exhibit $Y$ as a product of the collection $\{Y_i\}_{i \in I}$ in the $\infty$-category $N^\text{hc}(C)$.

2. For every object $X \in C$, composition with the morphisms $q_i$ determines a homotopy equivalence of Kan complexes

$$\text{Hom}_C(X, Y) \to \prod_{i \in I} \text{Hom}_C(X, Y_i)$$
Example 7.6.1.13 (Products in \(\mathcal{S}\)). Let \(\{Y_i\}_{i \in I}\) be a collection of Kan complexes and let \(Y = \prod_{i \in I} Y_i\) denote their product, formed in the ordinary category of simplicial sets. For each \(i \in I\), let \(q_i : Y \to Y_i\) denote the projection map. Applying Example 7.6.1.12 to the simplicial category category Kan, we deduce that the morphisms \(q_i\) also exhibit \(Y\) as a product of the collection \(\{Y_i\}_{i \in I}\) in the \(\infty\)-category of spaces \(\mathcal{S} = \mathcal{N}^{hc}(\text{Kan})\). Similarly, if \(Y' = \coprod_{i \in I} Y_i\) is the coproduct of the collection \(\{Y_i\}_{i \in I}\) in the ordinary category of simplicial sets, then the inclusion maps \(Y_i \to Y'\) exhibit \(Y'\) as a coproduct of \(\{Y_i\}_{i \in I}\) in the \(\infty\)-category \(\mathcal{S}\).

Example 7.6.1.14 (Products in \(\mathcal{QC}\)). Let \(\{C_i\}_{i \in I}\) be a collection of \(\infty\)-categories and let \(C = \prod_{i \in I} C_i\) denote their product, formed in the ordinary category of simplicial sets. For each \(i \in I\), let \(q_i : C \to C_i\) denote the projection map. Applying Example 7.6.1.12 to the simplicial category \(\mathcal{QC}\) (see Construction 5.6.4.1), we deduce that the morphisms \(q_i\) also exhibit \(C\) as a product of the collection \(\{C_i\}_{i \in I}\) in the \(\infty\)-category \(\mathcal{QC} = \mathcal{N}^{hc}(\mathcal{QC})\) (this is a special case of the diffraction criterion of Theorem 7.4.1.1). Similarly, if \(C' = \coprod_{i \in I} C_i\) is the coproduct of the collection \(\{C_i\}_{i \in I}\) in the ordinary category of simplicial sets, then the inclusion maps \(C_i \to C'\) exhibit \(C'\) as a coproduct of \(\{C_i\}_{i \in I}\) in the \(\infty\)-category \(\mathcal{QC}\) (this is a special case of the refraction criterion of Theorem 7.4.3.6).

Example 7.6.1.15 (Products in a Duskin Nerve). Let \(\mathcal{C}\) be a \((2,1)\)-category and let \(\{q_i : Y \to Y_i\}\) be a collection of 1-morphisms in \(\mathcal{C}\). Then the following conditions are equivalent:

1. The morphisms \(q_i\) exhibit \(Y\) as a product of the collection \(\{Y_i\}_{i \in I}\) in the \(\infty\)-category \(\mathcal{N}^D(\mathcal{C})\).

2. For every object \(X \in \mathcal{C}\), horizontal composition with the 1-morphisms \(q_i\) induces an equivalence of categories

\[
\text{Hom}_\mathcal{C}(X, Y) \to \prod_{i \in I} \text{Hom}_\mathcal{C}(X, Y_i).
\]

This follows from the explicit description of pinched morphism spaces in \(\mathcal{N}^D(\mathcal{C})\) supplied by Example 4.6.5.12.

Example 7.6.1.16 (Products in a Differential Graded Nerve). Let \(\mathcal{C}\) be a differential graded category and let \(\{q_i : Y \to Y_i\}\) be a collection of morphisms in the underlying category of \(\mathcal{C}\) (that is, each \(q_i\) is a 0-cycle of the chain complex \(\text{Hom}_\mathcal{C}(Y, Y_i)_*\)). Using Example 4.6.5.14 (together with Exercise 3.2.2.18), we see that the following conditions are equivalent:

1. The morphisms \(q_i\) exhibit \(Y\) as a product of the collection \(\{Y_i\}_{i \in I}\) in the \(\infty\)-category \(\mathcal{N}^\text{dg}(\mathcal{C})\).
7.6. EXAMPLES OF LIMITS AND COLIMITS

(2) For every object \( X \in C \), the map of chain complexes

\[
\text{Hom}_C(X,Y)_* \to \prod_{i \in I} \text{Hom}_C(X,Y_i)_*
\]

induces an isomorphism on homology in degrees \( \geq 0 \).

**Proposition 7.6.1.17** (Rewriting Limits as Products). Let \( C \) be an \( \infty \)-category, and let \( \{ f_i : K_i \to C \}_{i \in I} \) be a collection of diagrams, each of which admits a limit \( X_i = \lim_{\leftarrow} f_i \). Set \( K = \coprod_{i \in I} K_i \), so that the collection \( \{ f_i \}_{i \in I} \) determines a diagram \( f : K \to C \). Then an object of \( C \) is a limit of the diagram \( f \) if it is a product of the collection of objects \( \{ X_i \}_{i \in I} \).

**Proof.** This is a special case of (the dual of) Proposition 7.5.8.12. \( \square \)

**Remark 7.6.1.18.** In the situation of Proposition 7.6.1.17, let \( F : C \to D \) be a functor which preserves the limits of each of the diagrams \( f_i \). Suppose that the collection \( \{ X_i \}_{i \in I} \) admits a product in \( C \). Then the product of \( \{ X_i \}_{i \in I} \) is preserved by the functor \( F \) if and only if the limit of \( f \) is preserved by the functor \( F \).

**Corollary 7.6.1.19.** Let \( \{ K_i \}_{i \in I} \) be a collection of simplicial sets having coproduct \( K = \coprod_{i \in I} K_i \), and let \( C \) be an \( \infty \)-category. Suppose that \( C \) admits \( I \)-indexed products and \( K_i \)-indexed limits for each \( i \in I \). Then \( C \) admits \( K \)-indexed limits. Moreover, if \( F : C \to D \) is a functor which preserves \( I \)-indexed products and \( K_i \)-indexed colimits for each \( i \in I \), then \( F \) also preserves \( K \)-indexed limits.

**Corollary 7.6.1.20.** Let \( C \) be an \( \infty \)-category. Then \( C \) admits finite products if and only if it satisfies the following pair of conditions:

1. The \( \infty \)-category \( C \) has a final object \( 1 \).
2. The \( \infty \)-category \( C \) admits pairwise products. That is, every pair of objects \( X,Y \in C \) have a product \( X \times Y \) in \( C \).

**Proof.** The necessity of conditions (1) and (2) is clear (see Example 7.6.1.8). Conversely, suppose that (1) and (2) are satisfied, and let \( I \) be a finite set. We wish to show that \( C \) admits \( I \)-indexed limits. We proceed by induction on the cardinality of \( I \). If \( I \) is empty, then the desired result follows from assumption (1). If \( I \) is a singleton, then the desired result is obvious (see Example 7.6.1.9). Otherwise, we can write \( I \) as a disjoint union of proper subsets \( I_-, I_+ \subset I \). Our inductive hypothesis then guarantees that \( C \) admits \( I_- \)-indexed limits and \( I_+ \)-indexed limits. Combining assumption (2) with Corollary 7.6.1.19, we deduce that \( C \) admits limits indexed by \( I = I_- \coprod I_+ \). \( \square \)

**Remark 7.6.1.21.** Let \( F : C \to D \) be a functor of \( \infty \)-categories, where \( C \) admits finite products. Then \( F \) preserves finite products if and only if it preserves final objects and pairwise products.
7.6.2 Powers and Tensors

We now study limits and colimits which are indexed by constant diagrams of simplicial sets. Like products and coproducts, these can be characterized by universal properties in the (enriched) homotopy category.

**Definition 7.6.2.1.** Let \( \mathcal{C} \) be an \( \infty \)-category containing a pair of objects \( X \) and \( Y \), and let \( e : K \to \text{Hom}_\mathcal{C}(X, Y) \) be a morphism of simplicial sets. We will say that \( e \) exhibits \( X \) as a power of \( Y \) by \( K \) if, for every object \( W \in \mathcal{C} \), the composition law \( \circ : \text{Hom}_\mathcal{C}(X, Y) \times \text{Hom}_\mathcal{C}(W, X) \to \text{Hom}_\mathcal{C}(W, Y) \) of Construction 4.6.8.9 induces a homotopy equivalence of Kan complexes \( \text{Hom}_\mathcal{C}(W, X) \to \text{Fun}(K, \text{Hom}_\mathcal{C}(W, Y)) \).

We will say that \( e \) exhibits \( Y \) as a tensor product of \( X \) by \( K \) if, for every object \( Z \in \mathcal{C} \), the composition law \( \circ : \text{Hom}_\mathcal{C}(Y, Z) \times \text{Hom}_\mathcal{C}(X, Y) \to \text{Hom}_\mathcal{C}(X, Z) \) induces a homotopy equivalence of Kan complexes \( \text{Hom}_\mathcal{C}(Y, Z) \to \text{Fun}(K, \text{Hom}_\mathcal{C}(X, Z)) \).

**Warning 7.6.2.2.** In the situation of Definition 7.6.2.1, the composition law
\[
\circ : \text{Hom}_\mathcal{C}(Y, Z) \times \text{Hom}_\mathcal{C}(X, Y) \to \text{Hom}_\mathcal{C}(X, Z)
\]
is only well-defined up to homotopy. However, the requirement that it induces a homotopy equivalence \( \text{Hom}_\mathcal{C}(Y, Z) \to \text{Fun}(K, \text{Hom}_\mathcal{C}(X, Z)) \) depends only on its homotopy class.

**Remark 7.6.2.3.** In the situation of Definition 7.6.2.1, the condition that \( e : K \to \text{Hom}_\mathcal{C}(X, Y) \) exhibits \( X \) as a power of \( Y \) by \( K \) (or \( Y \) as a tensor product of \( X \) by \( K \)) depends only on the homotopy class \([e] \in \pi_0(\text{Fun}(K, \text{Hom}_\mathcal{C}(X, Y)))\).

**Remark 7.6.2.4 (Duality).** In the situation of Definition 7.6.2.1, the morphism \( e : K \to \text{Hom}_\mathcal{C}(X, Y) \) exhibits \( X \) as a power of \( Y \) by \( K \) in the \( \infty \)-category \( \mathcal{C} \) if and only if the morphism
\[
e^{\text{op}} : K^{\text{op}} \to \text{Hom}_{\mathcal{C}}(X, Y)^{\text{op}} \simeq \text{Hom}_{\mathcal{C}^{\text{op}}}(Y, X)
\]
exhibits \( X \) as a tensor product of \( Y \) by \( K^{\text{op}} \) in the opposite \( \infty \)-category \( \mathcal{C}^{\text{op}} \).

**Notation 7.6.2.5.** Let \( \mathcal{C} \) be an \( \infty \)-category, let \( Y \) be an object of \( \mathcal{C} \), and let \( K \) be a simplicial set. Suppose that there exists an object \( X \in \mathcal{C} \) and a morphism \( e : K \to \text{Hom}_\mathcal{C}(X, Y) \) which exhibits \( X \) as a power of \( Y \) by \( K \). In this case, the object \( X \) is uniquely determined up to isomorphism. To emphasize this uniqueness, we will sometimes denote the object \( X \) by \( Y^K \).

Similarly, if there exists an object \( Z \in \mathcal{C} \) and a morphism \( e : K \to \text{Hom}_\mathcal{C}(Y, Z) \) which exhibits \( Z \) as a tensor product of \( Y \) by \( K \), then \( Z \) is uniquely determined up to isomorphism. We will sometimes emphasize this dependence by denoting the object \( Z \) by \( K \otimes Y \).

**Remark 7.6.2.6 (Powers as Limits).** Let \( \mathcal{C} \) be an \( \infty \)-category containing objects \( X \) and \( Y \). Then a morphism of simplicial sets \( e : K \to \text{Hom}_\mathcal{C}(X, Y) \) can be identified with a natural transformation \( \alpha : X \to Y \), where \( X, Y : K \to \mathcal{C} \) denote the constant diagrams taking the values \( X \) and \( Y \), respectively. In this case:
7.6. EXAMPLES OF LIMITS AND COLIMITS

• The natural transformation $\alpha$ exhibits the object $X$ as a limit of the diagram $Y$ (in the sense of Definition 7.1.1.1) if and only if $e$ exhibits $X$ as a power of $Y$ by $K$ (in the sense of Definition 7.6.2.1).

• The natural transformation $\alpha$ exhibits the object $Y$ as a colimit of the diagram $X$ (in the sense of Definition 7.1.1.1) if and only if $e$ exhibits $Y$ as a tensor product of $X$ by $K$ (in the sense of Definition 7.6.2.1).

**Example 7.6.2.7.** Let $C$ be an $\infty$-category containing objects $X$ and $Y$, and suppose we are given a collection of morphisms $\{f_j : X \to Y\}_{j \in J}$ indexed by a set $J$. If we abuse notation by identifying $J$ with the corresponding discrete simplicial set, then the collection $\{f_j\}_{j \in J}$ can be identified with a map $e : J \to \text{Hom}_C(X,Y)$. In this case:

• The morphism $e$ exhibits $X$ as a power of $Y$ by $J$ (in the sense of Definition 7.6.2.1) if and only if the collection $\{f_j\}_{j \in J}$ exhibits $X$ as a product of the collection $\{Y\}_{j \in J}$ (in the sense of Definition 7.6.1.3). Stated more informally, we have a canonical isomorphism $Y^J \simeq \prod_{j \in J} Y$ (provided that either side is defined).

• The morphism $e$ exhibits $Y$ as a tensor product of $X$ by $J$ (in the sense of Definition 7.6.2.1) if and only if the collection $\{f_j\}_{j \in J}$ exhibits $Y$ as a coproduct of the collection $\{X\}_{j \in J}$ (in the sense of Definition 7.6.1.3). Stated more informally, we have a canonical isomorphism $J \otimes X \simeq \biguplus_{j \in J} X$ (provided that either side is defined).

**Example 7.6.2.8.** Let $C$ be an $\infty$-category containing objects $X$ and $Y$. Then the unique morphism $e : \emptyset \to \text{Hom}_C(X,Y)$ exhibits $X$ as a power of $Y$ by the empty simplicial set if and only if $X$ is a final object of $C$. Similarly, $e$ exhibits $Y$ as a tensor product of $X$ by the empty simplicial set if and only if $Y$ is an initial object of $C$.

**Proposition 7.6.2.9.** Let $C$ be a locally Kan simplicial category, let $X$ and $Y$ be objects of $C$, and let $e : K \to \text{Hom}_C(X,Y)$ be a morphism of simplicial sets. Let $N^{hc}(C)$ denote the homotopy coherent nerve of $C$, and let $\theta_{X,Y} : \text{Hom}_C(X,Y) \to \text{Hom}_{N^{hc}(C)}(X,Y)$ denote the comparison map of Remark 4.6.7.6. Then:

1. The morphism $\theta_{X,Y} \circ e$ exhibits $X$ as a power of $Y$ by $K$ in the $\infty$-category $N^{hc}(C)$ if and only if, for every object $W \in C$, composition with $e$ induces a homotopy equivalence of Kan complexes

$$c_W : \text{Hom}_C(W,X) \to \text{Fun}(K,\text{Hom}_C(W,Y)).$$

2. The morphism $\theta_{X,Y} \circ e$ exhibits $Y$ as a tensor product of $X$ by $K$ in the $\infty$-category $N^{hc}(C)$ if and only if, for every object $Z \in C$, precomposition with $e$ induces a homotopy equivalence of Kan complexes

$$\text{Hom}_C(Y,Z) \to \text{Fun}(K,\text{Hom}_C(X,Z)).$$
CHAPTER 7. LIMITS AND COLIMITS

Proof. We will prove (1); the proof of (2) is similar. Fix an object $W \in \mathcal{C}$, so that the composition law

$$\circ : \text{Hom}_{N^h_c(\mathcal{C})}(X,Y) \times \text{Hom}_{N^h_c(\mathcal{C})}(W,X) \to \text{Hom}_{N^h_c(\mathcal{C})}(W,Y)$$

of Construction 4.6.8.9 determines a morphism of Kan complexes $c'_W : \text{Hom}_{N^h_c(\mathcal{C})}(W,X) \to \text{Fun}(K,\text{Hom}_{N^h_c(\mathcal{C})}(W,Y) \bullet)$ (which is well-defined up to homotopy). To prove Proposition 7.6.2.9, it will suffice to show that $c'_W$ is a homotopy equivalence if and only if $c_W$ is a homotopy equivalence. Proposition 4.6.8.19 guarantees that the diagram

$$\text{Hom}_\mathcal{C}(W,X) \bullet \xrightarrow{c_W} \text{Fun}(K,\text{Hom}_\mathcal{C}(W,Y) \bullet) \xrightarrow{\theta_{W,X}} \text{Fun}(K,\text{Hom}_{N^h_c(\mathcal{C})}(W,Y) \bullet) \xrightarrow{\theta_{W,Y} \circ}$$

commutes up to homotopy. We conclude by observing that the horizontal maps are homotopy equivalences, by virtue of Theorem 4.6.7.5 (and Remark 4.6.7.6).

Example 7.6.2.10. Let $X$ and $Y$ be Kan complexes, let $e_0 : K \to \text{Fun}(X,Y)$ be a morphism of simplicial sets, and let $e : K \to \text{Hom}_\mathcal{S}(X,Y)$ denote the composition of $e_0$ with the homotopy equivalence $\text{Fun}(X,Y) \to \text{Hom}_\mathcal{S}(X,Y)$ of Remark 5.6.1.5. Then:

- The morphism $e$ exhibits $X$ as a power of $Y$ by $K$ in the $\infty$-category $\mathcal{S}$ and only the induced map $X \to \text{Fun}(K,Y)$ is a homotopy equivalence of Kan complexes.

- The morphism $e$ exhibits $Y$ as a tensor product of $X$ by $K$ in the $\infty$-category $\mathcal{S}$ if and only if the induced map $K \times X \to Y$ is a weak homotopy equivalence of simplicial sets.

Example 7.6.2.11. Let $Y$ be a Kan complex. Suppose we are given a morphism of simplicial sets $f : K \to \text{Hom}_\mathcal{S}(\Delta^0,Y)$, which we identify with a morphism $\tilde{f} : \Delta^0_K \to Y_K$ in the $\infty$-category $\text{Fun}(K,\mathcal{S})$. Then $f$ is a weak homotopy equivalence if and only if $\tilde{f}$ exhibits $Y$ as a tensor product of $\Delta^0$ by $K$ (in the $\infty$-category $\mathcal{S}$). To prove this, we are free to modify the morphism $f$ by a homotopy (see Remark 7.6.2.3). We may therefore assume without loss of generality that $f$ factors through the homotopy equivalence $e : \text{Fun}(\Delta^0,Y) \to \text{Hom}_\mathcal{S}(\Delta^0,Y)$ of Remark 5.6.1.5 in which case the desired result follows from the criterion of Example 7.6.2.10 (applied in the case $X = \Delta^0$). Taking $K = Y$ and $f = e$, we see that every Kan complex $Y$ can be viewed as a colimit of the constant diagram $Y \to \{\Delta^0\} \hookrightarrow \mathcal{S}$ (see Remark 7.6.2.6).

Remark 7.6.2.12 (Cofinality and Kan Extensions). Let $\mathcal{C}$ be an $\infty$-category and let $\delta : K \to \mathcal{C}$ be a morphism of simplicial sets. The following conditions are equivalent:
(1) The morphism \( \delta \) is left cofinal.

(2) The identity transformation \( \text{id} : \Delta^0_K \to \Delta^0_K \circ \delta \) exhibits the constant functor \( \Delta^0_C : C \to S \) as a left Kan extension of the constant diagram \( \Delta^0_K : K \to S \) along \( \delta \).

By virtue of Theorem 7.2.3.1 and Example 7.6.2.11, both conditions are equivalent to the requirement that, for every object \( C \in C \), the simplicial set \( K/C = K \times_C C/C \) is weakly contractible.

Example 7.6.2.13. Let \( C \) and \( D \) be \( \infty \)-categories, let \( e_0 : K \to \text{Fun}(C, D) \simeq \) be a morphism of Kan complexes, and let \( e \) denote the composition of \( e_0 \) with the homotopy equivalence \( \text{Fun}(C, D) \simeq \to \text{Hom}_{QC}(C, D) \) of Remark 5.6.4.5. Combining Propositions 7.6.2.9 and 4.4.3.20 we obtain the following:

- The morphism \( e \) exhibits \( C \) as a power of \( D \) by \( K \) in the \( \infty \)-category \( QC \) if and only if the induced map \( C \to \text{Fun}(K, D) \) is an equivalence of \( \infty \)-categories.

- The morphism \( e \) exhibits \( C \) as a tensor product of \( D \) by \( K \) in the \( \infty \)-category \( QC \) if and only if the induced map \( K \times C \to D \) is an equivalence of \( \infty \)-categories.

Warning 7.6.2.14. In the statement of Example 7.6.2.13, the assumption that \( K \) is a Kan complex cannot be omitted.

We can use Example 7.6.2.10 to give an alternative proof of the univerality of the left fibration \( S_* \to S \) (see Corollary 5.7.0.6).

Proposition 7.6.2.15 (Covariant Transport as a Kan Extension). Let \( U : E \to C \) be a left fibration of \( \infty \)-categories having essentially small fibers, let \( \Delta^0_E \) denote the constant functor \( E \to S \) taking the value \( \Delta^0 \), and let \( \mathcal{P} : C \to S \) be any functor. Suppose we are given a natural transformation \( \beta : \Delta^0_E \to \mathcal{P} \circ U \). The following conditions are equivalent:

(1) The natural transformation \( \beta \) exhibits \( \mathcal{P} \) as a left Kan extension of \( \Delta^0_E \) along \( U \) (in the sense of Variant 7.3.1.5).

(2) The commutative diagram

\[
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{\beta} & \Delta^0_E \times_S S \\
\downarrow U & & \downarrow \\
C & \xrightarrow{\mathcal{P}} & S
\end{array}
\]

is a categorical pullback square.

Proof. Fix an object \( C \in C \) and let \( \mathcal{E}_C \) denote the fiber \( \{C\} \times_C \mathcal{E} \), so that the restriction of \( \beta \) to \( \mathcal{E}_C \) can be identified with a morphism of Kan complexes \( e_C : \mathcal{E}_C \to \text{Hom}_S(\Delta^0, \mathcal{P}(C)) \). By virtue of Proposition 7.3.4.1 and Corollary 5.1.6.15, it will suffice to show that the following conditions are equivalent:
(1C) The morphism $e_C$ exhibits $\mathcal{F}(C)$ as a tensor product of $\Delta^0$ by $\mathcal{E}_C$ (as an object of the $\infty$-category $\mathcal{S}$).

(2C) The morphism $e_C$ is a homotopy equivalence.

This is a special case of Example 7.6.2.11.

**Corollary 7.6.2.16.** Let $U : \mathcal{E} \to \mathcal{C}$ be a left fibration of $\infty$-categories having essentially small fibers. Then a functor $\mathcal{F} : \mathcal{C} \to \mathcal{S}$ is a covariant transport representation for $U$ (in the sense of Definition 5.7.5.1) if and only if it is a left Kan extension of the constant functor $\Delta^0_\mathcal{E}$ along $U$.

**Proof.** Combine Proposition 7.6.2.15 with the equivalence $\mathcal{S}_* \leftrightarrow \{\Delta^0\times_\mathcal{S} \mathcal{S}\}$ of Theorem 4.6.4.17.

**Variant 7.6.2.17.** Let $U : \mathcal{E} \to \mathcal{C}$ be a left fibration of $\infty$-categories, and suppose that the fibers of $U$ are essentially $\kappa$-small for some uncountable cardinal $\kappa$. Then, in the statements of Proposition 7.6.2.15 and Corollary 7.6.2.16 we can replace $\mathcal{S}$ by the $\infty$-category $\mathcal{S}^{<\kappa}$ of $\kappa$-small spaces (see Variant 5.6.4.12).

We now consider a variant of Proposition 7.6.2.9. Suppose we are given a differential graded category $\mathcal{C}$ containing objects $X$ and $Y$. Let

$$\rho_{X,Y} : \text{K}(\text{Hom}_\mathcal{C}(X,Y)_*) \to \text{Hom}_{N^{dg}_\mathcal{C}}(X,Y)$$

denote the composition of the isomorphism $\text{K}(\text{Hom}_\mathcal{C}(X,Y)_*) \simeq \text{Hom}^{L}_{N^{dg}_\mathcal{C}}(X,Y)$ of Example 4.6.5.14 with the pinch inclusion morphism $\text{Hom}^{L}_{N^{dg}_\mathcal{C}}(X,Y) \to \text{Hom}^{L}_{N^{dg}_\mathcal{C}}(X,Y)$ of Construction 4.6.5.6.

**Proposition 7.6.2.18.** Let $\mathcal{C}$ be a differential graded category, let $X$ and $Y$ be objects of $\mathcal{C}$, and suppose we are given a morphism of simplicial sets $e_0 : S \to \text{K}(\text{Hom}_\mathcal{C}(X,Y)_*)$, which we identify with a morphism of chain complexes $f : N_*(S; \mathbb{Z}) \to \text{Hom}_\mathcal{C}(X,Y)_*$. Let $e : S \to \text{Hom}_{N^{dg}_\mathcal{C}}(X,Y)$ denote the composition of $e_0$ with the morphism $\rho_{X,Y}$. The following conditions are equivalent:

1. The morphism $e$ exhibits $X$ as a tensor product of $Y$ by $S$ in the $\infty$-category $N^{dg}_\mathcal{C}$.

2. Let $Z$ be an object of $\mathcal{C}$, so that $f$ induces a morphism of chain complexes

$$\theta : \text{Hom}_\mathcal{C}(Y,Z)_* \to \text{Hom}_{\text{Ch}([\mathbb{Z}])}(N_*(S; \mathbb{Z}), \text{Hom}_\mathcal{C}(X,Z)_*)_*$$

Then $\theta$ is an isomorphism on homology in degrees $\geq 0$. 

Proof of Proposition 7.6.2.18. Fix an object $Z \in \mathcal{C}$. Using Proposition 4.6.8.21, we see that the diagram of Kan complexes

\[
\begin{array}{c}
\text{K(Hom}_\mathcal{C}(Y,Z)_*) \xrightarrow{K(\theta)} \text{K(Hom}_{\text{Ch}(\mathcal{Z})}(N_*(S;Z), \text{Hom}_\mathcal{C}(X,Z)_*)_*) \\
\rho_{Y,Z} \downarrow \downarrow \psi \\
\text{Fun}(S, \text{K(Hom}_\mathcal{C}(X,Z)_*)) \\
\rho_{X,Z} \circ \downarrow \\
\text{Hom}_{N^\bullet_{\text{dg}}(\mathcal{C})}(Y,Z) \xrightarrow{\text{Fun}(S, \text{Hom}_{N^\bullet_{\text{dg}}(\mathcal{C})}(X,Z))}
\end{array}
\]

commutes up to homotopy, where $\psi$ is the homotopy equivalence of Example 3.1.6.11 and the bottom horizontal map is given by combining $e$ with the composition law on the $\infty$-category $N^\bullet_{\text{dg}}(\mathcal{C})$. Note that condition (1) is equivalent to the requirement that the bottom horizontal map is a homotopy equivalence (for each object $Z \in \mathcal{C}$). Since the map $\rho_{Y,Z}$ and $\rho_{X,Z}$ are also homotopy equivalences (Proposition 4.6.5.9), this is equivalent to the requirement that $K(\theta)$ is a homotopy equivalence (for each object $Z \in \mathcal{C}$). The equivalence of (1) and (2) now follows from the criterion of Corollary 3.2.7.7.

Example 7.6.2.19 (Homology as a Colimit). Let $\mathcal{C} = \text{Ch}(\mathcal{Z})$ denote the category of chain complexes of abelian groups, which we regard as a differential graded category (see Example 2.5.2.5). Let $A$ be an abelian group, and let us abuse notation by identifying $A$ with its image in $\mathcal{C}$ (by regarding it as a chain complex concentrated in degree zero). For every simplicial set $S$, let $N_*(S;A)$ denote the normalized chain complex of $S$ with coefficients in $A$, given by the tensor product $N^\bullet(S;Z) \boxtimes A$. Then the tautological map

\[ f : N_*(S;Z) \to \text{Hom}_{\text{Ch}(\mathcal{Z})}(A,N_*(S;A))_* \]

satisfies condition (2) of Proposition 7.6.2.18: in fact, for every object $M_* \in \mathcal{C}$, precomposition with $f$ induces an isomorphism of chain complexes

\[ \text{Hom}_\mathcal{C}(N_*(S;A),M)_* \to \text{Hom}_\mathcal{C}(N_*(S;Z),\text{Hom}_\mathcal{C}(A,M)_*)_*. \]

It follows that the induced map $S \to \text{Hom}_{N^\bullet_{\text{dg}}(\mathcal{C})}(A,N_*(S;A))$ exhibits $N_*(S;A)$ as a tensor product of $A$ by $S$ in the $\infty$-category $N^\bullet_{\text{dg}}(\mathcal{C})$. In particular, the chain complex $N_*(S;A)$ can be viewed as a colimit of the constant diagram $S \to \{A\} \hookrightarrow N^\bullet_{\text{dg}}(\text{Ch}(\mathcal{Z}))$. 

Variant 7.6.2.20 (Cohomology as a Limit). Let $A$ be an abelian group, let $S$ be a simplicial set, and let

$$N^*(S; A) = \text{Hom}_{\text{Ch}(\mathbb{Z})}(N_*(S; \mathbb{Z}), A)$$

denote the normalized cochain complex of $S$ with coefficients in $A$. Applying Proposition 7.6.2.18 to the differential graded category $\text{Ch}(\mathbb{Z})^{\text{op}}$ (and using Remark 7.6.2.4), we see that the tautological chain map $N^*(S; \mathbb{Z}) \to \text{Hom}_{\text{Ch}(\mathbb{Z})}(N^*(S; A), A)_*$ induces a morphism of simplicial sets

$$e : S \to \text{Hom}_{N^\bullet(\text{Ch}(\mathbb{Z}))}(N^*(S; A), A)$$

which exhibits $N^*(S; A)$ as a power of $A$ by $S$ in the $\infty$-category $N^\bullet(\text{Ch}(\mathbb{Z}))$. In particular, $N^*(S; A)$ can be viewed as a limit of the constant diagram $S \to \{A\} \hookrightarrow N^\bullet(\text{Ch}(\mathbb{Z}))$.

7.6.3 Pullbacks and Pushouts

Let $\mathcal{C}$ be an $\infty$-category. Recall that a commutative square in $\mathcal{C}$ is a morphism of simplicial sets $\Delta^1 \times \Delta^1 \to \mathcal{C}$ which we represent informally by a diagram

$$\begin{array}{ccc}
X' & \to & Y' \\
\downarrow & & \downarrow \\
X & \to & Y
\end{array}$$

(see Example 1.4.2.15). Note that the simplicial set $\Delta^1 \times \Delta^1 \simeq N_\bullet([1] \times [1])$ can be regarded both as a left cone (on the nerve of the partially ordered set $[1] \times [1] \setminus \{(0,0)\}$) and as a right cone (on the nerve of the partially ordered set $[1] \times [1] \setminus \{(1,1)\}$).

**Definition 7.6.3.1.** Let $\mathcal{C}$ be an $\infty$-category and let $\sigma : \Delta^1 \times \Delta^1 \to \mathcal{C}$ be a commutative square. We say that $\sigma$ is a pullback square if it is a limit diagram in $\mathcal{C}$ (see Definition 7.1.2.4), and that $\sigma$ is a pushout square if it is a colimit diagram in $\mathcal{C}$.

**Example 7.6.3.2.** Let $\mathcal{C}$ be an ordinary category. Then diagram $\sigma : [1] \times [1] \to \mathcal{C}$ is a pullback square in $\mathcal{C}$ (in the sense of classical category theory) if and only if the induced map

$$N_\bullet(\sigma) : \Delta^1 \times \Delta^1 \to N_\bullet(\mathcal{C})$$

is a pullback square in the $\infty$-category $N_\bullet(\mathcal{C})$ (in the sense of Definition 7.6.3.1); this follows from Example 7.1.1.4 and Remark 7.1.2.6. Similarly, $\sigma$ is a pushout square in $\mathcal{C}$ if and only if $N_\bullet(\sigma)$ is a pushout square in the $\infty$-category $N_\bullet(\mathcal{C})$. 
7.6. EXAMPLES OF LIMITS AND COLIMITS

**Warning 7.6.3.3.** Let $C$ be an $\infty$-category and let $\sigma : \Delta^1 \times \Delta^1 \to C$ be a morphism, which we depict as a diagram

$$
\begin{array}{ccc}
X_{01} & \xrightarrow{g_0} & X_0 \\
\downarrow^{g_1} & & \downarrow^{f_0} \\
X_1 & \xrightarrow{f_1} & X
\end{array}
$$

Beware that, if $\sigma$ is a pullback square in the $\infty$-category $C$, then the associated diagram

$$
\begin{array}{ccc}
X_{01} & \xrightarrow{[g_0]} & X_0 \\
\downarrow^{[g_1]} & & \downarrow^{[f_0]} \\
X_1 & \xrightarrow{[f_1]} & X
\end{array}
$$

need not be a pullback square in the homotopy category $\text{h}C$ (see Example 7.6.3.4 and Exercise 1.1.2.10). If $Y$ is an object of $C$, then the map of sets

$$
\text{Hom}_C(Y, X_{01}) \xrightarrow{([g_0], [g_1])_0} \text{Hom}_C(Y, X_0) \times \text{Hom}_C(Y, X_1)
$$

is surjective, but need not be injective. Given a commutative diagram

$$
\begin{array}{ccc}
Y & \xrightarrow{[g_0]} & X_0 \\
\downarrow^{[g_1]} & & \downarrow^{[f_0]} \\
X_1 & \xrightarrow{[f_1]} & X
\end{array}
$$

(7.50)

in the homotopy category $\text{h}C$, we can always find a morphism $g_{01} : Y \to X_{01}$ satisfying $g_{01} : Y \to X_0$ satisfying $[g_0] = [f'_0] \circ [g_{01}]$ and $[g_1] = [f'_1] \circ [g_{01}]$. However, the homotopy class $[g_{01}]$ is not uniquely determined: roughly speaking, to construct $g_{01}$, we need to lift (7.50) to a commutative diagram in the $\infty$-category $C$. Such a lift always exists (Exercise 1.4.2.10), but is not unique (even up to homotopy).

**Example 7.6.3.4.** Let $q : X \to S$ be a Kan fibration between Kan complexes, let $s \in S$ be a vertex, and let $X_s$ denote the fiber $\{s\} \times_S X$. Then the commutative diagram of simplicial
sets

\[
\begin{array}{ccc}
X_s & \rightarrow & X \\
\downarrow & & \downarrow q \\
\{s\} & \rightarrow & S \\
\end{array}
\]

(7.51)

is a homotopy pullback square (Example 3.4.1.3), and therefore induces a pullback square in the \(\infty\)-category \(S = \text{N}^\text{hc} (\text{Kan})\) (see Example 7.6.4.2). However, if \(X\) is contractible and \(X_s\) is not, then (7.51) is not a pullback square in the homotopy category \(\text{hKan}\).

**Exercise 7.6.3.5.** Let \(G\) be a group and let \(H \subseteq G\) be a commutative normal subgroup, so that we have a commutative diagram of Kan complexes

\[
\begin{array}{ccc}
B_\bullet H & \rightarrow & B_\bullet G \\
\downarrow & & \downarrow \\
\Delta^0 & \rightarrow & B_\bullet (G/H) \\
\end{array}
\]

(7.52)

- Show that (7.52) is a pullback diagram in the ordinary category of Kan complexes, and that it determines a pullback diagram in the \(\infty\)-category \(S = \text{N}^\text{hc} (\text{Kan})\) (see Example 7.6.4.2).
- Show that, if \(H\) is contained in the center of \(G\), then the diagram (7.52) is also pullback square in the homotopy category \(\text{hKan}\).
- Show that, if \(H\) is not contained in the center of \(G\), then the diagram \(B_\bullet G \rightarrow B_\bullet (G/H) \leftarrow \Delta^0\) does not have a limit in the homotopy category \(\text{hKan}\). In particular, the diagram (7.52) is not a pullback square in \(\text{hKan}\).

**Remark 7.6.3.6** (Symmetry). Let \(\mathcal{C}\) be an \(\infty\)-category, let \(\sigma : \Delta^1 \times \Delta^1 \rightarrow \mathcal{C}\) be a commutative square in \(\mathcal{C}\), and let \(\sigma' : \Delta^1 \times \Delta^1 \rightarrow \mathcal{C}\) denote the commutative square which is obtained from \(\sigma\) by precomposing with the automorphism of \(\Delta^1 \times \Delta^1\) given by permuting the factors. Then \(\sigma\) is a pullback square if and only if \(\sigma'\) is a pullback square, and \(\sigma\) is a pushout square if and only if \(\sigma'\) is a pushout square.

**Remark 7.6.3.7.** Let \(\mathcal{C}\) be an \(\infty\)-category and let \(\sigma : \Delta^1 \times \Delta^1 \rightarrow \mathcal{C}\) be a commutative diagram in \(\mathcal{C}\). Then \(\sigma\) is a pushout diagram in \(\mathcal{C}\) if and only if the opposite diagram \(\sigma^\text{op} : \Delta^1 \times \Delta^1 \rightarrow \mathcal{C}^\text{op}\) is a pullback diagram in the \(\infty\)-category \(\mathcal{C}^\text{op}\); here we implicitly identify the simplicial set \(\Delta^1 \times \Delta^1\) with its opposite (beware that there are two possible identifications we could choose, but the choice does not matter by virtue of Remark 7.6.3.6).
Remark 7.6.3.8. Let $\mathcal{C}$ be an ∞-category and let $\sigma, \sigma' : \Delta^1 \times \Delta^1 \to \mathcal{C}$ be square diagrams which are isomorphic (when viewed as objects of the ∞-category $\text{Fun}(\Delta^1 \times \Delta^1, \mathcal{C})$). Then $\sigma$ is a pullback square if and only if $\sigma'$ is a pullback square, and a pushout square if and only if $\sigma'$ is a pushout square.

Notation 7.6.3.9 (Fiber Products). Let $\mathcal{C}$ be an ∞-category, and suppose we are given a pair of morphisms $f_0 : X_0 \to X$ and $f_1 : X_1 \to X$ of $\mathcal{C}$ having the same target. It follows from Proposition 7.1.1.12 that if there exists a pullback diagram

$$
\begin{array}{ccc}
X_0 & \to & X_0 \\
\downarrow & & \downarrow \text{f_0} \\
X_1 & \to & X \\
\end{array}
$$

in $\mathcal{C}$, then the object $X_{01}$ is determined up to isomorphism by $f_0$ and $f_1$. To emphasize this, we will often denote the object $X_{01}$ by $X_0 \times_X X_1$ and refer to it as the fiber product of $X_0$ with $X_1$ over $X$. Similarly, if there exists a pushout diagram

$$
\begin{array}{ccc}
Y & \to & Y_0 \\
\downarrow \text{g_0} & & \downarrow \\
Y_1 & \to & Y_{01} \\
\end{array}
$$

in $\mathcal{C}$, then the object $Y_{01}$ is determined up to isomorphism by $g_0$ and $g_1$. To emphasize this, we often denote the object $Y_{01}$ by $Y_0 \coprod_Y Y_1$ and refer to it as the pushout of $Y_0$ with $Y_1$ along $Y$.

Definition 7.6.3.10. Let $\mathcal{C}$ be an ∞-category. We will say that $\mathcal{C}$ admits pullbacks if, for every pair of morphisms $f_0 : X_0 \to X$ and $f_1 : X_1 \to X$ having the same target, there exists a pullback diagram

$$
\begin{array}{ccc}
X_0 & \to & X_0 \\
\downarrow \text{f_0} & & \downarrow \\
X_1 & \to & X \\
\end{array}
$$

We say that a functor $F : \mathcal{C} \to \mathcal{D}$ preserves pullbacks if, for every pullback square $\sigma : \Delta^1 \times \Delta^1 \to \mathcal{C}$ in the ∞-category $\mathcal{C}$, the composition $(F \circ \sigma) : \Delta^1 \times \Delta^1 \to \mathcal{D}$ is a pullback square in the ∞-category $\mathcal{D}$. 
We say that \( \mathcal{C} \) admits pushouts if, for every pair of morphisms \( g_0 : Y \to Y_0 \) and \( g_1 : Y \to Y_1 \) having the same source, there exists a pushout diagram

\[
\begin{array}{ccc}
Y & \xrightarrow{g_0} & Y_0 \\
\downarrow{g_1} & & \downarrow{g_1} \\
Y_1 & \xrightarrow{} & Y_{01}
\end{array}
\]

We say that a functor \( F : \mathcal{C} \to \mathcal{D} \) preserves pullbacks if, for every pushout square \( \sigma : \Delta^1 \times \Delta^1 \to \mathcal{C} \) in the \( \infty \)-category \( \mathcal{C} \), the composition \((F \circ \sigma) : \Delta^1 \times \Delta^1 \to \mathcal{D}\) is a pushout square in the \( \infty \)-category \( \mathcal{D} \).

**Proposition 7.6.3.11.** Let \( \mathcal{C} \) be an \( \infty \)-category and let \( \sigma : \Delta^1 \times \Delta^1 \to \mathcal{C} \) be a commutative square, which we represent by a diagram

\[
\begin{array}{ccc}
X_{01} & \xrightarrow{} & X_0 \\
\downarrow & & \downarrow \\
X_1 & \xrightarrow{} & X.
\end{array}
\]

Then \( \sigma \) is a pullback diagram in \( \mathcal{C} \) if and only if it exhibits \( X_{01} \) as a product of \( X_0 \) with \( X_1 \) in the slice \( \infty \)-category \( \mathcal{C}_{/X} \).

**Proof.** This is a special case of Remark 7.1.2.11. ∎

Stated more informally, a fiber product \( X_0 \times_X X_1 \) (formed in an \( \infty \)-category \( \mathcal{C} \)) is a product of \( X_0 \) with \( X_1 \) in the \( \infty \)-category \( \mathcal{C}_{/X} \).

**Corollary 7.6.3.12.** Let \( \mathcal{C} \) be an \( \infty \)-category. Then \( \mathcal{C} \) admits pullbacks if and only if, for each object \( X \in \mathcal{C} \), the slice \( \infty \)-category \( \mathcal{C}_{/X} \) admits finite products.

**Proof.** By virtue of Proposition 7.6.3.11, the \( \infty \)-category \( \mathcal{C} \) admits pullbacks if and only if, for every object \( X \in \mathcal{C} \), the \( \infty \)-category \( \mathcal{C}_{/X} \) admits pairwise products. Since \( \mathcal{C}_{/X} \) has an initial object (given by the identity morphism \( \text{id}_X : X \to X \); see Proposition 4.6.6.23), this is equivalent to the requirement that \( \mathcal{C}_{/X} \) admits finite products (Corollary 7.6.1.20). ∎

**Remark 7.6.3.13.** Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor between \( \infty \)-categories, where \( \mathcal{C} \) admits pullbacks. Then \( F \) preserves pullbacks if and only if, for each object \( X \in \mathcal{C} \), the induced functor \( \mathcal{C}_{/X} \to \mathcal{D}_{/F(X)} \) preserves finite products.
**Corollary 7.6.3.14.** Let $C$ be an $\infty$-category and let $\sigma : \Delta^1 \times \Delta^1 \rightarrow C$ be a commutative square, which we represent by a diagram

\[
\begin{array}{ccc}
X & \xrightarrow{f_0} & X_0 \\
\downarrow{f_1} & & \downarrow \\
X_1 & \xrightarrow{} & 1.
\end{array}
\]

Suppose that $1$ is a final object of $C$. Then $\sigma$ is a pullback square if and only if the morphisms $f_0$ and $f_1$ exhibit $X$ as a coproduct of $X_0$ with $X_1$ in the $\infty$-category $C$.

**Proof.** The assumption that $1$ is final guarantees that the projection map $C/1 \rightarrow C$ is a trivial Kan fibration (Proposition 4.6.6.11), so that the desired result follows from the criterion of Proposition 7.6.3.11. \qed

**Proposition 7.6.3.15.** Let $C$ be an $\infty$-category and let $\sigma : \Delta^1 \times \Delta^1 \rightarrow C$ be a commutative square, represented informally by the diagram

\[
\begin{array}{ccc}
X' & \xrightarrow{f'} & Y' \\
\downarrow{f} & & \downarrow \\
X & \xrightarrow{} & Y.
\end{array}
\]

Then:

1. If $f$ is an isomorphism, then $\sigma$ is a pullback square if and only if $f'$ is also an isomorphism.

2. If $f'$ is an isomorphism, then $\sigma$ is a pushout square if and only if $f$ is also an isomorphism.

**Proof.** We will prove (1); the proof of (2) is similar. Note that $\sigma$ restricts to a diagram $\sigma_0 : N\{[1] \times [1] \setminus \{(0,0)\}) \rightarrow C$ satisfying $\sigma_0(0,1) = X$, $\sigma_0(1,1) = Y$, and $\sigma_0(1,0) = Y'$. The assumption that $f$ is an isomorphism guarantees that $\sigma_0$ is right Kan extended from the full subcategory $\{1\} \times \Delta^1 \subseteq N\{[1] \times [1] \setminus \{(0,0)\})$.

It follows that $\sigma$ is a pullback diagram if and only if the restriction $\sigma|_{N\{((0,0)<(1,1)<(1,1))\}}$ is a limit diagram (Corollary 7.3.7.2). By virtue of Corollary 7.2.2.6, this is equivalent to the requirement that $f'$ is an isomorphism. \qed
Proposition 7.6.3.16. Let $\mathcal{C}$ be an $\infty$-category and let $\sigma : \Delta^2 \times \Delta^1 \to \mathcal{C}$ be diagram, which we depict informally as

\[
\begin{array}{ccc}
X' & \longrightarrow & Y' \longrightarrow Z' \\
\downarrow & & \downarrow \\
X & \longrightarrow & Y \longrightarrow Z.
\end{array}
\] (7.53)

Then:

(1) Assume that the right square of (7.53) is a pullback. Then the left square is a pullback if and only if the outer rectangle is a pullback.

(2) Assume that the left square of (7.53) is a pushout. Then the left square is a pushout if and only if the outer rectangle is a pushout.

Proof. We will prove (1); the proof of (2) is similar. Let $A$ denote the partially ordered set $([2] \times [1]) \setminus \{(0,0)\}$. Note that the inclusion maps

\[
A \setminus \{(2,0),(2,1)\} \hookrightarrow A \quad A \setminus \{(1,0),(1,1)\} \hookrightarrow A \setminus \{(1,0)\}
\]

admit right adjoints, and therefore induce left cofinal morphisms

\[
N_\bullet(A \setminus \{(2,0),(2,1)\}) \to N_\bullet(A) \quad N_\bullet(A \setminus \{(1,0),(1,1)\}) \to N_\bullet(A \setminus \{(1,0)\})
\]

(Corollary 7.2.3.7). Applying Corollary 7.2.2.3, we obtain the following:

- The left square of (7.53) is a pullback diagram if and only if $\sigma$ is a limit diagram.
- The outer rectangle of (7.53) is a pullback diagram if and only if the restriction $\sigma|_{N_\bullet(([2] \times [1]) \setminus \{(1,0)\})}$ is a limit diagram.

If the right square of (7.53) is a pullback diagram, then $\sigma|_{N_\bullet(A)}$ is right Kan extended from $\sigma|_{N_\bullet(A \setminus \{(1,0)\})}$, so the desired equivalence follows from Corollary 7.3.7.2.

Proposition 7.6.3.17 (Rewriting Limits as Pullbacks). Suppose we are given a categorical pushout square of simplicial sets

\[
\begin{array}{ccc}
K & \longrightarrow & K_0 \\
\downarrow & & \downarrow \\
K_1 & \longrightarrow & K_{01}.
\end{array}
\]
Let $C$ be an $\infty$-category which admits pullbacks. If $C$ admits $K$-indexed limits, $K_0$-indexed limits, and $K_1$-indexed limits, then it also admits $K_{01}$-indexed limits. Moreover, if $F : C \to D$ is a functor of $\infty$-categories which preserves pullback squares, $K$-indexed limits, $K_0$-indexed limits, and $K_1$-indexed limits, then $F$ also preserves $K$-indexed limits.

**Proof.** Combine Corollary 7.5.8.5 with (the dual of) Corollary 7.5.8.13.

**Corollary 7.6.3.18.** Let $C$ be an $\infty$-category. Then $C$ admits finite limits if and only if it admits pullbacks and has a final object. If these conditions are satisfied, then a functor $F : C \to D$ preserves finite limits if and only if it preserves pullbacks and final objects.

**Proof.** We will prove the first assertion; the second follows by a similar argument. Assume that the $\infty$-category $C$ admits pullbacks and has a final object; we wish to show that $C$ admits $K$-indexed limits for every finite simplicial set $K$ (the converse is immediate from the definitions). We proceed by induction on the dimension of $K$. If $K$ is empty, then the desired result follows from our assumption that $C$ has an initial object. Let us therefore assume that $K$ has dimension $n \geq 0$, and proceed also by induction on the number of nondegenerate $n$-simplices of $K$. It follows from Proposition 1.1.3.13 that there exists a pushout square of simplicial sets

$$
\begin{array}{ccc}
\partial \Delta^n & \to & \Delta^n \\
\downarrow & & \downarrow \\
K' & \to & K,
\end{array}
$$

where $K'$ is a simplicial subset of $K$. Since the horizontal maps are monomorphisms, this pushout square is also a categorical pushout square (Example 4.5.4.12). By virtue of Proposition 7.6.3.17, it will suffice to show that the $\infty$-category $C$ admits $K'$-indexed limits, $\partial \Delta^n$-indexed limits, and $\Delta^n$-indexed limits. In the first two cases, this follows from our inductive hypothesis. To handle the third case, we observe that the inclusion $\{0\} \hookrightarrow \Delta^n$ is left cofinal (Example 4.3.7.11). Using Corollary 7.2.2.12, we are reduced to proving that $C$ admits $\Delta^0$-indexed limits, which is immediate (see Example 7.1.1.5).

**7.6.4 Examples of Pullback and Pushout Squares**

We now give some examples of $\infty$-categorical pullback diagrams.
**Proposition 7.6.4.1.** Let $\mathcal{C}$ be a locally Kan simplicial category and let $\sigma :$

\[
\begin{array}{ccc}
X_{01} & \longrightarrow & X_0 \\
\downarrow & & \downarrow \\
X_1 & \longrightarrow & X
\end{array}
\]

be a commutative diagram in $\mathcal{C}$. The following conditions are equivalent:

1. The composite map

\[
\Delta^1 \times \Delta^1 \xrightarrow{\Delta^1 \times \Delta^1 \cdot N_{\bullet}(\sigma)} N_{\bullet}(\mathcal{C}) \hookrightarrow N_{\bullet}(\mathcal{C})
\]

is a pullback square in the $\infty$-category $N_{\bullet}(\mathcal{C})$ (in the sense of Definition 7.6.3.1).

2. For every object $Y \in \mathcal{C}$, the diagram of Kan complexes

\[
\begin{array}{ccc}
\text{Hom}_\mathcal{C}(Y, X_{01}) & \longrightarrow & \text{Hom}_\mathcal{C}(Y, X_0) \\
\downarrow & & \downarrow \\
\text{Hom}_\mathcal{C}(Y, X_1) & \longrightarrow & \text{Hom}_\mathcal{C}(Y, X)
\end{array}
\]

is a homotopy pullback square (in the sense of Definition 3.4.1.1).

**Proof.** Combine Corollary 7.5.4.6 with Proposition 7.5.4.13.

**Example 7.6.4.2.** A (strictly) commutative diagram of Kan complexes

\[
\begin{array}{ccc}
X_{01} & \longrightarrow & X_0 \\
\downarrow & & \downarrow \\
X_1 & \longrightarrow & X
\end{array}
\]

is a homotopy pullback square (in the sense of Definition 3.4.1.1) if and only if the induced diagram $\Delta^1 \times \Delta^1 \rightarrow N_{\bullet}(\text{Kan}) = S$ is a pullback square in the $\infty$-category of spaces $S$. This follows by combining Propositions 7.5.4.13 and 7.5.4.5.
Example 7.6.4.3. A (strictly) commutative diagram of Kan complexes

\[
\begin{array}{ccc}
A & \rightarrow & A_0 \\
\downarrow & & \downarrow \\
A_1 & \rightarrow & A_{01}
\end{array}
\]

is a homotopy pushout square (in the sense of Definition 3.4.2.1) if and only if the induced diagram \(\Delta^1 \times \Delta^1 \rightarrow N^\bullet_{hc}(\text{Kan}) = S\) is a pushout square in the \(\infty\)-category of spaces \(S\). This follows by combining Corollaries 7.5.7.7 and 7.5.7.9.

Example 7.6.4.4. A (strictly) commutative diagram of \(\infty\)-categories

\[
\begin{array}{ccc}
C_{01} & \rightarrow & C_0 \\
\downarrow & & \downarrow \\
C_1 & \rightarrow & C
\end{array}
\]

is a categorical pullback square (in the sense of Definition 4.5.2.7) if and only if the induced diagram \(\Delta^1 \times \Delta^1 \rightarrow N^\bullet_{hc}(\text{QCat}) = QC\) is a pullback square in the \(\infty\)-category \(QC\). This follows by combining Corollaries 7.5.5.8 and 7.5.5.10.

Example 7.6.4.5. A (strictly) commutative diagram of \(\infty\)-categories

\[
\begin{array}{ccc}
C & \rightarrow & C_0 \\
\downarrow & & \downarrow \\
C_1 & \rightarrow & C_{01}
\end{array}
\]

is a categorical pushout square (in the sense of Definition 4.5.4) if and only if the induced diagram \(\Delta^1 \times \Delta^1 \rightarrow N^\bullet_{hc}(\text{QCat}) = QC\) is a pushout square in the \(\infty\)-category \(QC\). This follows by combining Corollaries 7.5.8.5 and 7.5.8.9.

Recall that the \(\infty\)-category of spaces \(S\) admits small limits and colimits (Corollary 7.4.5.6). In particular, if \(f_0 : X_0 \rightarrow X\) and \(f_1 : X_1 \rightarrow X\) are morphisms of Kan complexes,
then there exists a pullback diagram $\sigma$:

\[
\begin{array}{ccc}
X_{01} & \rightarrow & X_0 \\
\downarrow & & \downarrow f_0 \\
X_1 & \rightarrow & X \\
\end{array}
\]

in the $\infty$-category $\mathcal{S}$. However, it is not always possible to obtain $\sigma$ from a commutative diagram in the ordinary category Kan. It will therefore be useful to have a generalization of Proposition 7.6.4.1, which applies to homotopy coherent squares.

**Remark 7.6.4.6 (Homotopy Coherent Squares).** Let $\mathcal{C}$ be a simplicial category and let $N^{hc}_\bullet(\mathcal{C})$ denote the homotopy coherent nerve of $\mathcal{C}$. Combining Examples 1.4.2.9, 2.4.3.9, and 2.4.3.10, we see that morphisms from $\Delta^1 \times \Delta^1$ to $N^{hc}_\bullet(\mathcal{C})$ can be identified with the following data:

(a) A collection of objects $X_{01}, X_0, X_1,$ and $X$ of the category $\mathcal{C}$.

(b) A collection of morphisms $f_0 : X_0 \rightarrow X$, $f_1 : X_1 \rightarrow X$, $g_0 : X_{01} \rightarrow X_0$, $g_1 : X_{01} \rightarrow X_1$.

(c) A morphism $h : X_{01} \rightarrow X$ in $\mathcal{C}$ together with a pair of edges $\alpha_0 : f_0 \circ g_0 \rightarrow h$ and $\alpha_1 : f_1 \circ g_1 \rightarrow h$ in the simplicial set $\text{Hom}_\mathcal{C}(X_{01}, X)_\bullet$.

We can summarize this data in a diagram

\[
\begin{array}{ccc}
X_{01} & \rightarrow & X_0 \\
\downarrow & & \downarrow f_0 \\
X_1 & \rightarrow & X \\
\end{array}
\]

\[
\begin{array}{ccc}
X_{01} & \rightarrow & X_0 \\
\downarrow & & \downarrow f_0 \\
X_1 & \rightarrow & X \\
\end{array}
\]

Here we can regard (a) and (b) as supplying a (potentially) non-commutative square diagram in the category $\mathcal{C}$, and (c) as supplying a witness to the fact that it commutes up to homotopy.
Example 7.6.4.7 (Square Diagrams in QC). Let $F_0 : C_0 \to C$ and $F_1 : C_1 \to C$ be functors of $\infty$-categories. Using Remark 7.6.4.6, we see that the data of a commutative diagram

\[
\begin{array}{ccc}
C_0 & \to & C_0 \\
\downarrow & & \downarrow F_0 \\
C_1 & \to & C \\
\downarrow F_1 & & \\
C & & 
\end{array}
\]

in the $\infty$-category QC is equivalent to the data of an $\infty$-category $C_{01}$ equipped with functors $G_0 : C_{01} \to C_0$, $G_1 : C_{01} \to C_1$, $H : C_{01} \to C$ together with natural isomorphisms $\alpha_0 : (F_0 \circ G_0) \cong H$ and $\alpha_1 : (F_1 \circ G_1) \cong H$. In this case, we can identify the data of the tuple $(G_0, \alpha_0, G_1, \alpha_1, H)$ with a single functor of $\infty$-categories $G : C_{01} \to C_0 \times^h_C (C_1 \times^h_C C)$.

Proposition 7.6.4.8. Suppose we are given a commutative diagram

\[
\begin{array}{ccc}
C_0 & \to & C_0 \\
\downarrow & & \downarrow F_0 \\
C_1 & \to & C \\
\downarrow F_1 & & \\
C & & 
\end{array}
\]  

(7.54)

in the $\infty$-category QC, corresponding to a functor $G : C_{01} \to C_0 \times^h_C (C_1 \times^h_C C)$.

Then (7.54) is a pullback square in QC if and only if the functor $G$ is an equivalence of $\infty$-categories.

Proof. Let us identify the diagram (7.54) with a functor of simplicial categories $\mathcal{F} : \text{Path}[[1] \times [1]] \to 

\text{QCat}$. Using Corollary 5.3.7.5, we can factor the functor $F_0$ as a composition $C_0 \to C_0' \xrightarrow{F_0'} C$, where $T$ is an equivalence of $\infty$-categories and $F_0'$ is an isofibration. Let $C_{01}'$ denote the iterated homotopy fiber product $C_0' \times^h_C (C_1 \times^h_C C)$. Then Example 7.6.4.7 supplies a commutative diagram

\[
\begin{array}{ccc}
C_0' & \to & C_0' \\
\downarrow & & \downarrow F_0' \\
C_1 & \to & C \\
\downarrow F_1 & & \\
C & & 
\end{array}
\]  

(7.55)
in the ∞-category QC, which we view as a functor of simplicial categories \( F' : \text{Path}[[1] \times [1]], \bullet \to \text{QCat} \). The morphisms \( G \) and \( T \) determine a natural transformation of simplicial functors \( F \to F' \), which induces a natural transformation from the diagram (7.54) to the diagram (7.55) in the ∞-category Fun(\( \Delta^1 \times \Delta^1, \text{QC} \)). By virtue of Corollary 4.5.2.18 this natural transformation is an isomorphism of diagrams if and only if the functor \( G \) is an equivalence of ∞-categories. Consequently, Proposition 7.6.4.8 is equivalent to the assertion that (7.55) is a pullback square in the ∞-category QC (see Proposition 7.1.2.13).

Note that we have a (strictly) commutative diagram of simplicial sets

\[
\begin{array}{ccc}
C'_0 \times_C C_1 & \rightarrow & C'_0 \\
\downarrow & & \downarrow F'_0 \\
C_1 & \rightarrow & C,
\end{array}
\]

which determines a subfunctor \( F'' \subseteq F' \). Since \( F'_0 \) is an isofibration, it follows from Corollary 4.5.2.22, Proposition 5.3.7.4, and Corollary 4.5.2.23 that the inclusion maps

\[
C'_0 \times_C C_1 \rightarrow C'_0 \times^h_C C_1
\]

\[
\rightarrow C'_0 \times^h_C (C_1 \times^h_C C)
\]

are equivalences of ∞-categories. Consequently, the inclusion \( F'' \hookrightarrow F' \) is a levelwise categorical equivalence of simplicial functors and therefore induces an isomorphism from the diagram (7.56) to the diagram (7.55) in the ∞-category Fun(\( \Delta^1 \times \Delta^1, \mathcal{C} \)). By virtue of Proposition 7.1.2.13 it will suffice to show that the diagram (7.56) is a pullback square in the ∞-category QC. This is a special case of Example 7.6.4.4 since (7.56) is a categorical pullback square (see Corollary 4.5.2.21).

**Corollary 7.6.4.9.** Let \( F_0 : C_0 \to \mathcal{C} \) and \( F_1 : C_1 \to \mathcal{C} \) be functors of ∞-categories, let let \( C_0 \times^h_C C_1 \) denote the homotopy fiber product of Construction 4.5.2.1 and let

\[
G_0 : C_0 \times^h_C C_1 \to C_0 \quad G_1 : C_0 \times^h_C C_1 \to C_1
\]

denote the projection maps, so that we have a canonical isomorphism \( \alpha : F_0 \circ G_0 \to F_1 \circ G_1 \).
in the ∞-category $\text{Fun}(\mathcal{C}_0 \times^h_{\mathcal{C}} \mathcal{C}_1, \mathcal{C})$. Then the diagram corresponds to a pullback square in the ∞-category $\mathcal{QC}$. In particular, $\mathcal{C}_0 \times^h_{\mathcal{C}} \mathcal{C}_1$ is a fiber product of $\mathcal{C}_0$ with $\mathcal{C}_1$ over $\mathcal{C}$ in the ∞-category $\mathcal{QC}$.

**Proof.** By virtue of Proposition 7.6.4.8, it will suffice to show that the inclusion

$$\delta : \mathcal{C}_1 \simeq \mathcal{C}_1 \times_{\mathcal{C}} \mathcal{C} \hookrightarrow \mathcal{C}_0 \times^h_{\mathcal{C}} \mathcal{C}$$

induces an equivalence of homotopy fiber products

$$\mathcal{C}_0 \times^h_{\mathcal{C}} \mathcal{C}_1 \hookrightarrow \mathcal{C}_0 \times^h_{\mathcal{C}} (\mathcal{C}_1 \times^h_{\mathcal{C}} \mathcal{C}).$$

This is a special case of Corollary 4.5.2.18, since $\delta$ is an equivalence of ∞-categories (Proposition 5.3.7.4).

**Corollary 7.6.4.10.** Suppose we are given a commutative diagram

$$\begin{array}{ccc}
X_{01} & \rightarrow & X_0 \\
\downarrow & & \downarrow \\
X_1 & \rightarrow & X
\end{array}$$

(7.57)

in the ∞-category $\mathcal{S}$, classified by a map of Kan complexes

$$g : X_{01} \rightarrow X_0 \times^h_X (X_1 \times^h_X X).$$

Then (7.57) is a pullback square in $\mathcal{S}$ if and only if $g$ is a homotopy equivalence.

**Proof.** Combine Propositions 7.6.4.8 and 7.4.5.1.
Example 7.6.4.11. Let \( f_0 : X_0 \to X \) and \( f_1 : X_1 \to X \) be morphisms of Kan complexes. Applying the construction of Corollary 7.6.4.9, we obtain a pullback square

\[
\begin{array}{ccc}
X_0 \times_X X_1 & \rightarrow & X_0 \\
\downarrow & & \downarrow f_0 \\
X_1 & \rightarrow & X
\end{array}
\]

in the \( \infty \)-category \( \mathcal{S} \).

Corollary 7.6.4.12. Let \( \mathcal{C} \) be a locally Kan simplicial category, and suppose we are given a commutative diagram \( \sigma : \Delta^1 \times \Delta^1 \to \mathcal{N} \text{hc}^\bullet(\mathcal{C}) \), corresponding to a diagram

\[
\begin{array}{ccc}
X_{01} & \rightarrow & X_0 \\
g_0 & & \downarrow f_0 \\
\downarrow g_1 & & \downarrow f_1 \\
X_1 & \rightarrow & X
\end{array}
\]

in the \( \infty \)-category \( \mathcal{C} \) (see Remark 7.6.4.6). Then \( \sigma \) is a pullback square in the \( \infty \)-category \( \mathcal{N} \text{hc}^\bullet(\mathcal{C}) \) if and only if, for every object \( Y \in \mathcal{C} \), the induced map

\[
\text{Hom}_\mathcal{C}(Y, \Delta^1) \to \text{Hom}_\mathcal{C}(Y, X_0) \times_{\text{Hom}_\mathcal{C}(Y, X_1)} (\text{Hom}_\mathcal{C}(Y, X_0) \times \text{Hom}_\mathcal{C}(Y, X_1))
\]

is a homotopy equivalence of Kan complexes.

Proof. Combine Corollary 7.6.4.10 with Proposition 7.4.5.13.

7.6.5 Equalizers and Coequalizers

We now study (co)limits of a particularly simple shape.

Notation 7.6.5.1. Let \( \bullet \Rightarrow \bullet \) denote the simplicial set given by the pushout \( \Delta^1 \coprod_{\partial \Delta^1} \Delta^1 \). For any \( \infty \)-category \( \mathcal{C} \), we will identify morphisms from \( \bullet \Rightarrow \bullet \) to \( \mathcal{C} \) with pairs \( (f_0, f_1) \), where \( f_0 : Y \to X \) and \( f_1 : Y \to X \) are morphisms of \( \mathcal{C} \) having the same source and target.

Remark 7.6.5.2. The simplicial set \( \bullet \Rightarrow \bullet \) of Notation 7.6.5.1 is isomorphic to the nerve of its homotopy category \( \mathcal{J} \), which can be described concretely as follows:
7.6. EXAMPLES OF LIMITS AND COLIMITS

- The category \( \mathcal{J} \) has exactly two objects \( Y \) and \( X \).
- There are exactly two non-identity morphisms in \( \mathcal{J} \), both of which have source \( Y \) and target \( X \).

Remark 7.6.5.3. There is a tautological epimorphism of simplicial sets

\[
\bullet \Rightarrow \bullet = \Delta^1 \coprod_{\partial \Delta^1} \Delta^1
\]

\[
\Rightarrow \Delta^1 \coprod_{\partial \Delta^1} \Delta^0
\]

\[
\Rightarrow \Delta^1 / \partial \Delta^1.
\]

It follows from Example 6.3.4.4 that this epimorphism exhibits \( \Delta^1 / \partial \Delta^1 \) as a localization of \( \bullet \Rightarrow \bullet \). In particular, it is both left and right cofinal (Proposition 7.2.1.9).

Definition 7.6.5.4 (Equalizers and Coequalizers). Let \( C \) be an \( \infty \)-category and let \( f_0, f_1 : Y \to X \) be morphisms of \( C \) having the same source and target, which we identify with functor \( \sigma : (\bullet \Rightarrow \bullet) \to C \). An equalizer of \( f_0 \) and \( f_1 \) is a limit of the diagram \( \sigma \). A coequalizer of \( f_0 \) and \( f_1 \) is a colimit of the diagram \( \sigma \). We say that the \( \infty \)-category \( C \) admits equalizers if every pair of morphisms \( f_0, f_1 : Y \to X \) have an equalizer in \( C \), and that \( C \) admits coequalizers if every pair of morphisms \( f_0, f_1 : Y \to X \) have a coequalizer in \( C \).

Notation 7.6.5.5. Let \( C \) be an \( \infty \)-category and let \( f_0, f_1 : Y \to X \) be morphisms of \( C \) having the same source and target. If there exists an object \( Z \in C \) which is an equalizer of \( f_0 \) and \( f_1 \), then \( Z \) is uniquely determined up to isomorphism (Proposition 7.1.1.12). To emphasize this uniqueness, we denote the object \( Z \) (if it exists) by Eq(\( f_0, f_1 \)). Similarly, if there exists an object \( W \in C \) which is a coequalizer of \( f_0 \) and \( f_1 \), then \( W \) is uniquely determined up to isomorphism; to emphasize this, we denote \( W \) by Coeq(\( f_0, f_1 \)).

Remark 7.6.5.6 (Duality). The simplicial set \( \bullet \Rightarrow \bullet \) is canonically isomorphic to its opposite \( \bullet \Rightarrow \bullet^{\text{op}} \). Consequently, if \( f_0, f_1 : Y \to X \) are morphisms in an \( \infty \)-category \( C \) which admit an equalizer \( Z = \text{Eq}(f_0, f_1) \), then \( Z \) can be regarded as a coequalizer of \( f_0 \) and \( f_1 \) in the opposite \( \infty \)-category \( C^{\text{op}} \).

Remark 7.6.5.7 (Symmetry). The simplicial set \( \bullet \Rightarrow \bullet \) has a unique nontrivial automorphism, which exchanges its nondegenerate edges. It follows that, if \( f_0, f_1 : Y \to X \) are a pair of morphisms in an \( \infty \)-category \( C \), then we can identify (co)equalizers of the pair \( (f_0, f_1) \) with (co)equalizers of the pair \( (f_1, f_0) \).

Example 7.6.5.8 (Fixed Points of Endomorphisms). Let \( C \) be an \( \infty \)-category and let \( X \) be an object of \( C \). An endomorphism of \( X \) is a morphism \( f : X \to X \) from the object \( X \)
CHAPTER 7. LIMITS AND COLIMITS

to itself. Note that the pair \((X, f)\) can be identified with a morphism of simplicial sets \(\sigma : (\Delta^1 / \partial \Delta^1) \to C\). It follows from Remark 7.6.5.3 (together with Corollary 7.2.2.11) that an object of \(C\) is a limit of the diagram \(\sigma\) if and only if it is an equalizer of the pair of morphisms \(f, \text{id}_X : X \to X\). Similarly, an object of \(C\) is a colimit of \(\sigma\) if and only if it is a coequalizer of the pair \((f, \text{id}_X)\).

**Variant 7.6.5.9.** Let \(Z \geq 0\) denote the collection of nonnegative integers, which we regard as a commutative monoid under addition, and let \(B_* Z \geq 0\) denote the classifying simplicial set of Example 1.2.4.3. The simplicial set \(B_* Z \geq 0\) is an \(\infty\)-category which contains a (unique) object \(X\), and the generator \(1 \in Z \geq 0\) determines an endomorphism \(e : X \to X\). We can regard \(B_* Z \geq 0\) as freely generated by the endomorphism \(e\): more precisely, the pair \((X, e)\) determines a morphism of simplicial sets \(\sigma : \Delta^1 / \partial \Delta^1 \to B_* Z \geq 0\) which is inner anodyne (see Example 1.4.7.10), and therefore induces a trivial Kan fibration \(\text{Fun}(B_* Z \geq 0, C) \to \text{Fun}(\Delta^1 / \partial \Delta^1, C)\) for every \(\infty\)-category \(C\). In particular, the morphism \(\sigma\) is both left and right cofinal (Proposition 7.2.1.3).

If \(F : B_* Z \geq 0 \to C\) is a functor of \(\infty\)-categories, then Corollary 7.2.2.11 guarantees that an object of \(C\) is a limit of the functor \(F\) if and only if it is a limit of the diagram \(F \circ \sigma\): that is, if and only if it is an equalizer of the pair of morphisms \(F(e), \text{id}_{F(X)} : F(X) \to F(X)\) (see Example 7.6.5.8). Similarly, an object of \(C\) is a colimit of the functor \(F\) if and only if it is a coequalizer of the pair \((F(e), \text{id}_{F(X)})\).

**Definition 7.6.5.10 (Equalizer and Coequalizer Diagrams).** Let \(C\) be an \(\infty\)-category. An equalizer diagram in \(C\) is a limit diagram \((\bullet \Rightarrow \bullet)^e \to C\). A coequalizer diagram is a colimit diagram \((\bullet \Rightarrow \bullet)^c \to C\).

**Warning 7.6.5.11.** Let \(C\) be an \(\infty\)-category and suppose we are given an equalizer diagram

\[
\begin{array}{ccc}
Z & \xrightarrow{g} & Y & \xrightarrow{f_0} & X \\
\downarrow{f_1} & & \downarrow{f_1} & & \\
\end{array}
\]

in \(C\). Then the image of (7.58) in the homotopy category \(\text{h}C\) need not be an equalizer diagram. In other words, the forgetful functor \(\mathcal{C} \to \text{N}_*(\text{h}C)\) does not preserve equalizer diagrams in general.

**Example 7.6.5.12.** Let \(X\) be a Kan complex containing vertices \(x\) and \(y\). Then there exists an equalizer diagram

\[
\begin{array}{ccc}
\{x\} \times^h_X \{y\} & \xrightarrow{f} & \Delta^0 & \xrightarrow{x} & X \\
\end{array}
\]

in the \(\infty\)-category \(\mathcal{S}\) (for a more general statement, see Corollary 7.6.5.21). However, unless the homotopy fiber product \(\{x\} \times^h_X \{y\}\) is either empty or contractible, the image of (7.59) in the homotopy category \(\text{h}\text{Kan}\) is not an equalizer diagram (since the homotopy class \([f]\) is not a monomorphism in \(\text{h}\text{Kan}\)).
Exercise 7.6.5.13. Let $\mathcal{C}$ be an $\infty$-category and suppose we are given an equalizer diagram

$$
Z \xrightarrow{g} Y \xrightarrow{f_0} \xrightarrow{f_1} X
$$

(7.60)

in $\mathcal{C}$. Show that, for every object $C \in \mathcal{C}$, the map of sets

$$\text{Hom}_{\mathcal{C}}(C, Z) \xrightarrow{|g|_{\circ}} \text{Eq}(\text{Hom}_{\mathcal{C}}(C, Y) \Rightarrow \text{Hom}_{\mathcal{C}}(C, X))$$

is surjective (though it is generally not injective).

We now give some examples of (co)equalizer diagrams.

Proposition 7.6.5.14. Let $F_0, F_1: \mathcal{D} \to \mathcal{C}$ be functors of $\infty$-categories, and let $G: \mathcal{E} \to \mathcal{D}$ be a functor of $\infty$-categories satisfying $F_0 \circ G = F_1 \circ G$. The following conditions are equivalent:

(1) The resulting diagram of $\infty$-categories $(\bullet \rightrightarrows \bullet)^{\mathcal{C}} \to \mathcal{Q}\text{Cat}$ is an equalizer diagram.

(2) The commutative diagram

$$
\begin{array}{ccc}
\mathcal{E} & \xrightarrow{G} & \mathcal{D} \\
\downarrow & & \downarrow (F_0, F_1) \\
\mathcal{C} & \xrightarrow{(\text{id}, \text{id})} & \mathcal{C} \times \mathcal{C}
\end{array}
$$

(7.61)

is a categorical pullback square (Definition 4.5.2.7).

Proof. Let us identify the pair $(F_0, F_1)$ with a functor of ordinary categories $\mathcal{F}: \mathcal{J} \to \text{QCat}$, where $\mathcal{J}$ is the category described in Remark 7.6.5.2. The functor $G$ then induces a map $\mathcal{E} \to \text{holim}(\mathcal{F})$, which can be identified with the map

$$\mathcal{E} \to \mathcal{C} \times_{(\mathcal{C} \times \mathcal{C})} \mathcal{D}$$

determined by the diagram (7.61). Proposition 7.6.5.14 now follows from the criterion of Corollary 7.5.5.8.

Corollary 7.6.5.15. Let $f_0, f_1: Y \to X$ be morphisms of Kan complexes and let $g: Z \to Y$ be a morphism of Kan complexes satisfying $f_0 \circ g = f_1 \circ g$. The following conditions are equivalent:

(1) The resulting diagram of $\infty$-categories $(\bullet \rightrightarrows \bullet)^{\mathcal{S}} \to \mathcal{S}$ is an equalizer diagram.
(2) The commutative diagram of Kan complexes

\[ \begin{array}{ccc}
Z & \xrightarrow{g} & Y \\
\downarrow & & \downarrow (f_0, f_1) \\
X & \xrightarrow{(\text{id}, \text{id})} & X \times X
\end{array} \]

is a homotopy pullback square.

Proof. Combine Propositions 7.6.5.14 and 7.4.5.1. \qed

**Corollary 7.6.5.16.** Let \( C \) be a locally Kan simplicial category and suppose we are given morphisms

\[ Z \xrightarrow{g} Y \xrightarrow{f_0 \atop f_1} X \]

in \( C \) satisfying \( f_0 \circ g = f_1 \circ g \). The following conditions are equivalent:

1. The induced diagram \((\bullet \Rightarrow \bullet)^{\bullet} \rightarrow N^{hc}(C)\) is an equalizer diagram in the \(\infty\)-category \(N^{hc}(C)\), in the sense of Definition 7.6.5.10.

2. For every object \( C \in C \), the diagram of Kan complexes

\[ \begin{array}{ccc}
\text{Hom}_C(C, Z)_{\bullet} & \xrightarrow{g} & \text{Hom}_C(C, Y)_{\bullet} \\
\downarrow & & \downarrow \\
\text{Hom}_C(C, X)_{\bullet} & \xrightarrow{(f_0, f_1)} & \text{Hom}_C(C, X)_{\bullet} \times \text{Hom}_C(C, X)_{\bullet}
\end{array} \]

is a homotopy pullback square.

Proof. Combine Corollary 7.6.5.15 with Proposition 7.4.5.13. \qed

Let \( f_0, f_1 : Y \rightarrow X \) be morphisms of Kan complexes. By virtue of Corollary 7.4.5.6, the morphisms \( f_0 \) and \( f_1 \) have an equalizer in the \(\infty\)-category \( S \). Beware that this equalizer generally cannot be obtained from Corollary 7.6.5.15. For example, if \( f_0 \) and \( f_1 \) have disjoint images, then the existence of a morphism \( g : Z \rightarrow Y \) satisfying \( f_0 \circ g = f_1 \circ g \) guarantees that the simplicial set \( Z \) is empty. In such cases, to extend the pair \((f_0, f_1)\) to an equalizer diagram in \( S \), we are forced to consider homotopy coherent diagrams which do not strictly commute.
Remark 7.6.5.17. Let $F_0, F_1 : \mathcal{D} \to \mathcal{C}$ be functors of $\infty$-categories, which we identify with a diagram $\sigma : (\bullet \Rightarrow \bullet) \to \mathcal{QC}$. Unwinding the definitions, we see that extensions of $\sigma$ to a diagram $\overline{\sigma} : (\bullet \Rightarrow \bullet)^q \to \mathcal{QC}$ can be identified with the following data:

- An $\infty$-category $\mathcal{E}$ equipped with functors $G : \mathcal{E} \to \mathcal{D}$ and $H : \mathcal{E} \to \mathcal{C}$.
- Isomorphisms $\alpha_0 : F_0 \circ G \sim H$ and $\alpha_1 : F_1 \circ G \sim H$ in the $\infty$-category $\text{Fun}(\mathcal{E}, \mathcal{C})$.

In this case, we can identify the quadruple $(G, H, \alpha_0, \alpha_1)$ with a single functor of $\infty$-categories $U : \mathcal{E} \to \mathcal{D} \times_{[\mathcal{C} \times \mathcal{C}]} \mathcal{C}$.

Proposition 7.6.5.18. Let $F_0, F_1 : \mathcal{D} \to \mathcal{C}$ be functors of $\infty$-categories, which we identify with a diagram $\sigma : (\bullet \Rightarrow \bullet) \to \mathcal{QC}$. Suppose we are given an extension $\overline{\sigma} : (\bullet \Rightarrow \bullet)^q \to \mathcal{QC}$ of $\sigma$, corresponding to a functor of $\infty$-categories $T : \mathcal{E} \to \mathcal{D} \times_{[\mathcal{C} \times \mathcal{C}]} \mathcal{C}$.

Then $\sigma$ is an equalizer diagram in the $\infty$-category $\mathcal{QC}$ if and only if $T$ is an equivalence of $\infty$-categories.

Proof. We proceed as in the proof of Proposition 7.6.4.8 with minor modifications. Let $\mathcal{A}$ denote the simplicial path category of $(\bullet \Rightarrow \bullet)^q$, so that we can identify $\sigma$ with a simplicial functor $\mathcal{F} : \mathcal{A} \to \text{QCat}$. Using Corollary 5.3.7.5, we can factor the functor $(F_0, F_1) : \mathcal{D} \to \mathcal{C} \times \mathcal{C}$ as a composition $\mathcal{D} \xrightarrow{U} \mathcal{D}' \xrightarrow{(F'_0, F'_1)} \mathcal{C} \times \mathcal{C}$, where $U$ is an equivalence of $\infty$-categories and $(F'_0, F'_1)$ is an isofibration. The pair $(F'_0, F'_1)$ can be identified with a morphism of simplicial sets $\sigma' : (\bullet \Rightarrow \bullet)^q \to \mathcal{QC}$. Applying Remark 7.6.5.17, we can extend $\sigma'$ to a diagram $\overline{\sigma}' : (\bullet \Rightarrow \bullet)^q \to \mathcal{QC}$, carrying the cone point to the $\infty$-category $\mathcal{E}' = \mathcal{D}' \times_{[\mathcal{C} \times \mathcal{C}]} \mathcal{C}$. The diagram $\overline{\sigma}'$ corresponds to a simplicial functor $\overline{\mathcal{F}} : \mathcal{A} \to \text{QCat}$. The morphisms $T$ and $U$ determine a natural transformation of simplicial functors $\mathcal{F} \to \overline{\mathcal{F}}$, hence also a morphism $\sigma \to \overline{\sigma}'$ in the $\infty$-category $\text{Fun}((\bullet \Rightarrow \bullet)^q, \mathcal{QC})$. By virtue of Corollary 4.5.2.18, this natural transformation is an isomorphism of diagrams if and only if the functor $T$ is an equivalence of $\infty$-categories. Consequently, Proposition 7.6.5.18 is equivalent to the assertion that $\overline{\sigma}'$ is an equalizer diagram in $\mathcal{QC}$ (Proposition 7.1.2.13).

Invoking Remark 7.6.5.17 again, we obtain another diagram $\overline{\sigma}''$ extending $\sigma'$, which carries the cone point of $(\bullet \Rightarrow \bullet)^q$ to the equalizer $\text{Eq}(F'_0, F'_1) = \mathcal{D}' \times_{[\mathcal{C} \times \mathcal{C}]} \mathcal{C}$ (formed in the category of simplicial sets). The diagram $\overline{\sigma}''$ corresponds to another simplicial functor...
\( \mathcal{F}'' : A \to \text{QCat} \). Note that there is a natural inclusion map \( \mathcal{F}'' \hookrightarrow \mathcal{F}' \), which carries the cone point to the inclusion

\[
\iota : \mathcal{D}' \times_{(\mathcal{C} \times \mathcal{C})} \mathcal{C} \subseteq \mathcal{D}' \times_{(\mathcal{C} \times \mathcal{C})} \mathcal{C}.
\]

Since \((F'_0, F'_1)\) is an isofibration, the functor \( \iota \) is an equivalence of \( \infty \)-categories (Corollary 4.5.2.22). It follows that the inclusion \( \mathcal{F}'' \hookrightarrow \mathcal{F}' \) induces an isomorphism \( \sigma'' \to \sigma' \) in the \( \infty \)-category \( \text{Fun((} \mathbb{•} \Rightarrow \mathbb{•} )/ \mathcal{C}) \). By virtue of Proposition 7.1.2.13, we are reduced to showing that \( \sigma'' \) is an equalizer diagram in \( \mathcal{C} \). This follows from the criterion of Proposition 7.6.5.14 (since \( \iota \) is an equivalence of \( \infty \)-categories).

It follows from Proposition 7.6.5.18 that, if \( F_0, F_1 : \mathcal{D} \to \mathcal{C} \) are functors of \( \infty \)-categories, then the homotopy fiber product \( \mathcal{D} \times_{(\mathcal{C} \times \mathcal{C})} \mathcal{C} \) is an equalizer of \( F_0 \) and \( F_1 \) in the \( \infty \)-category \( \mathcal{QC} \) (this can also be viewed as a special case of Proposition 7.5.2.4). However, it is possible to be more efficient.

**Construction 7.6.5.19 (The Homotopy Equalizer).** Let \( F_0, F_1 : \mathcal{D} \to \mathcal{C} \) be functors of \( \infty \)-categories, and form a pullback diagram of simplicial sets

\[
\begin{array}{ccc}
h\text{Eq}(F_0, F_1) & \longrightarrow & \text{Isom}(\mathcal{C}) \\
\downarrow & & \downarrow \\
\mathcal{D} & \longrightarrow & \mathcal{C} \times \mathcal{C}.
\end{array}
\]

Note that the right vertical map is an isofibration (Corollary 4.5.5), so the left vertical map is also an isofibration; in particular, \( h\text{Eq}(F_0, F_1) \) is an \( \infty \)-category. We will refer to \( h\text{Eq}(F_0, F_1) \) as the *homotopy equalizer* of the functors \( F_0 \) and \( F_1 \). By construction, objects of \( h\text{Eq}(F_0, F_1) \) can be identified with pairs \((X, u)\), where \( X \) is an object of \( \mathcal{D} \) and \( u : F_0(X) \to F_1(X) \) is an isomorphism in the \( \infty \)-category \( \mathcal{C} \).

Set \( H = G \circ F_1 \), so that the construction \((X, u) \mapsto u\) determines an isomorphism \( \alpha_0 : G \circ F_0 \cong H \) in the \( \infty \)-category \( \text{Fun(Eq}(F_0, F_1), \mathcal{C}) \). Taking \( \alpha_1 \) to be the identity morphism \( \text{id} : G \circ F_1 \cong H \), we see that the quadruple \((G, H, \alpha_0, \alpha_1)\) determines a diagram \( \sigma : (\mathbb{•} \Rightarrow \mathbb{•})^a \to \mathcal{QC} \), carrying the cone point to the homotopy equalizer \( h\text{Eq}(F_0, F_1) \) (see Remark 7.6.5.17).

**Corollary 7.6.5.20.** Let \( F_0, F_1 : \mathcal{D} \to \mathcal{C} \) and \( F_1 : \mathcal{D} \to \mathcal{C} \) be functors of \( \infty \)-categories. Then the morphism \( \sigma : (\mathbb{•} \Rightarrow \mathbb{•})^a \to \mathcal{QC} \) of Construction 7.6.5.19 is an equalizer diagram. In particular, the homotopy equalizer \( h\text{Eq}(F_0, F_1) \) is an equalizer of \( F_0 \) and \( F_1 \) in the \( \infty \)-category \( \mathcal{QC} \).
**Proof.** The diagram $\sigma$ can be identified with a functor $U : \text{hEq}(F_0, F_1) \to \mathcal{D} \times_{(\mathcal{C} \times \mathcal{C})} \mathcal{C}$. By virtue of Proposition 7.6.5.18, it will suffice to show that $U$ is an equivalence of $\infty$-categories. Unwinding the definitions, we see that $U$ fits into a commutative diagram

$$
\begin{array}{ccc}
\text{hEq}(F_0, F_1) & \xrightarrow{U} & \mathcal{D} \times_{(\mathcal{C} \times \mathcal{C})} \mathcal{C} \\
\downarrow & & \downarrow \quad \downarrow \\
\mathcal{D} & \xrightarrow{} & \mathcal{D} \times_{\mathcal{C}} \mathcal{C}
\end{array}
$$

where the homotopy fiber product on the upper right is formed using the functor $F_0$, and the homotopy fiber product on the lower middle is formed using the functor $F_1$. Each of the squares in this diagram is a pullback, and the right vertical map is an isofibration (Remark 4.5.2.2). It follows that the left side of the diagram is a categorical pullback square (Corollary 4.5.2.21). Since the functor on the lower left is an equivalence of $\infty$-categories (Proposition 5.3.7.4), it follows that $U$ is an equivalence of $\infty$-categories.

**Corollary 7.6.5.21.** Let $f_0, f_1 : Y \to X$ be morphisms of Kan complexes. Then the homotopy equalizer $\text{hEq}(f_0, f_1)$ is a Kan complex, which is an equalizer of $f_0$ and $f_1$ in the $\infty$-category $\mathcal{S}$.

**Proof.** Combine Corollary 7.6.5.20 with Proposition 7.4.5.1.

Corollaries 7.6.5.20 and 7.6.5.21 illustrate a general phenomenon: if $\mathcal{C}$ is an $\infty$-category which admits pairwise products, then equalizers in $\mathcal{C}$ can be viewed as a special kind of fiber product.

**Proposition 7.6.5.22** (Rewriting Equalizers as Pullbacks). Let $\mathcal{C}$ be an $\infty$-category, let $f_0, f_1 : Y \to X$ be morphisms of $\mathcal{C}$. Let $X \times X$ be a product of $X$ with itself in the $\infty$-category $\mathcal{C}$, so that $f_0$ and $f_1$ determine a morphism $(f_0, f_1) : Y \to X \times X$, and let $\delta_X : X \to X \times X$ be the diagonal map. Then an object of $\mathcal{C}$ is an equalizer of $f_0$ and $f_1$ if and only if it is a fiber product of $Y$ with $X$ over $X \times X$.

**Proof.** Let $\mathcal{K}$ denote the simplicial set given by the product $(\bullet \rightrightarrows \bullet)^{\Delta^1} \times \Delta^1$. Then $\mathcal{K}$ is an $\infty$-category, which we depict informally by the diagram

$$
\begin{array}{ccc}
z & \xrightarrow{y} & x \\
\downarrow & & \downarrow \\
z' & \xrightarrow{y'} & x'
\end{array}
$$

We now proceed in several steps.
Let \( \mathcal{K}_0 \) denote the full subcategory of \( \mathcal{K} \) spanned by the objects \( x \) and \( y \). Then \( \mathcal{K}_0 \) is isomorphic to the simplicial set \((\bullet \rightarrow \bullet)\). In particular, the pair of morphisms \( f_0, f_1 : Y \rightarrow X \) can be identified with a functor \( \sigma_0 : \mathcal{K}_0 \rightarrow \mathcal{C} \), satisfying \( \sigma_0(x) = X \) and \( \sigma_0(y) = Y \). By definition, an object of \( \mathcal{C} \) is an equalizer of the pair \((f_0, f_1)\) if and only if it is a limit of the diagram \( \sigma_0 \).

Let \( \mathcal{K}_1 \) denote the full subcategory of \( \mathcal{K} \) spanned by the objects \( x, x', \) and \( y \). Note that the identity map \( \text{id}_{\mathcal{K}_0} \) extends uniquely to a retraction \( r : \mathcal{K}_1 \rightarrow \mathcal{K}_0 \), carrying the object \( x' \in \mathcal{K}_1 \) to \( x \in \mathcal{K}_0 \). Let \( \sigma_1 : \mathcal{K}_1 \rightarrow \mathcal{C} \) be the composition \( \sigma_0 \circ r \). Note that that the inclusion map \( \mathcal{K}_0 \hookrightarrow \mathcal{K}_1 \) admits a right adjoint (given by the retraction \( r \)), and is therefore left cofinal (Corollary 7.2.3.7). It follows that an object of \( \mathcal{C} \) is a limit of the diagram \( \sigma_0 \) if and only if it is a limit of the diagram \( \sigma_1 \) (Corollary 7.2.2.11).

Choose a pair of morphisms \( \pi_0, \pi_1 : X \times X \rightarrow X \) in the \( \infty \)-category \( \mathcal{C} \) which exhibit \( X \times X \) as a product of \( X \) with itself. The morphism \( (f_0, f_1) : Y \rightarrow X \) is characterized (up to homotopy) by the requirement that there exist 2-simplices \( \sigma_0 \) and \( \sigma_1 \) of \( \mathcal{C} \), where \( \sigma_i \) exhibits \( f_i \) as a composition of \( \pi_i \) with \( (f_0, f_1) \). Let \( \mathcal{K}_2 \) denote the full subcategory of \( \mathcal{K} \) spanned by the objects \( x, x', y, \) and \( y' \). Then the pair \((\sigma_0, \sigma_1)\) determines an extension of \( \sigma_1 \) to a functor \( \sigma_2 : \mathcal{K}_2 \rightarrow \mathcal{C} \) satisfying \( \sigma_2(y') = X \times X \).

The diagonal morphism \( \delta_X : X \rightarrow X \times X \) is characterized (up to homotopy) by the requirement that there exist 2-simplices \( \tau_0 \) and \( \tau_1 \) of \( \mathcal{C} \), where \( \tau_i \) exhibits \( \text{id}_X \) as a composition of \( \pi_i \) with \( \delta_X \). Let \( \mathcal{K}_3 \) denote the full subcategory of \( \mathcal{K} \) spanned by the objects \( x, x', y, y', \) and \( z' \). Then the pair \((\tau_0, \tau_1)\) determines an extension of \( \sigma_2 \) to a functor \( \sigma_3 : \mathcal{K}_3 \rightarrow \mathcal{C} \) satisfying \( \sigma_3(z') = X \). The diagram \( \sigma_3 \) can be represented informally by the diagram

\[
\begin{array}{ccc}
\bullet & \rightarrow & Y \\
\downarrow & & \downarrow \\
X & \xrightarrow{\delta_X} & X \times X \\
\downarrow & & \downarrow \\
X & \xrightarrow{\pi_0} & X \\
\downarrow & & \downarrow \\
\downarrow & & \downarrow \\
\downarrow & & \downarrow \\
X & \xrightarrow{\pi_1} & X \\
\end{array}
\]

Note that \( \sigma_3 \) is right Kan extended from the full subcategory \( \mathcal{K}_1 \subseteq \mathcal{K}_3 \). Consequently, an object of \( \mathcal{C} \) is a limit of the diagram \( \sigma_1 \) if and only if it is a limit of the diagram \( \sigma_3 \) (Remark 7.3.7.15).

Let \( \mathcal{K}_4 \) denote the full subcategory of \( \mathcal{K} \) spanned by the objects \( x', y, y', \) and \( z' \). Note that the functor \( \sigma_3 \) is right Kan extended from \( \mathcal{K}_4 \). It follows that an object of \( \mathcal{C} \) is a limit of the functor \( \sigma_3 \) if and only if it is a limit of the functor \( \sigma_4 = \sigma_3|_{\mathcal{K}_4} \).
7.6. EXAMPLES OF LIMITS AND COLIMITS

- Let $\mathcal{K}_5$ denote the full subcategory of $\mathcal{K}$ spanned by the objects $y$, $y'$, and $z'$. Using the criterion of Theorem 7.2.3.1, we see that the inclusion $\mathcal{K}_5 \hookrightarrow \mathcal{K}_4$ is left cofinal. It follows that an object of $\mathcal{C}$ is a limit of the diagram $\sigma_4$ if and only if it is a limit of the diagram $\sigma_5 = \sigma_4|_{\mathcal{K}_5}$ (Corollary 7.2.2.11).

Combining these steps, we deduce that an object of $\mathcal{C}$ is an equalizer of $f_0$ and $f_1$ if and only if it is a limit of the diagram $\sigma_5$: that is, if and only if it is a fiber product of $Y$ with $X$ over $X \times X$ (along the morphisms $(f_0, f_1)$ and $\delta_X$).

In an $\infty$-category which admits finite products, we can use a similar argument to describe pullbacks in terms of equalizers.

**Proposition 7.6.5.23** (Rewriting Pullbacks as Equalizers). Let $\mathcal{C}$ be an $\infty$-category and let $f_0 : X_0 \to X$ and $f_1 : X_1 \to X$ be morphisms of $\mathcal{C}$. Suppose that $X_0$ and $X_1$ admit a product $X_0 \times X_1$, and let $\pi_0 : X_0 \times X_1 \to X_0$ and $\pi_1 : X_0 \times X_1 \to X_1$ denote the projection maps. For $i \in \{0, 1\}$, let $g_i : X_0 \times X_1 \to X$ denote a composition of $\pi_i$ with $f_i$ in the $\infty$-category $\mathcal{C}$. Then an object of $\mathcal{C}$ is a pullback of $X_0$ with $X_1$ over $X$ if and only if it is an equalizer of the pair of morphisms $(g_0, g_1)$.

**Proof.** Let $\mathcal{K}$ denote the category which is freely generated by a non-commutative square, as indicated in the diagram

The upper right and lower left regions of this diagram determine monomorphisms $\tau_0, \tau_1 : \Delta^2 \hookrightarrow N_\bullet(\mathcal{K})$. The images of $\tau_0$ and $\tau_1$ are simplicial subsets of $N_\bullet(\mathcal{K})$, whose union is $N_\bullet(\mathcal{K})$ and whose intersection is the discrete simplicial set $\{Y_0, Y\}$. It follows that $\tau_0$ and $\tau_1$ induce an isomorphism of simplicial sets $(\tau_0, \tau_1) : \Delta^2 \coprod_{\{0, 2\}} \Delta^2 \simeq N_\bullet(\mathcal{K})$.

For $i \in \{0, 1\}$, let $\sigma_i$ be a 2-simplex of $\mathcal{C}$ which witnesses $g_i$ as a composition of $\pi_i$ with $f_i$ (in the sense of Definition 1.3.4.1). Then there is a unique morphism of simplicial sets
Let $q : N_\bullet(K) \to C$ be a functor of $\infty$-categories having the property that $q \circ \tau_i = \sigma_i$, which we indicate as a diagram

\[
\begin{array}{ccc}
X_0 \times X_1 & \xrightarrow{\pi_0} & X_0 \\
\pi_1 & \downarrow & \downarrow \pi_1 \\
X_1 & \xrightarrow{f_1} & X.
\end{array}
\]

Let $K_+ \subseteq K$ denote the full subcategory spanned by the objects $Y_0$, $Y_1$, and $Y_{01}$. Then the nerve $N_\bullet(K_+) \hookrightarrow N_\bullet(K)$ can be identified with the simplicial set $(\bullet \to \bullet)$ of Notation 7.6.5.1, and the restriction $q_+ = q |_{N_\bullet(K_+)}$ corresponds to the pair of morphisms $g_0, g_1 : X_0 \times X_1 \to X$. Note that the full subcategory $N_\bullet(K_+) \hookrightarrow N_\bullet(K)$ is coreflective, so the inclusion map $N_\bullet(K_+) \to N_\bullet(K)$ is left cofinal (Corollary 7.2.3.7). It follows that an object of $C$ is an equalizer of $g_0$ and $g_1$ if and only if it is a limit of the diagram $q$ (Corollary 7.2.2.1). To complete the proof, it will suffice to show that an object of $C$ is a limit of $q$ if and only if it is a fiber product of $X_0$ with $X_1$ over $X$. Let $K_- \subseteq K$ denote the full subcategory spanned by the objects $Y_0$, $Y_1$, and $Y_{01}$. By virtue of Corollaries 7.3.7.2 and 7.3.7.14, it will suffice to show that the functor $q$ is right Kan extended from $N_\bullet(K_-)$. Equivalently, we wish to show that the natural map

\[
N_\bullet(K_- \times_K K_{Y_{01}}) \to N_\bullet(K) \to C
\]

is a limit diagram in $C$. Unwinding the definitions, we see that $K_- \times_K K_{Y_{01}}$ can be written as a disjoint union of subcategories having initial objects $Y_0$ and $Y_1$, respectively. In particular, the inclusion map

\[
\{Y_0, Y_1\} \hookrightarrow N_\bullet(K_- \times_K K_{Y_{01}})
\]

is left cofinal. The desired result now follows from Corollary 7.2.2.3, together with our assumption that the maps $\pi_0$ and $\pi_1$ exhibit $X_0 \times X_1$ as a product of $X_0$ with $X_1$.  

**Exercise 7.6.5.24.** In the situation of Proposition 7.6.5.23, suppose that $X_0$ and $X_1$ admit a fiber product over $X$. Let $F : C \to D$ be a functor of $\infty$-categories which preserves the product of $X_0$ and $X_1$ (that is, $F(\pi_0)$ and $F(\pi_1)$ exhibit $F(X_0 \times X_1)$ as a product of $F(X_0)$ with $F(X_1)$ in the $\infty$-category $D$). Show that $F$ preserves the fiber product of $X_0$ with $X_1$ over $X$ if and only if it preserves the equalizer of the morphisms $g_0$ and $g_1$. 

**Corollary 7.6.5.25.** Let $C$ be an $\infty$-category. Then $C$ admits finite limits if and only if it admits finite products and equalizers. If these conditions are satisfied, then a functor $F : C \to D$ preserves finite limits if and only if it preserves finite products and equalizers.

**Proof.** Combine Corollary 7.6.3.18 with Proposition 7.6.5.23 (and Exercise 7.6.5.24).  

\[\square\]
7.6.6 Sequential Limits and Colimits

Throughout this section, we let $\mathbb{Z}_{\geq 0}$ denote the set of nonnegative integers, endowed with its usual ordering.

**Definition 7.6.6.1 (Towers).** Let $\mathcal{C}$ be an ∞-category. A tower in $\mathcal{C}$ is a functor $N_\bullet(\mathbb{Z}_{\geq 0}) \to \mathcal{C}$. We say that $\mathcal{C}$ admits sequential limits if every tower in $\mathcal{C}$ has a limit, and that $\mathcal{C}$ admits sequential colimits if every diagram $N_\bullet(\mathbb{Z}_{\geq 0}) \to \mathcal{C}$ has a colimit. We say that a functor of ∞-categories $F : \mathcal{C} \to \mathcal{D}$ preserves sequential limits if it preserves limits indexed by the simplicial set $N_\bullet(\mathbb{Z}_{\geq 0})$, and that it preserves sequential colimits if it preserves colimits indexed by the simplicial set $N_\bullet(\mathbb{Z}_{\geq 0})$.

**Notation 7.6.6.2.** Let $\mathcal{C}$ be an ∞-category. We will generally abuse notation by identifying a functor $X : N_\bullet(\mathbb{Z}_{\geq 0}) \to \mathcal{C}$ with the collection of objects $\{X(n)\}_{n \geq 0}$ and morphisms $f_n : X(n+1) \to X(n)$ obtained by the evaluating $X$ on the edges of $N_\bullet(\mathbb{Z}_{\geq 0})$ corresponding to ordered pairs of the form $(n,n+1)$; we will depict the pair $(\{X(n)\}_{n \geq 0}, \{f_n\}_{n \geq 0})$ as a diagram

$$X(0) \xrightarrow{f_0} X(1) \xrightarrow{f_1} X(2) \xrightarrow{f_2} X(3) \xrightarrow{f_3} X(4) \to \cdots$$

Similarly, we abuse notation by identifying towers $X : N_\bullet(\mathbb{Z}_{\geq 0}) \to \mathcal{C}$ with diagrams

$$\cdots \to X(4) \xrightarrow{f_3} X(3) \xrightarrow{f_2} X(2) \xrightarrow{f_1} X(1) \xrightarrow{f_0} X(0).$$

Beware that the convention of Notation 7.6.6.2 is slightly abusive: the simplicial set $N_\bullet(\mathbb{Z}_{\geq 0})$ has nondegenerate simplices in every dimension, so a functor $X : N_\bullet(\mathbb{Z}_{\geq 0}) \to \mathcal{C}$ is not literally determined by its underlying diagram $X(0) \xrightarrow{f_0} X(1) \xrightarrow{f_1} X(2) \xrightarrow{f_2} X(3) \xrightarrow{f_3} X(4) \to \cdots$. However, the abuse is essentially harmless:

**Remark 7.6.6.3.** Let $\text{Spine}[\mathbb{Z}_{\geq 0}]$ denote the simplicial subset of $N_\bullet(\mathbb{Z}_{\geq 0})$ whose $k$-simplices are sequences of nonnegative integers $(n_0, n_1, \cdots, n_k)$ satisfying $n_0 \leq n_1 \leq \cdots \leq n_k \leq n_0 + 1$. Then $\text{Spine}[\mathbb{Z}_{\geq 0}]$ is a 1-dimensional simplicial set, which corresponds (under the equivalence of Proposition 1.1.5.9) to the directed graph $G$ indicated in the diagram

$$0 \to 1 \to 2 \to 3 \to \cdots .$$

Moreover, the partially ordered set $(\mathbb{Z}_{\geq 0}, \leq)$ can be identified with the path category $\text{Path}[G]$ of Construction 1.2.6.1. It follows that the inclusion map $\text{Spine}[\mathbb{Z}_{\geq 0}] \hookrightarrow N_\bullet(\mathbb{Z}_{\geq 0})$ is inner anodyne (Proposition 1.4.7.3).

In particular, for any ∞-category $\mathcal{C}$, the restriction map

$$\text{Fun}(N_\bullet(\mathbb{Z}_{\geq 0}), \mathcal{C}) \to \text{Fun}(\text{Spine}[\mathbb{Z}_{\geq 0}], \mathcal{C})$$
is a trivial Kan fibration (Theorem 1.4.7.1). Stated more informally, every diagram
\[
X(0) \xrightarrow{f_0} X(1) \xrightarrow{f_1} X(2) \xrightarrow{f_2} X(3) \xrightarrow{f_3} X(4) \to \cdots
\]
admits an essentially unique extension to a functor \(N_\bullet(\mathbb{Z}_{\geq 0}) \to C\).

**Example 7.6.6.4.** Let \(C\) be a locally Kan simplicial category, and suppose we are given a collection of objects \(\{X(n)\}_{n \geq 0}\) and morphisms \(f_n : X(n) \to X(n+1)\) in \(C\). It follows from Remark 7.6.6.3 that the diagram
\[
X(0) \xrightarrow{f_0} X(1) \xrightarrow{f_1} X(2) \xrightarrow{f_2} X(3) \xrightarrow{f_3} X(4) \xrightarrow{f_4} \cdots
\]
can be extended to a functor \(N_\bullet(\mathbb{Z}_{\geq 0}) \to N_{\text{hc}}\bullet(C)\). In fact, there is a preferred choice of such an extension, which is uniquely determined by the requirement that it factors through the inclusion map \(N_\bullet(C) \hookrightarrow N_{\text{hc}}\bullet(C)\).

**Remark 7.6.6.5.** Let \(C\) be an \(\infty\)-category, and suppose we are given a tower \(X : N_\bullet(\mathbb{Z}_{\geq 0}^{\text{op}}) \to C\), which we depict as a diagram
\[
\cdots \to X(4) \xrightarrow{f_1} X(3) \xrightarrow{f_2} X(2) \xrightarrow{f_1} X(1) \xrightarrow{f_0} X(0),
\]
having a limit \(\text{lim}^{-} (X)\). Then, for every object \(Y \in C\), the map of sets
\[
\theta : \text{Hom}_{\text{hc}}(Y, \text{lim}^{-} (X)) \to \text{lim}^{-}(\text{Hom}_{\text{hc}}(Y, X(n)))
\]
is surjective. To prove this, suppose we are given a collection of morphisms \(g_n : Y \to X(n)\) satisfying \([f_n] \circ [g_{n+1}] = [g_n]\) in the homotopy category \(hC\). Then, for each \(n \geq 0\), we can choose a 2-simplex \(\sigma_n\) in \(C\) as indicated in the diagram
\[
\begin{array}{ccc}
X(n) & \xrightarrow{f_{n+1}} & X(n+1) \\
\downarrow g_{n+1} & & \downarrow f_n \\
Y & \xrightarrow{g_n} & X(n).
\end{array}
\]

Let \(X_0\) denote the restriction of \(X\) to the spine \(\text{Spine}[\mathbb{Z}_{\geq 0}^{\text{op}}] \subset N_\bullet(\mathbb{Z}_{\geq 0}^{\text{op}})\). Then the collection of 2-simplices \(\{\sigma_n\}_{n \geq 0}\) determines an extension of \(X_0\) to a diagram \(\overline{X}_0 : \text{Spine}[\mathbb{Z}_{\geq 0}^{\text{op}}] \to C\) carrying the cone point to the object \(Y\). The isomorphism class of this extension can be identified with a morphism \([g] : Y \to \text{lim}^{-}\text{lim}(X_0) \simeq \text{lim}^{-}(X)\) in the homotopy category \(hC\), which is a preimage of the sequence \(\{[g_n]\}_{n \geq 0}\) under the function \(\theta\).

**Warning 7.6.6.6.** In the situation of Remark 7.6.6.5, the map
\[
\theta : \text{Hom}_{\text{hc}}(Y, \text{lim}^{-}(X)) \to \text{lim}^{-}(\text{Hom}_{\text{hc}}(Y, X(n)))
\]
need not be injective. That is, the forgetful functor \(C \to N_\bullet(hC)\) generally does not preserve sequential limits (or colimits).
Example 7.6.6.7. Fix a prime number $p$. For every integer $n \geq 0$, let $p^n \mathbb{Z}$ denote the cyclic subgroup of $\mathbb{Z}$ generated by $p^n$, so that we have a tower of classifying simplicial sets

\[ \cdots \rightarrow B_\bullet(p^3 \mathbb{Z}) \rightarrow B_\bullet(p^2 \mathbb{Z}) \rightarrow B_\bullet(p \mathbb{Z}) \rightarrow B_\bullet(\mathbb{Z}). \] (7.62)

Then:

- The tower (7.62) has a limit in the ordinary category of simplicial sets, given by the simplicial set $\Delta^0$ (which we can identify with the classifying simplicial set for the trivial group $(0) = \cap_{n \geq 0} p^n \mathbb{Z}$).

- The simplicial set $\Delta^0$ is also a limit of the tower (7.62) in the homotopy category $\text{hKan}$.

- In the $\infty$-category $\mathcal{S}$, the tower (7.62) has a different limit, which has uncountably many connected components (see Remark [?]).

We now give some easy examples of sequential limits and colimits.

Example 7.6.6.8 (Sequential Colimits in $\mathcal{QC}$). Suppose we are given a collection of $\infty$-categories $\{\mathcal{C}(n)\}_{n \geq 0}$ and functors $F_n : \mathcal{C}(n) \rightarrow \mathcal{C}(n + 1)$, which we view as a diagram

\[ C(0) \xrightarrow{F_0} C(1) \xrightarrow{F_1} C(2) \xrightarrow{F_2} C(3) \rightarrow \cdots \]

Let $\lim_{\rightarrow n} \mathcal{C}(n)$ denote the colimit of this diagram (formed in the ordinary category of simplicial sets). Then $\lim_{\rightarrow n} \mathcal{C}(n)$ is also an $\infty$-category, which is also a colimit of the associated diagram $N_\bullet(\mathbb{Z}_{\geq 0}) \rightarrow \mathcal{QC}$. This is a special case of Corollary 7.5.9.3.

Variant 7.6.6.9 (Sequential Colimits in $\mathcal{S}$). Suppose we are given a collection of Kan complexes $\{X(n)\}_{n \geq 0}$ and morphisms $f_n : X(n) \rightarrow X(n + 1)$, which we view as a diagram

\[ X(0) \xrightarrow{f_0} X(1) \xrightarrow{f_1} X(2) \xrightarrow{f_2} X(3) \rightarrow \cdots \]

Let $\lim_{\rightarrow n} X(n)$ denote the colimit of this diagram (formed in the ordinary category of simplicial sets). Then $\lim_{\rightarrow n} X(n)$ is also a Kan complex, which is also a colimit of the associated diagram $N_\bullet(\mathbb{Z}_{\geq 0}) \rightarrow \mathcal{S}$. See Variant 7.5.9.4.

Example 7.6.6.10 (Towers of Isofibrations). Suppose we are given a collection of $\infty$-categories $\{\mathcal{C}(n)\}_{n \geq 0}$ and functors $F_n : \mathcal{C}(n + 1) \rightarrow \mathcal{C}(n)$, which we view as a tower

\[ \cdots \rightarrow \mathcal{C}(4) \xrightarrow{F_3} \mathcal{C}(3) \xrightarrow{F_2} \mathcal{C}(2) \xrightarrow{F_1} \mathcal{C}(1) \xrightarrow{F_0} \mathcal{C}(0) \]

If each of the functors $F_n$ is an isofibration, then the limit $\lim_{\leftarrow n} \mathcal{C}(n)$ (formed in the ordinary category of simplicial sets) is also an $\infty$-category, which can be also be viewed as a limit of the associated tower $N_\bullet(\mathbb{Z}^{op}_{\geq 0}) \rightarrow \mathcal{QC}$. This follows by combining Example 4.5.6.7, Example 7.5.5.3 and Proposition 7.5.5.7.
Variant 7.6.6.11 (Towers of Kan Fibrations). Suppose we are given a collection of Kan complexes \( \{X(n)\}_{n \geq 0} \) and morphisms \( f_n : X(n + 1) \to X(n) \), which we view as a tower
\[
\cdots \to X(4) \xrightarrow{f_3} X(3) \xrightarrow{f_2} X(2) \xrightarrow{f_1} X(1) \xrightarrow{f_0} X(0).
\]
If each of the morphisms \( f_n \) is a Kan fibration, then the limit \( \lim_{\leftarrow n} X(n) \) (formed in the ordinary category of simplicial sets) is also a Kan complex, which can be also be viewed as a limit of the associated tower \( N_* (\mathbb{Z}_{\geq 0}^\text{op}) \to \mathcal{S} \) (combine Example 7.6.6.10 with Proposition 7.4.5.1).

Variant 7.6.6.12 (Limits of General Towers). Suppose we are given a sequence of \( \infty \)-categories \( \{\mathcal{C}(n)\}_{n \geq 0} \) and functors \( F_n : \mathcal{C}(n + 1) \to \mathcal{C}(n) \), which we view as a tower
\[
\cdots \to \mathcal{C}(4) \xrightarrow{F_3} \mathcal{C}(3) \xrightarrow{F_2} \mathcal{C}(2) \xrightarrow{F_1} \mathcal{C}(1) \xrightarrow{F_0} \mathcal{C}(0)
\]
(7.63)
If the functors \( F_n \) are not assumed to be isofibrations, then the limit \( \lim_{\leftarrow n} \mathcal{C}(n) \) (formed in the ordinary category of simplicial sets) might not be a limit of the associated tower in \( \mathcal{QC} \) (for example, \( \lim_{\leftarrow n} \mathcal{C}(n) \) might fail to be an \( \infty \)-category). Nevertheless, we can always compute the relevant limit in \( \mathcal{QC} \) by replacing (7.63) by a levelwise equivalent diagram of \( \infty \)-categories in which the transition functors are isofibrations. For example, we can replace (7.63) by the isofibrant tower of iterated homotopy fiber products
\[
\cdots \to \mathcal{C}(2) \times \mathcal{C}(1)^h \mathcal{C}(0) \to \mathcal{C}(1) \times \mathcal{C}(0) \to \mathcal{C}(0).
\]
Let us denote the limit of this tower (in the category of simplicial sets) by
\[
\cdots \to \mathcal{C}(2) \times \mathcal{C}(1)^h \mathcal{C}(0) \times \mathcal{C}(1)^h \mathcal{C}(0) \times \mathcal{C}(0).
\]
It is an \( \infty \)-category whose objects can be identified with sequences of pairs \( \{(C_n, \alpha_n)\}_{n \geq 0} \), where each \( C_n \) is an object of the \( \infty \)-category \( \mathcal{C}(n) \) and each \( \alpha_n : F_n(C_{n+1}) \to C_n \) is an isomorphism in the \( \infty \)-category \( \mathcal{C}(n) \). Combining Example 7.6.6.10 with Remark 7.1.1.8 we see that it can be identified with a limit of the diagram (7.63) in the \( \infty \)-category \( \mathcal{QC} \).

Sequential limits are useful for building more complicated types of limits.

Proposition 7.6.6.13. Suppose we are given a diagram of simplicial sets
\[
K(0) \to K(1) \to K(2) \to K(3) \to \cdots
\]
having colimit \( K \). Let \( \mathcal{C} \) be an \( \infty \)-category and let \( f : K \to \mathcal{C} \) be a diagram, corresponding to a compatible sequence of diagrams \( f_n : K(n) \to \mathcal{C} \). Suppose that each of the diagrams \( f_n \) admits a limit in \( \mathcal{C} \). Then there exists a tower \( X : N_* (\mathbb{Z}_{\geq 0}^\text{op}) \to \mathcal{C} \) with the following properties:
7.6. EXAMPLES OF LIMITS AND COLIMITS

(1) For each \( n \geq 0 \), the object \( X(n) \in C \) is a limit of the diagram \( f_n \).

(2) An object of \( C \) is a limit of the diagram \( f \) if and only if it is a limit of the tower \( X \). In particular, the diagram \( f \) has a limit if and only if the tower \( X \) has a limit.

(3) Let \( F : C \to D \) be a functor of \( \infty \)-categories which preserves the limits of each of the diagrams \( f_n \). Then \( F \) preserves limits of the diagram \( f \) if and only if it preserves limits of the tower \( X \).

Proof. Combine Propositions 7.5.8.12 and 7.5.9.1. \( \square \)

Corollary 7.6.6.14. Suppose we are given a diagram of simplicial sets

\[ K(0) \to K(1) \to K(2) \to K(3) \to \cdots \]

having colimit \( K \), and let \( C \) be an \( \infty \)-category which admits sequential limits and \( K(n) \)-indexed limits, for each \( n \geq 0 \). Then \( C \) admits \( K \)-indexed colimits. If \( F : C \to D \) is a functor of \( \infty \)-categories which preserves the limits of each \( K(n) \)-indexed limits for each \( n \geq 0 \), then it also preserves \( K \)-indexed limits.

Example 7.6.6.15. Let \( C \) be an \( \infty \)-category which admits finite products. If \( C \) admits sequential limits, then it also admits countable products. More precisely, for any countable collection of objects \( \{ X_n \}_{n \geq 0} \) of \( C \), the product \( \prod_{n \geq 0} X_n \) can be computed as the limit of a tower

\[ \cdots \to X_2 \times X_1 \times X_0 \to X_1 \times X_0 \to X_0. \]

We now establish a partial converse to Example 7.6.6.15. Let \( C \) be an \( \infty \)-category which admits countable products, and suppose that we are given a tower

\[ \cdots \to X(3) \xrightarrow{f_2} X(2) \xrightarrow{f_1} X(1) \xrightarrow{f_0} X(0) \]

in \( C \). Then the collection of morphisms \( \{ f_n \}_{n \geq 0} \) determine an endomorphism \( f \) of the product \( P = \prod_{n \geq 0} X(n) \), given informally by the composition

\[
\begin{align*}
P &= \prod_{n \geq 0} X(n) \\
&\to \prod_{n > 0} X(n) \\
&= \prod_{m \geq 0} X(m + 1) \\
&\xrightarrow{\prod_{m \geq 0} f_m} \prod_{m \geq 0} X(m) \\
&= P.
\end{align*}
\]
In this case, we can identify limits of the tower $X$ with equalizers of the pair of morphisms $f, \text{id}_P : P \to P$. We can formulate this assertion more precisely as follows:

**Proposition 7.6.6.16 (Sequential Limits as Equalizers).** Let $C$ be an $\infty$-category and let $X : N_* \to C$ be a tower, which we identify with the diagram

$$
\cdots \to X(3) \overset{f_2}{\to} X(2) \overset{f_1}{\to} X(1) \overset{f_0}{\to} X(0).
$$

Suppose that there exists an object $P \in C$ equipped with morphisms $\{q_n : P \to X(n)\}_{n \geq 0}$ which exhibits $P$ as a product of the collection $\{X(n)\}_{n \geq 0}$. Then:

1. There exists a morphism $f : P \to P$ with the property that, for each $n \geq 0$, the diagram

$$
\begin{array}{ccc}
P & \overset{[f]}{\to} & P \\
\downarrow^{[q_{n+1}]} & & \downarrow^{[q_n]} \\
X(n+1) & \overset{[f_n]}{\to} & X(n)
\end{array}
$$

(7.64)

commutes in the homotopy category $hC$. Moreover, the morphism $f$ is uniquely determined up to homotopy.

2. An object of $C$ is a limit of the tower $X$ if and only if it is an equalizer of the pair of morphisms $f, \text{id}_P : P \to P$.

**Proof.** Assertion (1) follows immediately from the definitions (see Warning 7.6.1.11). To prove (2), let $M = \mathbb{Z}_{\geq 0}$ denote the set of nonnegative integers, which we regard as a commutative monoid with respect to addition. Let $BM$ denote the associated category (consisting of a single object $E$ having endomorphism monoid $\text{Hom}_{BM}(E,E) = M$) and let $B_* M$ denote the nerve of $BM$ (see Example 1.2.4.3). There is a functor of ordinary categories $(\mathbb{Z}_{\geq 0}, \leq)_{\text{op}} \to BM$ which is characterized by the requirement that, for every pair of nonnegative integers $m \leq n$, the induced map

$$
\text{Hom}_{\mathbb{Z}_{\geq 0}}(m,n) \to \text{Hom}_{BM}(E,E) = M
$$

carries the unique element of $\text{Hom}_{\mathbb{Z}_{\geq 0}}(m,n)$ to the difference $n - m \in M$. Passing to nerves, we obtain a functor of $\infty$-categories $U : N_* \to B_* M$. The functor $U$ is a cartesian fibration, whose fiber over the vertex $E \in B_* M$ can be identified with the discrete simplicial set $\{0, 1, 2, \cdots \}$. Applying Corollary 7.3.4.8, we deduce that there exists a functor $Y : B_* M \to C$ and a natural transformation $\alpha : Y \circ U \to X$ which exhibits $Y$ as a right Kan extension of $X$ along $U$. 
For every nonnegative integer \( n \), \( \alpha \) induces a morphism \( \alpha_n : Y(E) \to X(n) \) in the \( \infty \)-category \( C \). Using the criterion of Proposition 7.3.4.1 we see that the collection of morphisms \( \{ \alpha_n \}_{n \geq 0} \) exhibit \( Y(E) \) as a product of the collection of objects \( \{ X(n) \}_{n \geq 0} \). We may therefore assume without loss of generality that \( P = Y(E) \) and \( q_n = \alpha_n \), for each \( n \geq 0 \).

Let \( f : P \to P \) be the morphism obtained by evaluating the functor \( Y \) on the generator \( 1 \in M \). For each \( n \geq 0 \), the natural transformation \( \alpha \) carries the edge \( n + 1 \to n \) of \( N_\ast(Z \geq 0) \) to a commutative diagram

\[
P \xrightarrow{f} P \\
\downarrow{q_{n+1}} \quad \downarrow{q_n} \\
X(n+1) \xrightarrow{f_n} X(n)
\]

in the \( \infty \)-category \( C \), which witnesses the commutativity of the diagram (7.64) in the homotopy category \( hC \). Moreover, an object \( C \in C \) is an equalizer of the pair of morphisms \( f, \text{id}_P : P \to P \) if and only if it is a limit of the diagram \( Y \) (Variant 7.6.5.9). To prove (2), it suffices to observe that this is equivalent to the requirement that \( C \) is a limit of the tower \( X \), which follows from Corollary 7.3.7.20.

**Remark 7.6.6.17.** In the situation of Proposition 7.6.6.16, suppose that \( F : C \to D \) is a functor of \( \infty \)-categories which preserves the product of the collection \( \{ X(n) \}_{n \geq 0} \). Then \( F \) preserves limits of the tower \( X \) if and only if it preserves equalizers of the pair of morphisms \( f, \text{id}_P : P \to P \).

### 7.6.7 Small Limits

We now study limits and colimits indexed by diagrams of bounded size.

**Definition 7.6.7.1.** Let \( C \) be an \( \infty \)-category and let \( \kappa \) be an infinite cardinal. We say that \( C \) admits \( \kappa \)-small limits if it admits \( K \)-indexed limits for every \( \kappa \)-small simplicial set \( K \) (see Definition 5.4.4.1).

We say that a functor of \( \infty \)-categories \( F : C \to D \) preserves \( \kappa \)-small limits if it preserves \( K \)-indexed limits, for every \( \kappa \)-small simplicial set \( K \) (Definition 7.1.3.4).

**Remark 7.6.7.2.** Let \( C \) be an \( \infty \)-category and let \( \lambda \) be an infinite cardinal. If \( C \) admits \( \lambda \)-small limits, then it also admits \( \kappa \)-small limits for each infinite cardinal \( \kappa < \lambda \). Similarly, if a functor \( F : C \to D \) preserves \( \lambda \)-small limits, then it also preserves \( \kappa \)-small limits for each \( \kappa < \lambda \). In both cases, the converse holds if \( \lambda \) is an uncountable limit cardinal (since, in that case, every \( \lambda \)-small simplicial set \( K \) is \( \kappa \)-small for some \( \kappa < \lambda \)).
Example 7.6.7.3. An \(\infty\)-category \(\mathcal{C}\) admits \(\aleph_0\)-small limits if and only if it admits finite limits. Similarly, a functor \(F : \mathcal{C} \to \mathcal{D}\) preserves \(\aleph_0\)-small limits if and only if it preserves finite limits.

Example 7.6.7.4. Let \(\lambda\) be an uncountable regular cardinal and let \(\kappa = \text{ecf}(\lambda)\) be its exponential cofinality (Definition 5.4.3.16). Let \(\mathcal{S}^{<\lambda}\) denote the \(\infty\)-category of \(\lambda\)-small spaces (Variant 5.6.4.12) and let \(\mathcal{QC}^{<\lambda}\) denote the \(\infty\)-category of \(\lambda\)-small \(\infty\)-categories (Variant 5.6.4.10). Then the \(\infty\)-categories \(\mathcal{S}^{<\lambda}\) and \(\mathcal{QC}^{<\lambda}\) admit \(\kappa\)-small limits. Moreover, the inclusion maps

\[
\mathcal{S}^{<\lambda} \hookrightarrow \mathcal{S} \quad \mathcal{QC}^{<\lambda} \hookrightarrow \mathcal{QC}
\]

preserve \(\kappa\)-small limits. See Corollary 7.4.1.12 and Variant 7.4.5.8. In particular, if \(\kappa = \lambda\) is a strongly inaccessible cardinal, then the \(\infty\)-categories \(\mathcal{S}^{<\kappa}\) and \(\mathcal{QC}^{<\kappa}\) admit \(\kappa\)-small limits.

Remark 7.6.7.5. Let \(\kappa\) be an uncountable cardinal and let \(\mathcal{C}\) be an \(\infty\)-category. The following conditions are equivalent:

- The \(\infty\)-category \(\mathcal{C}\) admits \(K\)-indexed limits, for every simplicial set \(K\) which is \(\kappa\)-small.
- The \(\infty\)-category \(\mathcal{C}\) admits \(K\)-indexed limits, for every simplicial set \(K\) which is essentially \(\kappa\)-small.

Moreover, in either case, it suffices to consider the case where \(K\) is an \(\infty\)-category. See Remark 7.1.1.16 and Proposition 5.4.5.5. Similarly, a functor \(F : \mathcal{C} \to \mathcal{D}\) preserves \(\kappa\)-small limits if and only if it preserves \(K\)-indexed limits, for every simplicial set \(K\) which is essentially \(\kappa\)-small (and it again suffices to consider the case where \(K\) is an \(\infty\)-category).

Variant 7.6.7.6. Let \(\kappa\) be an infinite cardinal. We say that an \(\infty\)-category \(\mathcal{C}\) admits \(\kappa\)-small colimits if it admits \(K\)-indexed colimits, for every \(\kappa\)-small simplicial set \(K\). Equivalently, the \(\infty\)-category \(\mathcal{C}\) admits \(\kappa\)-small colimits if the opposite \(\infty\)-category \(\mathcal{C}^{\text{op}}\) admits \(\kappa\)-small limits.

We say that a functor of \(\infty\)-categories \(F : \mathcal{C} \to \mathcal{D}\) preserves \(\kappa\)-small colimits if it preserves \(K\)-indexed colimits, for every \(\kappa\)-small simplicial set \(K\). Equivalently, \(F\) preserves \(\kappa\)-small colimits if the opposite functor \(F^{\text{op}} : \mathcal{C}^{\text{op}} \to \mathcal{D}^{\text{op}}\) preserves \(\kappa\)-small limits.

Example 7.6.7.7. Let \(\lambda\) be an uncountable regular cardinal and let \(\kappa = \text{cf}(\lambda)\) denote its cofinality. Then the \(\infty\)-categories \(\mathcal{S}^{<\lambda}\) and \(\mathcal{QC}^{<\lambda}\) admit \(\kappa\)-small colimits. Moreover, the inclusion maps

\[
\mathcal{S}^{<\lambda} \hookrightarrow \mathcal{S} \quad \mathcal{QC}^{<\lambda} \hookrightarrow \mathcal{QC}
\]

preserve \(\kappa\)-small colimits. See Corollary 7.4.3.15 and Remark 7.4.5.7. In particular, if \(\kappa = \lambda\) is an uncountable regular cardinal, then the \(\infty\)-categories \(\mathcal{S}^{<\kappa}\) and \(\mathcal{QC}^{<\kappa}\) admit \(\kappa\)-small colimits.
Proposition 7.6.7.8. Let \( C \) be an \( \infty \)-category and let \( \kappa \) be an infinite cardinal. Then \( C \) admits \( \kappa \)-small limits if and only if it satisfies the following conditions:

1. The \( \infty \)-category \( C \) admits \( \kappa \)-small products. That is, every collection of objects \( \{X_j\}_{j \in J} \) indexed by a \( \kappa \)-small set \( J \) admits a product in \( C \).

2. The \( \infty \)-category \( C \) admits finite limits.

Proof. Assume that \( C \) satisfies conditions (1) and (2); we wish to show that \( C \) admits \( \kappa \)-small limits (the converse is immediate from the definitions). Let \( S \) be a \( \kappa \)-small simplicial set; we wish to show that \( C \) admits \( S \)-indexed limits. If \( \kappa = \aleph_0 \), this follows immediately from assumption (2) (Example 7.6.7.3). We may therefore assume that \( \kappa \) is uncountable, so that \( C \) admits countable products.

For each \( n \geq 0 \), let \( \text{sk}_n(S) \) denote the \( n \)-skeleton of \( S \) (Construction 1.1.3.5), so that \( S = \bigcup_n \text{sk}_n(S) \). It follows from Proposition 7.6.6.16 that \( C \) admits sequential limits. Consequently, to show that \( C \) admits \( S \)-indexed limits, it will suffice to show that it admits \( \text{sk}_n(S) \)-indexed limits, for each \( n \geq 0 \) (Corollary 7.6.6.14). We may therefore assume without loss of generality that the simplicial set \( S \) has finite dimension. We proceed by induction on the dimension \( n \) of \( S \). If \( n = -1 \), then \( S \) is empty and the desired result is immediate. Assume that \( n \geq 0 \) and let \( \{\sigma_j\}_{j \in J} \) denote the collection of nondegenerate \( n \)-simplices of \( S \), so that Proposition 1.1.3.13 supplies a pushout diagram of simplicial sets

\[
\begin{array}{ccc}
\prod_{j \in J} \partial \Delta^n & \rightarrow & \prod_{j \in J} \Delta^n \\
\downarrow & & \downarrow \\
\text{sk}_{n-1}(S) & \rightarrow & \text{sk}_n(S).
\end{array}
\]

Since the horizontal maps in this diagram are monomorphisms, it is also a categorical pushout square (Example 4.5.4.12). By virtue of Proposition 7.6.3.17, it will suffice to show that \( C \) admits limits indexed by the simplicial sets \( \text{sk}_{n-1}(S) \), \( J \times \partial \Delta^n \), and \( J \times \Delta^n \). In the first two cases, this follows from our inductive hypothesis. To handle the third case, we can use assumption (1) and Corollary 7.6.1.19 to reduce to showing that the \( \infty \)-category \( C \) admits \( \Delta^n \)-indexed limits. This is clear, since the simplicial set \( \Delta^n \) is an \( \infty \)-category containing an initial object (see Corollary 7.2.2.12).

Remark 7.6.7.9. In the situation of Proposition 7.6.7.8, we can replace (2) by either of the following \textit{a priori} weaker conditions:

(2') The \( \infty \)-category \( C \) admits pullbacks.
(2′′) The $\infty$-category $\mathcal{C}$ admits equalizers.

See Corollary 7.6.3.18 and 7.6.5.25

**Exercise 7.6.7.10.** Let $\kappa$ be an infinite cardinal, let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories, and suppose that $\mathcal{C}$ admits $\kappa$-small limits. Show that $F$ preserves $\kappa$-small limits if and only if it preserves finite limits and $\kappa$-small products.

**Corollary 7.6.7.11.** Let $\mathcal{C}$ be an $\infty$-category and let $\lambda$ be an infinite cardinal which is not regular. The following conditions are equivalent:

1. The $\infty$-category $\mathcal{C}$ admits $\lambda$-small limits.
2. For every infinite cardinal $\kappa < \lambda$, the $\infty$-category $\mathcal{C}$ admits $\kappa$-small limits.
3. The $\infty$-category $\mathcal{C}$ admits $\lambda^+$-small limits, where $\lambda^+$ denotes the successor of $\lambda$.

By virtue of Corollary 7.6.7.11, little information is lost by restricting the use of Definition 7.6.7.1 to the case where $\kappa$ is a regular cardinal.

**Proof of Corollary 7.6.7.11.** The equivalence (1) $\iff$ (2) and the implication (3) $\implies$ (1) follow from Remark 7.6.7.2. We will complete the proof by showing that (1) implies (3). Assume that $\mathcal{C}$ admits $\lambda$-small limits; we wish to show that it admits $\lambda^+$-small limits. By virtue of Proposition 7.6.7.8, it will suffice to show that every collection of objects $\{X_i\}_{i \in I}$ admits a product in $\mathcal{C}$, provided that the index set $I$ has cardinality $\leq \lambda$. Our assumption that $\lambda$ is not regular guarantees that we can decompose $I$ as a disjoint union of $\lambda$-small subsets $\{I_j \subseteq I\}_{j \in J}$, where the index set $J$ is $\lambda$-small. It follows from (1) that $\mathcal{C}$ admits $J$-indexed products and also that it admits $I_j$-indexed products for each $j \in J$, and therefore admits $I$-indexed products by virtue of Corollary 7.6.1.19.

The existence of $\kappa$-small colimits can be used to prove the existence of a large class of Kan extensions.

**Proposition 7.6.7.12.** Let $\kappa$ be an uncountable regular cardinal and let $K$ be a simplicial set which is essentially $\kappa$-small. Suppose we are given a pair of $\infty$-categories $\mathcal{C}$ and $\mathcal{D}$, together with diagrams $\delta : K \to \mathcal{C}$ and $F_0 : K \to \mathcal{D}$. Suppose that $\mathcal{C}$ is locally $\kappa$-small and that $\mathcal{D}$ admits $\kappa$-small colimits. Then $F_0$ admits a left Kan extension along $\delta$.

**Proof.** By virtue of Proposition 7.3.5.1, it will suffice to show that for every object $C \in \mathcal{C}$, the composite map

$\mathcal{K} \times_{\mathcal{C}} \mathcal{C} / C \to K \overset{F_0}{\longrightarrow} \mathcal{D}$

admits a colimit in the $\infty$-category $\mathcal{D}$. Note that the projection map $\mathcal{K} \times_{\mathcal{C}} \mathcal{C} / C$ is a right fibration of simplicial sets (Proposition 4.3.6.1), whose fiber over each vertex $x \in K$ can...
be identified with the Kan complex $\text{Hom}^R_C(\delta(x), C)$. Invoking Proposition 4.6.5.9 we see that $\text{Hom}^R_C(\delta(x), C)$ is homotopy equivalent to the morphism space $\text{Hom}_C(\delta(x), C)$, and is therefore essentially $\kappa$-small (by virtue of our assumption that $\mathcal{C}$ is locally $\kappa$-small). Since $K$ is essentially $\kappa$-small, Corollary 5.4.8.11 implies that $K \times_{\mathcal{C}} \mathcal{C}/C$ is essentially $\kappa$-small. The desired result now follows from our assumption that $\mathcal{D}$ admits $\kappa$-small colimits (Remark 7.6.7.5).
Chapter 8

The Yoneda Embedding

8.1 Twisted Arrows and Cospans

Let \( \mathcal{C} \) be an \( \infty \)-category. In §4.6.1 we associated to every pair of objects \( X, Y \in \mathcal{C} \) a Kan complex \( \text{Hom}_\mathcal{C}(X, Y) \), whose vertices are morphisms from \( X \) to \( Y \). In §[?], we will see that the construction \( (X, Y) \mapsto \text{Hom}_\mathcal{C}(X, Y) \) can be refined to a functor of \( \infty \)-categories

\[
\text{Hom}_\mathcal{C}(\bullet, \bullet) : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S} = \mathsf{N}^{\text{hc}}(\text{Kan}).
\]

It is somewhat cumbersome to give an explicit description of this functor. It will therefore be more convenient to specify it implicitly by realizing it as the covariant transport representation of a left fibration over \( \mathcal{C}^{\text{op}} \times \mathcal{C} \). We begin by discussing the counterpart of this fibration in the setting of classical category theory.

**Construction 8.1.0.1** (The Twisted Arrow Category). Let \( \mathcal{C} \) be a category. We define a new category \( \text{Tw}(\mathcal{C}) \) as follows:

- An object of \( \text{Tw}(\mathcal{C}) \) is a morphism \( f : X \to Y \) in \( \mathcal{C} \).
- Let \( f : X \to Y \) and \( f' : X' \to Y' \) be objects of \( \text{Tw}(\mathcal{C}) \). A morphism from \( f \) to \( f' \) in \( \text{Tw}(\mathcal{C}) \) is a pair of morphisms \( u : X' \to X \), \( v : Y \to Y' \) in \( \mathcal{C} \) satisfying \( f' = v \circ f \circ u \), so that we have a commutative diagram

\[
\begin{array}{ccc}
X & \xleftarrow{u} & X' \\
\downarrow{f} & & \downarrow{f'} \\
Y & \xrightarrow{v} & Y'.
\end{array}
\]
Let $f : X \to Y$, $f' : X' \to Y'$, and $f'' : X'' \to Y''$ be objects of $\text{Tw}(\mathcal{C})$. If $(u,v)$ is a morphism from $f$ to $f'$ in $\text{Tw}(\mathcal{C})$ and $(u',v')$ is a morphism from $f'$ to $f''$ in $\mathcal{C}$, then the composition $(u',v') \circ (u,v)$ in $\text{Tw}(\mathcal{C})$ is the pair $(u \circ u', v' \circ v)$.

We will refer to $\text{Tw}(\mathcal{C})$ as the twisted arrow category of $\mathcal{C}$.

**Remark 8.1.0.2.** Let $\mathcal{C}$ be a category. Then the construction $(f : X \to Y) \mapsto (X,Y)$ determines a forgetful functor $\lambda : \text{Tw}(\mathcal{C}) \to \mathcal{C}^{\text{op}} \times \mathcal{C}$. Moreover, $\lambda$ is a left covering functor, in the sense of Definition 4.2.3.1.

**Remark 8.1.0.3 (Tw(\mathcal{C}) as a Category of Elements).** Let $\mathcal{C}$ be a category. Then the construction $(X,Y) \mapsto \text{Hom}_\mathcal{C}(X,Y)$ determines a functor $\text{Hom}_\mathcal{C}(\bullet,\bullet) : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \text{Set}$. The twisted arrow category $\text{Tw}(\mathcal{C})$ of Construction 8.1.0.1 can be identified with the category of elements $\int_{\mathcal{C}^{\text{op}} \times \mathcal{C}} \text{Hom}_\mathcal{C}(\bullet,\bullet)$ (see Construction 5.2.6.1).

It follows that the functor $\text{Hom}_\mathcal{C}(\bullet,\bullet)$ is determined (up to canonical isomorphism) by the datum of the twisted arrow category $\text{Tw}(\mathcal{C})$ together with the forgetful functor $\lambda : \text{Tw}(\mathcal{C}) \to \mathcal{C}^{\text{op}} \times \mathcal{C}$ of Remark 8.1.0.2 (see Corollary 5.2.7.5).

**Warning 8.1.0.4 (Untwisted Arrow Categories).** Let $[1] = \{0 < 1\}$ denote a linearly ordered set with two elements. For any category $\mathcal{C}$, we can identify morphisms of $\mathcal{C}$ with functors $F : [1] \to \mathcal{C}$. The collection of such functors can be organized into a category $\text{Fun}([1],\mathcal{C})$, which we refer to as the arrow category of $\mathcal{C}$. The arrow category $\text{Fun}([1],\mathcal{C})$ has the same objects as the twisted arrow category $\text{Tw}(\mathcal{C})$. However, the morphisms are different: if $f : X \to Y$ and $f' : X' \to Y'$ are morphisms of $\mathcal{C}$, then morphisms from $f$ to $f'$ in $\text{Fun}([1],\mathcal{C})$ can be identified with commutative diagrams

$$
\begin{array}{ccc}
X & \longrightarrow & X' \\
\downarrow^{f} & & \downarrow^{f'} \\
Y & \longrightarrow & Y'
\end{array}
$$

where the horizontal maps are oriented in the same direction.

**Example 8.1.0.5.** Let $Q$ be a partially ordered set, which we regard as a category. Then the twisted arrow category $\text{Tw}(Q)$ can be identified (via the forgetful functor of Remark 8.1.0.2) with the partially ordered set

$$\{(p,q) \in Q^{\text{op}} \times Q : p \leq q\} \subseteq Q^{\text{op}} \times Q.$$

**Remark 8.1.0.6.** Let $\mathcal{C}$ be a category. For every object $X \in \mathcal{C}$, the fiber $\{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C})$ can be identified with the coslice category $\mathcal{C}_{/X}$ of Variant 4.3.1.4. Similarly, the fiber $\text{Tw}(\mathcal{C}) \times_{\mathcal{C}} \{X\}$ can be identified with the opposite of the slice category $\mathcal{C}_{/X}$ of Construction 4.3.1.1.
In §8.1.1, we generalize Construction 8.1.0.1 to the setting of \(\infty\)-categories. To every simplicial set \(C\), we associate another simplicial set \(\text{Tw}(C)\), whose \(n\)-simplices can be identified with \((2n + 1)\)-simplices of \(C\) (Construction 8.1.1.1). This construction has the following features:

- If \(C = N_\bullet(C_0)\) is (the nerve of) an ordinary category \(C_0\), then \(\text{Tw}(C)\) can be identified with the nerve of the twisted arrow category \(\text{Tw}(C_0)\) (Proposition 8.1.1.9). Consequently, the twisted arrow construction of §8.1.1 can be regarded as a generalization of Construction 8.1.0.1.

- The simplicial set \(\text{Tw}(C)\) is equipped with a projection map \(\lambda : \text{Tw}(C) \to C^\text{op} \times C\). If \(C\) is an \(\infty\)-category, then \(\lambda\) is a left fibration (Proposition 8.1.1.10); in particular, \(\text{Tw}(C)\) is also an \(\infty\)-category (Corollary 8.1.1.11).

Let \(C\) be an \(\infty\)-category. In §8.1.2, we study the fibers of the left fibration \(\lambda : \text{Tw}(C) \to C^\text{op} \times C\). Our main result asserts that if \(f : X \to Y\) is an isomorphism in the \(\infty\)-category \(C\), then \(f\) is initial when viewed as an object of the \(\infty\)-category \(\{X\} \times_{C^\text{op}} \text{Tw}(C)\) (see Proposition 8.1.2.1, and Corollary 8.1.2.16 for the converse). From this, we deduce an analogue of Remark 8.1.0.6: there is a canonical equivalence of \(\infty\)-categories \(C_{X/} \simeq \{X\} \times_{C^\text{op}} \text{Tw}(C)\) (Proposition 8.1.2.5), which induces a homotopy equivalence of Kan complexes

\[\text{Hom}_C(X, Y) \simeq \{X\} \times_{C^\text{op}} \text{Tw}(C) \times_{C} \{Y\}\]

for each object \(Y \in C\) (Notation 8.1.2.10). Moreover, we show that these homotopy equivalences are compatible with covariant transport for the left fibration \(\lambda\) (Corollary 8.1.2.13).

The twisted arrow construction can be characterized by a universal mapping property. Let \(C\) be an \(\infty\)-category, and let \(\lambda_+ : \text{Tw}(C) \to C\) denote the composition of \(\lambda\) with the projection map \(C^\text{op} \times C \to C\). Then \(\lambda_+\) is a cocartesian fibration of \(\infty\)-categories (Corollary 8.1.1.12). Moreover, for each object \(X \in C\), the fiber \(\lambda_+^{-1}\{X\}\) has an initial object (given by the identity morphism \(\text{id}_X\), regarded as an object of \(\text{Tw}(C)\)). In §8.1.3 we show that \(\lambda_+\) is universal with respect to these properties. More precisely, we show that if \(U : \mathcal{E} \to C\) is any cocartesian fibration having the property that each fiber \(\mathcal{E}_X = \mathcal{E} \times_C \{X\}\) has an initial object, then there is an essentially unique functor \(F \in \text{Fun}_{/C}^{\text{CCart}}(\text{Tw}(C), \mathcal{E})\) which carries each identity morphism \(\text{id}_X \in \text{Tw}(C)\) to an initial object of the \(\infty\)-category \(\mathcal{E}_X\). Moreover, the functor \(F\) is initial when regarded as an object of the larger \(\infty\)-category \(\text{Fun}_{/C}(\text{Tw}(C), \mathcal{E})\) (see Theorem 8.1.3.1 and Remark 8.1.3.2).

The twisted arrow construction \(\mathcal{S} \mapsto \text{Tw}(\mathcal{S})\) determines a functor from the category of simplicial sets to itself. In particular, to every simplicial set \(T\) we can associate a new simplicial set \(\text{Cospan}(T)\), whose \(n\)-simplices are given by maps \(\text{Tw}(\Delta^n) \to T\). We will refer to \(\text{Cospan}(T)\) as the \textit{simplicial set of cospans in} \(T\) (Construction 8.1.4.1). This construction has the following features:
8.1. TWISTED ARROWS AND COSPANS

- The construction \( T \mapsto \text{Cospan}(T) \) determines a functor from the category of simplicial sets to itself, which is right adjoint to the twisted arrow functor \( S \mapsto \text{Tw}(S) \) (Corollary 8.1.4.8).

- Let \( \mathcal{C} \) be an ordinary category which admits pushouts, and let \( \text{Cospan}(\mathcal{C}) \) denote the 2-category of cospans in \( \mathcal{C} \) (Example 2.2.2.1). Then there is a canonical isomorphism of simplicial sets
  \[ \text{Cospan}(N\bullet(C)) \cong N\bullet(\text{Cospan}(\mathcal{C})), \]
  which we construct in §8.1.4 (see Corollary 8.1.4.12).

- Let \( \mathcal{C} \) be a 2-category containing a pair of objects \( X \) and \( Y \), and let \( \text{Hom}_\mathcal{C}(X, Y) \) denote the category of 1-morphisms from \( X \) to \( Y \). Then there is a canonical isomorphism of simplicial sets
  \[ \text{Cospan}(N\bullet(\text{Hom}_\mathcal{C}(X, Y))) \cong \text{Hom}_{N\bullet(\mathcal{C})}(X, Y), \]
  which we construct in §8.1.5 (see Corollary 8.1.5.6).

- If \( \mathcal{C} \) is an \( \infty \)-category which admits pushouts, then the simplicial set \( \text{Cospan}(\mathcal{C}) \) is an \((\infty, 2)\)-category (Proposition 8.1.6.1). We prove this in §8.1.6 using an explicit characterization of the collection of thin 2-simplices of \( \text{Cospan}(\mathcal{C}) \) (Proposition 8.1.6.2), which we prove in §8.1.7.

8.1.1 The Twisted Arrow Construction

We now describe an \( \infty \)-categorical generalization of Construction 8.1.0.1.

**Construction 8.1.1.1** (Twisted Arrows in Simplicial Sets). Let \( \Delta \) denote the simplex category (Definition 1.1.1.2) and let \( \mathcal{C} \) be a simplicial set. We let \( \text{Tw}(\mathcal{C}) : \Delta^{\text{op}} \to \text{Set} \) denote the functor given by the construction

\[ (J \in \Delta^{\text{op}}) \mapsto \text{Hom}_{\Delta}(N\bullet(J^{\text{op}} \ast J), \mathcal{C}). \]

We will refer to \( \text{Tw}(\mathcal{C}) \) as the **simplicial set of twisted arrows of \( \mathcal{C} \).**

**Remark 8.1.1.2.** For every integer \( n \geq 0 \), there is a unique isomorphism of simplicial sets \( N\bullet([n]^{\text{op}} \ast [n]) \cong \Delta^{2n+1} \). It follows that, for every simplicial set \( \mathcal{C} \), we can identify \( n \)-simplices \( \sigma \) of \( \text{Tw}(\mathcal{C}) \) with \((2n + 1)\)-simplices \( \overline{\sigma} \) of \( \mathcal{C} \). In terms of these identifications, the face and degeneracy operators of \( \text{Tw}(\mathcal{C}) \) are given explicitly by the formulae

\[ d_i\overline{\sigma} = d_{n-i}d_{n+1+i}\overline{\sigma} \quad s_i\overline{\sigma} = s_{n-i}s_{n+1+i}\overline{\sigma}. \]
CHAPTER 8. THE YONEDA EMBEDDING

Remark 8.1.1.3. Let \( C \) be a simplicial set. We will generally use Remark 8.1.1.2 to identify vertices of the simplicial set \( \text{Tw}(C) \) with edges \( f : X \to Y \) of \( C \). More generally, it will be useful to think of \( n \)-simplices of \( \text{Tw}(C) \) as encoding diagrams

\[
\begin{array}{cccccc}
X_0 & \leftarrow & X_1 & \leftarrow & X_2 & \leftarrow & \cdots & \leftarrow & X_n \\
| & & | & & | & & | & & |
\downarrow f_0 & & \downarrow f_1 & & \downarrow f_2 & & \cdots & & \downarrow f_n \\
Y_0 & \rightarrow & Y_1 & \rightarrow & Y_2 & \cdots & & \rightarrow & Y_n.
\end{array}
\]

Remark 8.1.1.4. The construction \( C \mapsto \text{Tw}(C) \) determines a functor from the category of simplicial sets to itself, which preserves all limits and colimits (this follows from Remark 8.1.1.2, since limits and colimits in the category \( \text{Set}_\Delta \) are computed levelwise).

Notation 8.1.1.5 (Projection Maps). Let \( C \) be a simplicial set. Then the simplicial set \( \text{Tw}(C) \) is equipped with projection maps \( \lambda_- : \text{Tw}(C) \to C^{\text{op}} \) and \( \lambda_+ : \text{Tw}(C) \to C \).

Here \( \lambda_+ \) carries an \( n \)-simplex \( \sigma \) of \( \text{Tw}(C) \) to the \( n \)-simplex of \( C \) given by the composition

\[
\Delta^n = N_\bullet([n]) \to N_\bullet([n]^{\text{op}} \star [n]) \xrightarrow{\sigma} C,
\]

while \( \lambda_- \) carries \( \sigma \) to the \( n \)-simplex of \( C^{\text{op}} \) given by the composite map

\[
(\Delta^n)^{\text{op}} = N_\bullet([n]^{\text{op}}) \to N_\bullet([n]^{\text{op}} \star [n]) \xrightarrow{\sigma} C.
\]

Concretely, \( \lambda_- \) and \( \lambda_+ \) are given on vertices by the formulae \( \lambda_-(f : X \to Y) = X \) and \( \lambda_+(f : X \to Y) = Y \).

Remark 8.1.1.6 (Duality). Let \( C \) be a simplicial set. Then there is a canonical isomorphism of simplicial sets \( \rho : \text{Tw}(C) \simeq \text{Tw}(C^{\text{op}}) \), given on \( n \)-simplices by precomposition with the unique isomorphism

\[
N_\bullet([n]^{\text{op}} \star [n])^{\text{op}} \simeq N_\bullet([n]^{\text{op}} \star [n]).
\]

The isomorphism \( \rho \) interchanges the projection maps \( \lambda_- \) and \( \lambda_+ \) of Notation 8.1.1.5.

Exercise 8.1.1.7 (Slices of Twisted Arrows). Let \( C \) be a simplicial set and let \( f : X \to Y \) be an edge of \( C \), which we regard as a vertex of the simplicial set \( \text{Tw}(C) \). Show that there is a canonical isomorphism of simplicial sets

\[
\text{Tw}(C)/f \simeq \text{Tw}(C_{X/}/Y).
\]

Here \( C_{X/}/Y \) denotes the simplicial set \( (C_{X/})_{Y/} \simeq (C_{/Y})_{X/} \), obtained either by promoting \( Y \) to a vertex of \( C_{X/} \) or \( X \) to a vertex of \( C_{/Y} \) by means of the edge \( f \).
8.1. TWISTED ARROWS AND COSPANS

**Warning 8.1.8.** Let $C$ be a simplicial set. Then there is a tautological map $T : C \to \text{Tw}(C^{\text{op}} \star C)$, which carries an $n$-simplex $\sigma : \Delta^n \to C$ to the $n$-simplex $T(\sigma)$ of $\text{Tw}(C^{\text{op}} \star C)$ given by the composition

$$N_\bullet([n]^{\text{op}} \star [n]) \xrightarrow{\sigma^{\text{op}} \star \sigma} C^{\text{op}} \star C.$$

If $D$ is another simplicial set, then precomposition with $T$ induces a comparison map

$$\text{Hom}_{\text{Set}}(\text{Tw}(C^{\text{op}} \star C), D) \to \text{Hom}_{\text{Set}}(\text{Tw}(C^{\text{op}} \star C), \text{Tw}(D)) \xrightarrow{\circ T} \text{Hom}_{\text{Set}}(C, \text{Tw}(D)).$$

Beware that, in general, this map is not a bijection. However, it is a bijection whenever $C$ is isomorphic to the nerve of a linearly ordered set $Q$. To prove this, we can write $Q$ as a filtered colimit of its finite subsets and thereby reduce to the case where $Q$ is finite. In this case, the linearly ordered set $Q$ is either empty (in which case the desired result is obvious) or isomorphic to $[n]$ for some integer $n \geq 0$ (in which case the desired result follows from the definition of the $\text{Tw}(D)$).

We now show that Construction 8.1.1 can be regarded as a generalization of Construction 8.1.0.1.

**Proposition 8.1.9.** Let $C$ be a category. Then there is a canonical isomorphism of simplicial sets $T : N_\bullet(\text{Tw}(C)) \xrightarrow{\sim} \text{Tw}(N_\bullet(C))$, which is uniquely determined by the following requirements:

1. For every morphism $f : C \to D$ in the category $C$, the map $T$ carries $f$ (regarded as an object of $\text{Tw}(C)$) to itself (regarded as a vertex of $\text{Tw}(N_\bullet(C))$).

2. The diagram

$$
\begin{array}{ccc}
N_\bullet(\text{Tw}(C)) & \xrightarrow{T} & \text{Tw}(N_\bullet(C)) \\
\downarrow & & \downarrow_{(\lambda_-, \lambda_+)} \\
N_\bullet(\text{C}^{\text{op}} \times C) & \xrightarrow{\sim} & N_\bullet(\text{C}^{\text{op}} \times N_\bullet(C))
\end{array}
$$

commutes, where the right vertical map is given by Notation 8.1.3 and the left vertical map is the nerve of the forgetful functor $\text{Tw}(C) \to \text{C}^{\text{op}} \times C$ $(f : X \to Y) \mapsto (X, Y)$.

**Proof.** Let $\sigma$ be an $n$-simplex of the simplicial set $N_\bullet(\text{Tw}(C))$, which we identify with a diagram

$$
(f_0 : X_0 \to Y_0) \xrightarrow{(u_1, v_1)} (f_1 : X_1 \to Y_1) \xrightarrow{(u_2, v_2)} \cdots \xrightarrow{(u_n, v_n)} (f_n : X_n \to Y_n)
$$
in the category $\text{Tw}(C)$. Here each $f_i : X_i \rightarrow Y_i$ denotes a morphism in $C$, and each $(u_i, v_i)$ is a pair of morphisms in $C$ which determine a commutative diagram

\[
\begin{array}{ccc}
X_{i-1} & \overset{u_i}{\leftarrow} & X_i \\
\downarrow & & \downarrow \\
Y_{i-1} & \overset{v_i}{\rightarrow} & Y_i,
\end{array}
\]

In this case, we can regard the chain of morphisms

\[
\begin{array}{ccc}
X_0 & \overset{u_1}{\leftarrow} & X_1 & \overset{u_2}{\leftarrow} & X_2 & \cdots & \overset{u_n}{\leftarrow} & X_n \\
\downarrow & & & & & & & \\
Y_0 & \overset{v_1}{\rightarrow} & Y_1 & \overset{v_2}{\rightarrow} & Y_2 & \cdots & \overset{v_n}{\rightarrow} & Y_n
\end{array}
\]

as a $(2n + 1)$-simplex of $N_\bullet(C)$, which we identify with an $n$-simplex $T(\sigma)$ of $\text{Tw}(N_\bullet(C))$. The construction $\sigma \mapsto T(\sigma)$ then determines a morphism of simplicial sets $T : N_\bullet(\text{Tw}(C)) \rightarrow \text{Tw}(N_\bullet(C))$, which satisfies conditions (1) and (2) by construction.

We now claim that $T$ is an isomorphism of simplicial sets. Let $\tau$ be an $n$-simplex of $\text{Tw}(N_\bullet(C))$; we wish to show that there is a unique $n$-simplex $\sigma$ of $N_\bullet(\text{Tw}(C))$ satisfying $T(\sigma) = \tau$. Let us identify $\tau$ with a diagram of the form (8.1) in the category $C$. We wish to show that there is a unique collection of morphisms $\{f_i : X_i \rightarrow Y_i\}_{1 \leq i \leq n}$ satisfying the identities $f_i = v_i \circ f_{i-1} \circ u_i$, which follows immediately by induction on $i$.

We now complete the proof by establishing the uniqueness of $T$. Suppose that $T' : N_\bullet(\text{Tw}(C)) \rightarrow \text{Tw}(N_\bullet(C))$ is another morphism of simplicial sets satisfying conditions (1) and (2). Then $T^{-1} \circ T'$ determines a functor $F$ from the twisted arrow category $\text{Tw}(C)$ to itself. Because $T$ and $T'$ both satisfy condition (1), the functor $F$ carries each object of $\text{Tw}(C)$ to itself. Since the forgetful functor $\text{Tw}(C) \rightarrow C^{\text{op}} \times C$ is faithful, condition (2) guarantees that $F$ also carries each morphism of $\text{Tw}(C)$ to itself. It follows that $F$ is the identity functor, so that $T' = T$. \qed

Let $C$ be a simplicial set. It follows from Proposition 8.1.1.9 that if $C$ is isomorphic to the nerve of a category, then the simplicial set $\text{Tw}(C)$ is also isomorphic to the nerve of a category. Moreover, the projection maps of Notation 8.1.1.5 determine a left covering map $\text{Tw}(C) \rightarrow C^{\text{op}} \times C$ (see Remark 8.1.0.2). This observation has an $\infty$-categorical counterpart:

**Proposition 8.1.1.10.** Let $C$ be an $\infty$-category. Then the projection maps of Notation 8.1.1.5 determine a left fibration of simplicial sets

\[
(\lambda_-, \lambda_+) : \text{Tw}(C) \rightarrow C^{\text{op}} \times C.
\]
Corollary 8.1.1.11. Let $\mathcal{C}$ be an $\infty$-category. Then the simplicial set $\text{Tw}(\mathcal{C})$ is also an $\infty$-category.

Proof. Combine Proposition 8.1.1.10 with Remark 4.1.1.9.

In the situation of Corollary 8.1.1.11, we will refer to $\text{Tw}(\mathcal{C})$ as the twisted arrow $\infty$-category of $\mathcal{C}$.

Corollary 8.1.1.12. Let $\mathcal{C}$ be an $\infty$-category. Then the projection maps $\lambda_- : \text{Tw}(\mathcal{C}) \to \mathcal{C}^{\text{op}}$ and $\lambda_+ : \text{Tw}(\mathcal{C}) \to \mathcal{C}$ are cocartesian fibrations of $\infty$-categories. Moreover, a morphism $f$ of $\text{Tw}(\mathcal{C})$ is $\lambda_-$-cocartesian if and only if $\lambda_+(f)$ is an isomorphism, and $\lambda_+$-cocartesian if and only if $\lambda_-(f)$ is an isomorphism.

Proof. Let $\pi_- : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{C}^{\text{op}}$ and $\pi_+ : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{C}$ denote the projection maps. Then $\pi_-$ and $\pi_+$ are cocartesian fibrations of simplicial sets. Moreover, a morphism $(e_-, e_+)$ of $\mathcal{C}^{\text{op}} \times \mathcal{C}$ is $\pi_-$-cocartesian if and only if $e_+$ is an isomorphism in $\mathcal{C}$, and $\pi_+$-cocartesian if and only if $e_-$ is an isomorphism in $\mathcal{C}^{\text{op}}$ (this follows immediately from Remark 5.1.4.6 and Example 5.1.1.4). Corollary 8.1.1.12 now follows by applying Proposition 8.1.1.10 to left and right sides of the diagram

$$
\begin{array}{cccc}
\text{Tw}(\mathcal{C}) & \downarrow \lambda_- & & \\
\mathcal{C}^{\text{op}} & \xleftarrow{\pi_-} & \mathcal{C}^{\text{op}} \times \mathcal{C} & \xrightarrow{\pi_+} \mathcal{C},
\end{array}
$$

since the vertical map in the center is a left fibration (Proposition 8.1.1.10).

Proposition 8.1.1.10 is a special case of the following more general assertion:

Proposition 8.1.1.13. Let $U : \mathcal{C} \to \mathcal{D}$ be an inner fibration of simplicial sets. Then the projection maps of Notation 8.1.1.7 determine a left fibration of simplicial sets

$$
\text{Tw}(\mathcal{C}) \to (\mathcal{C}^{\text{op}} \times \mathcal{C}) \times_{(\mathcal{D}^{\text{op}} \times \mathcal{D})} \text{Tw}(\mathcal{D}).
$$

Proof. Fix a pair of integers $0 < i \leq n$; we wish to show that every lifting problem

$$
\begin{array}{cccc}
\Lambda^n_{n-i} & \xrightarrow{\Lambda^n_{n-i}} & \text{Tw}(\mathcal{C}) & \\
\Delta^n & \xrightarrow{\Delta^n} & (\mathcal{C}^{\text{op}} \times \mathcal{C}) \times_{(\mathcal{D}^{\text{op}} \times \mathcal{D})} \text{Tw}(\mathcal{D}).
\end{array}
$$
admits a solution.

For each nonempty subset \( S \subseteq [2n + 1] = \{0 < 1 < \cdots < 2n + 1\} \), let \( \sigma_S \) denote the corresponding nondegenerate simplex of \( \Delta^{2n+1} \). Let us say that \( S \) is basic if it satisfies one of the following conditions:

\( (a) \) The set \( S \) is contained in \( \{0 < 1 < \cdots < n\} \).

\( (b) \) The set \( S \) is contained in \( \{n + 1 < n_2 < \cdots < 2n + 1\} \).

\( (c) \) There exists an integer \( j \neq i \) such that \( 0 \leq j \leq n \) and \( S \cap \{j, 2n + 1 - j\} = \emptyset \).

Let \( K_0 \subseteq \Delta^{2n+1} \) be the simplicial subset whose nondegenerate simplices have the form \( \sigma_S \), where \( S \) is basic. Unwinding the definitions, we can rewrite (8.2) as a lifting problem

\[
\begin{array}{ccc}
K_0 & \rightarrow & C \\
\downarrow & & \downarrow U \\
\Delta^{2n+1} & \rightarrow & D.
\end{array}
\]

Since \( U \) is an inner fibration, it will suffice to show that the inclusion \( K_0 \hookrightarrow \Delta^{2n+1} \) is an inner anodyne map of simplicial sets.

We now introduce two more collections of subsets of \([2n + 1]\).

- We say that a subset \( S \subseteq [2n + 1] \) is primary if it is not basic, the intersection \( S \cap \{0, 1, \cdots, i - 1\} \) is empty, and \( 2n + 1 - i \in S \).

- We say that a subset \( S \subseteq [2n + 1] \) is secondary if it is not basic, the intersection \( S \cap \{0, 1, \cdots, i - 1\} \) is nonempty, and \( i \in S \).

Let \( \{S_1, S_2, \cdots, S_m\} \) be an ordering of the collection of all subsets of \([2n + 1]\) which are either primary or secondary, satisfying the following conditions:

- The sequence of cardinalities \( |S_1|, |S_2|, \cdots, |S_m| \) is nondecreasing. That is, for \( 1 \leq p \leq q \leq m \), we have \( |S_p| \leq |S_q| \).

- If \( |S_p| = |S_q| \) for \( p \leq q \) and \( S_q \) is primary, then \( S_p \) is also primary.

For \( 1 \leq q \leq m \), let \( \sigma_q \subseteq \Delta^{2n+1} \) denote the simplex spanned by the vertices of \( S_q \), and let \( K_q \) denote the union of \( K_0 \) with the simplices \( \{\sigma_1, \sigma_2, \cdots, \sigma_q\} \). We have inclusion maps

\[
K_0 \hookrightarrow K_1 \hookrightarrow K_2 \hookrightarrow \cdots \hookrightarrow K_m.
\]

Note that we have \( \sigma_m = K_m = \Delta^{2n+1} \) (since the set \([2n + 1]\) is secondary). It will therefore suffice to show that for \( 1 \leq q \leq m \), the inclusion map \( K_{q-1} \hookrightarrow K_q \) is inner anodyne.
8.1. TWISTED ARROWS AND COSPANS

In what follows, we regard $q$ as fixed. Let $d$ be the dimension of the simplex $\sigma_q$. Let us abuse notation by identifying $\sigma_q$ with a morphism of simplicial sets $\Delta^d \to K_q \subseteq \Delta^{2n+1}$, and set $L = \sigma_q^{-1}K_{q-1} \subseteq \Delta^d$. We then have a pushout diagram of simplicial sets

\[
\begin{array}{ccc}
L & \xrightarrow{\sigma_q} & K_{q-1} \\
\downarrow & & \downarrow \\
\Delta^d & & K_q,
\end{array}
\]

We will complete the proof by showing that $L$ is an inner horn of $\Delta^d$.

We first consider the case where the set $S_q = \{j_0 < j_1 < \cdots < j_d\}$ is primary, so that we have $j_0 \geq i$ and $j_k = 2n + 1 - i$ for some $0 \leq k \leq d$. Note that we must have $k > 0$ (otherwise $S_q$ satisfies condition (b)) and $k < d$ (otherwise, $S_q$ satisfies condition (c), since it is disjoint from $\{0, 2n + 1\}$). In this case, we will show that $L$ coincides with the inner horn $\Delta_q^d \subseteq \Delta^d$. This can be restated as follows:

(*) Let $j$ be an element of $S_q$, and set $S' = S_q \setminus \{j\}$. Then $\sigma_{S'}$ is contained in $K_{q-1}$ if and only if $j \neq 2n + 1 - i$.

Assume first that $j \neq 2n + 1 - i$. Then the set $S'$ contains $2n + 1 - i$ and satisfies $S' \cap \{0, 1, \cdots, i-1\} = \emptyset$. Consequently, the set $S'$ is either primary (and therefore coincides with $S_{q'}$ for some $q' < q$) or basic. In either case, the simplex $\sigma_{S'}$ belongs to the simplicial subset $K_{q-1} \subseteq \Delta^{2n+1}$.

We now prove (*) in the case $j = 2n + 1 - i$. Since $S_q$ does not satisfy conditions (b) or (c), the set $S'$ also does not satisfy conditions (b) or (c). It also cannot satisfy condition (a): if $S'$ were contained in the set $\{0, 1, \cdots, n\}$, then $S_q$ would be contained in the set $\{i, i+1, \cdots, n, 2n + 1 - i\}$, and would therefore satisfy condition (c). It follows that $S'$ is not basic. Assume, for a contradiction, that $\sigma_{S'}$ is contained in $K_{q-1}$. We then have $\sigma_{S'} \subseteq \sigma_{q'}$ for some $q' < q$. Since $S'$ is neither primary nor secondary, this must be a proper inclusion: that is, we must have

$$\dim(\sigma_q) - 1 = \dim(\sigma_{S'}) < \dim(\sigma_{q'}) \leq \dim(\sigma_q).$$

It follows that the second inequality must be an equality: that is, we have $|S_{q'}| = |S_q|$ and therefore $S_{q'}$ is also primary. In particular, the set $S_{q'}$ contains $2n + 1 - i$, and therefore contains the union $S' \cup \{2n + 1 - i\} = S_q$. Since $S_q$ and $S_{q'}$ have the same cardinality, it follows that $S_q = S_{q'}$ and therefore $q = q'$, contradicting our assumption that $q' < q$.

We now consider the case where $S_q = \{j_0 < j_1 < \cdots < j_d\}$ is secondary, so that we have $j_0 < i$ and $j_k = i$ for some $0 < k \leq d$. Note that we must have $k < d$ (otherwise, $S_q$ satisfies
condition (a)). In this case, we will show that $L$ coincides with the inner horn $\Lambda^d_k \subset \Delta^d$. This can be restated as follows:

\((*)')\) Let $j \in S_q$ and set $S' = S_q \setminus \{j\}$. Then the simplex $\sigma_{S'}$ is contained in $K_{q-1}$ if and only if $j = i$.

We first treat the case where $j \neq i$, so that $i \in S'$. If $S'$ is basic, then $\sigma_{S'} \subseteq K \subseteq K_{q-1}$. We may therefore assume that $S'$ is not basic. If the intersection $S' \cap \{0, 1, \ldots, i - 1\}$ is nonempty, then $S'$ is secondary and has smaller cardinality than $S_q$. It follows that $S' = S_{q'}$ for some $q' < q$, so that $\sigma_{S'} \subseteq K_{q'} \subseteq K_{q-1}$. We may therefore assume that the intersection $S' \cap \{0, 1, \ldots, i - 1\}$ is empty. In this case, the union $S' \cup \{2n + 1 - i\}$ is a primary set of cardinality $\leq |S_q|$, and therefore has the form $S_{q'}$ for some $q' < q$. From this, we again conclude that $\sigma_{S'} \subseteq K_{q'} \subseteq K_{q-1}$.

We now prove $(*)'$ in the case $j = i$. Since $S_q$ does not satisfy conditions (a) or (c), it follows that $S'$ also does not satisfy conditions (a) or (c). The set $S'$ also does not satisfy condition (b), since the intersection $S' \cap \{0, \ldots, i - 1\}$ is nonempty. It follows that $S'$ is not basic. Assume, for a contradiction, that $\sigma_{S'}$ is contained in $K_{q-1}$. We then have $\sigma_{S'} \subseteq \sigma_{S_{q'}}$ for some $q' < q$. Since the intersection $S_{q'} \cap \{1, \ldots, i - 1\}$ is nonempty, the set $S_{q'}$ cannot be primary and is therefore secondary. In particular, the set $S_{q'}$ contains the element $i$ and therefore contains the union $S' \cup \{i\} = S_q$. Combining this observation with the inequality $|S_{q'}| \leq |S_q|$, we deduce that $S_{q'} = S_q$ and therefore $q' = q$, contradicting our assumption that $q' < q$.

\[\square\]

### 8.1.2 Homotopy Transport for Twisted Arrows

Let $\mathcal{C}$ be an $\infty$-category and let $\text{Tw}(\mathcal{C})$ denote its twisted arrow $\infty$-category. For every pair of objects $X, Y \in \mathcal{C}$, Proposition 8.1.1.10 guarantees that the fiber product

\[
\{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \times_{\mathcal{C}} \{Y\}
\]

is a Kan complex, whose vertices can be identified with morphisms $f : X \to Y$. Our goal in this section is to show that this identification can be promoted to a homotopy equivalence of Kan complexes

\[
\text{Hom}^L_{\mathcal{C}}(X, Y) \hookrightarrow \{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \times_{\mathcal{C}} \{Y\},
\]

where $\text{Hom}^L_{\mathcal{C}}(X, Y) = \mathcal{C}_{X/} \times_{\mathcal{C}} \{Y\}$ denotes the left-pinched morphism space of Construction 4.6.5.1 (see Corollary 8.1.2.6). Our starting point is the following result:

**Proposition 8.1.2.1.** Let $\mathcal{C}$ be an $\infty$-category and let $f : X \to Y$ be an isomorphism in $\mathcal{C}$. Then $f$ is initial when viewed as an object of the $\infty$-category $\{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C})$.

**Remark 8.1.2.2.** The converse of Proposition 8.1.2.1 is also true: see Corollary 8.1.2.16.
We will prove Proposition 8.1.2.1 at the end of this section. First, let us record some consequences.

**Construction 8.1.2.3.** Let \( C \) be a simplicial set and let \( X \) be a vertex of \( C \). Let \( \sigma \) be an \( n \)-simplex of the coslice simplicial set \( C_{X/} \), which we identify with a morphism of simplicial sets \( \{ x \} \star \Delta^n \rightarrow C \) satisfying \( \sigma(x) = X \). Then the composite map

\[
(\Delta^n)^\text{op} \star \Delta^n \rightarrow \{ x \} \star \Delta^n \xrightarrow{\sigma} C
\]

can be identified with an \( n \)-simplex of the twisted arrow simplicial set \( \text{Tw}(C) \), which we will denote by \( \iota_X(\sigma) \). The construction \( \sigma \mapsto \iota_X(\sigma) \) is compatible with the formation of face and degeneracy maps, and therefore determines a morphism of simplicial sets \( \iota_X : C_{X/} \rightarrow \text{Tw}(C) \). Moreover, the diagram

\[
\begin{array}{ccc}
C_{X/} & \xrightarrow{\iota_X} & \text{Tw}(C) \\
\downarrow \quad \lambda_- & & \downarrow \lambda_- \\
\{ X \} & \xrightarrow{\iota_X} & C^{\text{op}}
\end{array}
\]

commutes, where \( \lambda_- \) is the projection map of Notation 8.1.1.5. It follows that \( \iota_X \) can be regarded as a morphism of simplicial sets from \( C_{X/} \) to the fiber \( \{ X \} \times_{C^{\text{op}}} \text{Tw}(C) \). We will refer to this morphism as the *coslice inclusion*.

**Remark 8.1.2.4.** Let \( C \) be a simplicial set and let \( X \in C \) be a vertex. Then an \( n \)-simplex \( \sigma \) of \( C_{X/} \) can be identified with an \( (n+1) \)-simplex of \( C \), which we represent informally as a diagram

\[
X \xrightarrow{f} Y_0 \xrightarrow{v_1} Y_1 \xrightarrow{v_2} Y_2 \rightarrow \cdots \xrightarrow{v_n} Y_n.
\]

The morphism \( \iota_X \) of Construction 8.1.2.3 carries \( \sigma \) to a \((2n+1)\)-simplex \( \tau \) of \( C \), which can be represented informally by the diagram

\[
\begin{array}{ccc}
X & \xleftarrow{id} & X & \xleftarrow{id} & X & \xleftarrow{id} & \cdots & \xleftarrow{id} & X \\
\downarrow f & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
Y_0 & \xrightarrow{v_1} & Y_1 & \xrightarrow{v_2} & Y_2 & \rightarrow & \cdots & \xrightarrow{v_n} & Y_n.
\end{array}
\]

Note that \( \sigma \) can be recover from \( \tau \) (by composing with the inclusion map \( \Delta^{n+1} \hookrightarrow \Delta^{2n+1} \), given on vertices by \( i \mapsto i + n \)). It follows that \( \iota_X \) is a monomorphism of simplicial sets \( C_{X/} \hookrightarrow \{ X \} \times_{C^{\text{op}}} \text{Tw}(C) \) (as suggested by our terminology).
Proposition 8.1.2.5. Let $C$ be an $\infty$-category. For every object $X \in C$, the coslice inclusion
\[ \iota_X : C_{X/} \hookrightarrow \{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \]
is an equivalence of $\infty$-categories.

Proof. By construction, we have a commutative diagram

\[
\begin{array}{ccc}
C_{X/} & \xrightarrow{\iota_X} & \{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \\
\downarrow{\lambda_+} & & \downarrow{\lambda_+} \\
C & & \{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C})
\end{array}
\]

where the vertical maps are left fibrations of $\infty$-categories (Propositions 4.3.6.1 and 8.1.1.10). Moreover, the $\infty$-category $C_{X/}$ has an initial object $\tilde{X}$, given by the identity morphism $\text{id}_X : X \to X$ (Proposition 4.6.6.23). Proposition 8.1.2.1 guarantees that $\iota_X(\tilde{X})$ is an initial object of the $\infty$-category $\{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C})$, so that $\iota_X$ is an equivalence of $\infty$-categories by virtue of Corollary 5.7.6.20.

Corollary 8.1.2.6. Let $C$ be an $\infty$-category. For every pair of objects $X,Y \in C$, the coslice inclusion $\iota_X$ restricts to a homotopy equivalence of Kan complexes
\[ \text{Hom}_h^\mathcal{C}(X,Y) \hookrightarrow \{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \times_C \{Y\}. \]

Proof. Combine Proposition 8.1.2.5 with Corollary 5.1.5.4.

Corollary 8.1.2.7. Let $C$ be an $\infty$-category and let $f,f' : X \to Y$ be morphisms of $C$. Then $f$ and $f'$ are homotopic (in the sense of Definition 1.3.3.1) if and only they belong to the same connected component of the Kan complex $\{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \times_C \{Y\}$. Consequently, we have a canonical isomorphism of sets
\[ \text{Hom}_h^\mathcal{C}(X,Y) \simeq \pi_0(\{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \times_C \{Y\}). \]

Exercise 8.1.2.8. Prove Corollary 8.1.2.7 directly from the definitions.

Exercise 8.1.2.9. Let $C$ be an $\infty$-category containing morphisms $u : X' \to X$ and $v : Y \to Y'$, so that covariant transport for the left fibration $\text{Tw}(\mathcal{C}) \to \mathcal{C}^{\text{op}} \times \mathcal{C}$ determines a morphism of Kan complexes
\[ T : \{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \times_C \{Y\} \to \{X'\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \times_C \{Y'\}. \]

Show that, under the identifications supplied by Corollary 8.1.2.7, the induced map of connected components $\pi_0(T) : \text{Hom}_h^\mathcal{C}(X,Y) \to \text{Hom}_h^\mathcal{C}(X',Y')$ is given by the construction $[f] \mapsto [v] \circ [f] \circ [u]$. 

8.1. TWISTED ARROWS AND COSPANS

We now apply Proposition 8.1.2.5 to describe the left fibration \((λ_−, λ_+) : \text{Tw}(C) \rightarrow C^{\text{op}} \times C\) of Proposition 8.1.1.13.

**Notation 8.1.2.10.** Let \(C\) be an \(\infty\)-category. For every pair of objects \(X, Y \in C\), Proposition 4.6.5.9 and Corollary 8.1.2.6 supply homotopy equivalences of Kan complexes

\[
\text{Hom}_C(X, Y) \leftrightarrow \text{Hom}_C^L(X, Y) \leftrightarrow \{X\} \times_{C^{\text{op}}} \text{Tw}(C) \times_C \{Y\}.
\]

Passing to homotopy, we obtain an isomorphism

\[
\alpha_{X,Y} : \text{Hom}_C(X, Y) \cong \{X\} \times_{C^{\text{op}}} \text{Tw}(C) \times_C \{Y\}
\]
in the homotopy category \(\text{hKan}\).

**Corollary 8.1.2.11.** Let \(F : C \rightarrow D\) be a functor of \(\infty\)-categories. Then \(F\) is fully faithful if and only if the diagram

\[
\begin{array}{ccc}
\text{Tw}(C) & \xrightarrow{\text{Tw}(F)} & \text{Tw}(D) \\
\downarrow & & \downarrow \\
C^{\text{op}} \times C & \xrightarrow{F^{\text{op}} \times F} & D^{\text{op}} \times D
\end{array}
\]

is a categorical pullback square.

**Proof.** Since the vertical maps in the diagram (8.3) are left fibrations (Proposition 8.1.1.10), it is a categorical pullback square if and only if, for every pair of objects \(X, Y \in C\), the induced map

\[
\{X\} \times_{C^{\text{op}}} \text{Tw}(C) \times_C \{Y\} \rightarrow \{F(X)\} \times_{D^{\text{op}}} \text{Tw}(D) \times_D \{F(Y)\}
\]

is a homotopy equivalence of Kan complexes (Corollary 5.1.6.15). Using Notation 8.1.2.10, we see that this is equivalent to the requirement that \(F\) induces a homotopy equivalence \(\text{Hom}_C(X, Y) \rightarrow \text{Hom}_D(F(X), F(Y))\).

**Corollary 8.1.2.12.** Let \(F : C \rightarrow D\) be an equivalence of \(\infty\)-categories. Then the induced map \(\text{Tw}(F) : \text{Tw}(C) \rightarrow \text{Tw}(D)\) is also an equivalence of \(\infty\)-categories.

**Proof.** Combine Corollary 8.1.2.11 with Proposition 4.5.2.19

**Corollary 8.1.2.13.** Let \(C\) be an \(\infty\)-category, let \(hC\) be its homotopy category, and let

\[
\text{Hom}_{hC} : hC^{\text{op}} \times hC \rightarrow \text{hKan} \quad \quad (X, Y) \mapsto \text{Hom}_C(X, Y)
\]
denote the functor determined by the \(\text{hKan}\)-enrichment of Construction 4.6.8.13. Then the assignment \((X, Y) \mapsto \alpha_{X,Y}\) of Notation 8.1.2.10 determines an isomorphism from \(\text{Hom}_{hC}\) to the homotopy transport representation of the left fibration \((λ_−, λ_+) : \text{Tw}(C) \rightarrow C^{\text{op}} \times C\).
Proof. Let \( H : h(C^{\text{op}}) \times hC \rightarrow h\text{Kan} \) denote the homotopy transport representation for the left fibration \((\lambda_-, \lambda_+)\), given on objects by the formula \( H(X, Y) = \{X\} \times_{C^{\text{op}}} \text{Tw}(C) \times_C \{Y\} \).

For every pair of objects \( X, Y \in C \), Notation 8.1.2.10 determines an isomorphism 
\[
\alpha_{X,Y} : \text{Hom}_{hC}(X, Y) \xrightarrow{\sim} H(X, Y)
\]
in the homotopy category \( h\text{Kan} \). We wish to show that \( \alpha_{X,Y} \) depends functorially on \( X \) and \( Y \).

We first establish a strong form of functoriality in \( Y \). Fix an object \( X \in C \), and let \( h^X : hC \rightarrow h\text{Kan} \) denote the \( h\text{Kan} \)-enriched functor corepresented by \( X \), given concretely by the formula \( h^X(Y) = \text{Hom}_{hC}(X, Y) = \text{Hom}_C(X, Y) \). Let \( H^X : hC \rightarrow h\text{Kan} \) denote the restriction \( H|_{\{X\} \times hC} \), which we also regard as an \( h\text{Kan} \)-enriched functor (using Variant 5.2.8.11). Note that \( h^X \) can be identified with the (enriched) homotopy transport representation of the left fibration \( \{X\} \times_C C \rightarrow C \) (see Example 5.2.8.13). Corollary 4.6.4.18 and Proposition 8.1.2.5 supply equivalences 
\[
\{X\} \times_C C \xleftarrow{\sim} C/ \xrightarrow{\sim} \{X\} \times_{C^{\text{op}}} \text{Tw}(C)
\]
of left fibrations over \( C \), which induce an isomorphism of \( h\text{Kan} \)-enriched functors \( \alpha_{X,-} : h^X \xrightarrow{\sim} H^X \). By construction, this isomorphism carries each object \( Y \in hC \) to the isomorphism 
\[
\alpha_{X,Y} : \text{Hom}_{hC}(X, Y) \xrightarrow{\sim} H(X, Y)
\]
of Notation 8.1.2.10, which proves that \( \alpha_{X,Y} \) depends functorially on \( Y \).

We now show that \( \alpha_{X,Y} \) depends functorially on \( X \). Fix a morphism \( f : W \rightarrow X \) in the \( \infty \)-category \( C \). We then have a diagram of \( h\text{Kan} \)-enriched functors

\[
\begin{array}{ccc}
  h^X & \xrightarrow{\alpha_{X,-}} & H^X \\
  \downarrow & & \downarrow \\
  h^W & \xrightarrow{\alpha_{X,-}} & H^W,
\end{array}
\]

where the vertical maps are induced by the homotopy class \([f] \in \text{Hom}_{hC^{\text{op}}}(X, W)\). To complete the proof, it will suffice to show that this diagram commutes. Using the corepresentability of the \( h\text{Kan} \)-enriched functor \( h^X \), we are reduced to showing that clockwise and counterclockwise composition around the diagram (8.4) carry \([\text{id}_X] \in \pi_0(h^X(X)) = \text{Hom}_{hC}(X, X)\) to the same element of \( \pi_0(H^W(X)) \). We conclude by observing that under the identification \( \pi_0(H^W(X)) \simeq \text{Hom}_{hC}(W, X) \) supplied by Corollary 8.1.2.7, both constructions carry \([\text{id}_X]\) to \([f]\) (Exercise 8.1.2.9). \( \square \)

Warning 8.1.2.14. Let \( C \) be an \( \infty \)-category. Our proof of Corollary 8.1.2.13 shows that the isomorphism \( \alpha_{X,Y} : \text{Hom}_{hC}(X, Y) \rightarrow H(X, Y) \) is compatible with the \( h\text{Kan} \)-enrichment in
the second variable. Beware that things are a bit more subtle if we wish to view \( \text{Hom}_{hC}(X, Y) \) and \( H(X, Y) \) as hKan-enriched functors of the first variable. The functor \( \text{Hom}_{hC} \) is defined using the enrichment of the category \( hC \), and can therefore be viewed an hKan-enriched functor

\[
(hC)^{\text{op}} \times hC \to \text{hKan}.
\]

On the other hand, the functor \( H \) is defined as the enriched homotopy transport representation of the left fibration \( (\lambda_-, \lambda_+) : \text{Tw}(C) \to C^{\text{op}} \times C \), which is an hKan-enriched functor

\[
h(C^{\text{op}}) \times hC \to \text{hKan}.
\]

The hKan-enriched categories \( (hC)^{\text{op}} \) and \( h(C^{\text{op}}) \) are a priori different objects: to a pair of objects \( X, Y \in C \), they assign morphism spaces \( \text{Hom}_C(X, Y) \) and \( \text{Hom}_C(X, Y)^{\text{op}} \), respectively. It is possible to address this point (since \( \text{Hom}_C(X, Y) \) and \( \text{Hom}_C(X, Y)^{\text{op}} \) are canonically isomorphic as objects of the homotopy category hKan), but we will not pursue the matter here.

We can use Proposition 8.1.2.5 to deduce a stronger form of Proposition 8.1.2.1.

**Corollary 8.1.2.15.** Let \( U : C \to D \) be an inner fibration of \( \infty \)-categories and let \( f : X \to Y \) be a morphism of \( C \), which we regard as an object of the twisted arrow \( \infty \)-category \( \text{Tw}(C) \). Then:

- The morphism \( f \) is \( U \)-cocartesian if and only if it is \( V \)-initial, where \( V \) denotes the induced map
  \[
  \{ X \} \times_{C^{\text{op}}} \text{Tw}(C) \to \{ U(X) \} \times_{D^{\text{op}}} \text{Tw}(D).
  \]

- The morphism \( f \) is \( U \)-cartesian if and only if it is \( V' \)-initial, where \( V' \) denotes the induced map
  \[
  \text{Tw}(C) \times_C \{ Y \} \to \text{Tw}(D) \times_D \{ U(Y) \}.
  \]

**Proof.** We will prove the first assertion; the proof of the second is similar. Construction 8.1.2.3 supplies a commutative diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
C_{X/} & \xrightarrow{\iota_X} & \{ X \} \times_{C^{\text{op}}} \text{Tw}(C) \\
\downarrow U_{X/} & & \downarrow V \\
D_{U(X)/} & \xrightarrow{\iota_{U(X)}} & \{ U(X) \} \times_{D^{\text{op}}} \text{Tw}(D),
\end{array}
\]

where the horizontal maps are equivalences of \( \infty \)-categories (Proposition 8.1.2.5). By virtue of Remark 7.1.4.9, it will suffice to show that \( f \) is \( U \)-cocartesian if and only if it is a \( U_{X/} \)-initial object of the \( \infty \)-category \( C_{X/} \), which is a special case of Example 7.1.5.9. \( \square \)
Corollary 8.1.2.16. Let $\mathcal{C}$ be an $\infty$-category and let $f : X \to Y$ be a morphism of $\mathcal{C}$. The following conditions are equivalent:

1. The morphism $f$ is an isomorphism in the $\infty$-category $\mathcal{C}$.
2. The morphism $f$ is initial when regarded as an object of the $\infty$-category $\{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C})$.
3. The morphism $f$ is initial when regarded as an object of the $\infty$-category $\text{Tw}(\mathcal{C}) \times_{\mathcal{C}} \{Y\}$.

Proof. Apply Corollary 8.1.2.15 in the special case $\mathcal{D} = \Delta^0$ (together with Examples 7.1.4.2 and 5.1.1.4).

Proof of Proposition 8.1.2.1. Let $\mathcal{C}$ be an $\infty$-category and let $f : X \to Y$ be an isomorphism in $\mathcal{C}$; we wish to show that $f$ is initial when viewed as an object of the $\infty$-category $\{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C})$. Fix an integer $n > 0$ and a morphism $\rho_0 : \partial \Delta^n \to \{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C})$ satisfying $\rho_0(0) = f$; we wish to show that $\rho_0$ can be extended to an $n$-simplex of $\{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C})$.

We now use a variation on the proof of Proposition 8.1.1.13. For every nonempty subset $S \subseteq \{0 < 1 < \cdots < n\}$, let $\sigma_S$ denote the corresponding nondegenerate simplex of $\Delta^{2n+1}$. Let us say that $S$ is basic if it satisfies one of the following conditions:

(a) The set $S$ is contained in $\{0 < 1 < \cdots < n\}$.

(b) There exists an integer $0 \leq i \leq n$ such that $S \cap \{i, 2n + 1 - i\} = \emptyset$.

Let $K_0 \subseteq \Delta^{2n+1}$ be the simplicial subset whose nondegenerate simplices have the form $\sigma_S$, where $S$ is basic. Unwinding the definitions, we can identify $\rho_0$ with a morphism of simplicial sets $\theta_0 : K \to \mathcal{C}$, where the composition $\Delta^n \to \{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C})$ is the constant map taking the value $X$ and the composition $\Delta^1 \simeq N_{\bullet}({\{n < n + 1\}}) \to K \xrightarrow{\theta_0} \mathcal{C}$ is the morphism $f$. To complete the proof, we must show that $\theta_0$ admits an extension $\theta : \Delta^{2n+1} \to \mathcal{C}$.

Let $S$ be a nonempty subset of $\{2n + 1\}$ which is not basic. Then there exists an integer $0 \leq i \leq n$ such that $2n + 1 - i$ belongs to $S$. We denote the largest such integer by $\text{pr}(S)$ and refer to it as the priority of $S$. We say that $S$ is prioritized if it also contained the integer $\text{pr}(S)$. Let $\{S_1, S_2, \cdots, S_m\}$ be an ordering of the collection of all prioritized (non-basic) subsets of $\{2n + 1\}$ which satisfies the following conditions:

1. The sequence of priorities $\text{pr}(S_1), \text{pr}(S_2), \cdots, \text{pr}(S_m)$ is nondecreasing. That is, if $1 \leq p \leq q \leq m$, then we have $\text{pr}(S_p) \leq \text{pr}(S_q)$.
2. If $\text{pr}(S_p) = \text{pr}(S_q)$ for $p \leq q$, then $|S_p| \leq |S_q|$.
For $1 \leq q \leq m$, let $\sigma_q \subseteq \Delta^{2n+1}$ denote the simplex spanned by the vertices of $S_q$, and let $K_q \subseteq \Delta^{2n+1}$ denote the union of $K_0$ with the simplices $\{\sigma_1, \sigma_2, \cdots, \sigma_q\}$, so that we have inclusion maps

$$K_0 \hookrightarrow K_1 \hookrightarrow K_2 \hookrightarrow \cdots \hookrightarrow K_m.$$ 

Note that the set $S = [2n + 1]$ is prioritized (with priority $n$), and is therefore equal to $S_m$. It follows that $K_m = \Delta^{2n+1}$. We will complete the proof by showing that $\theta_0$ admits a compatible sequence of extensions $\{\theta_q : K_q \to C\}_{0 \leq q \leq m}$, so that $\theta = \theta_m$ is an extension of $\theta_0$ to $\Delta^{2n+1}$.

For the remainder of the proof, we fix an integer $1 \leq q \leq m$, and suppose that the morphism $\theta_{q-1} : K_{q-1} \to C$ has already been constructed. Let $d$ denote the dimension of the simplex $\sigma_q$, let us abuse notation by identifying $\sigma_q$ with a morphism of simplicial sets $\Delta^d \to K_q \subseteq \Delta^{2n+1}$, and set $L = \sigma_q^{-1}K_{q-1} \subseteq \Delta^d$. We then have a pushout diagram of simplicial sets

$$\begin{array}{ccc}
L & \to & K_{q-1} \\
\downarrow & & \downarrow \\
\Delta^d & \xrightarrow{\sigma_q} & K_q.
\end{array}$$

Let $\tau_0$ denote the composite map $L \xrightarrow{\sigma_q} K_{q-1} \xrightarrow{\theta_{q-1}} C$. We will complete the proof by showing that $\tau_0$ admits an extension $\tau : \Delta^d \to C$ (which then determines a morphism $\theta_q : K_q \to C$ extending $\theta_{q-1}$).

Let $i = \text{pr}(S_q)$ denote the priority of $S_q$, so that $S_q$ contains both $i$ and $2n+1-i$. Write $S_q = \{j_0 < j_1 < \cdots < j_d\}$, so that $i = j_k$ for some integer $0 \leq k \leq d$. We will prove below that $L$ is equal to the horn $\Lambda^d_k \subseteq \Delta^d$. Assuming this, we can split the proof into four cases:

- Suppose that $0 < k < d$. Then $\Lambda^d_k \subseteq \Delta^d$ is an inner horn, so that $\tau_0$ admits an extension $\tau : \Delta^d \to C$ by virtue of our assumption that $C$ is an $\infty$-category.

- Suppose that $k = d$. Then $S_q$ is contained in $\{0, 1, \cdots, n\}$, contradicting our assumption that $S_q$ is not basic.

- Suppose $k = 0$ and $i < n$, so that $i$ is the least element of $S_q$. Our assumption $\text{pr}(S_q) = i$ guarantees that $2n - i \notin S$. Since $S_q$ does not satisfy (b), we must also have $i + 1 \in S_q$. It follows that $d \geq 2$ (otherwise, $S_q$ would satisfy (a)), and that $\tau_0 : \Lambda^d_0 \to C$ carries the initial edge $N_\bullet(\{0 < 1\})$ to the identity morphism $\text{id}_X$. In this case, the existence of the extension $\tau$ follows from Theorem 4.4.2.6.

- Suppose $k = 0$ and $i = n$, so that $i = n$ is the least element of $S_q$. Since $S_q$ has priority $n$, the element $n+1$ also belongs to $S_q$. We must then have $d \geq 2$ (otherwise, $S_q$ would...
satisfy condition (b)). It follows that \( \tau_0 : \Lambda^d_k \to \mathcal{C} \) carries the initial edge \( N_\bullet(\{0 < 1\}) \) to the morphism \( f \), which is an isomorphism in \( \mathcal{C} \). In this case, the existence of the extension \( \tau \) again follows from Theorem \( \ref{4.4.2.6} \).

It remains to prove that \( L = \Lambda^d_k \), which we can formulate more concretely as follows:

\( (*) \) Let \( j \) be an element of \( S_q \), and set \( S' = S_q \setminus \{j\} \). Then \( \sigma_{S'} \) is contained in \( K_{q-1} \) if and only if \( j \neq i \).

We first treat the case \( j = i \); in this case, we wish to show that \( \sigma_{S'} \) is not contained in \( K_{q-1} \). Note that \( S' \) cannot be basic: it cannot be contained in \( \{0, 1, \cdots, n\} \) (otherwise \( S_q = S' \cup \{i\} \) would have the same property) and cannot have empty intersection with a set of the form \( \{i', 2n + 1 - i'\} \) (otherwise \( S_q \) would have the same property; here we use the fact that \( 2n + 1 - i \) is contained in \( S_q \)). Moreover, we have \( \text{pr}(S') = i \notin S' \), so that \( S' \) is not prioritized. Assume, for a contradiction, that \( \sigma_{S'} \) is contained in \( K_{q-1} \). Then we must have \( S' \subseteq S_q' \), for some \( 1 \leq q' < q \). Note that \( 2n + 1 - i \subseteq S_q' \), so that \( S_q' \) has priority \( \geq i \). Since \( q' < q \), it follows that \( S_q' \) has priority \( i \) and that \( |S_q'| \leq |S_q| \). Since \( S_q' \) is prioritized, it contains the element \( i \), and therefore contains \( S_q = S' \cup \{i\} \). It follows that \( S_q' = S_q \), contradicting our assumption that \( q' < q \).

We now treat the case \( j \neq i \); in this case, we wish to show that \( \sigma_{S'} \) is contained in \( K_{q-1} \). We may assume without loss of generality that \( S' \) is not basic (otherwise, the simplex \( \sigma_{S'} \) is already contained in \( K_0 \)). Let \( i' = \text{pr}(S') \) denote the priority of \( S' \); note that the inclusion \( S' \subseteq S_q \) guarantees that \( i' \leq i \). If \( i' < i \), then \( S' \cup \{i'\} \) is a prioritized set of priority \( < i \), and therefore of the form \( S_q' \) for some \( q' < q \). If \( i' = i \), then \( S' \) is a prioritized set of priority \( i \) and cardinality \( |S_q| - 1 \), and therefore of the form \( S_q' \) for some \( q' < q \). In either case, we obtain \( \sigma_{S'} \subseteq \sigma_q \subseteq K_{q-1} \).

\[ \square \]

### 8.1.3 The Universal Property of Twisted Arrows

Let \( \mathcal{C} \) be an \( \infty \)-category, let \( \text{Tw}(\mathcal{C}) \) denote the twisted arrow \( \infty \)-category of \( \mathcal{C} \), and let \( \lambda_+: \text{Tw}(\mathcal{C}) \to \mathcal{C} \) be the projection map of Notation \( \ref{8.1.1.5} \) (given on objects by the formula \( \lambda_+(u : C' \to C) = C \)). Then:

(a) The functor \( \lambda_+: \text{Tw}(\mathcal{C}) \to \mathcal{C} \) is a cocartesian fibration of \( \infty \)-categories (Corollary \( \ref{8.1.1.12} \)).

(b) For every object \( C \in \mathcal{C} \), the fiber \( \lambda_+^{-1}\{C\} = \text{Tw}(\mathcal{C}) \times_C \{C\} \) has an initial object (given by the identity morphism \( \text{id}_C \); see Proposition \( \ref{8.1.2.1} \)).

Our goal in this section is to show that, in some sense, \( \text{Tw}(\mathcal{C}) \) is universal with respect to these properties. More precisely, we have the following:
Theorem 8.1.3.1. Let $U : \mathcal{E} \to \mathcal{C}$ be a cocartesian fibration of simplicial sets. Suppose that, for every object $C \in \mathcal{C}$, the $\infty$-category $\mathcal{E}_C = \mathcal{E} \times_{\mathcal{C}} \{C\}$ has an initial object. Then the $\infty$-category $Fun_{/\mathcal{C}}(\Tw(\mathcal{C}), \mathcal{E})$ has an initial object. Moreover, an object $F \in Fun_{/\mathcal{C}}(\Tw(\mathcal{C}), \mathcal{E})$ is initial if and only if it satisfies the following pair of conditions:

1. For every vertex $C \in \mathcal{C}$, the image $F(id_C)$ is an initial object of the $\infty$-category $\mathcal{E}_C$.
2. Let $e$ be an edge of $\Tw(\mathcal{C})$ having the property that $\lambda_+(e)$ is a degenerate edge of $\mathcal{C}^{\text{op}}$. Then $F(e)$ is a $U$-cocartesian edge of $\mathcal{E}$.

Remark 8.1.3.2. We will be primarily interested in the special case of Theorem 8.1.3.1 where $\mathcal{C}$ is an $\infty$-category. In this case, we can reformulate conditions (1) and (2) as follows:

1'. For every object $C \in \mathcal{C}$, the induced functor $F_C : \Tw(\mathcal{C}) \times_{\mathcal{C}} \{C\} \to \mathcal{E}_C$ carries initial objects of $\Tw(\mathcal{C}) \times_{\mathcal{C}} \{C\}$ to initial objects of $\mathcal{E}_C$.
2'. The functor $F$ carries $\lambda_+$-cocartesian morphisms of $\Tw(\mathcal{C})$ to $U$-cocartesian morphisms of $\mathcal{E}$.

The equivalence $(1) \iff (1')$ follows from Corollary 4.6.6.16 since $id_C$ is an initial object of $\Tw(\mathcal{C}) \times_{\mathcal{C}} \{C\}$ (Proposition 8.1.2.1). Note that a morphism $e$ of $\Tw(\mathcal{C})$ is $\lambda_+$-cocartesian if and only if $\lambda_-(e)$ is an isomorphism in the $\infty$-category $\mathcal{C}^{\text{op}}$ (Corollary 8.1.1.12). This condition is automatically satisfied when $\lambda_-(e)$ is a degenerate edge of $\mathcal{C}^{\text{op}}$, which shows that $(2') \Rightarrow (2)$. To prove the converse, we can factor $e$ as a composition $e'' \circ e'$, where $e'$ is $\lambda_-$-cocartesian and $\lambda_-(e'')$ is an identity morphism of $\mathcal{C}^{\text{op}}$ (see Remark 5.1.3.8). If condition (2) is satisfied, then $F(e'')$ is a $U$-cocartesian morphism of $\mathcal{E}$. If $\lambda_-(e)$ is an isomorphism in $\mathcal{C}^{\text{op}}$, then $\lambda_-(e')$ is also an isomorphism in $\mathcal{C}^{\text{op}}$, so that $e'$ is an isomorphism in $\Tw(\mathcal{C})$ (Proposition 5.1.1.8). It follows that $U(e')$ is an isomorphism in $\mathcal{E}$, so that $U(e)$ is also $U$-cocartesian Corollary 5.1.2.4.

Remark 8.1.3.3. In the situation of Theorem 8.1.3.1 let $F$ and $F'$ be isomorphic objects of the $\infty$-category $Fun_{/\mathcal{C}}(\Tw(\mathcal{C}), \mathcal{E})$. Then $F$ satisfies conditions (1) and (2) of Theorem 8.1.3.1 if and only if $F'$ satisfies conditions (1) and (2) of Theorem 8.1.3.1. See Corollaries 4.6.6.16 and 5.1.2.5.

Example 8.1.3.4. In the situation of Theorem 8.1.3.1, suppose that $\mathcal{C} = \Delta^n$ is a standard simplex, so that $\Tw(\mathcal{C})$ can be identified with the nerve of the partially ordered set $Q = \{(i, j) \in [n]^{\text{op}} \times [n] : i \leq j\}$. For $0 \leq i \leq n$, let $\mathcal{E}_i$ denote the fiber $\{i\} \times_{\Delta^n} \mathcal{E}$. Then an object of $Fun_{/\mathcal{C}}(\Tw(\mathcal{C}), \mathcal{E})$ can be identified with a functor $F : N_{\bullet}(Q) \to \mathcal{E}$ having the property that $F(i, j) \in \mathcal{E}_j$ for $0 \leq i \leq j \leq n$. In this case, conditions (1) and (2) of Theorem 8.1.3.1 can be stated more concretely as follows:
(1) For $0 \leq i \leq n$, the image $F(i, i)$ is an initial object of the $\infty$-category $\mathcal{E}_i$.

(2) For $0 \leq i \leq j \leq k \leq n$, the functor $F$ determines a $U$-cocartesian morphism $F(i, j) \to F(i, k)$ in the $\infty$-category $\mathcal{E}$.

Moreover, since the collection of $U$-cocartesian morphisms of $\mathcal{E}$ contains all identity morphisms (Proposition 5.1.1.8) and is closed under composition (Corollary 5.1.2.4), it suffices to verify condition (2) under the additional assumption that $j = k - 1$.

**Remark 8.1.3.5.** In the situation of Example 8.1.3.4, let us identify $\text{Tw}(\Delta^{n-1})$ with the nerve of the partially ordered subset $Q' \subset Q$ consisting of pairs $(i, j)$ satisfying $i \leq j < n$. Suppose we are given an object of the $\infty$-category $\text{Fun}_{/\Delta^n}(\text{Tw}(\Delta^n), \mathcal{E})$, corresponding to a functor $F : N_\bullet(Q) \to \mathcal{E}$ having the property that $F' = F|_{N_\bullet(Q')}$ satisfies conditions (1) and (2) of Theorem 8.1.3.1, when regarded as an object of the $\infty$-category $\text{Fun}_{/\Delta^{n-1}}(\text{Tw}(\Delta^{n-1}), \Delta^{n-1} \times \Delta^n \mathcal{E})$. Then the analogous conditions for $F$ can be restated as follows:

(1) The image $F(n, n)$ is an initial object of the $\infty$-category $\mathcal{E}_n$. Equivalently, $F(n, n)$ is a $U$-initial object of the $\infty$-category $\mathcal{E}$. Since the set $\{q \in Q' : q < (n, n)\}$ is empty, this is equivalent to the requirement that $F$ is $U$-left Kan extended from $N_\bullet(Q')$ at the element $(n, n) \in Q$.

(2) For $0 \leq i \leq n - 1$, the functor $F$ determines a $U$-cocartesian morphism $F(i, n - 1) \to F(i, n)$ in the $\infty$-category $\mathcal{E}$. Since the partially ordered set $\{q \in Q' : q < (i, n)\}$ has a largest element $(i, n - 1)$, this is equivalent to the requirement that $F$ is $U$-left Kan extended from $N_\bullet(Q')$ at the element $(i, n) \in Q$ (Corollary 7.2.2.5).

In particular, $F$ satisfies both of these conditions if and only if it is $U$-left Kan extended from $N_\bullet(Q')$.

We begin by proving a weak form of Theorem 8.1.3.1.

**Lemma 8.1.3.6.** Suppose we are given a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
\text{Tw}(\mathcal{C}) & \xrightarrow{F} & \mathcal{E} \\
\downarrow{\lambda_+} & & \downarrow{U} \\
\mathcal{C}_+ & \xrightarrow{\mathcal{E}} & \\
\end{array}
\]

where $U$ is a cocartesian fibration and $F$ satisfies conditions (1) and (2) of Theorem 8.1.3.1. Then $F$ is an initial object of the $\infty$-category $\text{Fun}_{/\mathcal{C}}(\text{Tw}(\mathcal{C}), \mathcal{E})$. 
Proof. Fix an object $G$ of the $\infty$-category $\mathcal{M} = \text{Fun}_{/C}(\text{Tw}(C), E)$. We wish to show that the Kan complex $X = \text{Hom}_{\mathcal{M}}(F, G)$ is contractible. For every morphism of simplicial sets $S \to C$, set $\mathcal{M}_S = \text{Fun}_{/C}(\text{Tw}(S), E)$, let $F_S$ and $G_S$ denote the images of $F$ and $G$ in the $\infty$-category $\mathcal{M}_S$, and let $X_S$ denote the Kan complex $\text{Hom}_{\mathcal{M}_S}(F_S, G_S)$. Let us say that $S$ is good if the Kan complex $X_S$ is contractible. We will complete the proof by showing that every object $S \in (\text{Set}_\Delta)_{/C}$ is good. We make the following observations:

(i) Since the functor $S \mapsto \text{Tw}(S)$ commutes with colimits (Remark 8.1.1.4), the construction $S \mapsto \mathcal{M}_S$ carries colimits (in the category $(\text{Set}_\Delta)_{/C}$) to limits (in the category of simplicial sets). It follows that the construction $S \mapsto X_S$ has the same property.

(ii) Let $S' \hookrightarrow S$ be a monomorphism in the category $(\text{Set}_\Delta)_{/C}$. Then the induced map $\text{Tw}(S') \to \text{Tw}(S)$ is also a monomorphism, so the restriction map $\mathcal{M}_S \to \mathcal{M}_{S'}$ is an isofibration of $\infty$-categories (Proposition 4.5.5.14). It follows that the induced map $X_S \to X_{S'}$ is a Kan fibration (Proposition 4.6.1.19).

Let $S \to C$ be any morphism of simplicial sets. Using (i) and (ii), we see that $X_S$ can be realized as the limit of a tower of Kan fibrations

$$
\cdots \to X_{\text{sk}_3(S)} \to X_{\text{sk}_2(S)} \to X_{\text{sk}_1(S)} \to X_{\text{sk}_0(S)}.
$$

Consequently, to show that $S$ is good, it will suffice to show that each skeleton $\text{sk}_n(S)$ is good (Example 4.5.6.16). Replacing $S$ by $\text{sk}_n(S)$, we can reduce to the case where $S$ has dimension $\leq n$, for some integer $n \geq -1$.

We now proceed by induction on $n$. If $n = -1$, then the simplicial set $S$ is empty and the Kan complex $X_S$ is isomorphic to $\Delta^0$ (by virtue of (i)). Let us therefore assume that $n \geq 0$. Let $T$ denote the coproduct $\coprod_\sigma \Delta^n$, indexed by the collection of nondegenerate $n$-simplices of $S$, so that Proposition 1.1.3.13 supplies a pushout diagram of simplicial sets

$$
\begin{array}{ccc}
\text{sk}_{n-1}(T) & \to & T \\
\downarrow & & \downarrow \\
\text{sk}_{n-1}(S) & \to & S.
\end{array}
$$

Applying (i), we obtain a pullback diagram of Kan complexes

$$
\begin{array}{ccc}
X_S & \to & X_T \\
\downarrow & & \downarrow \\
X_{\text{sk}_{n-1}(S)} & \to & X_{\text{sk}_{n-1}(T)},
\end{array}
$$

(8.5)
It follows from (ii) that the vertical maps in this diagram are Kan fibrations, so that (8.5) is a homotopy pullback diagram (Example 3.4.1.3). Our inductive hypothesis guarantees that the Kan complexes $X_{sk_n-1}(S)$ and $X_{sk_n-1}(T)$ are contractible, so that the lower horizontal map is a homotopy equivalence. Applying Corollary 3.4.1.5 we see that the map $X_S \to X_T$ is also a homotopy equivalence. We may therefore replace $S$ by $T$, and thereby reduce to the case where $S$ is a coproduct of simplices. Since the collection of contractible Kan complexes is closed under the formation of products (Remark 3.1.6.8), we can use (i) to further reduce to the special case where $S = \Delta^n$ is a standard simplex. Replacing $U : E \to C$ by the projection map $S \times C \to S$, we are reduced to proving Lemma 8.1.3.6 in the special case where $C = \Delta^n$ is a standard simplex.

Let us identify the twisted arrow $\infty$-category $\text{Tw}(C)$ with the nerve of the partially ordered set $Q = \{(i, j) \in [n]^\text{op} \times [n] : i \leq j\}$, so that $F$ and $G$ can be identified with functors from $N_\bullet(Q)$ into $E$. Let $Q' \subset Q$ be as in Remark 8.1.3.5 so that $F$ is $U$-left Kan extended from $N_\bullet(Q')$. Set $M' = \text{Fun}_{/\Delta^n}(N_\bullet(Q'), E)$, so that the restriction map

$$X = \text{Hom}_M(F, G) \to \text{Hom}_{M'}(F|_{N_\bullet(Q')}, G|_{N_\bullet(Q')})$$

is a homotopy equivalence (Proposition 7.3.6.7). It will therefore suffice to show that the mapping space $\text{Hom}_{M'}(F|_{N_\bullet(Q')}, G|_{N_\bullet(Q')})$, which follows from our inductive hypothesis (applied to the inclusion map $\Delta^{n-1} \to \Delta^n$).

\[ \square \]

**Lemma 8.1.3.7.** Let $U : E \to C$ be a cocartesian fibration of simplicial sets. Suppose that, for every object $C \in C$, the $\infty$-category $E_C = \{C\} \times C E$ has an initial object. Then there exists an object $F \in \text{Fun}_{/C}(\text{Tw}(C), E)$ which satisfies conditions (1) and (2) of Theorem 8.1.3.1.

**Proof.** We proceed as in the proof of Lemma 8.1.3.6. For every morphism of simplicial sets $S \to C$, let $M_S$ denote the $\infty$-category

$$\text{Fun}_{/C}(\text{Tw}(S), E) \simeq \text{Fun}_{/S}(\text{Tw}(S), S \times C E),$$

and let $Y_S \subseteq M_S$ denote the full subcategory spanned by those objects which satisfy conditions (1) and (2) of Theorem 8.1.3.1 (after replacing $C$ by $S$). It follows from Lemma 8.1.3.6 that $Y_S$ is spanned by initial objects of $M_S$. In particular, $Y_S$ is a Kan complex which is either empty or contractible (Corollary 4.6.6.15). Let us say that $S$ is \textit{good} if the Kan complex $Y_S$ is contractible. We will complete the proof by showing that each object $S \in (\text{Set}_\Delta)/C$ is good. We make the following observations:

(i) The construction $S \mapsto Y_S$ carries colimits (in the category $(\text{Set}_\Delta)/C$) to limits (in the category of simplicial sets).
(ii) Let $S' \hookrightarrow S$ be a monomorphism in the category $(\text{Set}_\Delta)/C$. Then the restriction map $\mathcal{M}_S \to \mathcal{M}_{S'}$ is an isofibration of $\infty$-categories (Proposition 4.5.5.14), and therefore restricts to an isofibration of replete full subcategories $\theta : Y_S \to Y_{S'}$ (Remark 8.1.3.3). Since $Y_S$ and $Y_{S'}$ are Kan complexes, the restriction map $\theta$ is a Kan fibration (Corollary 4.4.3.8).

Let $S \to C$ be any morphism of simplicial sets. Using (i) and (ii), we see that $Y_S$ can be realized as the limit of a tower of Kan fibrations

$$\cdots \to Y_{\text{sk}_3(S)} \to Y_{\text{sk}_2(S)} \to Y_{\text{sk}_1(S)} \to Y_{\text{sk}_0(S)}.$$  

Consequently, to show that $S$ is good, it will suffice to show that each skeleton $\text{sk}_n(S)$ is good (Example 4.5.6.16). Replacing $S$ by $\text{sk}_n(S)$, we can reduce to the case where $S$ has dimension $\leq n$, for some integer $n \geq -1$.

We now proceed by induction on $n$. If $n = -1$, then the simplicial set $S$ is empty and the Kan complex $Y_S$ is isomorphic to $\Delta^0$ (by virtue of (i)). Let us therefore assume that $n \geq 0$. Let $T$ denote the coproduct $\coprod_\sigma \Delta^n$, indexed by the collection of nondegenerate $n$-simplices of $S$, so that Proposition 1.1.3.13 supplies a pushout diagram of simplicial sets

$$\begin{array}{ccc}
\text{sk}_{n-1}(T) & \to & T \\
\downarrow & & \downarrow \\
\text{sk}_{n-1}(S) & \to & S.
\end{array}$$

Applying (i), we obtain a pullback diagram of Kan complexes

$$\begin{array}{ccc}
Y_S & \to & Y_T \\
\downarrow & & \downarrow \\
Y_{\text{sk}_{n-1}(S)} & \to & Y_{\text{sk}_{n-1}(T)}.
\end{array}$$  

(8.6)

It follows from (ii) that the vertical maps in this diagram are Kan fibrations, so that (8.6) is a homotopy pullback diagram (Example 3.4.1.3). Our inductive hypothesis guarantees that the Kan complexes $Y_{\text{sk}_{n-1}(S)}$ and $Y_{\text{sk}_{n-1}(T)}$ are contractible, so that the lower horizontal map is a homotopy equivalence. Applying Corollary 3.4.1.5, we see that the map $Y_S \to Y_T$ is also a homotopy equivalence. We may therefore replace $S$ by $T$, and thereby reduce to the case where $S$ is a coproduct of simplices. Since the collection of contractible Kan complexes is closed under the formation of products (Remark 3.1.6.8), we can use (i) to further reduce to
the special case where \( S = \Delta^n \) is a standard simplex. Replacing \( U : \mathcal{E} \to \mathcal{C} \) by the projection map \( S \times_{\mathcal{C}} \mathcal{E} \to S \), we are reduced to proving Lemma \[8.1.3.7\] in the special case where \( \mathcal{C} = \Delta^n \) is a standard simplex.

For \( 0 \leq i \leq n \), let \( \mathcal{E}_i \) denote the fiber \( \{i\} \times_{\Delta^n} \mathcal{E} \). Let us identify the twisted arrow \( \infty \)-category \( \text{Tw}(\mathcal{C}) \) with the nerve of the partially ordered set \( Q = \{(i,j) \in [n]^{\text{op}} \times [n] : i \leq j\} \). Let \( Q' \subseteq Q \) denote the partially ordered subset consisting of pairs \((i,j)\) satisfying \( j < n \).

Applying our inductive hypothesis to the simplicial subset \( \Delta_{n-1} \subseteq \Delta^n = \mathcal{C} \), we deduce that the Kan complex \( Y_{\Delta_{n-1}} \subseteq \text{Fun}_{/\Delta^n}(\text{Tw}(\Delta_{n-1}), \mathcal{E}) \) contains a vertex, which we can identify with a functor \( F' : \text{N}_\bullet(Q') \to \mathcal{E} \) satisfying \( F'(i,j) \in \mathcal{E}_j \) for \( 0 \leq i \leq j \leq n-1 \). To complete the proof, it will suffice to show that \( F' \) admits a \( U \)-left Kan extension \( F : \text{N}_\bullet(Q) \to \mathcal{E} \) satisfying \( F(i,j) \in \mathcal{E}_j \) for \( 0 \leq i \leq j \leq n \) (Remark \[8.1.3.5\]). We will prove this by verifying that \( F' \) satisfies the hypothesis of Proposition \[7.3.5.5\].

Fix an element \( q = (i,n) \in Q \setminus Q' \), and set \( Q'_{<q} = \{q' \in Q' : q' < q\} \) and \( F'_{<q} = F'|_{\text{N}_\bullet(Q'_{<q})} \). We wish to show that \( F'_{<q} \) can be extended to a \( U \)-colimit diagram \( \text{N}_\bullet(Q'_{<q})^p \to \mathcal{E} \) which carries the cone point to an object of the fiber \( \mathcal{E}_n \). We distinguish two cases:

- If \( i = n \), then the set \( Q' \) is empty. In this case, the existence of \( F'_{<q}^+ \) follows from our assumption that the \( \infty \)-category \( \mathcal{E}_n \) has an initial object.

- If \( i < n \), then the partially ordered set \( Q'_{<q} \) has a largest element, given by the ordered pair \((i,n-1)\). By virtue of Corollary \[7.2.2.5\], it will suffice to show that there exists an object \( E \in \mathcal{E}_n \) and a \( U \)-cocartesian morphism \( F_0(i,n-1) \to E \) of \( \mathcal{E} \). This follows from our assumption that \( U \) is a cocartesian fibration.

\[ \square \]

**Proof of Theorem \[8.1.3.1\]** Let \( U : \mathcal{E} \to \mathcal{C} \) be a cocartesian fibration of simplicial sets. Suppose that, for every object \( C \in \mathcal{C} \), the \( \infty \)-category \( \mathcal{E}_C \) has an initial object. Applying Lemma \[8.1.3.7\], we see that there exists an object \( F \in \text{Fun}_{/\mathcal{C}}(\text{Tw}(\mathcal{C}), \mathcal{E}) \) satisfying conditions (1) and (2) of Theorem \[8.1.3.1\]. Moreover, any object satisfying these conditions is initial in \( \text{Fun}_{/\mathcal{C}}(\text{Tw}(\mathcal{C}), \mathcal{E}) \) (Lemma \[8.1.3.6\]). To complete the proof, we must prove the converse: if \( F' \) is an initial object \( \text{Fun}_{/\mathcal{C}}(\text{Tw}(\mathcal{C}), \mathcal{E}) \), then \( F' \) also satisfies conditions (1) and (2). This follows from Remark \[8.1.3.3\] since \( F' \) is isomorphic to \( F \) (Corollary \[4.6.6.16\]). \[ \square \]

### 8.1.4 The Cospan Construction

Let \( \mathcal{C}_0 \) be a category which admits pushouts. In \[2.2.1\], we introduced a 2-category \( \text{Cospan}(\mathcal{C}_0) \) having the same objects, where 1-morphisms from \( X \) to \( Y \) in \( \text{Cospan}(\mathcal{C}_0) \) are **cospans** from \( X \) to \( Y \): that is, diagrams \( X \xrightarrow{f} B \xleftarrow{g} Y \) in the category \( \mathcal{C}_0 \) (see Example \[2.2.2.1\]). In this section, we introduce a generalization of this construction, which will allow us to replace the ordinary category \( \mathcal{C}_0 \) by an \( \infty \)-category. More precisely, we will associate to
every simplicial set $C$ a simplicial set $\text{Cospans}(C)$ of cospans in $C$ (Construction 8.1.4.1). In the special case where $C = N_\bullet(C_0)$ is the nerve of a category $C_0$ which admits pushouts, we show that $\text{Cospans}(C)$ can be identified with the Duskin nerve of the 2-category $\text{Cospans}(C_0)$ (Corollary 8.1.4.12).

**Construction 8.1.4.1.** Let $C$ be a simplicial set. For every integer $n \geq 0$, we let $\text{Cospans}_n(C)$ denote the collection of morphisms $\text{Tw}(\Delta^n) \to C$ in the category of simplicial sets. The construction $[n] \mapsto \text{Cospans}_n(C)$ depends functorially on the set $[n] = \{0 < 1 < \cdots < n\}$ as an object of the category $\Delta^{op}$, and can therefore be viewed as a simplicial set. We will denote this simplicial set by $\text{Cospans}(C)$ and refer to it as the simplicial set of cospans in $C$.

**Remark 8.1.4.2.** Let $n \geq 0$ be an integer. Then the simplicial set $\text{Tw}(\Delta^n)$ can be identified with the nerve of the partially ordered set $Q = \{(i, j) \in [n]^{op} \times [n] : i \leq j\}$ (see Example 8.1.0.5). Consequently, if $C$ is an arbitrary simplicial set, then $n$-simplices of $\text{Cospans}(C)$ can be identified with morphisms $N_\bullet(Q) \to C$, which we depict informally as diagrams

```
X_{0,0} \to X_{1,1} \to \cdots \to X_{n-1,n-1} \to X_{n,n}
\downarrow \downarrow \downarrow \downarrow \downarrow \downarrow \downarrow
\cdots \cdots \cdots \cdots \cdots 
\downarrow \downarrow \downarrow \downarrow \downarrow \downarrow 
X_{0,n-1} \to X_{1,n} 
\downarrow \downarrow 
X_{0,n}
```

**Example 8.1.4.3.** Let $C$ be a simplicial set. Then:

- Vertices of the simplicial set $\text{Cospans}(C)$ can be identified with vertices of $C$.
- Let $X$ and $Y$ be vertices of $C$. Then edges of $\text{Cospans}(C)$ joining $X$ to $Y$ can be identified with pairs $(f, g)$, where $f : X \to B$ and $g : Y \to B$ are edges of $C$ having the same target.

**Remark 8.1.4.4 (Duality).** Let $C$ be a simplicial set and let $\sigma$ be an $n$-simplex of $\text{Cospans}(C)$, which we identify with a morphism of simplicial sets $\text{Tw}(\Delta^n) \to C$. Composing with the automorphism

$$\text{Tw}(\Delta^n) \xrightarrow{\sim} \text{Tw}(\Delta^n) \quad (i, j) \mapsto (n - j, n - i),$$

we obtain maps $X_{i,j} \to X_{n-i,n-j}$. This defines an automorphism of $\text{Cospans}(C)$.
we obtain a new \( n \)-simplex \( \sigma \) of \( \text{Cospan}(\mathcal{C}) \). The construction \( \sigma \mapsto \sigma \) determines an isomorphism of simplicial sets \( \tau : \text{Cospan}(\mathcal{C}) \simeq \text{Cospan}(\mathcal{C})^{\text{op}} \), which can be described concretely as follows:

- For every vertex \( X \in \mathcal{C} \), the morphism \( \tau \) carries \( X \) (regarded as a vertex of \( \text{Cospan}(\mathcal{C}) \)) to itself.

- Let \( X \) and \( Y \) be vertices of \( \mathcal{C} \), and let \( e : X \to Y \) be an edge of \( \text{Cospan}(\mathcal{C}) \), given by a pair of edges \((f : X \to B, g : Y \to B)\) of \( \mathcal{C} \). Then \( \tau(e) : Y \to X \) is the edge of \( \text{Cospan}(\mathcal{C}) \) given by the pair \((g, f)\).

Note that \( \tau \) is involutive: that is, the composition \( \text{Cospan}(\mathcal{C}) \xrightarrow{\tau} \text{Cospan}(\mathcal{C})^{\text{op}} \xrightarrow{\tau^{\text{op}}} \text{Cospan}(\mathcal{C}) \) is the identity automorphism of \( \text{Cospan}(\mathcal{C}) \).

**Example 8.1.4.5.** Let \( \mathcal{C} \) be a simplicial set. Then Notation 8.1.1.5 supplies a projection map \( \lambda_+ : \text{Tw}(\mathcal{C}) \to \mathcal{C} \), carrying each vertex \((f : X \to Y)\) of \( \text{Tw}(\mathcal{C}) \) to the vertex \( Y \in \mathcal{C} \). Under the bijection supplied by Proposition 8.1.4.7, we can identify \( \lambda_+ \) with a morphism of simplicial sets \( \rho_+ \) \( \mathcal{C} \to \text{Cospan}(\mathcal{C}) \). If \( \sigma \) is an \( n \)-simplex of \( \mathcal{C} \), which we display informally as a diagram

\[
\begin{array}{cccccccc}
X_0 & \xrightarrow{f_1} & X_1 & \xrightarrow{f_2} & X_2 & \cdots & \xrightarrow{f_n} & X_n, \\
& f_1 & & f_2 & & & & f_n \\
\downarrow & & & & & & & & \\
X_1 & & & & & & & & X_{n-1} \\
& f_2 & & f_3 & & & & f_n \\
\downarrow & & & & & & & & \\
\cdots & & & & & & & & \cdots \\
& f_{n-1} & & f_n & & & & & \\
\downarrow & & & & & & & & \\
X_{n-1} & & & & & & & & X_n \\
& f_n & & & & & & & \\
\downarrow & & & & & & & & \\
X_n & & & & & & & & .
\end{array}
\]

then \( \rho_-(\sigma) \) is an \( n \)-simplex of \( \text{Cospan}(\mathcal{C}) \) which can be depicted informally as a diagram

Similarly, the projection map \( \lambda_- : \text{Tw}(\mathcal{C}) \to \mathcal{C}^{\text{op}} \) determines a morphism of simplicial sets \( \rho_- : \mathcal{C}^{\text{op}} \to \text{Cospan}(\mathcal{C}) \). If \( \tau \) is an \( n \)-simplex of \( \mathcal{C}^{\text{op}} \), which we display informally as a diagram

\[
\begin{array}{cccccccc}
Y_0 & \xleftarrow{g_1} & Y_1 & \xleftarrow{g_2} & Y_2 & \cdots & \xleftarrow{g_n} & Y_n, \\
& g_1 & & g_2 & & & & g_n \\
\downarrow & & & & & & & & \\
Y_1 & & & & & & & & Y_{n-1} \\
& g_2 & & g_3 & & & & g_n \\
\downarrow & & & & & & & & \\
\cdots & & & & & & & & \cdots \\
& g_{n-1} & & g_n & & & & & \\
\downarrow & & & & & & & & \\
Y_{n-1} & & & & & & & & Y_n \\
& g_n & & & & & & & \\
\downarrow & & & & & & & & \\
Y_n & & & & & & & & .
\end{array}
\]
Then \( \rho_-(\tau) \) is an \( n \)-simplex of \( \text{Cospan}(\mathcal{C}) \) which is depicted informally by the diagram:

\[
\begin{array}{c}
Y_0 \\
\downarrow_{\text{id}} \downarrow_{\text{id}} \downarrow_{\text{id}} \downarrow_{\text{id}} \downarrow_{\text{id}} \downarrow_{\text{id}} \\
Y_1 \\
\downarrow_{g_1} \downarrow_{g_1} \downarrow_{g_1} \downarrow_{g_1} \downarrow_{g_1} \\
\vdots \\
Y_{n-1} \\
\downarrow_{g_{n-1}} \downarrow_{g_{n-1}} \downarrow_{g_{n-1}} \downarrow_{g_{n-1}} \\
Y_n \\
\downarrow_{\text{id}} \downarrow_{\text{id}} \downarrow_{\text{id}} \downarrow_{\text{id}} \downarrow_{\text{id}} \\
Y_0.
\end{array}
\]

Note that both \( \rho_- \) and \( \rho_+ \) are monomorphisms of simplicial sets.

**Construction 8.1.4.6.** Let \( \mathcal{D} \) be a simplicial set and let \( \sigma : \Delta^n \to \mathcal{D} \) be an \( n \)-simplex of \( \mathcal{D} \). Invoking the functionality of the twisted arrow construction, we obtain a map \( \text{Tw}(\Delta^n) \xrightarrow{\text{Tw}(\sigma)} \text{Tw}(\mathcal{D}) \), which we can identify with an \( n \)-simplex \( u(\sigma) \) of the simplicial set \( \text{Cospan}(\text{Tw}(\mathcal{D})) \). The construction \( \sigma \mapsto u(\sigma) \) is compatible with face and degeneracy maps, and therefore determines a morphism of simplicial sets \( u : \mathcal{D} \to \text{Cospan}(\text{Tw}(\mathcal{D})) \) which we will refer to as the **unit map**.

**Proposition 8.1.4.7.** Let \( \mathcal{D} \) be a simplicial set and let \( u : \mathcal{D} \to \text{Cospan}(\text{Tw}(\mathcal{D})) \) be the unit map of Construction 8.1.4.6. For every simplicial set \( \mathcal{C} \), the composite map

\[
\text{Hom}_{\Delta}^{\text{Set}}(\text{Tw}(\mathcal{D}), \mathcal{C}) \to \text{Hom}_{\Delta}^{\text{Set}}(\text{Cospan}(\text{Tw}(\mathcal{C})), \text{Cospan}(\mathcal{D})) \\
\xrightarrow{\circ u} \text{Hom}_{\Delta}^{\text{Set}}(\mathcal{D}, \text{Cospan}(\mathcal{C}))
\]

is a bijection.

**Proof.** Let us regard the simplicial set \( \mathcal{C} \) as fixed. For every simplicial set \( \mathcal{D} \), the unit map \( u \) of Construction 8.1.4.6 determines a function

\[
\theta_{\mathcal{D}} : \text{Hom}_{\Delta}^{\text{Set}}(\text{Tw}(\mathcal{C}), \mathcal{D}) \to \text{Hom}_{\Delta}^{\text{Set}}(\mathcal{D}, \text{Cospan}(\mathcal{C})).
\]

Using Remark 8.1.1.4, we see that the construction \( \mathcal{D} \mapsto \theta_{\mathcal{D}} \) carries colimits (in the category of simplicial sets) to limits (in the arrow category \( \text{Fun}([1], \text{Set}) \)). Consequently, to show that \( \theta_{\mathcal{D}} \) is a bijection, we may assume without loss of generality that \( \mathcal{D} = \Delta^n \) is a standard simplex (see Corollary 1.1.8.17). In this case, the desired result follows immediately from the definition of the simplicial set \( \text{Cospan}(\mathcal{C}) \). \( \square \)
Corollary 8.1.4.8. The twisted arrow functor

\[ \text{Tw} : \text{Set}_\Delta \to \text{Set}_\Delta \quad D \mapsto \text{Tw}(D) \]

has a right adjoint, given on objects by the construction \( C \mapsto \text{Cospan}(C) \).

We now study the relationship between Construction 8.1.4.1 with the classical cospan construction (Example 2.2.2.1).

Construction 8.1.4.9. Let \( \mathcal{C} \) be a category which admits pushouts, and let \( \text{Cospan}(\mathcal{C}) \) denote the 2-category of Example 2.2.2.1. Suppose we are given another category \( \mathcal{D} \) and a functor \( F : \text{Tw}(\mathcal{D}) \to \mathcal{C} \). We define a strictly unitary lax functor \( F^+ : \mathcal{D} \to \text{Cospan}(\mathcal{C}) \) as follows:

- For each \( X \in \mathcal{D} \), we define \( F^+(X) = F(\text{id}_X) \); here we regard the identity morphism \( \text{id}_X : X \to X \) as an object of the twisted arrow category \( \text{Tw}(\mathcal{C}) \).

- For each morphism \( f : X \to Y \) in \( \mathcal{D} \), we define \( F^+(f) \) to be the 1-morphism of \( \text{Cospan}(\mathcal{C}) \) given by the cospan

\[
\begin{array}{c}
F(\text{id}_X) \xrightarrow{F(\text{id}_X,f)} F(f) \xleftarrow{F(f,\text{id}_Y)} F(\text{id}_Y).
\end{array}
\]

Note that this determines the values of \( F^+ \) on 2-morphisms, since every 2-morphism in \( \mathcal{D} \) is an identity 2-morphism.

- For every pair of composable morphisms \( X \xrightarrow{f} Y \xrightarrow{g} Z \) in \( \mathcal{D} \), the composition constraint \( \mu_{g,f} : F^+(g) \circ F^+(f) \Rightarrow F^+(g \circ f) \) is the 2-morphism of \( \text{Cospan}(\mathcal{C}) \) corresponding to the map \( F(f) \Pi_{F(\text{id}_Y)} F(g) \to F(g \circ f) \) classifying the commutative diagram

\[
\begin{array}{ccc}
F(\text{id}_Y) & \xrightarrow{F(f,\text{id}_Y)} & F(f) \\
\downarrow F(\text{id}_Y,g) & & \downarrow F(\text{id}_X,g) \\
F(g) & \xleftarrow{F(f,\text{id}_Z)} & F(g \circ f)
\end{array}
\]

in the category \( \mathcal{C} \).

Example 8.1.4.10. Let \( \mathcal{C} \) be a category which admits pushouts and let \( n \) be a nonnegative integer. Applying Construction 8.1.4.9 in the special case where \( \mathcal{D} = [n] \), we obtain a function

\[ \{\text{Functors } \text{Tw}([n]) \to \mathcal{C}\} \xrightarrow{\sim} \{\text{Strictly unitary lax functors } [n] \to \text{Cospan}(\mathcal{C})\}. \]
8.1. TWISTED ARROWS AND COSPANS

Using Propositions 1.2.2.1 and 8.1.1.9 we can identify the left hand side with the collection of \( n \)-simplices of the simplicial set \( \text{Cospan}(N_\bullet(C)) \). This construction depends functorially on \( n \), and therefore determines a morphism of simplicial sets from \( \text{Cospan}(N_\bullet(C)) \) to the Duskin nerve \( N^D_\bullet(\text{Cospan}(C)) \).

We can now formulate our main result.

**Theorem 8.1.4.11.** Let \( \mathcal{C} \) and \( \mathcal{D} \) be categories, where \( \mathcal{C} \) admits pushouts. Then Construction 8.1.4.9 induces a bijection of sets

\[
\{\text{Functors } F : \text{Tw}(\mathcal{D}) \to \mathcal{C} \} \overset{\sim}{\to} \{\text{Strictly unitary lax functors } F^+ : \mathcal{D} \to \text{Cospan}(\mathcal{C})\}.
\]

**Corollary 8.1.4.12.** Let \( \mathcal{C} \) be a category which admits pushouts. Then the comparison map of Example 8.1.4.10 determines an isomorphism of simplicial sets

\[
\text{Cospan}(N_\bullet(C)) \to N^D_\bullet(\text{Cospan}(C)).
\]

**Exercise 8.1.4.13.** Show that Corollary 8.1.4.12 implies Theorem 8.1.4.11. That is, to prove Theorem 8.1.4.11 in general, it suffices to treat the special case where \( \mathcal{D} \) is a category of the form \( [n] = \{0 < 1 < \cdots < n\} \) for \( n \geq 0 \).

**Remark 8.1.4.14.** Let \( \mathcal{C} \) be a category which admits pushouts. The construction of the 2-category \( \text{Cospan}(\mathcal{C}) \) of Example 2.2.2.1 involves some auxiliary choices: if \( X \leftarrow B \to Y \) and \( Y \leftarrow C \to Z \) are cospans in \( \mathcal{C} \), then their composition (as 1-morphisms of \( \text{Cospan}(\mathcal{C}) \)) is given by \( X \leftarrow (B \amalg_Y C) \to Z \), where the pushout \( B \amalg_Y C \) is only well-defined up to (canonical) isomorphism. Corollary 8.1.4.12 supplies a description of the Duskin nerve \( N^D_\bullet(\text{Cospan}(\mathcal{C})) \) which does not depend on these choices. This shows, in particular, that the 2-category \( \text{Cospan}(\mathcal{C}) \) is well-defined up to (non-strict) isomorphism; see Example 2.2.6.13.

**Example 8.1.4.15.** Let \( \mathcal{C} \) be a category which admits pushouts. Then 2-simplices \( \sigma \) of the Duskin nerve \( N^D_\bullet(\text{Cospan}(\mathcal{C})) \) can be identified with commutative diagrams

\[
\begin{array}{ccc}
X_{0,0} & \rightarrow & X_{1,1} & \rightarrow & X_{2,2} \\
\downarrow & & \downarrow & & \downarrow \\
X_{0,1} & \rightarrow & X_{1,2} & \rightarrow & \\
\downarrow & & \downarrow & & \\
X_{0,2} & & & & \\
\end{array}
\]
in the category $C$. It follows from Theorem 2.3.2.5 that the 2-simplex $\sigma$ is thin (in the sense of Definition 2.3.2.3) if and only if the square appearing in the diagram is a pushout: that is, it induces an isomorphism $X_{0,1} \amalg_{X_{1,1}} X_{1,2} \to X_{0,2}$ in the category $C$.

**Proof of Theorem 8.1.4.11.** Let $C$ and $D$ be categories, where $C$ admits pushouts, and let $G : D \to \text{Cospan}(C)$ be a strictly unitary lax functor of 2-categories. For every morphism $f : X \to Y$ in the category $D$, we can identify $G(f)$ with a cospan from $G(X)$ to $G(Y)$ in the category $C$, given by a diagram we will denote by $G(X) \xrightarrow{b_{-}(f)} B(f) \leftarrow b_{+}(f)G(Y)$. Our assumption that $G$ is strictly unitary guarantees the following:

(∗) For each object $X \in D$, the object $B(\text{id}_X)$ is equal to $G(X)$, and the maps $b_{-}(\text{id}_X) : G(X) \to B(\text{id}_X)$ and $b_{+}(\text{id}_X) : G(X) \to B(\text{id}_X)$ are the identity morphisms from $G(X)$ to itself in the category $C$.

For every pair of composable 1-morphisms $X \xrightarrow{f} Y \xrightarrow{g} Z$, the composition constraint $\mu_{g,f}$ for the lax functor $G$ can be identified with a morphism from the pushout $B(f) \amalg_{B(g)} B(g \circ f)$, or equivalently with a pair of morphisms $p(g,f) : B(f) \to B(g \circ f)$ and $q(g,f) : B(g) \to B(g \circ f)$ satisfying $p(g,f) \circ b_{+}(f) = q(g,f) \circ b_{-}(g)$. The axioms for a lax functor (Definition 2.2.4.5) then translate to the following additional conditions:

(a) For every morphism $f : X \to Y$ in the category $D$, $p(\text{id}_Y,f)$ is the identity morphism from $B(f)$ to itself.

(b) For every morphism $f : X \to Y$ in the category $D$, $q(f,\text{id}_X)$ is the identity morphism from $B(f)$ to itself.

(c) For every composable triple of 1-morphisms $W \xrightarrow{f} X \xrightarrow{g} Y \xrightarrow{h} Z$ in the category $D$, we have

$$p(h \circ g,f) = p(h,g \circ f) \circ p(g,f) \quad q(h,g \circ f) = q(h \circ g,f) \circ q(h,g)$$

$$p(h,g \circ f) \circ q(g,f) = q(h \circ g,f) \circ p(h,g).$$

We wish to show that there exists a unique functor of ordinary categories $F : \text{Tw}(D) \to C$ such that $G = F^{+}$, where $F^{+}$ is the lax functor associated to $F$ by Construction 8.1.4.9. For this condition to be satisfied, the functor $F$ must satisfy the following conditions:

(0) For each object $X \in D$, we have $F(\text{id}_X) = G(X)$ (this guarantees that $G$ and $F^{+}$ coincide on objects).
8.1. TWISTED ARROWS AND COSPANS

(1) For each morphism \( f : X \to Y \) in \( D \) (regarded as an object of \( \text{Tw}(D) \)), we have \( F(f) = B(f) \), and the morphisms \( b_-(f) \) and \( b_+(f) \) are given by \( F(\text{id}_X, f) \) and \( F(f, \text{id}_Y) \), respectively (this guarantees that \( G \) and \( F^+ \) coincide on 1-morphisms, and therefore also on 2-morphisms).

(2) For every pair of composable 1-morphisms \( X \xrightarrow{f} Y \xrightarrow{g} Z \), the morphisms \( p(g, f) : B(f) \to B(g \circ f) \) and \( q(g, f) : B(g) \to B(g \circ f) \) are given by \( F(\text{id}_X, g) : F(f) \to F(g \circ f) \) and \( F(f, \text{id}_Z) : F(g) \to F(g \circ f) \), respectively (this guarantees that the composition constraints on \( G \) and \( F^+ \) coincide).

Note that the value of \( F \) on each object of \( \text{Tw}(D) \) is determined by condition (1). Moreover, if \((u, v)\) is a morphism from \( f: X \to Y \) to \( f': X' \to Y' \) in the category \( \text{Tw}(D) \), then condition (2) guarantees that \( F(u, v) \) must be equal to the composition

\[
F(f) = B(f) \xrightarrow{q(f,u)} B(f \circ u) \xrightarrow{p(v,f \circ u)} B(v \circ f \circ u) = B(f') = F(f').
\]

This proves the uniqueness of the functor \( F \).

To prove existence, we define \( F \) on objects \( f \) of \( \text{Tw}(D)^{op} \) by the formula \( F(f) = B(f) \), and on morphisms \((u, v): f \to f'\) by the formula \( F(u, v) = p(v, f \circ u) \circ q(f, u) \). For any morphism \( f: X \to Y \) in \( C \), we can use (a) and (b) to compute

\[
F(\text{id}_X, \text{id}_Y) = p(\text{id}_X, f) \circ q(f, \text{id}_Y) = \text{id}_{B(f)} \circ \text{id}_{B(f)} = \text{id}_{B(f)},
\]

so that \( F \) carries identity morphisms in \( \text{Tw}(D) \) to identity morphisms in \( C \). To complete the proof that \( F \) is a functor, we note that for every pair of composable morphisms

\[
(f : X \to Y) \xrightarrow{(u,v)} (f' : X' \to Y') \xrightarrow{(u',v')} (f'' : X'' \to Y'')
\]

in the twisted arrow category \( \text{Tw}(D) \), the identities given in (c) allow us to compute

\[
F(u', v') \circ F(u, v) = p(v', f' \circ u') \circ q(f', u') \circ p(v, f \circ u) \circ q(f, u) = p(v', v \circ f \circ u \circ u') \circ q(v \circ f \circ u, u') \circ p(v, f \circ u) \circ q(f, u) = p(v', v \circ f \circ u \circ u') \circ p(v, f \circ u \circ u') \circ q(f \circ u, u') \circ q(f, u) = p(v' \circ v, f \circ u \circ u') \circ q(f, u \circ u') = F(u \circ u', v' \circ v).
\]

We now complete the proof by showing that the functor \( F \) satisfies conditions (0), (1), and (2). Condition (0) is an immediate consequence of (*). To prove (2), we note that for any pair of composable morphisms \( X \xrightarrow{f} Y \xrightarrow{g} Z \) in \( D \), identities (a) and (b) yield equalities

\[
F(\text{id}_X, g) = p(g, f) \circ q(f, \text{id}_X) = p(g, f) \quad F(f, \text{id}_Z) = p(\text{id}_Z, g \circ f) \circ q(g, f) = q(g, f).
\]
To prove (1), we note that if \( f : X \to Y \) is a morphism in \( \mathcal{D} \), then we have
\[
F(\text{id}_X, f) = p(f, \text{id}_X \circ \text{id}_X) \circ q(\text{id}_X, \text{id}_X) = p(f, \text{id}_X) \circ \text{id}_{G(X)} = p(f, \text{id}_X) \circ b_+(f) = b_+(f),
\]
and a similar calculation yields \( F(f, \text{id}_Y) = b_-(f) \).

8.1.5 Morphisms in the Duskin Nerve

Let \( S \) be a simplicial set. Recall that, for every pair of vertices \( X, Y \in S \), the morphism space \( \text{Hom}_S(X, Y) \) is defined by the formula
\[
\text{Hom}_S(X, Y) = \{X\} \xrightarrow{\sim} S \{Y\} = \{X\} \times_{\text{Fun}\{\{0\},S\}} \text{Fun}(\Delta^1, S) \times_{\text{Fun}\{\{1\},S\}} \{Y\}.
\]
In this section, we specialize to the case where \( S = N^\bullet_D(\mathcal{C}) \) is the Duskin nerve of a 2-category \( \mathcal{C} \). In this case, we will see that there is close relationship between the simplicial set \( \text{Hom}_S(X, Y) \) and the category \( \text{Hom}_\mathcal{C}(X, Y) \) of 1-morphisms from \( X \) to \( Y \). More precisely, we will construct a comparison map
\[
\text{Cospan}(N^\bullet_{\text{Hom}_\mathcal{C}(X, Y)}) \to \text{Hom}_{N^\bullet_D(\mathcal{C})}(X, Y),
\]
and show that it is an isomorphism of simplicial sets (Corollary 8.1.5.6).

**Warning 8.1.5.1.** Let \( \mathcal{C} \) be a 2-category. If every 2-morphism in \( \mathcal{C} \) is invertible, then the Duskin nerve \( N^\bullet_D(\mathcal{C}) \) is an \( \infty \)-category (Theorem 2.3.2.1). It follows that, for every pair of objects \( X, Y \in \mathcal{C} \), the simplicial set \( \text{Hom}_{N^\bullet_D(\mathcal{C})}(X, Y) \) is a Kan complex. Beware that, in the case where \( \mathcal{C} \) contains non-invertible 2-morphisms, then the simplicial set \( \text{Hom}_{N^\bullet_D(\mathcal{C})}(X, Y) \) is generally not an \( \infty \)-category (in fact, it is not even an \( (\infty, 2) \)-category unless the category \( \text{Hom}_\mathcal{C}(X, Y) \) admits pushouts: see Proposition 8.1.6.1. In such cases, it may be more useful to consider the *pinched* morphism spaces of \( N^\bullet_D(\mathcal{C}) \): see Example 4.6.5.12 and Remark 8.1.5.8.

**Construction 8.1.5.2.** Let \( \mathcal{A} \) be a category, let \( \mathcal{C} \) be a 2-category containing objects \( X \) and \( Y \), and let \( F : \text{Tw}(\mathcal{A}) \to \text{Hom}_\mathcal{C}(X, Y) \) be a functor. We define a strictly unitary lax functor \( U_F : [1] \times \mathcal{A} \to \mathcal{C} \) as follows:

1. The lax functor \( U_F \) is given on objects by \( U_F(0, A) = X \) and \( U_F(1, A) = Y \) for each object \( A \in \mathcal{A} \).
(2) Let \( f : A \to B \) be a morphism in the category \( \mathcal{A} \), which we also regard as an object of the twisted arrow category \( \text{Tw}(\mathcal{A}) \). For \( 0 \leq i \leq j \leq 1 \), we let \( f_{ji} \) denote the corresponding morphism from \((i, A)\) to \((j, B)\) in the product category \([1] \times \mathcal{A}\). Then the lax functor \( U_F \) is given on 1-morphisms by the formula

\[
U_F(f_{ji}) = \begin{cases} 
\text{id}_X & \text{if } i = j = 0 \\
\text{id}_Y & \text{if } i = j = 1 \\
F(f) & \text{if } 0 = i < j = 1.
\end{cases}
\]

(3) Let \( f : A \to B \) and \( v : B \to C \) be composable morphisms in the category \( \mathcal{A} \), and let \( 0 \leq i \leq j \leq k \leq 1 \). Then the composition constraint \( \mu_{g_{kj},f_{ji}} \) for the lax functor \( U_F \) is given as follows:

- If \( i = j = k = 0 \), then \( \mu_{g_{kj},f_{ji}} \) is the unit constraint \( \nu_X : \text{id}_X \circ \text{id}_X \xrightarrow{\sim} \text{id}_X \) of the 2-category \( \mathcal{C} \).
- If \( i = 0 \) and \( j = k = 1 \), then \( \mu_{g_{kj},f_{ji}} \) is given by the composition

\[
\text{id}_Y \circ F(f) \xrightarrow{\lambda_{F(f)}} F(f) \xrightarrow{F(id_A,g)} F(g \circ f),
\]

where \( \lambda_{F(f)} \) is the left unit constraint of Construction 2.2.1.11 and we regard the pair \((id_A, g)\) as an element of \( \text{Hom}_{\text{Tw}(\mathcal{A})}(f, g \circ f) \).

- If \( i = j = 0 \) and \( k = 1 \), then \( \mu_{g_{kj},f_{ji}} \) is given by the composition

\[
F(g) \circ \text{id}_X \xrightarrow{\rho_{F(g)}} F(g) \xrightarrow{F(f, \text{id}_C)} F(g \circ f),
\]

where \( \rho_{F(g)} \) is the right unit constraint of Construction 2.2.1.11 and we regard the pair \((f, \text{id}_C)\) as an element of \( \text{Hom}_{\text{Tw}(\mathcal{A})}(g, g \circ f) \).

- If \( i = j = k = 1 \), then \( \mu_{g_{kj},f_{ji}} \) is equal to the unit constraint \( \nu_Y : \text{id}_Y \circ \text{id}_Y \xrightarrow{\sim} \text{id}_Y \) of the 2-category \( \mathcal{C} \).

Exercise 8.1.5.3. Show that Construction 8.1.5.2 is well-defined. That is, given a functor \( F : \text{Tw}(\mathcal{A}) \to \text{Hom}_\mathcal{C}(X, Y) \) as in Construction 8.1.5.2, show that there is a unique strictly unitary lax functor \( U_F \) satisfying properties (1), (2), and (3) of Construction 8.1.5.2.

We can now formulate the main result of this section.
Theorem 8.1.5.4. Let \( A \) be a category and let \( C \) be a 2-category containing objects \( X \) and \( Y \). Then the assignment \( F \mapsto U_F \) of Construction 8.1.5.2 induces a monomorphism of sets

\[
\{ \text{Functors } F : \text{Tw}(A) \to \text{Hom}_C(X,Y) \} \xrightarrow{\sim} \{ \text{Strictly unitary lax functors } U : [1] \times A \to C \}.
\]

The image of this monomorphism consists of those strictly unitary lax functors \( U : [1] \times C \to D \) having the property that \( U|_{\{0\} \times A} \) and \( U|_{\{1\} \times A} \) are the constant functors taking the values \( X \) and \( Y \), respectively.

Remark 8.1.5.5. Let \( C \) be a 2-category containing objects \( X \) and \( Y \). For every category \( A \), we can use Theorem 2.3.4.1 to identify strictly unitary lax functors \( U : [1] \times A \to C \) with morphisms of simplicial sets \( G : \Delta^1 \times N_\bullet(A) \to N_\bullet^D(C) \). Consequently, Theorem 8.1.5.4 supplies a bijection

\[
\{ \text{Functors } F : \text{Tw}(A) \to \text{Hom}_C(X,Y) \} \xrightarrow{\sim} \{ \text{Morphisms of simplicial sets } N_\bullet(A) \to \text{Hom}_{N_\bullet^D(C)}(X,Y) \}.
\]

Note that the bijection of Remark 8.1.5.5 depends functorially on the simplicial set \( A \). Specializing to categories of the form \( A = [n] \), we obtain the following:

Corollary 8.1.5.6. Let \( C \) be a 2-category containing objects \( X \) and \( Y \). Then Construction 8.1.5.2 induces an isomorphism of simplicial sets

\[
\text{Cospan}(N_\bullet \text{Hom}_C(X,Y)) \xrightarrow{\sim} \text{Hom}_{N_\bullet^D(C)}(X,Y).
\]

Exercise 8.1.5.7. Show that Theorem 8.1.5.4 follows from Corollary 8.1.5.6. In other words, to prove Theorem 8.1.5.4 there is no loss of generality in assuming that \( A \) has the form \( \{0 < 1 < \cdots < n\} \) for some integer \( n \geq 0 \).

Remark 8.1.5.8. Let \( C \) be a 2-category containing a pair of objects \( X \) and \( Y \). Then we
have a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
N_* \mathbf{Hom}_{\mathcal{C}}(X, Y) & \xrightarrow{\rho^+} & \text{Cospan}(N_* \mathbf{Hom}_{\mathcal{C}}(X, Y)) \\
\sim & & \sim \\
\downarrow & & \downarrow \\
\mathbf{Hom}_{N^D_{\mathcal{C}}}(X, Y) & \xrightarrow{\iota^L} & \mathbf{Hom}_{N^D_{\mathcal{C}}}(X, Y) \\
\sim & & \sim \\
\downarrow & & \downarrow \\
\mathbf{Hom}_{N^D_{\mathcal{C}}}(X, Y) & \xleftarrow{\iota^R} & \mathbf{Hom}_{N^D_{\mathcal{C}}}(X, Y)
\end{array}
\]

where the upper horizontal maps are the inclusions of Example 8.1.4.5, the lower horizontal maps are the the pinch inclusion maps of Construction 4.6.5.6, the outer vertical maps are the isomorphisms of Example 4.6.5.12, and the inner vertical map is the isomorphism of Corollary 8.1.5.6.

Stated more concretely, Corollary 8.1.5.6 asserts that we can identify \(n\)-simplices of the simplicial set \(\mathbf{Hom}_{N^D_{\mathcal{C}}}(X, Y)\) with commutative diagrams

\[
\begin{array}{ccccccc}
& f_{0,0} & \rightarrow & \cdots & f_{n-1,n-1} & \rightarrow & f_{n,n} \\
\downarrow & \cdots & \downarrow & \cdots & \downarrow & \cdots & \downarrow \\
& f_{0,n-2} & \rightarrow & f_{1,n-1} & \rightarrow & f_{2,n} & \rightarrow \\
& & f_{0,n-1} & \rightarrow & f_{1,n} & \rightarrow & \\
& & & f_{0,n} & & & \\
\end{array}
\]

in the category of 1-morphisms \(\mathbf{Hom}_{\mathcal{C}}(X, Y)\). The image of the left-pinch inclusion morphism

\[
\iota^L : \mathbf{Hom}^L_{N^D_{\mathcal{C}}}(X, Y) \hookrightarrow \mathbf{Hom}_{N^D_{\mathcal{C}}}(X, Y)
\]

consists of those simplices which correspond (under this identification) to commutative diagrams in which each of the leftward pointing 2-morphisms \(f_{i,j} \Rightarrow f_{i-1,j}\) is an identity map. In this case, the entire diagram is determined by the sequence of composable morphisms \(f_{0,0} \Rightarrow f_{0,1} \Rightarrow f_{0,2} \Rightarrow \cdots \Rightarrow f_{0,n}\) in the category \(\mathbf{Hom}_{\mathcal{C}}(X, Y)\). Similarly, the image of the right-pinch inclusion morphism

\[
\iota^R : \mathbf{Hom}^R_{N^D_{\mathcal{C}}}(X, Y) \hookrightarrow \mathbf{Hom}_{N^D_{\mathcal{C}}}(X, Y)
\]

consists of those simplices which correspond to commutative diagrams in which the rightward pointing 2-morphisms \(f_{i,j} \Rightarrow f_{i,j+1}\) are identity maps, which ensures that the entire diagram is determined by the sequence of composable morphisms \(f_{n,n} \Rightarrow f_{n-1,n} \Rightarrow f_{n-2,n} \Rightarrow \cdots \Rightarrow f_{0,n}\) in \(\mathbf{Hom}_{\mathcal{C}}(X, Y)\).
We wish to prove an equality $F$. This proves the uniqueness of $F$. Whenever either $g$ or $h$ is an identity morphism (Remark 2.2.7.5), which shows that $F$ satisfies condition (2) and that it carries identity morphisms to identity morphisms. We will complete the proof by showing that $F$ is compatible with composition. Let $f : A \to B$, $f' : A' \to B'$, and $f'' : A'' \to B''$ be objects of the twisted arrow category $\text{Tw}(\mathcal{A})$, and suppose we are given morphisms $(u,v) \in \text{Hom}_{\text{Tw}(\mathcal{A})}(f,f')$ and $(u',v') \in \text{Hom}_{\text{Tw}(\mathcal{A})}(f',f'')$. We wish to prove an equality $F(u \circ u', v' \circ v) = F(u',v') \circ F(u,v)$ of morphisms from $F(f)$.

\textit{Proof of Theorem 8.1.5.4.} Let $\mathcal{A}$ be an ordinary category, let $\mathcal{C}$ be a 2-category containing objects $X$ and $Y$, and let $U : [1] \times \mathcal{A} \to \mathcal{C}$ be a strictly unitary lax functor having the property that $U|_{\{0\} \times \mathcal{A}}$ and $U|_{\{1\} \times \mathcal{A}}$ are the constant functors taking the values $X$ and $Y$, respectively. We wish to show that there exists a unique functor of ordinary categories $F : \text{Tw}(\mathcal{A}) \to \text{Hom}_{\mathcal{C}}(X,Y)$ such that $U$ is equal to the strictly unitary lax functor $U_F$ given by Construction 8.1.5.2. To prove this, we may assume without loss of generality that the 2-category $\mathcal{C}$ is strictly unitary (Proposition 2.2.7.7). Given a morphism $f : A \to B$ in the category $\mathcal{A}$ and a pair of integers $0 \leq i \leq j \leq 1$, we write $f_{ji} : (i,A) \to (j,B)$ for the corresponding morphism in the product category $[1] \times \mathcal{A}$. Unwinding the definitions, we see that the identity $U = U_F$ imposes the following requirements on the functor $F$:

(1) Let $f : A \to B$ be a morphism in the category $\mathcal{C}$, which we identify with an object of the twisted arrow category $\text{Tw}(\mathcal{A})$. Then $F(f)$ is equal to $U(f_{10}) \in \text{Hom}_{\mathcal{C}}(X,Y)$.

(2) Let $f : A \to B$ and $g : B \to C$ be composable morphisms in the category $\mathcal{A}$, and regard the pairs $(\text{id}_A,g)$ and $(f,\text{id}_C)$ as elements of $\text{Hom}_{\text{Tw}(\mathcal{A})}(f,g \circ f)$ and $\text{Hom}_{\text{Tw}(\mathcal{A})}(g,g \circ f)$, respectively. Then $F((\text{id}_A,g))$ and $F((f,\text{id}_C)$ are equal to the composition constraints $\mu_{g_{11},f_{10}}$ and $\mu_{g_{10},f_{10}}$ for the lax functor $U$, respectively.

We now establish the uniqueness of the functor $F$. The value of $F$ on objects is determined by condition (1). If $f : A \to B$ and $f' : A' \to B'$ are objects of the twisted arrow category $\text{Tw}(\mathcal{A})$, then an element of $\text{Hom}_{\text{Tw}(\mathcal{A})}(f,f')$ can be identified with a pair $(u,v)$ where $u \in \text{Hom}_{\mathcal{A}}(A',A)$ and $v \in \text{Hom}_{\mathcal{A}}(B,B')$ satisfy $f' = v \circ f \circ u$. In this case, the morphism $(u,v)$ factors as a composition $(u,\text{id}_B) \circ (\text{id}_A,v)$, so condition (2) guarantees the identity

$$F(u,v) = F(u,\text{id}_B) \circ F(\text{id}_A,v) = \mu_{(f,v)_{10},u_{00}} \circ \mu_{v_{11},f_{10}}.$$ 

This proves the uniqueness of $F$ on morphisms.

To prove existence, we define the functor $F$ on objects $f \in \text{Tw}(\mathcal{A})$ by setting $F(f) = U(f_{10})$, and on morphisms $(u,v) \in \text{Hom}_{\text{Tw}(\mathcal{A})}(f,f')$ by the formula

$$F(u,v) = \mu_{(f,v)_{10},u_{00}} \circ \mu_{v_{11},f_{10}}.$$ 

Note that this prescription automatically satisfies condition (1). Since $U$ is a strictly unitary functor between strictly unitary 2-categories, its composition constraints $\mu_{g,h}$ are the identity whenever either $g$ or $h$ is an identity morphism (Remark 2.2.7.5), which shows that $F$ satisfies condition (2) and that it carries identity morphisms to identity morphisms. We will complete the proof by showing that $F$ is compatible with composition. Let $f : A \to B$, $f' : A' \to B'$, and $f'' : A'' \to B''$ be objects of the twisted arrow category $\text{Tw}(\mathcal{A})$, and suppose we are given morphisms $(u,v) \in \text{Hom}_{\text{Tw}(\mathcal{A})}(f,f')$ and $(u',v') \in \text{Hom}_{\text{Tw}(\mathcal{A})}(f',f'')$. We wish to prove an equality $F(u \circ u',v' \circ v) = F(u',v') \circ F(u,v)$ of morphisms from $F(f)$.
to \(F(f'')\) in the category \(\text{Hom}_C(X,Y)\). Unwinding the definitions, this is equivalent to the commutativity of the outer cycle of the diagram

\[
\begin{array}{c}
\mu_{(vf)_{10},w_{00}} \\
\mu'_{v',11,vf_{10}} \\
\mu_{v_{11},f_{10}} \\
\mu'_{v',11,vf_{10}} \\
\mu_{vf,10,w_{00}} \\
\mu'_{v',10,vf_{10}} \\
\mu_{vf,10,w_{00}} \\
\mu'_{v',11,vf_{10}} \\
\end{array}
\]

in the category \(\text{Hom}_C(X,Y)\). In fact, the entire diagram commutes. The commutativity of the upper square follows by applying property (c) of Definition 2.2.4.5 to the composable triple of morphisms

\[
(0, A') \xrightarrow{u_{00}} (0, A) \xrightarrow{(vf)_{10}} (1, B') \xrightarrow{\nu_{11}} (1, B'')
\]

in the product category \([1] \times A\). The commutativity of the lower left triangle follows by applying property (c) to the composable triple of morphisms

\[
(0, A) \xrightarrow{f_{10}} (1, B) \xrightarrow{\nu_{11}} (1, B') \xrightarrow{\nu'_{11}} (1, B'')
\]

and noting that the composition constraint \(\mu'_{v',11,vf_{10}}\) is equal to the identity (by virtue of our assumption that the lax functor \(U|_{\{1\} \times A}\) is constant). Similarly, the commutativity of the lower right triangle follows by applying (c) to the composable triple of morphisms

\[
(0, A'') \xrightarrow{u'_{00}} (0, A') \xrightarrow{u_{00}} (0, A) \xrightarrow{(v'vf)_{10}} (1, B''')
\]

and noting that the composition constraint \(\mu_{u_{00},u'_{00}}\) is equal to the identity (by virtue of our assumption that the lax functor \(U|_{\{0\} \times A}\) is constant).

8.1.6 Cospans in \(\infty\)-Categories

Let \(\mathcal{C}\) be an \(\infty\)-category, and let \(\text{Cospan}(\mathcal{C})\) denote the simplicial set of cospans in \(\mathcal{C}\) (Construction 8.1.4.1). In the special case where \(\mathcal{C} = N_\bullet(C_0)\) is the nerve of an ordinary category \(C_0\) which admits pushouts, Corollary 8.1.4.12 supplies an isomorphism of \(\text{Cospan}(\mathcal{C})\) with the Duskin nerve of the 2-category \(\text{Cospan}(\mathcal{C}_0)\) of Example 2.2.2.1. In particular, \(\text{Cospan}(\mathcal{C})\) is an \((\infty, 2)\)-category (see Proposition 5.5.1.7). Our goal in this section is to prove an \(\infty\)-categorical generalization of this result.
Proposition 8.1.6.1. Let \( \mathcal{C} \) be an \( \infty \)-category. Then the simplicial set \( \text{Cospan}(\mathcal{C}) \) is an \( (\infty, 2) \)-category if and only if \( \mathcal{C} \) admits pushouts.

Our proof of Proposition 8.1.6.1 will require several steps. The main ingredient is the following characterization of thin 2-simplices of \( \text{Cospan}(\mathcal{C}) \), which we will establish in §8.1.7.

Proposition 8.1.6.2. Let \( \mathcal{C} \) be an \( \infty \)-category and let \( \sigma \) be a 2-simplex of \( \text{Cospan}(\mathcal{C}) \), which we identify with a diagram

\[
\begin{array}{ccc}
X_{0,0} & \to & X_{1,1} & \to & X_{2,2} \\
\downarrow & & \downarrow & & \downarrow \\
X_{0,1} & \to & X_{1,2} & \to & \\
\downarrow & & \downarrow & & \\
X_{0,2} & & & & \\
\end{array}
\]

in the \( \infty \)-category \( \mathcal{C} \). Then \( \sigma \) is thin (in the sense of Definition 2.3.2.3) if and only if the inner region is a pushout square in the \( \infty \)-category \( \mathcal{C} \).

Corollary 8.1.6.3. Let \( \mathcal{C} \) be an \( \infty \)-category. Then every degenerate 2-simplex of \( \text{Cospan}(\mathcal{C}) \) is thin.

Proof. Let \( \sigma \) be a 1-simplex of \( \text{Cospan}(\mathcal{C}) \), corresponding to a diagram \( X \xrightarrow{f} B \xleftarrow{g} Y \) in the \( \infty \)-category \( \mathcal{C} \). We will show that the left-degenerate 2-simplex \( s_0(\sigma) \) is thin; a similar argument will show that the right-degenerate 2-simplex \( s_1(\sigma) \) is thin (see Remark 8.1.4.4). Unwinding the definitions, we see that \( s_0(\sigma) \) corresponds to a diagram in \( \mathcal{C} \) of the form

\[
\begin{array}{ccc}
X & \to & X & \to & Y \\
\downarrow & & \downarrow & & \downarrow \\
\id_X & \to & \id_X & \to & \id_Y \\
\downarrow & & \downarrow & & \downarrow \\
X & \to & B & \to & Y \\
\end{array}
\]

By virtue of Proposition 8.1.6.2 it will suffice to show that the inner region of the diagram is a pushout square in \( \mathcal{C} \). This follows from Proposition 7.6.3.15 since \( \id_B \) and \( \id_X \) are isomorphisms in \( \mathcal{C} \).

\( \square \)
Corollary 8.1.6.4. Let $\mathcal{C}$ be an $\infty$-category and let $\sigma_0 : \Lambda^2_1 \to \text{Cospan}(\mathcal{C})$ be a morphism, which we identify with a diagram

\[ \begin{array}{ccc}
X_{0,0} & \rightarrow & X_{1,1} \\
\downarrow & & \downarrow \\
X_{0,1} & \rightarrow & X_{1,2}
\end{array} \]

\[ \begin{array}{ccc}
X_{0,2} & \rightarrow & X_{2,2}
\end{array} \]  \hspace{1cm} (8.8)

in the $\infty$-category $\mathcal{C}$. Then $\sigma_0$ can be extended to a thin 2-simplex $\sigma : \Delta^2 \to \text{Cospan}(\mathcal{C})$ if and only if there exists a pushout $X_{0,1}$ with $X_{1,2}$ along $X_{1,1}$ in the $\infty$-category $\mathcal{C}$.

Proof. By virtue of Proposition 8.1.6.2, any extension of $\sigma_0$ to a thin 2-simplex of $\mathcal{C}$ determines a pushout of $X_{0,1}$ with $X_{1,2}$ over $X_{1,1}$. To prove the converse, let us identify $\text{Tw}(\Delta^2)$ with the simplicial set $N_\bullet(Q)$, where $Q$ denotes the partially ordered set $\{(i,j) \in [2]^{\text{op}} \times [2] : i \leq j\}$. Under this identification, $\text{Tw}(\Lambda^2_1)$ corresponds to the simplicial subset $N_\bullet(Q) \subseteq N_\bullet(Q)$, where $Q = \overline{Q} \setminus \{(0,2)\}$; in particular, we can identify (8.8) with a morphism of simplicial sets $\tau : N_\bullet(Q) \to \mathcal{C}$. Set $Q_0 = Q \setminus \{(0,0), (2,2)\}$ and $\tau_0 = \tau|_{N_\bullet(Q_0)}$.

Assume that $X_{0,1}$ and $X_{1,2}$ admit a pushout along $X_{1,1}$: that is, the diagram $\tau_0$ has a colimit in $\mathcal{C}$. Note that the inclusion map $Q_0 \hookrightarrow Q$ has a left adjoint (given by $(0,0) \mapsto (0,1)$ and $(2,2) \mapsto (1,2)$), and therefore induces a right cofinal morphism of simplicial sets $N_\bullet(Q_0) \hookrightarrow N_\bullet(Q)$ (Corollary 7.2.3.7). Applying Corollary 7.2.2.10 we deduce that $\tau$ can be extended to a colimit diagram

\[ \tau : N_\bullet(Q)^\circ \simeq N_\bullet(\overline{Q}) \simeq \text{Tw}(\Delta^2) \to \mathcal{C}, \]

which we can identify with a 2-simplex $\sigma : \Delta^2 \to \text{Cospan}(\mathcal{C})$ satisfying $\sigma|_{\Lambda^2_1} = \sigma_0$. Applying Corollary 7.2.2.3 we see that $\tau|_{N_\bullet(Q_0)}$ is also a colimit diagram in $\mathcal{C}$, so that $\sigma$ is thin by virtue of Proposition 8.1.6.2. \qed

Remark 8.1.6.5. Let $\mathcal{C}$ be an $\infty$-category and suppose we are given a morphism of simplicial sets $\varphi : \text{Tw}(\Delta^2) \to \mathcal{C}$, which we display as a diagram

\[ \begin{array}{ccc}
X_{0,0} & \rightarrow & X_{1,1} \\
\downarrow & & \downarrow \\
X_{0,1} & \rightarrow & X_{1,2}
\end{array} \]

\[ \begin{array}{ccc}
X_{0,2} & \rightarrow & X_{2,2}
\end{array} \]
The proof of Corollary 8.1.6.4 shows that $\varphi$ is a colimit diagram if and only if the inner region is a pushout square.

We now study the problem of filling outer horns in the simplicial set $\text{Cospan}(\mathcal{C})$.

**Lemma 8.1.6.6.** Let $\mathcal{C}$ be an $\infty$-category and let $\sigma_0 : \Lambda^n_0 \to \text{Cospan}(\mathcal{C})$ be a morphism of simplicial sets. Assume that $n \geq 3$ and that the composite map

$$\Delta^2 \simeq N_\bullet(\{0 < 1 < n\}) \hookrightarrow \Lambda^n_0 \xrightarrow{\sigma_0} \text{Cospan}(\mathcal{C})$$

is a left-degenerate 2-simplex of $\text{Cospan}(\mathcal{C})$ (Definition 5.5.1.1). Then $\sigma_0$ can be extended to an n-simplex of $\text{Cospan}(\mathcal{C})$.

**Proof.** Using Proposition 8.1.4.7, we can identify $\sigma_0$ with a morphism of simplicial sets $F_0 : \text{Tw}(\Lambda^n_0) \to \mathcal{C}$; we wish to show that $F_0$ can be extended to a morphism of simplicial sets $\text{Tw}(\Delta^n) \to \mathcal{C}$. Let $P$ denote the set of all ordered pairs $(i, j)$, where $i$ and $j$ are integers satisfying $0 \leq i \leq j \leq n$. We regard $P$ as a partially ordered set by identifying it with its image in the product $[n]^{\text{op}} \times [n]$ (so that $(i, j) \leq (i', j')$ if and only if $i' \leq i$ and $j \leq j'$).

In what follows, we will identify $\text{Tw}(\Delta^n)$ with the nerve $N_\bullet(P)$; under this identification, $\text{Tw}(\Lambda^n_0)$ corresponds to a simplicial subset $K_0 \subseteq N_\bullet(P)$.

Let $S = \{(i_0, j_0) < (i_1, j_1) < \cdots < (i_d, j_d)\}$ be a nonempty linearly ordered subset of $P$, so that we have inequalities $0 \leq i_d \leq i_{d-1} \leq \cdots \leq i_0 \leq j_0 \leq j_1 \leq \cdots \leq j_d \leq n$. In this case, we write $\tau_S$ for the corresponding nondegenerate $d$-simplex of $N_\bullet(P)$. We will say that $S$ is basic if $\tau_S$ is contained in $K_0$. Equivalently, $S$ is basic if the set $\{i_0, i_1, \cdots, i_d, j_0, j_1, \cdots, j_d\}$ does not contain $\{1 < 2 < \cdots < n\}$. If $S$ is not basic, we let $\text{pr}(S)$ denote the largest integer $j$ such that $S$ contains the pair $(i, j)$ for some $i \neq 0$. If no such integer exists, we define $\text{pr}(S) = 0$. We will refer to $\text{pr}(S)$ as the priority of $S$. We say that $S$ is prioritized if it is not basic and contains the pair $(0, \text{pr}(S))$.

Let $\{S_1, S_2, \cdots, S_m\}$ be an enumeration of the collection of all prioritized linearly ordered subsets of $P$ which satisfies the following conditions:

- The sequence of priorities $\text{pr}(S_1), \text{pr}(S_2), \cdots, \text{pr}(S_m)$ is nondecreasing. That is, if $1 \leq k \leq \ell \leq m$, then we have $\text{pr}(S_k) \leq \text{pr}(S_\ell)$.
- If $\text{pr}(S_k) = \text{pr}(S_\ell)$ for $k \leq \ell$, then $|S_k| \leq |S_\ell|$.

For $1 \leq \ell \leq m$, let $\tau_\ell \subseteq N_\bullet(P)$ denote the simplex $\tau_{S_\ell}$ and let $K_\ell \subseteq N_\bullet(P)$ denote the union of $K_0$ with the simplices $\{\tau_1, \tau_2, \cdots, \tau_\ell\}$, so that we have inclusion maps

$$K_0 \hookrightarrow K_1 \hookrightarrow K_2 \hookrightarrow \cdots \hookrightarrow K_m.$$  

We claim that $K_m = N_\bullet(P)$: that is, $K_m$ contains $\tau_S$ for every nonempty linearly ordered subset $S \subseteq P$. If $S$ is basic, there is nothing to prove. We may therefore assume that $S$
We first prove that $\rho \leq 1$ will suffice to show that the assumption that $k < \ell$ ensures that $S$ contains $K$ for some $1 \leq \ell \leq m$. In this case, we have $\tau_S \subseteq \tau_\ell \subseteq K_\ell \subseteq K_m$.

We will complete the proof by constructing a compatible sequence of maps $F_\ell : K_\ell \rightarrow \mathcal{C}$ extending $F_0$. Fix an integer $1 \leq \ell \leq m$, and suppose that $F_{\ell-1}$ has already been constructed. Write $S_\ell = \{(i_0, j_0) < (i_1, j_1) < \cdots < (i_d, j_d)\}$, so that the simplex $\tau_\ell$ has dimension $d$. Let $p$ be the priority of $S_\ell$. Since $S_\ell$ is prioritized, it contains $(0, p)$; we can therefore write $(0, p) = (i_d', j_d')$ for some integer $0 \leq d' \leq d$. Let $L \subseteq \Delta^d$ denote the inverse image of $K_{\ell-1}$ under the map $\tau_\ell : \Delta^d \rightarrow N_\bullet(P)$, so that we have a pushout diagram of simplicial sets

$$
\begin{array}{ccc}
L & \longrightarrow & K_{\ell-1} \\
\downarrow & & \downarrow \\
\Delta^d & \xrightarrow{\tau_\ell} & K_\ell.
\end{array}
$$

We claim that $L$ coincides with the horn $\Lambda^d_{d'}$. This can be stated more concretely as follows:

(*) Let $(i, j)$ be an element of $S_\ell$, and set $S' = S_\ell \setminus \{(i, j)\}$. Then the simplex $\tau_{S'}$ is contained in $K_{\ell-1}$ if and only if $(i, j) \neq (0, p)$.

We first prove (*) in the case where $(i, j) \neq (0, p)$; in this case, we wish to show that $\tau_{S'}$ is contained in $K_{\ell-1}$. If $S'$ is basic, then $\tau_{S'}$ is contained in $K_0$ and there is nothing to prove. Let us therefore assume that $S'$ is not basic. Let $p' = \text{pr}(S')$ denote the priority of $S'$. Then the union $S' \cup \{(0, p')\}$ is a prioritized subset of $P$, and therefore has the form $S_k$ for some $1 \leq k \leq m$. By construction, we have $\text{pr}(S_k) = p' \leq p = \text{pr}(S_\ell)$. Moreover, if $p' = p$, then our assumption $(i, j) \neq (0, p)$ guarantees that $S_k = S'$, so that $|S_k| < |S_\ell|$. It follows that $k < \ell$, so that we have $\tau_{S'} \subseteq \tau_k \subseteq K_k \subseteq K_{\ell-1}$.

We now prove (*) in the case $(i, j) = (0, p)$; in this case, we wish to show that $\tau_{S'}$ is not contained in $K_{\ell-1}$. Assume otherwise. Then, since $S'$ is not basic, it is contained in $S_k$ for some $k < \ell$. The inequalities

$$p = \text{pr}(S') \leq \text{pr}(S_k) \leq \text{pr}(S_\ell) = p.$$

ensure that $S_k$ has priority $p$. Since $S_k$ is prioritized, it contains $(0, p)$, and therefore contains the union $S_\ell = S' \cup \{(0, p)\}$. The inequality $|S_k| \leq |S_\ell|$ then forces $k = \ell$, contradicting our assumption that $k < \ell$. This completes the proof of (*).

Let $\rho_0$ denote the composite map $\Lambda^d_{d'} = L \xrightarrow{\tau_\ell} K_{\ell-1} \xrightarrow{F_{\ell-1}} \mathcal{C}$. To complete the proof, it will suffice to show that $\rho_0$ can be extended to a $d$-simplex of $\mathcal{C}$. We consider three cases:

- If $0 < d' < d$, then $\Lambda^d_{d'}$ is an inner horn of $\Delta^d$, so that $\rho_0$ admits an extension $\rho : \Delta^d \rightarrow \mathcal{C}$ by virtue of our assumption that $\mathcal{C}$ is an $\infty$-category.
Suppose that \( d' = 0 \): that is, the pair \((0, p)\) is the smallest element of \( S_\ell \). Then \( S_\ell \) does not contain any pairs \((i, j)\) with \( i \neq 0 \), so we have \( p = 0 \). Since the set \( S_\ell \) is not basic, we must have

\[
S_\ell = \{(0, 0) < (0, 1) < \cdots < (0, n - 1) < (0, n)\}.
\]

Our assumption that \( \sigma_0|_{\mathcal{N} (\{0 < 1\})} \) is a degenerate edge of \( \text{Cospan}(\mathcal{C}) \) guarantees that \( F_0(0, 1) \to F_0(0, 0) \) is an identity morphism of \( \mathcal{C} \). In particular, it is an isomorphism in \( \mathcal{C} \), so that \( \rho_0 \) admits an extension \( \rho : \Delta^d \to \mathcal{C} \) by virtue of Theorem 4.4.2.6.

Suppose that \( d' = d \): that is, the pair \((0, p)\) is the largest element of \( S_\ell \). Our assumption that \( S_\ell \) is not basic then guarantees that \( p = n \) and \((1, n) = S_\ell \): that is, we have

\[
S_\ell = \{(i_0, j_0) < (i_1, j_1) < \cdots < (1, n) < (0, n)\}.
\]

Our assumption that \( \sigma_0|_{\mathcal{N} (\{0 < 1 < n\})} \) is left-degenerate guarantees that \( F_0(1, n) \to F_0(0, n) \) is an identity morphism of \( \mathcal{C} \). In particular, it is an isomorphism in \( \mathcal{C} \), so that \( \rho_0 \) admits an extension \( \rho : \Delta^d \to \mathcal{C} \) by virtue of Theorem 4.4.2.6.

Proof of Proposition 8.1.6.1. Let \( \mathcal{C} \) be an \( \infty \)-category. By virtue of Corollary 8.1.6.4 and Lemma 8.1.6.6, the simplicial set \( \text{Cospan}(\mathcal{C}) \) satisfies conditions (2) and (3) of Definition 5.5.1.3. Since \( \text{Cospan}(\mathcal{C}) \) is isomorphic to its opposite \( \text{Cospan}(\mathcal{C})^{\text{op}} \) (Remark 8.1.4.4), it also satisfies condition (4) of Definition 5.5.1.3. It follows that \( \mathcal{C} \) is an \((\infty, 2)\)-category if and only if it satisfies the following condition:

\[(\ast)\] Every morphism of simplicial sets \( \sigma_0 : \Lambda_1^2 \to \text{Cospan}(\mathcal{C}) \) can be extended to a thin 2-simplex \( \sigma : \text{Cospan}(\mathcal{C}) \).

Using Corollary 8.1.6.4, we can rewrite condition \((\ast)\) as follows:

\[(\ast')\] For every diagram

\[
\begin{array}{ccc}
X & \rightarrow & Y \\
\downarrow & & \downarrow \\
B & \rightarrow & C \\
\downarrow & & \downarrow \\
& & \downarrow \\
& & Z
\end{array}
\]

in the \( \infty \)-category \( \mathcal{C} \), there exists a pushout of \( B \) and \( C \) along \( Y \).
It is clear that if the ∞-category $C$ admits pushouts, then it satisfies condition ($*'$). The converse follows by applying condition ($*'$) to diagrams of the form

\[
\begin{array}{ccc}
X & \to & Y \\
\downarrow^{\text{id}_X} & & \downarrow^{\text{id}_Y} \\
X & \to & Z
\end{array}
\]

\[\begin{array}{ccc}
\downarrow^{\text{id}_X} & & \downarrow^{\text{id}_Z} \\
X & \to & Z
\end{array}\]

\[\begin{array}{ccc}
X & \to & X \\
\downarrow & & \downarrow \\
X & \to & X
\end{array}\]

\[\begin{array}{ccc}
\downarrow^{\text{id}_X} & & \downarrow^{\text{id}_X} \\
X & \to & X
\end{array}\]

\[\begin{array}{ccc}
\downarrow^{\text{id}_X} & & \downarrow^{\text{id}_X} \\
X & \to & X
\end{array}\]

\[\begin{array}{ccc}
\downarrow^{\text{id}_X} & & \downarrow^{\text{id}_X} \\
X & \to & X
\end{array}\]

**Corollary 8.1.6.7.** Let $F : C \to D$ be a functor of ∞-categories, where $C$ and $D$ admit pushouts. The following conditions are equivalent:

1. The functor $F$ carries pushout squares in $C$ to pushout squares in $D$.

2. The induced map $\text{Cospan}(F) : \text{Cospan}(C) \to \text{Cospan}(D)$ is a functor of $(\infty, 2)$-categories, in the sense of Definition 5.5.7.1.

**Proof.** The implication (1) ⇒ (2) follows immediately from the criterion of Proposition 8.1.6.2. For the converse implication, suppose that $\text{Cospan}(F) : \text{Cospan}(C) \to \text{Cospan}(D)$ is a functor of 2-categories, and let $\sigma : \Delta^1 \times \Delta^1 \to C$ be a pushout square, which we display as a diagram

\[
\begin{array}{ccc}
X & \to & X_0 \\
\downarrow & & \downarrow \\
X_1 & \to & X_{01}
\end{array}
\]

Let $\rho : \text{Tw}(\Delta^2) \to \Delta^1 \times \Delta^1$ denote the morphism of simplicial sets given on vertices by the formula $\rho(i, j) = (\max(0, 1 - i), \max(0, j - 1))$. Then $\sigma \circ \rho$ can be identified with a 2-simplex $\tau$ of $\text{Cospan}(C)$, corresponding to a diagram

\[
\begin{array}{ccc}
X_0 & \to & X \\
\downarrow^{\text{id}} & & \downarrow^{\text{id}} \\
X_0 & \to & X
\end{array}
\]

\[
\begin{array}{ccc}
X_1 & \to & X_1 \\
\downarrow^{\text{id}} & & \downarrow^{\text{id}} \\
X_1 & \to & X_1
\end{array}
\]

\[
\begin{array}{ccc}
X_0 & \to & X_0 \\
\downarrow & & \downarrow \\
X_0 & \to & X_0
\end{array}
\]

\[\begin{array}{ccc}
X_1 & \to & X_1 \\
\downarrow & & \downarrow \\
X_1 & \to & X_1
\end{array}\]
in the $\infty$-category $C$. It follows from the criterion of Proposition 8.1.6.2 that $\tau$ is a thin 2-simplex of $\text{Cospan}(C)$. If $\text{Cospan}(F)$ is a functor of $(\infty, 2)$-categories, then it carries $\tau$ to a thin 2-simplex of $\text{Cospan}(D)$. Applying the criterion of Proposition 8.1.6.2 again, we conclude that $F(\sigma)$ is a pushout square in $D$.

8.1.7 Thin 2-Simplices of $\text{Cospan}(C)$

Let $C$ be an $\infty$-category. Our goal in this section is to prove Proposition 8.1.6.2 which provides necessary and sufficient conditions for a 2-simplex of the simplicial set $\text{Cospan}(C)$ to be thin. By virtue of Remark 8.1.6.5, it will suffice to prove the following pair of assertions:

**Lemma 8.1.7.1.** Let $C$ be an $\infty$-category and let $\sigma$ be a 2-simplex of $\text{Cospan}(C)$, which we identify with a diagram $\varphi : \text{Tw}(\Delta^2) \to C$. If $\sigma$ is thin, then $\varphi$ is a colimit diagram.

**Lemma 8.1.7.2.** Let $C$ be an $\infty$-category and let $\sigma$ be a 2-simplex of $\text{Cospan}(C)$, which we identify with a diagram $\varphi : \text{Tw}(\Delta^2) \to C$. If $\varphi$ is a colimit diagram, then $\sigma$ is thin.

**Proof of Lemma 8.1.7.1.** Let $Q$ denote the partially ordered set appearing in the proof of Corollary 8.1.6.4, so that we can identify $\text{Tw}(\Lambda^2_1)$ with the nerve of $Q$. Set $\varphi_0 = \varphi|_{\text{N}_\bullet(Q)}$.

Assume that $\sigma$ is thin. We wish to show that the restriction map $C_{\varphi/} \to C_{\varphi_0/}$ is a trivial Kan fibration: that is, every lifting problem

$\begin{array}{ccc}
\partial\Delta^n & \longrightarrow & C_{\varphi/} \\
\downarrow & & \downarrow \\
\Delta^n & \longrightarrow & C_{\varphi_0/}
\end{array}$

admits a solution.

Let $K$ denote the coproduct $(\text{Tw}(\Delta^2) \ast \partial\Delta^n) \coprod (\text{N}_\bullet(Q) \ast \partial\Delta^n)(\text{N}_\bullet(Q) \ast \Delta^n)$, which we regard as a simplicial subset of $\text{Tw}(\Delta^2) \ast \Delta^n$. Unwinding the definitions, we can identify the lifting problem (8.9) with a morphism of simplicial sets $\tau : K \to C$ satisfying $\tau_0|_{\text{Tw}(\Delta^2)} = \varphi$. We wish to show that $\tau_0$ can be extended to a morphism $\tau : \text{Tw}(\Delta^2) \ast \Delta^n \to C$.

Let $\iota : \text{Tw}(\Delta^2) \ast \Delta^n \to \text{Tw}(\Delta^{n+3})$ be the morphism of simplicial sets given on vertices by the formula

$\iota(x) = \begin{cases} 
(i, j) & \text{if } x = (i, j) \in \text{Tw}(\Delta^2) \\
(0, x+3) & \text{if } x \in \Delta^n.
\end{cases}$

The morphism $\iota$ has a left inverse $\rho : \text{Tw}(\Delta^{n+3}) \to \text{Tw}(\Delta^2) \ast \Delta^n$, given on vertices by the formula

$\rho(i, j) = \begin{cases} 
(i, j) \in \text{Tw}(\Delta^2) & \text{if } j \leq 2 \\
j - 2 \in \Delta^n & \text{otherwise}.
\end{cases}$
We observe that \( \iota \) and \( \rho \) restrict to morphisms of simplicial subsets

\[
\iota_0 : K \to \text{Tw}(\Lambda_1^{n+3}) \quad \rho_0 : \text{Tw}(\Lambda_1^{n+3}) \to K,
\]

so that we have a commutative diagram of simplicial sets

\[
\begin{array}{ccc}
K & \xrightarrow{\iota_0} & \Lambda_1^{n+3} \\
\downarrow & & \downarrow \\
\text{Tw}(\Delta^2) \ast \Delta^n & \xrightarrow{\iota} & \Delta^{n+3} \quad \xrightarrow{\rho} \quad \text{Tw}(\Delta^2) \ast \Delta^n
\end{array}
\]

where the horizontal compositions are equal to the identity.

The composition \( \tau_0 \circ \rho_0 \) can be identified with a morphism of simplicial sets \( \psi_0 : \Lambda_1^{n+3} \to \text{Cospan}(C) \) having the property that the composition

\[
\Delta^2 \simeq N_\bullet(\{(0 < 1 < 2)\}) \xrightarrow{\psi_0} \text{Cospan}(C)
\]

coinsides with \( \sigma \). Since \( \sigma \) is thin, we can extend \( \psi_0 \) to an \((n + 3)\)-simplex \( \psi \) of \( \text{Cospan}(C) \), which we identify with a map \( \tau' : \text{Tw}(\Delta^{n+3}) \to C \). It follows that the composition \( \tau = \tau' \circ \iota \) is a morphism \( \text{Tw}(\Delta^2) \ast \Delta^n \to C \) satisfying \( \tau|_K = \tau_0 \).

**Proof of Lemma 8.1.7.2.** Let \( C \) be an \( \infty \)-category and let \( \sigma \) be a 2-simplex of \( \text{Cospan}(C) \), which we identify with a diagram \( \varphi : \text{Tw}(\Delta^2) \to C \). Assume that \( \varphi \) is a colimit diagram. We wish to show that \( \sigma \) is thin. We proceed by a (somewhat more complicated) variation on the proof of Lemma 8.1.6.6.

Fix integers \( 0 < q < n \) with \( n \geq 3 \), and suppose that we are given a morphism \( f_0 : \Lambda_q^n \to \text{Cospan}(C) \) for which the composition

\[
\Delta^2 \simeq N_\bullet(\{q - 1 < q < q + 1\}) \leftrightarrow \Lambda_q^n \xrightarrow{f_0} \text{Cospan}(C)
\]

is equal to \( \sigma \); we wish to show that \( f_0 \) can be extended to an \( n \)-simplex of \( \text{Cospan}(C) \). Using Proposition 8.1.4.7, we can identify \( f_0 \) with a morphism of simplicial sets \( F_0 : \text{Tw}(\Lambda_q^n) \to C \); we wish to show that \( F_0 \) admits an extension \( \text{Tw}(\Delta^n) \to C \).

Let \( P \) denote the set of all ordered pairs \((i,j)\), where \( i \) and \( j \) are integers satisfying \( 0 \leq i \leq j \leq n \). We regard \( P \) as a partially ordered set by identifying it with its image in the product \([n]^{\text{op}} \times [n] \) (so that \((i,j) \leq (i',j')\) if and only if \( i' \leq i \) and \( j \leq j' \)). In what follows, we will identify \( \text{Tw}(\Delta^n) \) with the nerve \( N_\bullet(P) \); under this identification, \( \text{Tw}(\Lambda_q^n) \) corresponds to a simplicial subset \( K_0 \subseteq N_\bullet(P) \).

Let \( S = \{(i_0,j_0) < (i_1,j_1) < \cdots < (i_d,j_d)\} \) be a nonempty linearly ordered subset of \( P \), so that we have inequalities

\[
0 \leq i_d \leq i_{d-1} \leq \cdots \leq i_0 \leq j_0 \leq j_1 \leq \cdots \leq j_d \leq n.
\]
In this case, we write $\tau_S$ for the corresponding nondegenerate $d$-simplex of $N_\bullet(P)$. Let $C(S)$ denote the set of integers $\{i_0, i_1, \ldots, i_d, j_0, j_1, \ldots, j_d\}$, which we regard as a subset of $[n] = \{0 < 1 < \cdots < n\}$; we will refer to $C(S)$ as the content of $S$. We will say that:

- The set $S$ is basic if $C(S) \cup \{q\} \neq [n]$. Equivalently, $S$ is basic if the simplex $\tau_S$ is contained in $K_0$.

- The set $S$ is low if it is not basic and it contains an ordered pair $(p, q + 1)$ for some $p \leq q - 2$. In this case, we denote the largest such integer $p$ by $\text{pr}(S)$ and refer to it as the priority of $S$.

- The set $S$ is high if it is not basic and it contains an ordered pair $(q - 1, r)$ for some $r \geq q + 2$.

Note that the set $S$ cannot be both low and high, since the elements $(p, q + 1)$ and $(q - 1, r)$ are incomparable in $Q$ when $p < q < r$. Moreover, if $S$ is low, then any nonempty subset $S' \subseteq S$ is either low (and satisfies $\text{pr}(S') \leq \text{pr}(S)$) or satisfies $q + 1 \notin C(S')$, so that $S'$ is basic (the set $S'$ cannot contain any elements of the form $(q + 1, r)$, since these are incomparable with $(p, q + 1)$). Consequently, the collection of simplices of the form $\tau_S$ where $S$ is either basic or low determine a simplicial subset $K_{\text{low}} \subseteq N_\bullet(P)$. Similarly, the collection of simplices of the form $\tau_S$ where $S$ is either basic or high determine a simplicial subset $K_{\text{high}} \subseteq N_\bullet(P)$, and the intersection $K_{\text{low}} \cap K_{\text{high}}$ is equal to $K_0$.

We will prove the following:

(*) The inclusion maps $K_0 \hookrightarrow K_{\text{low}}$ and $K_0 \hookrightarrow K_{\text{high}}$ are inner anodyne.

We will prove that the inclusion map $K_0 \hookrightarrow K_{\text{low}}$ is inner anodyne; the analogous assertion for the inclusion $K_0 \hookrightarrow K_{\text{high}}$ follows by a similar argument. Let us say that a linearly ordered subset $S \subseteq Q$ is prioritized if it low and contains the ordered pair $(p, q)$, where $p = \text{pr}(S)$ denotes the priority of $S$.

Let $\{S_1, S_2, \ldots, S_m\}$ be an enumeration of the collection of all prioritized low subsets of $P$ which satisfies the following conditions:

- The sequence of priorities $\text{pr}(S_1), \text{pr}(S_2), \ldots, \text{pr}(S_m)$ is nondecreasing. That is, if $1 \leq k \leq \ell \leq m$, then we have $\text{pr}(S_k) \leq \text{pr}(S_\ell)$.

- If $\text{pr}(S_k) = \text{pr}(S_\ell)$ for $k \leq \ell$, then $|S_k| \leq |S_\ell|$.

For $1 \leq \ell \leq m$, let $\tau_\ell \subseteq N_\bullet(P)$ denote the simplex $\tau_{S_\ell}$ and let $K_\ell$ denote the union of $K_0$ with the simplices $\{\tau_1, \tau_2, \ldots, \tau_\ell\}$, so that we have inclusion maps

$$K_0 \hookrightarrow K_1 \hookrightarrow K_2 \hookrightarrow \cdots \hookrightarrow K_m.$$
We claim that \( K_m = K_{\text{low}} \): that is, every low subset \( S \subseteq P \) is contained in \( S_\ell \) for some \( 1 \leq \ell \leq m \). This is clear: if \( p = \text{pr}(S) \) is the priority of \( S \), then the union \( S \cup \{(p,q)\} \) is a prioritized low subset of \( Q \) (having the same priority \( p \)).

We will prove \((\ast)\) by showing that, for \( 1 \leq \ell \leq m \), the inclusion map \( K_{\ell-1} \hookrightarrow K_\ell \) is inner anodyne. Set \( S_q = \{(i_0,j_0) < (i_1,j_1) < \cdots < (i_d,j_d)\} \). Let \( p \) denote the priority of \( S_\ell \). Since \( S_\ell \) is prioritized, it contains the ordered pair \((p,q)\). We therefore have \((p,q) = (i_c,j_c)\) for some \( 0 \leq c \leq d \). Note that since \( p \leq r - 2 \), we must have \( c > 0 \): otherwise, we have \( q - 1 \notin C(S_\ell) \), contradicting our assumption that \( S_\ell \) is not basic. Since \( S_\ell \) also contains \((p,q+1)\), we must also have \( c < d \). Let \( L \subseteq \Delta^d \) denote the inverse image of \( K_{\ell-1} \) under the map \( \tau_\ell : \Delta^d \to N_\bullet(P) \), so that we have a pushout diagram of simplicial sets

\[
\begin{array}{ccc}
L & \to & K_{\ell-1} \\
\downarrow & & \downarrow \\
\Delta^d & \to & K_\ell
\end{array}
\]

We will complete the proof of \((\ast)\) by showing that \( L \) coincides with the inner horn \( \Lambda^d_{\ell-1} \). This can be stated more concretely as follows:

\((\ast')\) Let \((i,j)\) be an element of \( S_\ell \), and set \( S' = S_\ell \setminus \{(i,j)\} \). Then the simplex \( \tau_{S'} \) is contained in \( K_{\ell-1} \) if and only if \((i,j) \neq (p,q)\).

We first prove \((\ast')\) in the case where \((i,j) \neq (p,q)\); in this case, we wish to show that \( \tau_{S'} \) is contained in \( K_{\ell-1} \). If \( S' \) is basic, then \( \tau_{S'} \) is contained in \( K_0 \) and there is nothing to prove. We may therefore assume that \( S' \) is not basic, and is therefore low. If \((i,j) \neq (p,q+1)\), then \( S' \) is a prioritized low subset of \( Q \) satisfying \( \text{pr}(S') = p = \text{pr}(S_\ell) \) and \( |S'| < |S_\ell| \). It follows that \( S' = S_k \) for some \( k < \ell \), so that \( \tau_{S'} \) is contained in \( K_k \subseteq K_{\ell-1} \). In the case \((i,j) = (p,q+1)\), the set \( S' \) has priority \( p' = \text{pr}(S') < p \). It follows that \( S' \cup \{(p',q)\} \) is a prioritized low subset of \( Q \) having priority \( p' < \text{pr}(S_q) \), and is therefore of the form \( S_k \) for some \( k < \ell \). In this case, we again conclude that \( \tau_{S'} \) is contained in \( K_k \subseteq K_{\ell-1} \).

We now prove \((\ast')\) in the case where \((i,j) = (p,q)\); in this case, we wish to show that \( \tau_{S'} \) is not contained in \( K_{\ell-1} \). Note that, since \( S' \) contains \((p,q+1)\), we have \( C(S') \cup \{q\} = C(S_\ell) \cup \{q\} \). Since \( S_\ell \) is not basic, it follows that \( S' \) is not basic. Assume, for a contradiction, that \( \tau_{S'} \) is contained in \( K_{\ell-1} \); it follows that we have \( S' \subseteq S_k \) for some \( 1 \leq k \leq \ell \). We then have \( \text{pr}(S_k) \leq \text{pr}(S_\ell) = p \). Since \( S_k \) contains \((p,q+1)\), we must have \( \text{pr}(S_k) = p \). Since \( S_k \) is prioritized, it contains \((p,q)\), and therefore contains \( S' \cup \{(p,q)\} = S_\ell \). The inequality \( k < \ell \) guarantees that \( |S_k| \leq |S_\ell| \). It follows that \( S_k = S_\ell \), contradicting our assumption that \( k < \ell \). This completes the proof of \((\ast)\).
Since $\mathcal{C}$ is an $\infty$-category, assertion (\dagger) guarantees that the morphism $F_0 : K_0 \to \mathcal{C}$ admits an extension $F_{\text{low}} : K_{\text{low}} \to \mathcal{C}$ (Proposition 4.6.7). Similarly, the morphism $F_0$ admits an extension $F_{\text{high}} : K_{\text{high}} \to \mathcal{C}$. Let $K$ denote the union of $K_{\text{low}}$ with $K_{\text{high}}$ (as simplicial subsets of $\mathcal{N}_*(P)$). Since the intersection $K_{\text{low}} \cap K_{\text{high}}$ coincides with $K_0$, we can amalgamate $F_{\text{low}}$ with $F_{\text{high}}$ to obtain a morphism of simplicial sets $F : K \to \mathcal{C}$. We will complete the proof of Proposition 8.1.6.2 by showing that $F$ can be extended to a morphism $\mathcal{N}_*(P) \to \mathcal{C}$.

Set $P_- = \{(i, j) \in P : (i, j) < (q - 1, q + 1)\}$ and $P_+ = \{(i, j) \in P : (i, j) > (q - 1, q + 1)\}$. Let us say that a nonempty linearly ordered subset $S \subseteq P$ is decomposable if the union $S \cup \{(q - 1, q + 1)\}$ is also linearly ordered. In this case, we can write $S$ (uniquely) as a union $S_- \cup S_0 \cup S_+$, where $S_- \subseteq P_-$, $S_0 \subseteq \{(q - 1, q + 1)\}$, and $S_+ \subseteq P_+$. The collection of simplices $\tau_S$, where $S$ is decomposable, span a simplicial subset of $\mathcal{N}_*(P)$ which will identify with the join $\mathcal{N}_*(P_-) \ast \{(q - 1, q + 1)\} \ast \mathcal{N}_*(P_+)$. We next claim that $\mathcal{N}_*(P)$ is the union of $K$ with the join $\mathcal{N}_*(P_-) \ast \{(q - 1, q + 1)\} \ast \mathcal{N}_*(P_+)$. In other words, if a nonempty linearly ordered subset $S \subseteq P$ is not decomposable, then $\tau_S$ is contained in $K$. Choose an element $(i, j) \in S$ which is incomparable with $(q - 1, q + 1)$ in the partially ordered set $P$. Without loss of generality, we may assume that $i < q - 1$ and $j < q + 1$. If $S$ is basic, there is nothing to prove. We may therefore assume that $q + 1$ belongs to the content $C(S)$. Note that ordered pairs of the form $(q + 1, r)$ are incomparable with $(i, j)$, and therefore cannot be contained in $S$. It follows that $S$ contains an element of the form $(p, q + 1)$. Since $(p, q + 1)$ is comparable with $(i, j)$ in $P$, we must have $p \leq i \leq q - 2$. It follows that $S$ is low, so that $\tau_S$ is contained in $K_{\text{low}} \subseteq K$.

Let $K' \subseteq K$ denote the intersection of $K$ with the join $\mathcal{N}_*(P_-) \ast \{(q - 1, q + 1)\} \ast \mathcal{N}_*(P_+)$, so that we have a pushout diagram of simplicial sets

$$
\begin{array}{ccc}
K' & \rightarrow & K \\
\downarrow & & \downarrow \\
\mathcal{N}_*(P_-) \ast \{(q - 1, q + 1)\} \ast \mathcal{N}_*(P_+) & \rightarrow & \mathcal{N}_*(P).
\end{array}
$$

Set $F' = F|_{K'}$. To complete the proof, it will suffice to show that $F'$ can be extended to a morphism of simplicial sets $\mathcal{N}_*(P_-) \ast \{(q - 1, q + 1)\} \ast \mathcal{N}_*(P_+) \to \mathcal{C}$.

We now give a more explicit description of $K'$. Let us say that a linearly ordered subset $S_+ \subseteq P_+$ is odd if the simplex $\tau_{S_+ \cup \{(q - 1, q + 1)\}}$ is contained in $K$. Let $S \subseteq P$ be an arbitrary decomposable subset, and write $S = S_- \cup S_0 \cup S_+$ as above. We then make the following observations:

(a) Suppose that $S_0 = \{(q - 1, q + 1)\}$. Then replacing $S$ by the subset $S_0 \cup S_+$ does not change the set $C(S) \cup \{q\}$. In particular, $S$ is basic if and only if $S_0 \cup S_+$ is basic.
Moreover, since $S_-$ does not contain any pairs of the form $(p, q + 1)$ for $p \leq q - 1$, it follows that $S$ is low if and only if $S_0 \cup S_+$ is low. Similarly, $S$ is high if and only if $S_0 \cup S_+$ is high. It follows that $\tau_S$ is contained in $K$ if and only if $\tau_{S_0 \cup S_+}$ is contained in $K$: that is, if and only if $S_+$ is old.

(b) Suppose that $S_0 = \emptyset$. In this case, we claim that $\tau_S$ is automatically contained in $K$. Assume otherwise. Then $S$ is not basic, so the set $C(S)$ contains the element $q + 1$. Since ordered pairs of the form $(q + 1, q')$ are incomparable with $(q - 1, q + 1)$ for $q' > q + 1$, it follows that $S$ contains an ordered pair of the form $(p, q + 1)$ for some $p \leq q + 1$. Since $S$ is not low, we must have $p \geq q - 1$. By assumption, $S$ does not contain $(q - 1, q + 1)$, so we must have $p \in \{q, q + 1\}$. By the same reasoning (using the fact that $C(S)$ contains $q - 1$ and $S$ is not high), we conclude that $S$ contains an element of the form $(q - 1, r)$ for $r \in \{q - 1, q\}$. This is a contradiction, since $S$ is linearly ordered and the ordered pairs $(p, q + 1)$ and $(q - 1, r)$ are incomparable in $P$.

Let $A \subseteq N_\bullet(P_+)$ denote the simplicial subset spanned by the simplices $\tau_{S_+}$, where $S_+$ is old. Combining (a) and (b), we deduce that $K'$ can be identified with the pushout

$$
(N_\bullet(P_-) \ast \{(q - 1, q + 1)\} \ast A) \coprod_{N_\bullet(P_-) \ast A} (N_\bullet(P_-) \ast N_\bullet(P_+)).
$$

This lifting problem admits a solution by virtue of our assumption that $\varphi$ is a colimit diagram in $C$.

### 8.2 The Yoneda Embedding

Let $C$ be a category. For every object $X \in C$, we let $h^X : C \to \text{Set}$ denote the functor corepresented by $X$, given on objects by the formula $h^X(Y) = \text{Hom}_C(X, Y)$. The construction $X \mapsto h^X$ determines a functor from $C^{\text{op}}$ to the functor category $\text{Fun}(C, \text{Set})$, which we refer to as the (contravariant) Yoneda embedding. This terminology is justified by the following:
**Proposition 8.2.0.1** (Yoneda’s Lemma, Weak Form). For any (locally small) category $C$, the Yoneda embedding
$$C^{\text{op}} \to \text{Fun}(C, \text{Set}) \quad X \mapsto h^X$$
is fully faithful.

The goal of this section is to generalize Proposition 8.2.0.1 to the $\infty$-categorical setting. Our first step is to construct an appropriate analogue of the Yoneda embedding for an $\infty$-category $C$. For every pair of objects $X, Y \in C$, the morphism space $\text{Hom}_C(X, Y)$ is a Kan complex (Proposition 4.6.1.9), which we can regard as an object of the $\infty$-category $S$. In §8.2.3, we show that the construction $(X, Y) \mapsto \text{Hom}_C(X, Y)$ can be upgraded to a functor from the product $C^{\text{op}} \times C$ to the $\infty$-category $S$. More precisely, every locally small $\infty$-category $C$ admits a $\text{Hom}$-functor $H : C^{\text{op}} \times C \to S$, which is characterized (up to isomorphism) by the requirement that it is a covariant transport representation for twisted arrow fibration $\text{Tw}(C) \to C^{\text{op}} \times C$ or Proposition 8.2.3.10. This condition guarantees that for every object $X \in C$, the functor $H(X, -) : C \to S$ is corepresentable by $X$. We can therefore identify $H$ with a functor $h^\bullet : C^{\text{op}} \to \text{Fun}(C, S) X \mapsto H(X, -)$ carrying each object of $C$ to a functor that it corepresents; we will refer to $h^\bullet$ as a contravariant Yoneda embedding for $C$ (Definition 8.2.5.1).

To show that the Yoneda embedding is fully faithful, we will need an additional ingredient. Let us return to the situation where $C$ is an ordinary category. Proposition 8.2.0.1 asserts that for every pair of objects $X, Y \in C$, the natural map $\text{Hom}_C(Y, X) \to \text{Hom}_{\text{Fun}(C, \text{Set})}(h^X, h^Y)$ is a bijection. It is easy to see that this map is injective: in fact, it has a left inverse $T : \text{Hom}_{\text{Fun}(C, \text{Set})}(h^X, h^Y) \to \text{Hom}_C(Y, X)$, which carries a natural transformation $\alpha : h^X \to h^Y$ to the element $\alpha_X(id_X) \in h^Y(X) = \text{Hom}_C(Y, X)$. It will therefore suffice to show that $T$ is bijective. This is a consequence of the following strong version of Yoneda’s lemma: for every functor $\mathcal{F} : C \to \text{Set}$, the evaluation map
$$\text{Hom}_{\text{Fun}(C, \text{Set})}(h^X, \mathcal{F}) \to \mathcal{F}(X) \quad \alpha \mapsto \alpha_X(id_X)$$
is a bijection (Proposition 8.2.1.1). This assertion also has a counterpart in the setting of $\infty$-categories (Proposition 8.2.1.3), which we prove in §8.2.1.

To exploit the universal mapping property of (co)representable functors, it will be convenient to introduce some terminology. Let $\mathcal{C}$ and $\mathcal{D}$ be $\infty$-categories. We define a profunctor from $\mathcal{D}$ to $\mathcal{C}$ to be a functor $\mathcal{K} : C^{\text{op}} \times D \to S$ (Definition 8.2.2.1). We say that a profunctor $\mathcal{K}$ is corepresentable if, for every object $X \in \mathcal{C}$, the functor $\mathcal{K}(X, -) : \mathcal{D} \to S$ is corepresentable. In this case, the construction $X \mapsto \mathcal{K}(X, -)$ determines a functor from $C^{\text{op}}$ to the full subcategory $\text{Fun}^{\text{corep}}(\mathcal{D}, S) \subseteq \text{Fun}(\mathcal{D}, S)$ spanned by the corepresentable functors.
In §8.2.2, we give necessary and sufficient conditions for this functor to be fully faithful (Proposition 8.2.2.10) or an equivalence of ∞-categories (Corollary 8.2.2.12). In §8.2.5 we specialize these results to the situation where \(C = D\) and \(\mathcal{H}\) is a Hom-functor for \(\mathcal{C}\), and show that the contravariant Yoneda embedding \(C^{op} \to \text{Fun}(\mathcal{C}, \mathcal{S})\) is fully faithful (Theorem 8.2.5.5).

Let \(\mathcal{C}\) and \(\mathcal{D}\) be ∞-categories. Assume that \(\mathcal{C}\) is locally small, so that it admits a Hom-functor \(H : \mathcal{C}^{op} \times \mathcal{C} \to \mathcal{S}\). For every functor \(G : \mathcal{D} \to \mathcal{C}\), the composition

\[
\mathcal{C}^{op} \times \mathcal{D} \xrightarrow{id \times G} \mathcal{C}^{op} \times \mathcal{C} \xrightarrow{\mathcal{H}} \mathcal{S},
\]

can be regarded as a profunctor from \(\mathcal{D}\) to \(\mathcal{C}\), given informally by the construction \((X,Y) \mapsto \text{Hom}_{\mathcal{D}}(X, G(Y))\). In §8.2.6, we show that this construction determines a fully faithful functor \(\text{Fun}(\mathcal{C}, \mathcal{D})^{op} \to \text{Fun}(\mathcal{C}^{op} \times \mathcal{D}, \mathcal{S})\) (Proposition 8.2.6.1). Similarly, if \(\mathcal{D}\) is locally small, then there is a fully faithful functor \(\text{Fun}(\mathcal{C}, \mathcal{D})^{op} \to \text{Fun}(\mathcal{C}^{op} \times \mathcal{D}, \mathcal{S})\), which carries a functor \(F : \mathcal{C} \to \mathcal{D}\) to the profunctor \((X,Y) \mapsto \text{Hom}_{\mathcal{D}}(F(X), Y)\). In §8.2.7, we show that functors \(F : \mathcal{C} \to \mathcal{D}\) and \(G : \mathcal{D} \to \mathcal{C}\) are adjoint if and only if the corresponding profunctors are isomorphic (Proposition 8.2.7.1). Stated more informally, \(F\) is left adjoint to \(G\) if it is possible to choose homotopy equivalences \(\text{Hom}_{\mathcal{D}}(F(X), Y) \simeq \text{Hom}_{\mathcal{C}}(X, G(Y))\) which depend functorially on \(X\) and \(Y\). To prove this, we exploit the fact that (co)representable profunctors can be characterized by a universal mapping property (Proposition 8.2.6.15).

Warning 8.2.0.2. If \(\mathcal{C}\) is an ordinary category, the Yoneda embedding

\[
h^\bullet : C^{op} \to \text{Fun}(\mathcal{C}, \text{Set}) \quad X \mapsto h^X
\]

is given by a completely explicit construction. Beware that in the ∞-categorical setting, the Yoneda embedding depends on a choice of covariant transport representation for the twisted arrow fibration \(\text{Tw}(\mathcal{C}) \to \mathcal{C}^{op} \times \mathcal{C}\), which is well-defined only up to isomorphism. However, it is sometimes possible to eliminate this ambiguity. In §8.2.4, we study the case where \(\mathcal{C} = N_{hc}(\mathcal{C}_0)\) is the homotopy coherent nerve of a locally Kan simplicial category \(\mathcal{C}_0\). In this case, we give a concrete example of a Hom-functor for \(\mathcal{C}\), obtained as the homotopy coherent nerve of the functor

\[
C_0^{op} \times \mathcal{C}_0 \to \text{Kan} \quad (X,Y) \mapsto \text{Hom}_{\mathcal{C}_0}(X,Y)\bullet.
\]

determined by the simplicial enrichment of \(\mathcal{C}_0\) (see Proposition 8.2.4.2).

8.2.1 Yoneda’s Lemma

Let \(\mathcal{C}\) be a category. Every object \(X \in \mathcal{C}\) determines a corepresentable functor \(h^X : \mathcal{C} \to \text{Set}\), given on objects by the formula \(h^X(Y) = \text{Hom}_{\mathcal{C}}(X,Y)\). This functor can be characterized by a universal mapping property:
**Proposition 8.2.1.1** (Yoneda’s Lemma, Strong Form). Let $\mathcal{C}$ be a category containing an object $X$. For every functor $\mathcal{F} : \mathcal{C} \to \text{Set}$, evaluation on the identity morphism $\text{id}_X \in h^X(X)$ induces a bijection

$$\text{Hom}_{\text{Fun}(\mathcal{C}, \text{Set})}(h^X, \mathcal{F}) \to \mathcal{F}(X).$$

**Proof.** Fix an element $x \in \mathcal{F}(X)$. We wish to show that there is a unique natural transformation $\alpha : h^X \to \mathcal{F}$ which carries $\text{id}_X \in h^X(X)$ to the element $x \in \mathcal{F}(X)$.

For any object $Y \in \mathcal{C}$, every element $f \in h^X(Y) \in \text{Hom}_\mathcal{C}(X, Y)$ can be obtained by evaluating the function $h^X(f) : h^X(X) \to h^X(Y)$ on the object $\text{id}_X$. It follows that, if $\alpha : h^X \to \mathcal{F}$ is a natural transformation satisfying $\alpha_X(\text{id}_X) = x$, then it must satisfy the identity

$$\alpha_Y(f) = \alpha_Y(h^X(f)(\text{id}_X)) = \mathcal{F}(f)(h^X(\text{id}_X)) = \mathcal{F}(f)(x).$$

This proves uniqueness. To establish existence, it will suffice to show that the collection of functions

$$\alpha_Y : \text{Hom}_\mathcal{C}(X, Y) \to \mathcal{F}(Y) \quad f \mapsto \mathcal{F}(f)(x)$$

determine a natural transformation from $h^X$ to $\mathcal{F}$. In other words, we must show that for each morphism $g : Y \to Z$ in $\mathcal{C}$, the diagram of sets

$$\begin{array}{ccc}
\text{Hom}_\mathcal{C}(X, Y) & \xrightarrow{g^\circ} & \text{Hom}_\mathcal{C}(X, Z) \\
\downarrow{\alpha_Y} & & \downarrow{\alpha_Z} \\
\mathcal{F}(Y) & \xrightarrow{\mathcal{F}(g)} & \mathcal{F}(Z)
\end{array}$$

is commutative. This follows from the observation that, for every morphism $f : X \to Y$ of $\mathcal{C}$, we have an equality $\mathcal{F}(g \circ f)(x) = (\mathcal{F}(g) \circ \mathcal{F}(f))(x)$ in the set $\mathcal{F}(Z)$. \qed

Our goal in this section is prove a generalization of Yoneda’s lemma, where we replace $\mathcal{C}$ by an $\infty$-category and Set by the $\infty$-category $\mathcal{S}$ of spaces (Proposition 8.2.1.3). In the $\infty$-categorical setting, the proof is more subtle: to construct a natural transformation $\alpha$ between functors $\mathcal{F}, \mathcal{G} : \mathcal{C} \to \mathcal{S}$, it is not enough to specify a collection of morphisms $\{\alpha_Y : \mathcal{G}(Y) \to \mathcal{F}(Y)\}_{Y \in \mathcal{C}}$ and to verify a compatibility condition. To address this difficulty, we will use the formalism of Kan extensions developed in §7.3 (see Lemma 8.2.1.7).

**Notation 8.2.1.2.** Let $\mathcal{S}$ denote the $\infty$-category of spaces (Construction 5.6.1.1). Let $\mathcal{C}$ be an $\infty$-category and suppose we are given a pair of functors $\mathcal{F}, \mathcal{G} : \mathcal{C} \to \mathcal{S}$. Fix an object $X \in \mathcal{C}$ and a vertex $\eta \in \mathcal{F}(X)$. We then obtain a comparison morphism

$$\begin{array}{ccc}
\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{S})}(\mathcal{F}, \mathcal{G}) & \xrightarrow{\eta_X} & \text{Hom}_\mathcal{S}(\mathcal{F}(X), \mathcal{G}(X)) \\
\circ[\eta] & \xrightarrow{} & \text{Hom}_\mathcal{S}(\Delta^0, \mathcal{G}(X)) \\
& \simeq & \mathcal{G}(X)
\end{array}$$
8.2. THE YONEDA EMBEDDING

in the homotopy category hKan, where the first map is given by evaluation on the object $X$, the second by the composition law of Notation 4.6.8.15 and the third is (the inverse of) the homotopy equivalence of Remark 5.6.1.5.

**Proposition 8.2.1.3** ($\infty$-Categorical Yoneda Lemma). Let $\mathcal{C}$ be an $\infty$-category containing an object $X$, let $\mathcal{F} : \mathcal{C} \to \mathcal{S}$ be a functor, and let $\eta \in \mathcal{F}(X)$ be a vertex which exhibits the functor $\mathcal{F}$ as corepresented by $X$ (see Definition 5.7.6.1). Then, for every functor $\mathcal{G} : \mathcal{C} \to \mathcal{S}$, the comparison map

$$\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{S})}(\mathcal{F}, \mathcal{G}) \to \mathcal{G}(X)$$

of Notation 8.2.1.2 is an isomorphism in the homotopy category hKan.

**Remark 8.2.1.4.** In the special case where $\mathcal{C}$ is (the nerve of) an ordinary category and $\mathcal{G}$ is a set-valued functor, Proposition 8.2.1.3 reduces to Proposition 8.2.1.1.

**Remark 8.2.1.5.** Let $\mathcal{C}$ be a small $\infty$-category and let $X$ be an object of $\mathcal{C}$. In §5.7.6, we showed that there exists a functor $\mathcal{F} : \mathcal{C} \to \mathcal{S}$ which is corepresented by $X$, and that $\mathcal{F}$ is uniquely determined up to isomorphism (Theorem 5.7.6.13). Proposition 8.2.1.3 can be regarded as a more refined version of this uniqueness assertion: the functor $\mathcal{F}$ is characterized, up to isomorphism, by the requirement that it corepresents the evaluation functor

$$\text{ev}_X : \text{Fun}(\mathcal{C}, \mathcal{S}) \to \mathcal{S} \quad \mathcal{G} \mapsto \mathcal{G}(X).$$

**Corollary 8.2.1.6.** Let $\mathcal{C}$ be an $\infty$-category containing an object $X$. Suppose that, for every object $Y \in \mathcal{C}$, the Kan complex $\text{Hom}_{\mathcal{C}}(X, Y)$ is essentially small (this condition is satisfied, for example, if $\mathcal{C}$ is small). Let $\mathcal{F} : \mathcal{C} \to \mathcal{S}$ be a functor, and let $\eta$ be a vertex of the Kan complex $\mathcal{F}(X)$. The following conditions are equivalent:

1. The vertex $\eta$ exhibits the functor $\mathcal{F}$ as corepresented by $X$, in the sense of Definition 5.7.6.1.

2. For every functor $\mathcal{G} : \mathcal{C} \to \mathcal{S}$, the comparison map of Notation 8.2.1.2 is a homotopy equivalence $\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{S})}(\mathcal{F}, \mathcal{G}) \to \mathcal{G}(X)$.

3. For every functor $\mathcal{F} : \mathcal{C} \to \mathcal{S}$, the comparison map of Notation 8.2.1.2 induces a bijection $\pi_0(\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{S})}(\mathcal{F}, \mathcal{G})) \to \pi_0(\mathcal{G}(X))$.

**Proof.** The implication (1) $\Rightarrow$ (2) follows from Proposition 8.2.1.3, and the implication (2) $\Rightarrow$ (3) is immediate. We will complete the proof by showing that (3) implies (1). Our assumption that the morphism space $\text{Hom}_{\mathcal{C}}(X, Y)$ is essentially small for each $Y \in \mathcal{C}$ guarantees that there exists a functor $\mathcal{F}' : \mathcal{C} \to \mathcal{S}$ and a vertex $\eta' \in \mathcal{F}'(X)$ which exhibits $\mathcal{F}'$ as corepresented by $X$ (see Theorem 5.7.6.13). Applying assumption (3), we deduce that
there exists a natural transformation \( \alpha : \mathcal{F}' \to \mathcal{F} \) such that \( \alpha_X(\eta') \) and \( \eta \) lie in the same connected component of \( \mathcal{F}' \). Since the pair \( (\mathcal{F}', \eta') \) also satisfies condition (3), composition with \( \alpha \) induces a bijection \( \pi_0(\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{S})}(\mathcal{F}, \mathcal{G})) \to \pi_0(\text{Hom}_{\text{Fun}(\mathcal{C}, \mathcal{S})}(\mathcal{F}', \mathcal{G})) \) for each object \( \mathcal{G} \in \text{Fun}(\mathcal{C}, \mathcal{S}) \). It follows that \( \alpha \) is an isomorphism. Applying Remark 5.7.6.4, we deduce that \( \alpha_X(\eta') \in \mathcal{F}(X) \) exhibits the functor \( \mathcal{F} \) as corepresented by \( X \). Since \( \eta \) and \( \alpha_X(\eta) \) belong to the same connected component of \( \mathcal{F}(X) \), it follows that \( \eta \) has the same property (Remark 5.7.6.3).

Proposition 8.2.1.3 is an easy consequence of the following:

**Lemma 8.2.1.7.** Let \( \mathcal{C} \) be an \( \infty \)-category containing an object \( X \), let \( \mathcal{F} : \mathcal{C} \to \mathcal{S} \) be a functor, and let \( \eta \in \mathcal{F}(X) \) be a vertex. The following conditions are equivalent:

1. The vertex \( \eta \) exhibits \( \mathcal{F} \) as corepresented by the object \( X \), in the sense of Definition 5.7.6.1.

2. Let \( \iota : \{X\} \hookrightarrow \mathcal{C} \) denote the inclusion map and let \( \mathcal{F}_0 : \{X\} \to \mathcal{S} \) denote the constant functor taking the value \( \Delta^0 \), so that \( \eta \) can be regarded as a natural transformation from \( \mathcal{F}_0 \) to the composite functor \( \mathcal{F} \circ \iota \). Then \( \eta \) exhibits \( \mathcal{F} \) as a left Kan extension of \( \mathcal{F}_0 \) along \( \iota \), in the sense of Variant 7.3.1.5.

**Proof.** Fix an object \( Y \in \mathcal{C} \) and set \( M = \text{Hom}_\mathcal{C}(X, Y) \). For every Kan complex \( K \), let \( K_M \) denote the constant functor \( M \to \mathcal{S} \) taking the value \( K \), so that the functor \( \mathcal{F} \) determines a natural transformation \( \gamma : \mathcal{F}(X)_M \to \mathcal{F}(Y)_M \). We will show that the following pair of conditions is equivalent:

1. The composite map \( \text{Hom}_\mathcal{C}(X, Y) \to \text{Hom}_\mathcal{S}(\mathcal{F}(X), \mathcal{F}(Y)) \xrightarrow{\circ[\eta]} \text{Hom}_\mathcal{S}(\Delta^0, \mathcal{F}(Y)) \) is a homotopy equivalence of Kan complexes.

2. The composite natural transformation

\[
\Delta^0_M \xrightarrow{\eta} \mathcal{F}(X)_M \xrightarrow{\gamma} \mathcal{F}(Y)_M
\]

exhibits \( \mathcal{F}(Y) \) as a colimit of the constant diagram \( \Delta^0|_M \) in the \( \infty \)-category \( \mathcal{S} \).

The equivalence of (1) and (2) is a special case of Proposition 7.6.2.9 (see Example 7.6.2.11). Lemma 8.2.1.7 follows by allowing the object \( Y \in \mathcal{C} \) to vary. 

**Proof of Proposition 8.2.1.3** Combine Lemma 8.2.1.7 and 7.3.6.1.

\[\square\]
8.2.2 Profunctors of $\infty$-Categories

Let $\mathcal{C}$ and $\mathcal{D}$ be categories. A profunctor from $\mathcal{D}$ to $\mathcal{C}$ is a Set-valued functor on the product category $\mathcal{C}^{\text{op}} \times \mathcal{D}$. This notion has an evident $\infty$-categorical analogue, where we replace the ordinary category of sets by the $\infty$-category $S$ of spaces (see Construction 5.6.1.1).

**Definition 8.2.2.1.** Let $\mathcal{C}$ and $\mathcal{D}$ be $\infty$-categories. A profunctor from $\mathcal{D}$ to $\mathcal{C}$ is a functor $\mathcal{K} : \mathcal{C}^{\text{op}} \times \mathcal{D} \to S$.

**Example 8.2.2.2.** Let $\mathcal{C}$ and $\mathcal{D}$ be ordinary categories. Then every functor $K : \mathcal{C}^{\text{op}} \times \mathcal{D} \to \text{Set}$ determines a morphism of simplicial sets $N_{\bullet}(K) : N_{\bullet}(\mathcal{C})^{\text{op}} \times N_{\bullet}(\mathcal{D}) \to N_{\bullet}(\text{Set}) \subset S$.

This construction determines a monomorphism from the collection of profunctors from $\mathcal{D}$ to $\mathcal{C}$ (in the sense of classical category theory) to the collection of profunctors from $N_{\bullet}(\mathcal{D})$ to $N_{\bullet}(\mathcal{C})$ (in the sense of Definition 8.2.2.1). Beware that this map is (usually) not bijective: its image consists of those profunctors $\mathcal{K} : N_{\bullet}(\mathcal{C})^{\text{op}} \times N_{\bullet}(\mathcal{D}) \to S$ having the property that for every pair of objects $X \in \mathcal{C}$ and $Y \in \mathcal{D}$, the Kan complex $\mathcal{K}(X,Y)$ is a constant simplicial set (see Proposition 1.2.2.1 and Remark 5.6.1.7).

**Remark 8.2.2.3 (Symmetry).** Let $\mathcal{C}$ and $\mathcal{D}$ be $\infty$-categories and let $\mathcal{K} : \mathcal{C}^{\text{op}} \times \mathcal{D} \to S$ be a profunctor from $\mathcal{D}$ to $\mathcal{C}$. Then, by transposing its arguments, we can also regard $\mathcal{K}$ as a profunctor from $\mathcal{C}^{\text{op}}$ to $\mathcal{D}^{\text{op}}$.

Let $\mathcal{C}$ and $\mathcal{D}$ be ordinary categories. Every functor $G : \mathcal{D} \to \mathcal{C}$ determines a profunctor $\mathcal{C}^{\text{op}} \times \mathcal{D} \to \text{Set} \quad (X,Y) \mapsto \text{Hom}_{\mathcal{C}}(X,G(Y))$.

We say that a profunctor is representable if (up to isomorphism) it is obtained in this way. Equivalently, a profunctor $K : \mathcal{C}^{\text{op}} \times \mathcal{D} \to \text{Set}$ is representable if, for each object $Y \in \mathcal{D}$, the functor $K(\_,Y) : \mathcal{C}^{\text{op}} \to \text{Set}$ is representable by an object of $\mathcal{C}$ (Exercise 8.2.2.9). This condition generalizes to the setting of $\infty$-categories.

**Definition 8.2.2.4.** Let $\mathcal{C}$ and $\mathcal{D}$ be $\infty$-categories, and let $\mathcal{K} : \mathcal{C}^{\text{op}} \times \mathcal{D} \to S$ be a profunctor from $\mathcal{D}$ to $\mathcal{C}$. We say that $\mathcal{K}$ is corepresentable if, for each object $X \in \mathcal{C}$, the functor $\mathcal{K}(X,\_) : \mathcal{D} \to S$ is corepresentable, in the sense of Definition 5.7.6.1. We will say that $\mathcal{K}$ is representable if, for each object $Y \in \mathcal{D}$, the functor $\mathcal{K}(\_,Y) : \mathcal{C}^{\text{op}} \to S$ is representable, in the sense of Variant 5.7.6.2.
Warning 8.2.2.5. The terminology of Definition 8.2.2.4 is potentially confusing. Let $C$ and $D$ be ∞-categories, let $E$ denote the product $C^{\text{op}} \times D$, and let $\mathcal{K} : E \to S$ be a morphism of simplicial sets. In general, there is no relationship between the corepresentability of $\mathcal{K}$ as a $S$-valued functor $E$ (in the sense of Definition 5.7.6.1) and the corepresentability of $\mathcal{K}$ as a profunctor from $D$ to $C$ (in the sense of Definition 8.2.2.4). However, these notions of corepresentability coincide when $C$ is a contractible Kan complex (see Example 8.2.2.8).

Remark 8.2.2.6. Let $C$ and $D$ be ∞-categories and let $\mathcal{K} : C^{\text{op}} \times D \to S$ be a profunctor from $D$ to $C$. Then $\mathcal{K}$ is representable if and only if it is corepresentable when regarded as a profunctor from $C^{\text{op}}$ to $D^{\text{op}}$ (see Remark 8.2.2.3).

Remark 8.2.2.7 (Symmetry). Let $C$ and $D$ be ∞-categories and let $\mathcal{K}$ and $\mathcal{K}'$ be profunctors from $D$ to $C$ which are isomorphic as objects of the ∞-category $\text{Fun}(C^{\text{op}} \times D, S)$. Then $\mathcal{K}$ is representable if and only if $\mathcal{K}'$ is representable. Similarly, $\mathcal{K}$ is corepresentable if and only if $\mathcal{K}'$ is corepresentable. See Remark 5.7.6.4.

Example 8.2.2.8. Let $C$ and $D$ be ∞-categories and let $\mathcal{K} : C^{\text{op}} \times D \to S$ be a profunctor. If $C = \Delta^0$, then the profunctor $\mathcal{K}$ is corepresentable (in the sense of Definition 8.2.2.4) if and only if it is corepresentable when regarded as a functor $D \to S$ (in the sense of Definition 5.7.6.1). Similarly, if $D = \Delta^0$, then the profunctor $\mathcal{K}$ is representable (in the sense of Definition 8.2.2.4) if and only if it is representable when viewed as a functor $C^{\text{op}} \to S$ (in the sense of Variant 5.7.6.2).

Exercise 8.2.2.9. Let $C$ and $D$ be ordinary categories. Show that a profunctor

$$\mathcal{K} : \text{N}_\bullet(C)^{\text{op}} \times \text{N}_\bullet(D) \to S$$

is representable (in the sense of Definition 8.2.2.4) if and only if it is isomorphic to the profunctor $(X, Y) \mapsto \text{Hom}_C(X, G(Y))$, for some functor $G : D \to C$. See Proposition 8.2.6.1 for a more general result.

Let $C$ and $D$ be ∞-categories. Then a profunctor $\mathcal{K} : C^{\text{op}} \times D \to S$ can be identified with a functor from $C^{\text{op}}$ to the ∞-category $\text{Fun}(D, S)$. We now study conditions which guarantee that this functor is fully faithful.

Proposition 8.2.2.10. Let $C$ and $D$ be ∞-categories, and let $\mathcal{K} : C^{\text{op}} \times D \to S$ be a corepresentable profunctor from $C$ to $D$. The following conditions are equivalent:

1. The profunctor $\mathcal{K}$ determines a fully faithful functor

$$C^{\text{op}} \to \text{Fun}(D, S) \quad X \mapsto \mathcal{K}(X, -).$$
Let $X$ be an object of $\mathcal{C}$, let $Y$ be an object of $\mathcal{D}$, and let $\eta$ be a vertex of the Kan complex $\mathcal{K}(X,Y)$. If $\eta$ exhibits the functor $\mathcal{K}(X, -) : \mathcal{D} \to \mathcal{S}$ as corepresented by $Y$, then it also exhibits the functor $\mathcal{K}(-, Y) : \mathcal{C}^{\text{op}} \to \mathcal{S}$ as represented by $X$.

**Proof.** Choose an object $X$ be an object of $\mathcal{C}$. Then the functor $\mathcal{K}(X, -) : \mathcal{C} \to \mathcal{S}$ is corepresentable. We can therefore choose an object $Y \in \mathcal{D}$ and a vertex $\eta \in \mathcal{K}(X,Y)$ which exhibits the functor $\mathcal{K}(X, -)$ as corepresented by $Y$. We will show that the following conditions are equivalent:

1. For every object $X' \in \mathcal{C}$, the profunctor $\mathcal{K}$ induces a homotopy equivalence
   \[ \text{Hom}_{\mathcal{C}^{\text{op}}}(X, X') \to \text{Hom}_{\text{Fun}(\mathcal{D}, \mathcal{S})}(\mathcal{K}(X, -), \mathcal{K}(X' -)). \]

2. The vertex $\eta$ exhibits the functor $\mathcal{K}(-, Y)$ as represented by $X$.

Proposition 8.2.2.10 will then follow by allowing the triple $(X, Y, \eta)$ to vary.

Condition $(2_X)$ is the assertion that, for each object $X' \in \mathcal{C}$, the composite map

\[
\begin{align*}
\text{Hom}_{\mathcal{C}^{\text{op}}}(X, X') & \to \text{Hom}_{\text{Fun}(\mathcal{D}, \mathcal{S})}(\mathcal{K}(X, -), \mathcal{K}(X' -)) \\
& \to \text{Hom}_{\mathcal{S}}(\mathcal{K}(X, Y), \mathcal{K}(X', Y)) \\
& \overset{\circ[n]}{\to} \text{Hom}_{\mathcal{S}}(\Delta^0, \mathcal{K}(X', Y)) \\
& \simeq \mathcal{K}(X', Y)
\end{align*}
\]

is an isomorphism in the homotopy category $\text{hKan}$. The equivalence of this assertion with $(1_X)$ follows immediately from Proposition 8.2.1.3.

---

**Definition 8.2.2.11 (Balanced Profunctors).** Let $\mathcal{C}$ and $\mathcal{D}$ be $\infty$-categories. We say that a profunctor $\mathcal{K} : \mathcal{C}^{\text{op}} \times \mathcal{D} \to \mathcal{S}$ is balanced if it satisfies the following conditions:

- The profunctor $\mathcal{K}$ is representable and corepresentable (Definition 8.2.2.4).
- Let $X$ be an object of $\mathcal{C}$, let $Y$ be an object of $\mathcal{D}$, and let $\eta$ be a vertex of the Kan complex $\mathcal{K}(X,Y)$. Then $\eta$ exhibits the functor $\mathcal{K}(-, Y) : \mathcal{C}^{\text{op}} \to \mathcal{S}$ as represented by $X$ if and only if it exhibits the functor $\mathcal{K}(X, -) : \mathcal{D} \to \mathcal{S}$ as corepresented by $Y$.

In other words, $\mathcal{K} : \mathcal{C}^{\text{op}} \times \mathcal{D} \to \mathcal{S}$ is balanced if it satisfies the hypotheses of Proposition 8.2.2.10 both when regarded as a profunctor from $\mathcal{D}$ to $\mathcal{C}$ and when regarded as a profunctor from $\mathcal{C}^{\text{op}}$ to $\mathcal{D}^{\text{op}}$.

**Corollary 8.2.2.12.** Let $\mathcal{C}$ and $\mathcal{D}$ be $\infty$-categories and let $\mathcal{K} : \mathcal{C}^{\text{op}} \times \mathcal{D} \to \mathcal{S}$ be a profunctor from $\mathcal{D}$ to $\mathcal{C}$. The following conditions are equivalent:

1. The profunctor $\mathcal{K}$ is balanced (in the sense of Definition 8.2.2.11).
(2) The \( \infty \)-category \( \mathcal{D} \) is locally small and \( \mathcal{K} \) induces a fully faithful functor
\[
\mathcal{C}^{\text{op}} \to \text{Fun}(\mathcal{D}, \mathcal{S}) \quad X \mapsto \mathcal{K}(X,-),
\]
whose essential image is spanned by the corepresentable functors \( \mathcal{D} \to \mathcal{S} \).

(3) The \( \infty \)-category \( \mathcal{C} \) is locally small and \( \mathcal{K} \) induces a fully faithful functor
\[
\mathcal{D} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}) \quad Y \mapsto \mathcal{K}(-,Y),
\]
whose essential image is spanned by the representable functors \( \mathcal{C}^{\text{op}} \to \mathcal{S} \).

Proof. We will prove the equivalence of (1) and (2); the equivalence of (1) and (3) follows by a similar argument. Assume first that \( \mathcal{K} : \mathcal{C}^{\text{op}} \times \mathcal{D} \to \mathcal{S} \) is a balanced profunctor. Invoking Proposition 8.2.2.10, we see that the functor \( \Phi : \mathcal{C}^{\text{op}} \to \text{Fun}(\mathcal{D}, \mathcal{S}) \) \( X \mapsto \mathcal{K}(X,-) \) is fully faithful, and that the essential image of \( \Phi \) consists of corepresentable functors \( \mathcal{D} \to \mathcal{S} \). Fix an object \( Y \in \mathcal{D} \). Since \( \mathcal{K} \) is representable, there exists an object \( X \in \mathcal{C} \) and a vertex \( \eta \in \mathcal{K}(X,Y) \) which exhibits the functor \( \mathcal{K}(-,Y) \) as represented by \( X \). Our assumption that \( \mathcal{K} \) is balanced guarantees that \( \eta \) also exhibits the functor \( \mathcal{K}(X,-) \) as corepresented by \( Y \). In particular, for every object \( Y' \in \mathcal{D} \), \( \eta \) induces a homotopy equivalence \( \text{Hom}_\mathcal{D}(Y,Y') \to \mathcal{K}(X,Y') \), so that the Kan complex \( \text{Hom}_\mathcal{C}(X,Y') \) is essentially small. If \( F : \mathcal{D} \to \mathcal{S} \) is any functor corepresented by \( Y \), then Theorem 5.7.6.13 guarantees that \( F \) is isomorphic to \( \mathcal{K}(X,-) \) (as an object of the \( \infty \)-category \( \text{Fun}(\mathcal{D}, \mathcal{S}) \)), and therefore belongs to the essential image of \( \Phi \). Allowing the object \( Y \) to vary, we deduce that the profunctor \( \mathcal{K} \) satisfies condition (2).

We now prove the converse. Assume that the functor \( \Phi \) is fully faithful and that the essential image of \( \Phi \) consists of corepresentable functors from \( \mathcal{D} \) to \( \mathcal{S} \). Fix an object \( Y \in \mathcal{D} \). Since \( \mathcal{K} \) is representable, there exists an object \( X \in \mathcal{C} \) and a vertex \( \eta \in \mathcal{K}(X,Y) \) which exhibits the functor \( \mathcal{K}(-,Y) \) as represented by \( X \). Our assumption that \( \mathcal{K} \) is balanced guarantees that \( \eta \) also exhibits the functor \( \mathcal{K}(X,-) \) as corepresented by \( Y \). In particular, for every object \( Y' \in \mathcal{D} \), \( \eta \) induces a homotopy equivalence \( \text{Hom}_\mathcal{D}(Y,Y') \to \mathcal{K}(X,Y') \), so that the Kan complex \( \text{Hom}_\mathcal{C}(X,Y') \) is essentially small. If \( F : \mathcal{D} \to \mathcal{S} \) is any functor corepresented by \( Y \), then Theorem 5.7.6.13 guarantees that \( F \) is isomorphic to \( \mathcal{K}(X,-) \) (as an object of the \( \infty \)-category \( \text{Fun}(\mathcal{D}, \mathcal{S}) \)), and therefore belongs to the essential image of \( \Phi \). Allowing the object \( Y \) to vary, we deduce that the profunctor \( \mathcal{K} \) satisfies condition (2).

To complete the proof, we must show that the profunctor \( \mathcal{K} \) satisfies the second condition of Definition 8.2.2.11. Let \( Y \in \mathcal{D} \) be as above, let \( X \) be any object of \( \mathcal{C} \), and let \( \eta \) be a vertex
of the Kan complex $\mathcal{K}(X,Y)$. Assume that $\eta$ exhibits the functor $\mathcal{K}(-,Y)$ as represented by $X$; we wish to show that it also exhibits the functor $\mathcal{K}(X,-)$ as corepresented by $Y$ (the reverse implication follows from Proposition 8.2.2.10). Let $\eta_0 \in \mathcal{K}(X_0,Y)$ be as above. Since $\eta_0$ exhibits $\mathcal{K}(-,Y)$ as represented by $X_0$, there exists an isomorphism $u : X \to X_0$ in the $\infty$-category $\mathcal{C}$ such that $\mathcal{K}(u,\text{id}_Y)(\eta_0)$ and $\eta$ belong to the same connected component of the Kan complex $\mathcal{K}(X,Y)$ (Remark 5.7.6.6). We may therefore assume without loss of generality that $\eta = \mathcal{K}(u,\text{id}_Y)(\eta_0)$ (Remark 5.7.6.3). The desired result now follows by applying Remark 5.7.6.4 to the isomorphism of functors $\mathcal{K}(u,-) : \mathcal{K}(X_0,-) \to \mathcal{K}(X,-)$.

**Corollary 8.2.2.13.** Let $\mathcal{C}$ be a locally small $\infty$-category, and let $\text{Fun}^{\text{corep}}(\mathcal{C},\mathcal{S})$ denote the full subcategory of $\text{Fun}(\mathcal{C},\mathcal{S})$ spanned by the corepresentable functors. Then the evaluation map $\text{ev} : \text{Fun}^{\text{corep}}(\mathcal{C},\mathcal{S}) \times \mathcal{C} \to \mathcal{S}(F,C) \mapsto F(C)$ is a balanced profunctor.

**Remark 8.2.2.14** (Uniqueness). Up to equivalence, every balanced profunctor can be obtained from the construction of Corollary 8.2.2.13. More precisely, let $\text{Fun}^{\text{corep}}(\mathcal{D},\mathcal{S})$ denote the full subcategory of $\text{Fun}(\mathcal{D},\mathcal{S})$ spanned by the corepresentable functors. If $\mathcal{K}$ is a balanced profunctor from $\mathcal{D}$ to $\mathcal{C}$, then it factors as a composition $C^{\text{op}} \times D \xrightarrow{\Phi \times \text{id}} \text{Fun}^{\text{corep}}(\mathcal{D},\mathcal{S}) \times D \xrightarrow{\text{ev}} \mathcal{S}$, where $\Phi$ is an equivalence of $\infty$-categories (Corollary 8.2.2.12).

### 8.2.3 Hom-Functors for $\infty$-Categories

**Definition 8.2.3.2** (Hom-Functors). Let $\mathcal{C}$ be an $\infty$-category and let $\lambda : \text{Tw}(\mathcal{C})$ denote its twisted arrow $\infty$-category (Construction 8.1.1.10). For any profunctor $\mathcal{K} : C^{\text{op}} \times \mathcal{C} \to \mathcal{S}$, we let $\mathcal{K}|_{\text{Tw}(\mathcal{C})} : \text{Tw}(\mathcal{C}) \to \mathcal{S}$ denote the composition of $\mathcal{K}$ with the left fibration $\text{Tw}(\mathcal{C}) \to C^{\text{op}} \times \mathcal{C}$ of Proposition 8.1.1.10. A Hom-functor for $\mathcal{C}$ is a pair $(\mathcal{K},\lambda)$, where $\mathcal{K} : C^{\text{op}} \times \mathcal{C} \to \mathcal{S}$ is a functor and $\lambda : \Delta^0_{\text{Tw}(\mathcal{C})} \to \mathcal{K}|_{\text{Tw}(\mathcal{C})}$ is a natural transformation which satisfies the following condition:
For every pair of objects \(X, Y \in \mathcal{C}\), the natural transformation \(\alpha\) induces a homotopy equivalence of Kan complexes
\[
\alpha_{X,Y} : \{X\} \times_{\mathcal{C}} \text{Tw}(\mathcal{C}) \times_{\mathcal{C}} \{Y\} \to \text{Hom}_S(\Delta^0, \mathcal{H}(X,Y)).
\]

**Remark 8.2.3.3.** Let \(\mathcal{C}\) be an \(\infty\)-category. We will often abuse terminology by referring to a functor \(\mathcal{H} : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S}\) as a Hom-functor for \(\mathcal{C}\) if there exists a natural transformation \(\alpha : \Delta^0_{\text{Tw}(\mathcal{C})} \to \mathcal{H}|_{\text{Tw}(\mathcal{C})}\) which satisfies condition (\(\ast\)) of Definition 8.2.3.2. In this case, we will say that \(\alpha\) exhibits \(\mathcal{H}\) as a Hom-functor for \(\mathcal{C}\).

**Remark 8.2.3.4.** Let \(\mathcal{C}\) be an \(\infty\)-category, let \(\mathcal{H} : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S}\) be a functor, and let \(\alpha : \Delta^0_{\text{Tw}(\mathcal{C})} \to \mathcal{H}|_{\text{Tw}(\mathcal{C})}\) be a natural transformation. For every pair of objects \(X, Y \in \mathcal{C}\), Notation 8.1.2.10 and Remark 5.6.1.5 supply canonical isomorphisms
\[
\text{Hom}_\mathcal{C}(X,Y) \cong \{X\} \times_{\mathcal{C}} \text{Tw}(\mathcal{C}) \times_{\mathcal{C}} \{Y\} \cong \text{Hom}_S(\Delta^0, \mathcal{H}(X,Y))
\]
in the homotopy category \(\text{hKan}\). Consequently, the homotopy class of the morphism \(\alpha_{X,Y}\) appearing in Definition 8.2.3.2 can be identified with a map \([\alpha_{X,Y}] : \text{Hom}_\mathcal{C}(X,Y) \to \mathcal{H}(X,Y)\) in \(\text{hKan}\). The natural transformation \(\alpha\) exhibits \(\mathcal{H}\) as a Hom-functor for \(\mathcal{C}\) if and only if \([\alpha_{X,Y}]\) is an isomorphism for every pair of objects \(X, Y \in \mathcal{C}\).

**Example 8.2.3.5.** Let \(\mathcal{C}\) be a (locally small) category. Then the construction \((X,Y) \mapsto \text{Hom}_\mathcal{C}(X,Y)\) determines a functor
\[
\mathcal{H} : N_\bullet(\mathcal{C})^{\text{op}} \times N_\bullet(\mathcal{C}) \to N_\bullet(\text{Set}) \subset \mathcal{S},
\]
which is a Hom-functor for the \(\infty\)-category \(N_\bullet(\mathcal{C})\). More precisely, there is a natural transformation \(\alpha : \Delta^0_{\text{Tw}(\mathcal{C})} \to \mathcal{H}|_{\text{Tw}(N_\bullet(\mathcal{C}))}\) which exhibits \(\mathcal{H}\) as a Hom-functor for \(N_\bullet(\mathcal{C})\), given explicitly by assigning to each object \((f : X \to Y)\) of \(\text{Tw}(N_\bullet(\mathcal{C}))\) the inclusion map \(\{f\} \hookrightarrow \text{Hom}_\mathcal{C}(X,Y) = \mathcal{H}(X,Y)\).

**Remark 8.2.3.6** (Naturality). Let \(\mathcal{C}\) be an \(\infty\)-category and let \(\text{h}\mathcal{C}\) denotes its homotopy category, which we view as enriched over the homotopy category of Kan complexes \(\text{hKan}\) (see Construction 4.6.8.13). The enrichment determines a functor
\[
\text{Hom}_{\text{h}\mathcal{C}}(-,-) : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \text{hKan},
\]
given on objects by the formula \((X,Y) \mapsto \text{Hom}_\mathcal{C}(X,Y)\). Suppose we are given a functor of \(\infty\)-categories \(\mathcal{H} : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S}\). Passing to homotopy categories, we obtain a functor
\[
\text{h}\mathcal{H} : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \text{h}\mathcal{S} = \text{hKan}.
\]
For any natural transformation \(\alpha : \Delta^0_{\text{Tw}(\mathcal{C})} \to \mathcal{H}|_{\text{Tw}(\mathcal{C})}\), the construction \(X,Y \mapsto [\alpha_{X,Y}]\) described in Remark 8.2.3.4 determines a natural transformation from \(\text{Hom}_{\text{h}\mathcal{C}}(-,-)\) to the functor \(\text{h}\mathcal{H}\) (see Corollary 8.1.2.13). This natural transformation is an isomorphism if and only if \(\alpha\) exhibits \(\mathcal{H}\) as a Hom-functor for \(\mathcal{C}\).
8.2. THE YONEDA EMBEDDING

Remark 8.2.3.7 (Duality). Let \( \mathcal{C} \) be an \( \infty \)-category, let \( \mathcal{H} : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S} \) be a functor, and let \( \mathcal{H}' : \mathcal{C} \times \mathcal{C}^{\text{op}} \to \mathcal{S} \) be the functor obtained from \( \mathcal{H} \) by transposing its arguments. If \( \mathcal{H} \) is a Hom-functor for \( \mathcal{C} \), then \( \mathcal{H}' \) is a Hom-functor for the opposite \( \infty \)-category \( \mathcal{C}^{\text{op}} \). More precisely, if \( \alpha : \Delta^0_{\text{Tw}(\mathcal{C})} \to \mathcal{H}|_{\text{Tw}(\mathcal{C})} \) exhibits \( \mathcal{H} \) as a Hom-functor for \( \mathcal{C} \), then it also exhibits \( \mathcal{H}' \) as a Hom-functor for \( \mathcal{C}^{\text{op}} \) (by means of the identification \( \text{Tw}(\mathcal{C}) \simeq \text{Tw}(\mathcal{C}^{\text{op}}) \) supplied by Remark 8.1.1.6).

Remark 8.2.3.8. Let \( \mathcal{C} \) be an \( \infty \)-category and let \( \mathcal{H} : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S} \) be a functor. The datum of a natural transformation \( \alpha : \Delta^0_{\text{Tw}(\mathcal{C})} \to \mathcal{H}|_{\text{Tw}(\mathcal{C})} \) can be identified with a commutative diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\text{Tw}(\mathcal{C}) & \to & \{\Delta^0\} \times_{\mathcal{S}} \mathcal{S} \\
\downarrow & & \downarrow \\
\mathcal{C}^{\text{op}} \times \mathcal{C} & \xrightarrow{\mathcal{H}} & \mathcal{S}.
\end{array}
\] (8.10)

In this case, the natural transformation \( \alpha \) exhibits \( \mathcal{H} \) as a Hom-functor for \( \mathcal{C} \) if and only if the diagram (8.10) is a categorical pullback square (see Corollary 5.1.6.15).

Remark 8.2.3.9. Let \( \mathcal{C} \) be an \( \infty \)-category. Using Remark 8.2.3.8, we see that a functor \( \mathcal{H} : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S} \) is a Hom-functor for \( \mathcal{C} \) if and only if it is a covariant transport representation for the left fibration \( \lambda : \text{Tw}(\mathcal{C}) \to \mathcal{C}^{\text{op}} \times \mathcal{C} \). In other words, \( \mathcal{H} \) is a Hom-functor for \( \mathcal{C} \) if \( \lambda \) can be lifted to an equivalence of \( \text{Tw}(\mathcal{C}) \) with the \( \infty \)-category of elements \( \int_{\mathcal{C}^{\text{op}} \times \mathcal{C}} \mathcal{H} \).

Proposition 8.2.3.10 (Existence and Uniqueness). Let \( \mathcal{C} \) be an \( \infty \)-category. Then \( \mathcal{C} \) admits a Hom-functor \( \mathcal{H} : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S} \) if and only if it is locally small. If this condition is satisfied, then \( \mathcal{H} \) is uniquely determined up to isomorphism.

Proof. Combine Remark 8.2.3.9 with Corollary 5.7.0.6 (applied to the left fibration \( \lambda : \text{Tw}(\mathcal{C}) \to \mathcal{C}^{\text{op}} \times \mathcal{C} \)).

Variant 8.2.3.11. Let \( \kappa \) be an uncountable cardinal, and let \( \mathcal{S}^{<\kappa} \) denote the \( \infty \)-category of \( \kappa \)-small spaces (Variant 5.6.4.12). Then an \( \infty \)-category \( \mathcal{C} \) admits a Hom-functor

\[
\mathcal{H} : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S}^{<\kappa}
\]

if and only if it is locally \( \kappa \)-small. If this condition is satisfied, then \( \mathcal{H} \) is uniquely determined up to isomorphism.

For many applications, the uniqueness assertion of Proposition 8.2.3.10 is insufficiently precise. When viewed abstractly as an object of the \( \infty \)-category \( \text{Fun}(\mathcal{C}^{\text{op}} \times \mathcal{C}, \mathcal{S}) \), a Hom-functor \( \mathcal{H} \) is uniquely determined up to isomorphism but not up to canonical isomorphism.
We can remedy the situation by considering the additional datum of a natural transformation \( \alpha : \Delta^0_{\text{Tw}(\mathcal{C})} \to \mathcal{H}|_{\text{Tw}(\mathcal{C})} \) which exhibits \( \mathcal{H} \) as a Hom-functor for \( \mathcal{C} \). In this case, the pair \((\mathcal{H}, \alpha)\) is unique up to a contractible choice, when viewed as an object of the \( \infty \)-category \( \{\Delta^0_{\text{Tw}(\mathcal{C})}\} \times_{\text{Fun}(\text{Tw}(\mathcal{C}), \mathcal{S})} \text{Fun}(\mathcal{C}^{\text{op}} \times \mathcal{C}, \mathcal{S}) \). This is a consequence of the following:

**Proposition 8.2.3.12.** Let \( \mathcal{C} \) be a locally small \( \infty \)-category, let \( \mathcal{H} : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S} \) be a functor, and let \( \alpha : \Delta^0_{\text{Tw}(\mathcal{C})} \to \mathcal{H}|_{\text{Tw}(\mathcal{C})} \) be a natural transformation. The following conditions are equivalent:

1. The natural transformation \( \alpha \) exhibits \( \mathcal{H} \) as a Hom-functor for \( \mathcal{C} \): that is, it satisfies condition \((*)\) of Definition 8.2.3.2.

2. The diagram

\[
\begin{array}{ccc}
\Delta^0_{\text{Tw}(\mathcal{C})} & \xrightarrow{\alpha} & \mathcal{H}|_{\text{Tw}(\mathcal{C})} \\
\downarrow & & \downarrow \\
\text{Tw}(\mathcal{C}) & \xrightarrow{\lambda} & \mathcal{S}.
\end{array}
\]

exhibits \( \mathcal{H} \) as a left Kan extension of the constant functor \( \Delta^0_{\text{Tw}(\mathcal{C})} \) along the left fibration \( \text{Tw}(\mathcal{C}) \to \mathcal{C}^{\text{op}} \times \mathcal{C} \).

3. The pair \((\mathcal{H}, \alpha)\) is initial when viewed as an object of the oriented fiber product

\[
\{\Delta^0_{\text{Tw}(\mathcal{C})}\} \times_{\text{Fun}(\text{Tw}(\mathcal{C}), \mathcal{S})} \text{Fun}(\mathcal{C}^{\text{op}} \times \mathcal{C}, \mathcal{S}).
\]

**Proof.** The equivalence \((1) \iff (2)\) follows from Proposition 7.6.2.15 and Remark 8.2.3.8. Since \( \mathcal{C} \) is locally small, Proposition 8.2.3.10 guarantees that the functor \( \Delta^0_{\text{Tw}(\mathcal{C})} \) admits a left Kan extension along \( \lambda \), so the equivalence \((2) \iff (3)\) follows from Corollary 7.3.6.5.

**Variant 8.2.3.13.** Let \( \kappa \) be an uncountable cardinal and let \( \mathcal{C} \) be an \( \infty \)-category which is locally \( \kappa \)-small. Then, in the statement of Proposition 8.2.3.12, we can replace \( \mathcal{S} \) with the \( \infty \)-category \( \mathcal{S}^{<\kappa} \) of \( \kappa \)-small spaces (Variant 5.6.4.12).

**Notation 8.2.3.14.** Let \( \mathcal{C} \) be a locally small \( \infty \)-category. We will often use the notation \( \text{Hom}_{\mathcal{C}}(-,-) \) to denote a Hom-functor \( \mathcal{H} : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S} \). Beware that this convention introduces a slight potential for confusion. Given a pair of objects \( X, Y \in \mathcal{C} \), we have two potentially different definitions of \( \text{Hom}_{\mathcal{C}}(X,Y) \):

(a) The Kan complex \( \{X\} \times_{\mathcal{C}} \{Y\} \) of Construction 4.6.1.1, which is well-defined up to canonical isomorphism.

(b) The Kan complex \( \mathcal{H}(X,Y) \), which is only well-defined up to homotopy equivalence (since it depends on a choice of Hom-functor \( \mathcal{H} \)).
8.2. THE YONEDA EMBEDDING

However, the danger is slight: if we choose a natural transformation $\alpha : \Delta^0 \Rightarrow T(C)$ which exhibits $\mathcal{H}$ as a Hom-functor for $C$, then Remark 8.2.3.4 supplies canonical isomorphisms $[\alpha_{X,Y}] : \{X\} \times_C \{Y\} \to \mathcal{H}(X,Y)$ in the homotopy category $h \text{Kan}$. Consequently, if each of the Kan complexes $\{X\} \times_C \{Y\}$ is small, we can modify the choice of Hom-functor $H$ to arrange that definitions (a) and (b) coincide (see Corollary 4.4.5.3).

8.2.4 Strict Models for Hom-Functors

Let $E$ be a (locally small) $\infty$-category. Proposition 8.2.3.10 guarantees the existence of a Hom-functor $\mathcal{H} : E^{op} \times E \to S$, which is well-defined up to isomorphism. Our goal in this section is to give an explicit construction of a Hom-functor in the special case where $E = N^{hc} \circ (C)$ arises as the homotopy coherent nerve of a (locally Kan) simplicial category $C$.

Construction 8.2.4.1. Let $C$ be a locally Kan simplicial category. Then the construction $(X, Y) \mapsto \text{Hom}_C(X, Y)_\bullet$ determines a simplicial functor $C^{op} \times C \to \text{Kan}$. Passing to homotopy coherent nerves, we obtain a functor of $\infty$-categories

$$\mathcal{H}_C : N^{hc}(C)^{op} \times N^{hc}(C) \to N^{hc}(\text{Kan}) = S.$$ 

Proposition 8.2.4.2. Let $C$ be a locally Kan simplicial category. Then the functor $\mathcal{H}_C$ of Construction 8.2.4.1 is a Hom-functor for the $\infty$-category $N^{hc}(C)$.

Remark 8.2.4.3. Let $C$ be an ordinary category, which we identify with the corresponding constant simplicial category (see Example 2.4.2.4). In this case, Proposition 8.2.4.2 reduces to Example 8.2.3.5.

Remark 8.2.4.4. By combining Proposition 8.2.4.2 with the rectification results of §[?], we can give an explicit construction of a Hom-functor for an arbitrary (small) $\infty$-category $\mathcal{E}$. Let $\text{Path}[\mathcal{E}]_\bullet$ denote the simplicial path category of $\mathcal{E}$ (Definition 2.4.4.1) and let $C$ be the locally Kan simplicial having the same objects, with morphism spaces given by $\text{Hom}_C(X, Y)_\bullet = \text{Ex}^\infty(\text{Hom}_{\text{Path}[\mathcal{E}]_\bullet}(X, Y)_\bullet)$ (see Example [?]). It follows from Proposition 3.3.6.7 that the tautological map $\text{Path}[\mathcal{E}]_\bullet \to C$ is a weak equivalence of simplicial categories (in the sense of Definition 4.6.7.7), and therefore corresponds to an equivalence of $\infty$-categories $F : \mathcal{E} \to N^{hc}(C)$ (Theorem [?]). Using Proposition 8.2.4.2, we deduce that the composition

$$\mathcal{E}^{op} \times \mathcal{E} \xrightarrow{F^{op} \times F} N^{hc}(C)^{op} \times N^{hc}(C) \xrightarrow{\mathcal{H}_C} S$$

is a Hom-functor for $\mathcal{E}$, given on objects by $(X, Y) \mapsto \text{Ex}^\infty(\text{Hom}_{\text{Path}[\mathcal{E}]_\bullet}(X, Y))$.

Beware that, although this construction is completely explicit in principle, it is hard to use in practice (since the operations $\mathcal{E} \mapsto \text{Path}[\mathcal{E}]_\bullet$ and $S \mapsto \text{Ex}^\infty(S)$ are both difficult to control).
Proposition 8.2.4.2 asserts that the functor $\mathcal{H}_C$ is a covariant transport representation for the left fibration $\text{Tw}(N^\text{hc}(C)) \to N^\text{hc}(C)^\text{op} \times N^\text{hc}(C)$ (Remark 8.2.3.9). We will prove this by constructing a categorical pullback square of $\infty$-categories

\[
\begin{array}{ccc}
\text{Tw}(N^\text{hc}(C)) & \xrightarrow{\mathcal{H}_C} & S_* \\
\downarrow & & \downarrow U \\
N^\text{hc}(C)^\text{op} \times N^\text{hc}(C) & \xrightarrow{\mathcal{H}_C} & S \\
\end{array}
\]

To define the upper horizontal map, we will use a variant of Construction 8.2.4.1.

**Construction 8.2.4.5.** Let $C$ be a locally Kan simplicial category, let $N^\text{hc}(C)$ denote its homotopy coherent nerve. Let $J$ be a linearly ordered set and let $\overline{J}$ denote its opposite; for each element $j \in J$, we write $\overline{j}$ for the corresponding element of $\overline{J}$. Suppose we are given a morphism of simplicial sets $\sigma : N_\bullet(J) \to \text{Tw}(N^\text{hc}(C))$, which we identify with a simplicial functor $f : \text{Path}[\overline{J} \ast J]_\bullet \to C$ (see Warning 8.1.1.8 and Proposition 2.4.4.15). Note that the composition $N_\bullet(J) \to \text{Tw}(N^\text{hc}(C)) \to N^\text{hc}(C)^\text{op} \times N^\text{hc}(C) \xrightarrow{\mathcal{H}_C} S$ can be identified with a simplicial functor $F_\sigma : \text{Path}[\overline{J}]_\bullet \to \text{Kan}$, given on objects by the formula $F_\sigma(j) = \text{Hom}_C(f(\overline{j}), f(j))_\bullet$ (see Proposition 2.4.4.15). Let $J^\circ = \{x\} \ast J$ denote the linearly ordered set obtained from $J$ by adding a new smallest element $x$. We extend $F_\sigma$ to a simplicial functor $\tilde{F}_\sigma : \text{Path}[J^\circ]_\bullet \to \text{Kan}$ as follows:

(a) The functor $\tilde{F}_\sigma$ carries the element $x \in J^\circ$ to the Kan complex $\Delta^0$.

(b) Let $j$ be an element of $J$. Let us identify $\text{Hom}_{\text{Path}[J^\circ]}(x, j)_\bullet$ with the nerve $N_\bullet(Q)$, where $Q$ is the collection of finite subsets $I \subseteq J$ satisfying $\max(I) = j$ (partially ordered by reverse inclusion). Similarly, we identify $\text{Hom}_{\text{Path}[\overline{J} \ast J]}(\overline{j}, j)_\bullet$ with the nerve $N_\bullet(Q')$, where $Q'$ is the collection of finite subsets $I' \subseteq \overline{J} \ast J$ satisfying $\max(I') = j$ and $\min(I') = \overline{j}$ (partially ordered by reverse inclusion). Then $\tilde{F}_\sigma$ is defined on the morphism space $\text{Hom}_{\text{Path}[J^\circ]}(x, j)_\bullet$ by the composition

\[
\text{Hom}_{\text{Path}[J^\circ]}(x, j)_\bullet \xrightarrow{\sim} N_\bullet(Q) \\
I \mapsto I \uplus \overline{J} \\
\xrightarrow{\sim} \text{Hom}_{\text{Path}[\overline{J} \ast J]}(\overline{J}, j)_\bullet \\
\xrightarrow{f} \text{Hom}_C(f(\overline{j}), f(j))_\bullet \\
\xrightarrow{\sim} \text{Fun}(\tilde{F}_\sigma(x), \tilde{F}_\sigma(j)).
\]
In the special case where $J$ is the linearly ordered set $[n] = \{0 < 1 < \cdots < n\}$, we can identify $\tilde{F}_\sigma$ with an $n$-simplex of the $\infty$-category of pointed spaces $S_* = N_{hc}^\bullet(Kan)_{\Delta^0/}$. The assignment $\sigma \mapsto \tilde{F}_\sigma$ depends functorially on $[n]$, and therefore determines a functor $\mathcal{H}_C : \text{Tw}(N_{hc}^\bullet(C)) \to S_*$. By construction, this functor fits into a commutative diagram

$$
\begin{array}{ccc}
\text{Tw}(N_{hc}^\bullet(C)) & \xrightarrow{\mathcal{H}_C} & S_* \\
\downarrow & & \uparrow U \\
N_{hc}^\bullet(C)^{\text{op}} \times N_{hc}^\bullet(C) & \xrightarrow{\mathcal{H}} & S_*,
\end{array}
$$

(8.11)

where the left vertical map is the twisted arrow fibration of Proposition 8.1.1.10 and the right vertical map is the forgetful functor.

**Exercise 8.2.4.6.** Verify that Construction 8.2.4.5 is well-defined. That is, for every linearly ordered set $J$ and every morphism $\sigma : N_{\bullet}(J) \to \text{Tw}(N_{hc}^\bullet(C))$, show that the simplicial functor $F_\sigma$ admits a unique extension $\tilde{F}_\sigma : \text{Path}[J^0, \bullet] \to \text{Kan}$ which satisfies conditions (a) and (b).

Proposition 8.2.4.2 is an immediate consequence of the following more precise result:

**Proposition 8.2.4.7.** Let $C$ be a locally Kan simplicial category. Then the diagram (8.11) is a categorical pullback square.

**Proof.** Note that the vertical maps in the diagram (8.11) are left fibrations (Propositions 8.1.1.10 and 5.6.3.2). It will therefore suffice to show that, for every pair of objects $X, Y \in C$, the induced map of fibers

$$
\tilde{\mathcal{H}}_{X,Y} : \{X\} \times_{\mathcal{E}^{\text{op}}} \text{Tw}(\mathcal{E}) \times_{\mathcal{E}} \{Y\} \to \{\mathcal{H}_C(X,Y)\} \times_S S_*
$$

$$
= \text{Hom}_{\mathcal{E}}^L(\Delta^0, \text{Hom}_C(X,Y)_{\bullet})
$$

is a homotopy equivalence of Kan complexes (see Corollary 5.1.6.15). Note that the coslice inclusion of Construction 8.1.2.3 induces a monomorphism of simplicial sets $\iota : \text{Hom}_{\mathcal{E}}^L(X,Y) \hookrightarrow \{X\} \times_{\mathcal{E}^{\text{op}}} \text{Tw}(\mathcal{E}) \times_{\mathcal{E}} \{Y\}$. Unwinding the definitions, we see that the composite map

$$
(\tilde{\mathcal{H}}_{X,Y} \circ \iota) : \text{Hom}_{\mathcal{E}}^L(X,Y) \to \text{Hom}_{\mathcal{E}}^L(\Delta^0, \text{Hom}_C(X,Y)_{\bullet})
$$

coincides with isomorphism described in Remark 4.6.7.18. It will therefore suffice to show that $\iota$ is a homotopy equivalence, which is a special case of Corollary 8.1.2.6. □
8.2.5 The Yoneda Embedding

We now use the results of 8.2.3 to construct an $\infty$-categorical analogue of the Yoneda embedding.

**Definition 8.2.5.1.** Let $\mathcal{C}$ be an $\infty$-category and let $h_\bullet : \mathcal{C} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}) \quad Y \mapsto h_Y$

be a functor. We say that $h_\bullet$ is a **covariant Yoneda embedding for** $\mathcal{C}$ if the construction $(X,Y) \mapsto h_Y(X)$ is a Hom-functor for $\mathcal{C}$, in the sense of Definition 8.2.3.2. Similarly, we say that a functor $h^\bullet : \mathcal{C}^{\text{op}} \to \text{Fun}(\mathcal{C}, \mathcal{S})\quad X \mapsto h_X$

is a **contravariant Yoneda embedding for** $\mathcal{C}$ if the construction $(X,Y) \mapsto h^X(Y)$ is a Hom-functor for $\mathcal{C}$.

**Remark 8.2.5.2 (Duality).** A functor $h^\bullet : \mathcal{C}^{\text{op}} \to \text{Fun}(\mathcal{C}, \mathcal{S})$ is a contravariant Yoneda embedding for $\mathcal{C}$ if and only if it is a covariant Yoneda embedding for the opposite $\infty$-category $\mathcal{C}^{\text{op}}$; see Remark 8.2.3.7.

**Remark 8.2.5.3.** Let $\mathcal{C}$ be an $\infty$-category. By virtue of Proposition 8.2.3.10, the following conditions are equivalent:

- The $\infty$-category $\mathcal{C}$ is locally small.
- The $\infty$-category $\mathcal{C}$ admits a covariant Yoneda embedding $h_\bullet : \mathcal{C} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$.
- The $\infty$-category $\mathcal{C}$ admits a contravariant Yoneda embedding $h^\bullet : \mathcal{C}^{\text{op}} \to \text{Fun}(\mathcal{C}, \mathcal{S})$.

If these conditions are satisfied, then the functors $h_\bullet$ and $h^\bullet$ are uniquely determined up to isomorphism. Moreover, for every object $X \in \mathcal{C}$, the functor $h_X : \mathcal{C}^{\text{op}} \to \mathcal{S}$ is representable by $X$, and the functor $h^X : \mathcal{C} \to \mathcal{S}$ is corepresentable by $X$ (Proposition 8.2.5.6).

**Variant 8.2.5.4.** Let $\kappa$ be an uncountable cardinal and let $\mathcal{S}^{<\kappa}$ denote the $\infty$-category of $\kappa$-small spaces (see Variant 5.6.4.12). For every $\infty$-category $\mathcal{C}$, the following conditions are equivalent:

- The $\infty$-category $\mathcal{C}$ is locally $\kappa$-small.
- The $\infty$-category $\mathcal{C}$ admits a covariant Yoneda embedding $h_\bullet : \mathcal{C} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa})$.
- The $\infty$-category $\mathcal{C}$ admits a contravariant Yoneda embedding $h^\bullet : \mathcal{C}^{\text{op}} \to \text{Fun}(\mathcal{C}, \mathcal{S}^{<\kappa})$.

See Variant 8.2.3.13.
Our main goal in this section is to prove the following:

**Theorem 8.2.5.5** (Yoneda’s Lemma for $\infty$-Categories). Let $\mathcal{C}$ be a locally small $\infty$-category. Then the covariant and contravariant Yoneda embeddings

$$h_{\cdot} : \mathcal{C} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}) \quad h^\ast : \mathcal{C}^{\text{op}} \to \text{Fun}(\mathcal{C}, \mathcal{S})$$

are fully faithful functors, whose essential images are the full subcategories

$$\text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}) \subseteq \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}) \quad \text{Fun}^{\text{corep}}(\mathcal{C}, \mathcal{S}) \subseteq \text{Fun}(\mathcal{C}, \mathcal{S})$$

spanned by the representable and corepresentable functors, respectively.

By virtue of Corollary 8.2.2.12, Theorem 8.2.5.5 is equivalent to the assertion that the Hom-functor $\text{Hom}_C : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S}$ is a balanced profunctor, in the sense of Definition 8.2.2.11. This is a consequence of the following more precise result:

**Proposition 8.2.5.6.** Let $\mathcal{C}$ be an $\infty$-category, let $\mathcal{H} : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S}$ be a functor, and let $\alpha : \Delta^0_{\text{Tw}(\mathcal{C})} \to \mathcal{H}|_{\text{Tw}(\mathcal{C})}$ be a natural transformation. For every object $X \in \mathcal{C}$, we can evaluate $\alpha$ on the object $\text{id}_X \in \text{Tw}(\mathcal{C})$ to obtain a vertex $\alpha(\text{id}_X) \in \mathcal{H}(X, X)$. The following conditions are equivalent:

1. The natural transformation $\alpha$ exhibit $\mathcal{H}$ as a Hom-functor for $\mathcal{C}$, in the sense of Remark 8.2.3.3.

2. For every object $X \in \mathcal{C}$, the vertex $\alpha(\text{id}_X) \in \mathcal{H}(X, X)$ exhibits the functor $\mathcal{H}(X, -) : \mathcal{C} \to \mathcal{S}$ as corepresented by the object $X \in \mathcal{C}$ (in the sense of Definition 5.7.6.1).

3. For every object $X \in \mathcal{C}$, the vertex $\alpha(\text{id}_X) \in \mathcal{H}(X, X)$ exhibits the functor $\mathcal{H}(-, X) : \mathcal{C}^{\text{op}} \to \mathcal{S}$ as represented by the object $X \in \mathcal{C}$ (in the sense of Variant 5.7.6.2).

**Proof.** We will show that (1) $\iff$ (2); the proof of the equivalence (1) $\iff$ (3) is similar. The natural transformation $\alpha$ can be identified with a functor $\mathcal{T} : \text{Tw}(\mathcal{C}) \to \{\Delta^0\} \times_{\mathcal{S}} \mathcal{S}$. For each object $X \in \mathcal{C}$, let $T_X$ denote the restriction of $\mathcal{T}$ to the simplicial subset $\{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) \subseteq \text{Tw}(\mathcal{C})$, and consider the following condition:

(1) The diagram of $\infty$-categories

$$\begin{align*}
\{X\} \times_{\mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C}) & \xrightarrow{T_X} \{\Delta^0\} \times_{\mathcal{S}} \mathcal{S} \\
\mathcal{C} & \xrightarrow{\mathcal{H}(X, -)} \mathcal{S}
\end{align*}
$$

is a categorical pullback square.
By virtue of Corollary 5.1.6.15, the natural transformation \( \alpha \) exhibits \( \mathcal{H} \) as a Hom-functor for \( C \) if and only if it satisfies condition \((1_X)\) for every object \( X \in C \). To complete the proof, it will suffice to show that \((1_X)\) is satisfied if and only if \( \alpha(\text{id}_X) \in \mathcal{H}(X, X) \) exhibits the functor \( \mathcal{H}(X, -) \) as corepresented by \( X \). This is a special case of Proposition 5.7.6.21, since the \( \text{id}_X \) is an initial object of the \( \infty \)-category \( \{X\} \times_{C^{\text{op}}} \text{Tw}(C) \) (Proposition 8.1.2.1).

\[ \text{Corollary 8.2.5.7.} \]

Let \( C \) be an \( \infty \)-category, let \((\mathcal{H}, \alpha)\) be a Hom-functor for \( C \), let \( f : X \to Y \) be a morphism in \( C \). Then the following conditions are equivalent:

1. The morphism \( f \) is an isomorphism in the \( \infty \)-category \( C \).
2. The vertex \( \alpha(f) \in \mathcal{H}(X, Y) \) exhibits the functor \( \mathcal{H}(X, -) : C \to S \) as corepresented by \( Y \).
3. The vertex \( \alpha(f) \in \mathcal{H}(X, Y) \) exhibits the functor \( \mathcal{H}(-, Y) : C^{\text{op}} \to S \) as represented by \( X \).

\[ \text{Corollary 8.2.5.8.} \]

Let \( C \) be an \( \infty \)-category and let \( \mathcal{H} : C^{\text{op}} \times C \to S \) be a Hom-functor for \( C \). Then \( \mathcal{H} \) is a balanced profunctor from \( C \) to itself.

\[ \text{Proof.} \]

By virtue of Proposition 8.2.5.6, the profunctor \( \mathcal{H} \) is both representable and corepresentable. Fix a pair of objects \( X, Y \in C \) and a vertex \( \eta \in \mathcal{H}(X, Y) \). We wish to show that \( \eta \) exhibits the functor \( \mathcal{H}(-, Y) : C^{\text{op}} \to S \) as represented by \( X \) if and only if it exhibits the functor \( \mathcal{H}(X, -) : C \to S \) as corepresented by \( Y \). Both conditions depend only on the image of \( \eta \) in \( \pi_0(\mathcal{H}(X, Y)) \). We may therefore assume without loss of generality that \( \eta = \alpha(f) \), where \( \alpha : \Delta^0_{\text{Tw}(C)} \to \mathcal{H}|_{\text{Tw}(C)} \) is a natural transformation which exhibits \( \mathcal{H} \) as a Hom-functor for \( C \), and \( f : X \to Y \) is a morphism in the \( \infty \)-category \( C \). In this case, the equivalence follows from Corollary 8.2.5.7.

\[ \text{Proof of Theorem 8.2.5.5.} \]

Combine Corollaries 8.2.2.12 and 8.2.5.8.

We close this section by recording a simple observation about the Yoneda embedding.

\[ \text{Proposition 8.2.5.9.} \]

Let \( C \) be a locally small \( \infty \)-category and let \( h_* : C \to \text{Fun}(C^{\text{op}}, S) \) be a covariant Yoneda embedding for \( C \). Suppose we are given a diagram \( \mathcal{F} : K^\omega \to C \), where \( K \) is a small simplicial set. The following conditions are equivalent:

1. The morphism \( \mathcal{F} \) is a limit diagram in \( C \).
2. The composition \( h_* \circ \mathcal{F} \) is a limit diagram in the \( \infty \)-category \( \text{Fun}(C^{\text{op}}, S) \).

Following the convention of Remark 5.4.0.5, we can regard Proposition 8.2.5.9 as a special case of the following more precise assertion (applied in the special case where \( \kappa = \lambda \) is a strongly inaccessible cardinal):
Variant 8.2.5.10. Let \( \lambda \) be an uncountable cardinal, let \( C \) be a locally \( \lambda \)-small \( \infty \)-category, and let \( h_\bullet : C \to \text{Fun}(C^{\text{op}}, S^{<\lambda}) \) be a covariant Yoneda embedding for \( C \). Let \( \kappa = \text{ecf}(\lambda) \) be the exponential cofinality of \( \lambda \), let \( K \) be a \( \kappa \)-small simplicial set, and let \( \overline{f} : K^a \to C \) be a diagram. Then the following conditions are equivalent:

1. The morphism \( \overline{f} \) is a limit diagram in \( C \).
2. The composition \( h_\bullet \circ \overline{f} \) is a limit diagram in the \( \infty \)-category \( \text{Fun}(C^{\text{op}}, S^{<\lambda}) \).

*Proof.* Since \( K \) is \( \kappa \)-small, the \( \infty \)-category \( S^{<\lambda} \) admits \( K \)-indexed limits (Example 7.6.7.4). For each object \( X \in C \), let \( \text{ev}_X : \text{Fun}(C^{\text{op}}, S^{<\lambda}) \to S^{<\lambda} \) denote the functor given by evaluation at \( X \). By virtue of Proposition 7.1.6.1, condition (2) is equivalent to the requirement that for each object \( X \in C \), the composition

\[
K^a \xrightarrow{\overline{f}} C \xrightarrow{h_\bullet} \text{Fun}(C^{\text{op}}, S^{<\lambda}) \xrightarrow{\text{ev}_X} S^{<\lambda}
\]

is a limit diagram in the \( \infty \)-category \( S^{<\lambda} \). Since the composite functor \( (\text{ev}_X \circ h_\bullet) : C \to S^{<\lambda} \) is corepresentable by \( X \), the equivalence (1) \( \Leftrightarrow \) (2) follows from Proposition 7.4.5.13 (and Remark 7.4.5.15). \( \square \)

Remark 8.2.5.11. In the situation of Variant 8.2.5.10, suppose that the \( \infty \)-category \( C \) admits \( K \)-indexed limits. Then the \( \infty \)-category of representable functors \( \text{Fun}^{\text{rep}}(C^{\text{op}}, S^{<\lambda}) \) also admits \( K \)-indexed limits, which are preserved by the inclusion functor \( \text{Fun}^{\text{rep}}(C^{\text{op}}, S^{<\lambda}) \hookrightarrow \text{Fun}(C^{\text{op}}, S^{<\lambda}) \).

8.2.6 Representable Profunctors

Let \( C \) and \( D \) be categories. There is a fully faithful embedding from the category of functors \( \text{Fun}(D, C) \) to the category of profunctors \( \text{Fun}(C^{\text{op}} \times D, \text{Set}) \), which assigns to each functor \( G : D \to C \) the representable profunctor

\[
C^{\text{op}} \times D \to \text{Set} \quad (X, Y) \mapsto \text{Hom}_C(X, G(Y)).
\]

This construction has an \( \infty \)-categorical counterpart:

Proposition 8.2.6.1 (Classification of Representable Profunctors). Let \( C \) and \( D \) be \( \infty \)-categories. Assume that \( C \) is locally small, and let

\[
\text{Hom}_C(-, -) : C^{\text{op}} \times C \to \mathcal{S}
\]

be a Hom-functor for \( C \) (see Notation 8.2.3.14). Then the construction \( G \mapsto \text{Hom}_C(-, G(-)) \) determines a fully faithful functor

\[
\text{Fun}(D, C) \to \text{Fun}(C^{\text{op}} \times D, \mathcal{S}),
\]

whose essential image is spanned by the representable profunctors from \( D \) to \( C \).
**Proof.** Let $\text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S})$ denote the full subcategory of $\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$ spanned by the representable functors. By virtue of Theorem 8.2.5.5, the construction $Y \mapsto \text{Hom}_{\mathcal{C}}(-, Y)$ determines an equivalence of $\infty$-categories $h^* : \mathcal{C} \rightarrow \text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S})$. It follows that postcomposition with $h^*$ induces an equivalence of $\infty$-categories

$$\text{Fun}(\mathcal{D}, \mathcal{C}) \rightarrow \text{Fun}(\mathcal{D}, \text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S})),$$

which is a restatement of Proposition 8.2.6.1. \qed

**Definition 8.2.6.2.** Let $G : \mathcal{D} \rightarrow \mathcal{C}$ be a functor of $\infty$-categories. Assume that $\mathcal{C}$ is locally small and let $\text{Hom}_{\mathcal{C}}(-, -) : \mathcal{C}^{\text{op}} \times \mathcal{C} \rightarrow \mathcal{S}$ be a Hom-functor for $\mathcal{C}$. We say that a profunctor $\mathcal{K} : \mathcal{C}^{\text{op}} \times \mathcal{D} \rightarrow \mathcal{S}$ is representable by $G$ if it isomorphic to the composition

$$\mathcal{C}^{\text{op}} \times \mathcal{D} \xrightarrow{id \times G} \mathcal{C}^{\text{op}} \times \mathcal{C} \xrightarrow{\text{Hom}_{\mathcal{C}}(-, -)} \mathcal{S} \quad (X, Y) \mapsto \text{Hom}_{\mathcal{C}}(X, G(Y))$$

as an object of the $\infty$-category $\text{Fun}(\mathcal{C}^{\text{op}} \times \mathcal{D}, \mathcal{S})$. By virtue of Proposition 8.2.3.10 this condition does not depend on the choice of Hom-functor $\text{Hom}_{\mathcal{C}}(-, -)$.

**Example 8.2.6.3.** Let $\mathcal{C}$ be a locally small $\infty$-category, and let $\mathcal{F} : \mathcal{C}^{\text{op}} \rightarrow \mathcal{S}$ be a functor. Then $\mathcal{F}$ is representable by an object $X \in \mathcal{C}$ (in the sense of Variant 5.7.6.2) if and only if, when regarded as a profunctor from $\Delta^0$ to $\mathcal{C}$, it is representable by the functor $\Delta^0 \rightarrow \{X\} \hookrightarrow \mathcal{C}$ (in the sense of Definition 8.2.6.2).

Interchanging the roles of $\mathcal{C}$ and $\mathcal{D}$, we obtain the following dual notion:

**Variant 8.2.6.4.** Let $F : \mathcal{C} \rightarrow \mathcal{D}$ be a functor of $\infty$-categories. Assume that $\mathcal{D}$ is locally small and let $\text{Hom}_{\mathcal{D}}(-, -) : \mathcal{D}^{\text{op}} \times \mathcal{D} \rightarrow \mathcal{S}$ be a Hom-functor for $\mathcal{D}$. We say that a profunctor $\mathcal{K} : \mathcal{C}^{\text{op}} \times \mathcal{D} \rightarrow \mathcal{S}$ is corepresentable by $F$ if it isomorphic to the composition

$$\mathcal{C}^{\text{op}} \times \mathcal{D} \xrightarrow{F^{\text{op}} \times \text{id}} \mathcal{D}^{\text{op}} \times \mathcal{D} \xrightarrow{\text{Hom}_{\mathcal{D}}(-, -)} \mathcal{S} \quad (X, Y) \mapsto \text{Hom}_{\mathcal{D}}(F(X), Y)$$

as an object of the $\infty$-category $\text{Fun}(\mathcal{C}^{\text{op}} \times \mathcal{D}, \mathcal{S})$. By virtue of Proposition 8.2.3.10 this condition does not depend on the choice of Hom-functor $\text{Hom}_{\mathcal{C}}(-, -)$.

**Example 8.2.6.5.** Let $\mathcal{C}$ be a locally small $\infty$-category and let $\mathcal{H} : \mathcal{C}^{\text{op}} \times \mathcal{C} \rightarrow \mathcal{S}$ be a profunctor from $\mathcal{C}$ to itself. The following conditions are equivalent:

- The profunctor $\mathcal{H}$ is a Hom-functor for $\mathcal{C}$.
- The profunctor $\mathcal{H}$ is representable by the identity functor $\text{id}_{\mathcal{C}} : \mathcal{C} \rightarrow \mathcal{C}$ (Definition 8.2.6.2).
- The profunctor $\mathcal{H}$ is corepresentable by the identity functor $\text{id}_{\mathcal{C}} : \mathcal{C} \rightarrow \mathcal{C}$ (Variant 8.2.6.4).
Remark 8.2.6.6 (Uniqueness). Let $\mathcal{K}: \mathcal{C}^{\text{op}} \times \mathcal{D} \to \mathcal{S}$ be a profunctor of $\infty$-categories. If $\mathcal{C}$ is locally small, then Proposition 8.2.6.1 guarantees that $\mathcal{K}$ is representable (in the sense of Definition 8.2.2.4) if and only if it is representable by $G$, for some functor $G: \mathcal{D} \to \mathcal{C}$. Moreover, if this condition is satisfied, then the functor $G$ is determined uniquely up to isomorphism. Similarly, if $\mathcal{D}$ is locally small, then $\mathcal{K}$ is corepresentable if and only if it is corepresentable by some functor $F: \mathcal{C} \to \mathcal{D}$. In this case, the functor $F$ is also uniquely determined up to isomorphism.

For many applications, Definition 8.2.6.2 is insufficiently precise. Given a functor of $\infty$-categories $G: \mathcal{D} \to \mathcal{C}$, we would like to be able to consider not only profunctors which are representable by $G$ (meaning that they are abstractly isomorphic to the profunctor $(X,Y) \mapsto \text{Hom}_{\mathcal{C}}(X,G(Y))$) but profunctors which are represented by $G$ (meaning that we have chosen an isomorphism with the profunctor $(X,Y) \mapsto \text{Hom}_{\mathcal{C}}(X,G(Y))$, or some essentially equivalent datum). Here it is inconvenient that the functor $\text{Hom}_{\mathcal{C}}(\mathcal{-},\mathcal{-})$ is well-defined only up to isomorphism. To address this point, it is convenient to encode representability in a different way.

Definition 8.2.6.7. Let $G: \mathcal{D} \to \mathcal{C}$ be a functor of $\infty$-categories, let $\mathcal{K}: \mathcal{C}^{\text{op}} \times \mathcal{D} \to \mathcal{S}$ be a profunctor from $\mathcal{D}$ to $\mathcal{C}$, and let $\mathcal{K}|_{\text{Tw}(\mathcal{D})}$ denote the composite functor

$$\text{Tw}(\mathcal{D}) \to \mathcal{D}^{\text{op}} \times \mathcal{D} \xrightarrow{G^{\text{op}} \times \text{id}} \mathcal{C}^{\text{op}} \times \mathcal{D} \xrightarrow{\mathcal{K}} \mathcal{S}.$$

Suppose we are given a natural transformation $\beta: \Delta^0_{\text{Tw}(\mathcal{D})} \to \mathcal{K}|_{\text{Tw}(\mathcal{D})}$, where $\Delta^0_{\text{Tw}(\mathcal{D})}$ denotes the constant functor $\text{Tw}(\mathcal{D}) \to \mathcal{S}$ taking the value $\Delta^0$. We say that $\beta$ exhibits the profunctor $\mathcal{K}$ as represented by $G$ if, for every object $Y \in \mathcal{D}$, the evaluation of $\beta$ at the object $\text{id}_Y \in \text{Tw}(\mathcal{D})$ determines a vertex $\beta(\text{id}_Y) \in \mathcal{K}(G(Y),Y)$ which exhibits the functor $\mathcal{K}(\mathcal{-},Y)$ as represented by the object $G(Y) \in \mathcal{C}$ (see Variant 5.7.6.2).

Our main goal is to show that Definitions 8.2.6.2 and 8.2.6.7 are compatible. More precisely, we will prove at the end of this section that a profunctor $\mathcal{K}: \mathcal{C}^{\text{op}} \times \mathcal{D} \to \mathcal{S}$ is representable by a functor $G: \mathcal{D} \to \mathcal{C}$ if and only if there exists a natural transformation $\beta: \Delta^0_{\text{Tw}(\mathcal{D})} \to \mathcal{K}|_{\text{Tw}(\mathcal{D})}$ which satisfies the requirement of Definition 8.2.6.7 (see Proposition 8.2.6.15).

Example 8.2.6.8. In the situation of Definition 8.2.6.7, suppose that $\mathcal{D} = \Delta^0$. In this case, we can identify the profunctor $\mathcal{K}$ with a functor $K: \mathcal{C}^{\text{op}} \to \mathcal{S}$, we can identify the functor $G$ with an object $X \in \mathcal{C}$, and we can identify $\beta$ with a vertex of the Kan complex $K(X)$. Then $\beta$ exhibits the profunctor $\mathcal{K}$ as represented by the functor $G$ (in the sense of Definition 8.2.6.7) if and only if it exhibits the functor $K$ as represented by the object $X$ (in the sense of Variant 5.7.6.2).
Example 8.2.6.9. Let $\mathcal{C}$ be an $\infty$-category and let $\mathcal{H} : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S}$ be a functor. Then a natural transformation $\beta : \Delta^0_{\text{Tw}(\mathcal{C})} \to \mathcal{H}|_{\text{Tw}(\mathcal{C})}$ exhibits $\mathcal{H}$ as represented by the identity functor $\text{id}_\mathcal{C} : \mathcal{C} \to \mathcal{C}$ (in the sense of Definition 8.2.6.7) if and only if it exhibits $\mathcal{H}$ as a Hom-functor for $\mathcal{C}$. This is a reformulation of Proposition 8.2.5.6.

Remark 8.2.6.10 (Homotopy Invariance). In the situation of Definition 8.2.6.7, the condition that $\beta$ exhibits $\mathcal{K}$ as corepresented by $G$ depends only on the homotopy class $[\beta]$ (as a morphism in the homotopy category $\text{hFun}(\text{Tw}(\mathcal{D}), \mathcal{S})$) (see Remark 5.7.6.3).

Remark 8.2.6.11 (Change of $\mathcal{K}$). Let $G : \mathcal{D} \to \mathcal{C}$ be a functor of $\infty$-categories. Suppose we are given a pair of profunctors $\mathcal{K}, \mathcal{K}' : \mathcal{C}^{\text{op}} \times \mathcal{D} \to \mathcal{S}$, a natural transformation $\alpha : \mathcal{K} \to \mathcal{K}'$, and a commutative diagram

in the $\infty$-category $\text{Fun}(\text{Tw}(\mathcal{D}), \mathcal{S})$. Then any two of the following conditions imply the third:

- The natural transformation $\beta$ exhibits $\mathcal{K}$ as represented by $G$.
- The natural transformation $\beta'$ exhibits the profunctor $\mathcal{K}'$ as represented by $G$.
- The natural transformation $\alpha$ is an isomorphism.

See Remark 5.7.6.4.

Proposition 8.2.6.12. Suppose we are given a functor of $\infty$-categories $G : \mathcal{D} \to \mathcal{C}$ and a profunctor $\mathcal{K} : \mathcal{C}^{\text{op}} \times \mathcal{D} \to \mathcal{S}$. Let $\beta : \Delta^0_{\text{Tw}(\mathcal{D})} \to \mathcal{K}|_{\text{Tw}(\mathcal{D})}$ be a natural transformation, which we identify with a functor of $\infty$-categories

$T : \text{Tw}(\mathcal{D}) \to \{\Delta^0\} \tilde{\times}_S (\mathcal{C}^{\text{op}} \times \mathcal{D})$.

Then $\beta$ exhibits $\mathcal{K}$ as represented by $G$ (in the sense of Definition 8.2.6.7) if and only if the functor $T$ is left cofinal.

Proof. We have a commutative diagram of $\infty$-categories
where the vertical maps are cocartesian fibrations and the functor $T$ carries $\lambda_+$-cocartesian morphisms of $\Tw(D)$ to $\pi$-cocartesian morphisms of the $\infty$-category $\{\Delta^0\} \times_S \mathcal{C}^{\op} \times D$ (see Corollary 8.1.1.12). By virtue of Corollary 7.2.3.16, the functor $T$ is left cofinal if and only if, for every object $X \in D$, the induced map

$$T_X : \Tw(D) \times_D \{X\} \to \{\Delta^0\} \times_S \mathcal{C}^{\op}$$

is left cofinal; here the oriented fiber product on the right is formed with respect to the functor $\mathcal{K}(\cdot, X) : \mathcal{C}^{\op} \to \mathcal{S}$. Proposition 8.1.2.1 guarantees that the identity morphism $\id_X$ is initial when viewed as an object of the $\infty$-category $\Tw(D) \times_D \{X\}$: that is, so that the inclusion map $\{\id_X\} \to \Tw(D) \times_D \{X\}$ is left cofinal (Example 7.2.1.4).

Using Proposition 7.2.1.6, we see that $T_X$ is left cofinal if and only if the inclusion map $\{\beta(\id_X)\} \to \{\Delta^0\} \times_S \mathcal{C}^{\op}$ is left cofinal: that is, if and only if $\beta(\id_X)$ is initial when viewed as an object of the $\infty$-category $\{\Delta^0\} \times_S \mathcal{C}^{\op}$. By virtue of Proposition 5.7.6.21, this is equivalent to the requirement that $\beta(\id_X)$ exhibits the functor $\mathcal{K}(\cdot, X)$ as represented by the object $G(X) \in \mathcal{C}$.

\begin{proposition}[Representable Profunctors as Kan Extensions] Let $G : D \to \mathcal{C}$ be a functor of $\infty$-categories, let $\mathcal{K} : \mathcal{C}^{\op} \times D \to \mathcal{S}$ be a profunctor, and let $\beta : \Delta_0^{\mathcal{C}^{\op} \times D} \to \mathcal{K}|_{\Tw(D)}$ be a natural transformation which exhibits $\mathcal{K}$ as represented by $G$. Then $\beta$ exhibits $\mathcal{K}$ as a left Kan extension of the constant diagram $\Delta_0^{\mathcal{C}^{\op} \times D}$ along the composite map

$$\Tw(D) \to \mathcal{D}^{\op} \times D \xrightarrow{G^{\op} \times \id} \mathcal{C}^{\op} \times D.$$ 

Proof. Let $E$ denote the oriented fiber product $\{\Delta^0\} \times_S (\mathcal{C}^{\op} \times D)$ and let $\mu : E \to \mathcal{C}^{\op} \times D$ be the projection onto the second factor, so that we have a tautological natural transformation $\tilde{\beta} : \Delta_0^E \to \mathcal{K} \circ \mu$. It follows from Proposition 7.6.2.15 that $\tilde{\beta}$ exhibits $\mathcal{K}$ as a left Kan extension of $\Delta_0^E$ along $\mu$. The natural transformation $\beta$ then determines a functor $T : \Tw(D) \to E$ such that precomposition with $T$ carries $\tilde{\beta}$ to $\beta$. By the transitivity of the formation of Kan extensions (Proposition 7.3.7.18), we are reduced to showing that the identity transformation $\id : \Delta_0^{\Tw(D)} \to \Delta_0^E \circ T$ exhibits $\Delta_0^E$ as a left Kan extension of $\Tw(D)$ along $T$. This is a special case of Remark 7.6.2.12 (since the functor $T$ is left cofinal (Proposition 8.2.6.12)).

\begin{remark} Let $F : D' \to D$ and $G : D \to \mathcal{C}$ be functors of $\infty$-categories, let $\mathcal{K} : \mathcal{C}^{\op} \times D \to \mathcal{S}$ be a profunctor from $D$ to $\mathcal{C}$, and let $\mathcal{K}'$ denote the composition $\mathcal{C}^{\op} \times D' \xrightarrow{\id \times F} \mathcal{C}^{\op} \times D \xrightarrow{\mathcal{K}} \mathcal{S}$, which we regard as a profunctor from $D'$ to $\mathcal{C}$. If $\beta : \Delta_0^D \to \mathcal{K}|_{\Tw(D)}$ is a natural transformation which exhibits $\mathcal{K}$ as represented by $G$, then the restriction $\beta|_{\Tw(D')}$ exhibits $\mathcal{K}'$ as represented by $G \circ F$. 

03P3 \begin{proposition} Proposition 8.2.6.13 (Representable Profunctors as Kan Extensions). \end{proposition} 

03P4 \begin{remark} Remark 8.2.6.14. \end{remark}
Proposition 8.2.6.15. Let \( G : \mathcal{D} \rightarrow \mathcal{C} \) be a functor of \( \infty \)-categories, where \( \mathcal{C} \) is locally small, and let \( \mathcal{H} : \mathcal{C}^{\text{op}} \times \mathcal{D} \rightarrow \mathcal{S} \) be a profunctor. The following conditions are equivalent:

1. The profunctor \( \mathcal{H} : \mathcal{C}^{\text{op}} \times \mathcal{D} \rightarrow \mathcal{S} \) is representable by \( G \), in the sense of Definitions 8.2.6.2.

2. There exists a natural transformation \( \beta : \Delta^0_{\text{Tw}(\mathcal{D})} \rightarrow \mathcal{H} \mid_{\text{Tw}(\mathcal{D})} \) which exhibits \( \mathcal{H} \) as represented by \( G \), in the sense of Definition 8.2.6.7.

3. The functor \( \mathcal{H} \) is a left Kan extension of the constant diagram \( \Delta^0_{\text{Tw}(\mathcal{D})} \) along the composite functor

\[
\text{Tw}(\mathcal{D}) \rightarrow \mathcal{D}^{\text{op}} \times \mathcal{D} \xrightarrow{G^{\text{op}} \times \text{id}} \mathcal{C}^{\text{op}} \times \mathcal{D}.
\]

Proof. We first show that (1) implies (2). Since \( \mathcal{C} \) is locally small, it admits a Hom-functor \( \mathcal{H} : \mathcal{C}^{\text{op}} \times \mathcal{C} \rightarrow \mathcal{S} \) (Proposition 8.2.3.10). Choose a natural transformation \( \alpha : \Delta^0_{\text{Tw}(\mathcal{C})} \rightarrow \mathcal{H} \) which exhibits \( \mathcal{H} \) as a Hom-functor for \( \mathcal{C} \). Then \( \alpha \) exhibits the profunctor \( \mathcal{H} \) as represented by the identity functor \( \text{id}_\mathcal{C} \) (Example 8.2.6.9). By virtue of Remark 8.2.6.11, we may assume that the profunctor \( \mathcal{H} \) is given by the composition

\[
\mathcal{C}^{\text{op}} \times \mathcal{D} \xrightarrow{\text{id} \times G} \mathcal{C}^{\text{op}} \times \mathcal{C} \xrightarrow{\mathcal{H}} \mathcal{S} \quad (X, Y) \mapsto \mathcal{H}(X, G(Y)).
\]

Applying Remark 8.2.6.14, we see that precomposition with the functor \( \text{Tw}(G) : \text{Tw}(\mathcal{D}) \rightarrow \text{Tw}(\mathcal{C}) \) carries \( \alpha \) to a natural transformation

\[
\beta : \Delta^0_{\text{Tw}(\mathcal{D})} \rightarrow \mathcal{H} \mid_{\text{Tw}(\mathcal{D})}
\]

which exhibits \( \mathcal{H} \) as represented by \( G \).

The implication (2) \( \Rightarrow \) (3) follows from Proposition 8.2.6.13. It follows that (1) implies (3), and the reverse implication follows from the uniqueness of Kan extensions up to isomorphism (Remark 7.3.6.6). \( \square \)

Remark 8.2.6.16 (The Universal Mapping Property of Representable Profunctors). Let \( G : \mathcal{D} \rightarrow \mathcal{C} \) be a functor of \( \infty \)-categories. Suppose we are given a pair of profunctors \( \mathcal{H}, \mathcal{H}' : \mathcal{C}^{\text{op}} \times \mathcal{D} \rightarrow \mathcal{S} \), and let \( \beta : \Delta^0_{\text{Tw}(\mathcal{D})} \rightarrow \mathcal{H} \mid_{\text{Tw}(\mathcal{D})} \) be a natural transformation which exhibits \( \mathcal{H} \) as represented by \( G \). Combining Propositions 8.2.6.13 and 7.3.6.1 we see that precomposition with \( \beta \) induces a homotopy equivalence

\[
\text{Hom}_{\text{Fun}(\mathcal{C}^{\text{op}} \times \mathcal{D}, \mathcal{S})}(\mathcal{H}, \mathcal{H}') \rightarrow \text{Hom}_{\text{Fun}(\text{Tw}(\mathcal{D}), \mathcal{S})}(\Delta^0_{\text{Tw}(\mathcal{D})}, \mathcal{H} \mid_{\text{Tw}(\mathcal{D})}).
\]

Example 8.2.6.17 (Spaces of Natural Transformation). Let \( G, G' : \mathcal{D} \rightarrow \mathcal{C} \) be functors of \( \infty \)-categories. Assume that \( \mathcal{C} \) admits a Hom-functor \( \mathcal{H} \). Combining Remark 8.2.6.16 with
Proposition 8.2.6.1, we obtain homotopy equivalences of Kan complexes

\[ \text{Hom}_{\text{Fun}(\mathcal{D},\mathcal{C})}(G, G') \cong \text{Hom}_{\text{Fun}(\mathcal{C}^{\text{op}} \times \mathcal{D}, \mathcal{S})}(\mathcal{H} \circ (\text{id} \times G), \mathcal{H} \circ (\text{id} \times G')) \]

\[ \cong \text{Hom}_{\text{Fun}(\text{Tw}(\mathcal{D}), \mathcal{S})}(\Delta^0_{\text{Tw}(\mathcal{D})}; \mathcal{H}|_{\text{Tw}(\mathcal{D})}) \]

\[ \cong \lim_{\leftarrow} (\mathcal{H}|_{\text{Tw}(\mathcal{D})}). \]

In other words, the space of natural transformations from \( G \) to \( G' \) can be viewed as a limit of the diagram

\[ \text{Tw}(\mathcal{D}) \to \mathcal{S} \]

\[ (f : X \to Y) \mapsto \text{Hom}_\mathcal{C}(G(X), G(Y)). \]

For later use, we record a dual version of Definition 8.2.6.7.

**Variant 8.2.6.18 (Corepresentable Profunctors).** Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories and let \( \mathcal{K} : \mathcal{C}^{\text{op}} \times \mathcal{D} \to \mathcal{S} \) be a profunctor. We say that a natural transformation \( \beta : \Delta^0_{\text{Tw}(\mathcal{C})} \to \mathcal{K}|_{\text{Tw}(\mathcal{C})} \) exhibits \( \mathcal{K} \) as corepresented by \( F \) if, for every object \( X \in \mathcal{C} \), the image \( \beta(\text{id}_X) \in \mathcal{K}(X, F(X)) \) exhibits the functor \( \mathcal{K}(X, -) : \mathcal{D} \to \mathcal{S} \) as corepresented by the object \( F(X) \in \mathcal{D} \), in the sense of Definition 5.7.6.1. Equivalently, \( \beta \) exhibits \( \mathcal{K} \) as corepresented by \( F \) if it exhibits \( \mathcal{K} \) as represented by the opposite functor \( F^{\text{op}} \), when regarded as a profunctor from \( \mathcal{C}^{\text{op}} \) to \( \mathcal{D}^{\text{op}} \) (see Remark 8.2.2.3).

We say that a profunctor \( \mathcal{K} \) is corepresentable by \( F \) if there exists a natural transformation which exhibits \( \mathcal{K} \) as corepresented by \( F \). If the \( \infty \)-category \( \mathcal{D} \) admits a Hom-functor \( \text{Hom}_\mathcal{D}(-, -) : \mathcal{D}^{\text{op}} \times \mathcal{D} \to \mathcal{S} \), this condition is equivalent to the requirement that \( \mathcal{K} \) is isomorphic to the profunctor given by the composite map

\[ \mathcal{C}^{\text{op}} \times \mathcal{D} \xrightarrow{F^{\text{op}} \times \text{id}} \mathcal{D}^{\text{op}} \times \mathcal{D} \xrightarrow{\text{Hom}_\mathcal{D}(-, -)} \mathcal{S} \]

\[ (X, Y) \mapsto \text{Hom}_\mathcal{D}(F(X), Y). \]

**8.2.7 Adjunctions as Profunctors**

**Proposition 8.2.7.1.** Let \( F : \mathcal{C} \to \mathcal{D} \) be a functor between locally small \( \infty \)-categories and let \( \mathcal{K} : \mathcal{C}^{\text{op}} \times \mathcal{D} \to \mathcal{S} \) be a profunctor which is corepresented by \( F \). Then a functor \( G : \mathcal{D} \to \mathcal{C} \) is right adjoint to \( F \) if and only if it represents the profunctor \( \mathcal{K} \).
We will deduce Proposition 8.2.7.1 from a more precise statement (Proposition 8.2.7.7), which classifies natural transformations $\text{id}_C \to G \circ F$ which are units of adjunctions between $F$ and $G$. First, we study the functoriality of the constructions introduced in §8.2.3. To avoid confusion, we will denote Hom-functors on $C$ and $D$ by $\mathcal{H}_C$ and $\mathcal{H}_D$, respectively.

**Proposition 8.2.7.2** (Functoriality of Hom-Functors). Let $F : C \to D$ be a functor between $\infty$-categories which admit Hom-functors $(\mathcal{H}_C, \alpha)$ and $(\mathcal{H}_D, \beta)$, respectively. Then there exists a natural transformation $\gamma : \mathcal{H}_C(-,-) \to \mathcal{H}_D(F(-), F(-))$ for which the diagram

$$
\begin{array}{ccc}
\Delta^0_{\text{Tw}(C)} & \xleftarrow{\Delta^0_{\text{Tw}(C)}} & \\
\mathcal{H}_C|_{\text{Tw}(C)} & \xrightarrow{[\alpha]} & \mathcal{H}_D|_{\text{Tw}(C)} \\
\gamma & \xrightarrow{[\gamma]} & \\
\mathcal{H}_C|_{\text{Tw}(C)} & \xrightarrow{[\gamma]} & \mathcal{H}_D|_{\text{Tw}(C)}
\end{array}
$$

(8.13)

commutes (in the homotopy category $\text{hFun}((\text{Tw}(C), S))$). Moreover, the natural transformation $\gamma$ is uniquely determined up to homotopy.

**Proof.** This is a special case of Proposition 7.3.6.1, since $\alpha$ exhibits $\mathcal{H}_C$ as a left Kan extension of $\Delta^0_{\text{Tw}(C)}$ along the left fibration $\text{Tw}(C) \to C^{\text{op}} \times C$ (see Proposition 8.2.3.12).

**Remark 8.2.7.3.** In the situation of Proposition 8.2.7.2, suppose that we are given a pair of objects $X, Y \in C$. The commutativity of (8.13) guarantees that the diagram

$$
\begin{array}{ccc}
\text{Hom}_C(X,Y) & \xrightarrow{F} & \text{Hom}_D(F(X), F(Y)) \\
\sim & & \sim \\
\mathcal{H}_C(X,Y) & \xrightarrow{\gamma} & \mathcal{H}_D(F(X), F(Y))
\end{array}
$$

commutes in the homotopy category $\text{hKan}$, where the vertical maps are the isomorphisms of Remark 8.2.3.4. We can summarize the situation more informally as follows: if $F : C \to D$ is a functor between (locally small) $\infty$-categories, then the induced map of Kan complexes $\text{Hom}_C(X,Y) \to \text{Hom}_D(F(X), F(Y))$ depends functorially on the pair $(X,Y)$ (as an object of the $\infty$-category $C^{\text{op}} \times C$).

**Proposition 8.2.7.4.** Let $F : C \to D$ be a functor between locally small $\infty$-categories, and let $\gamma : \mathcal{H}_C(-,-) \to \mathcal{H}_D(F(-), F(-))$ be as in Proposition 8.2.7.2. Then:

- The natural transformation $\gamma$ exhibits the functor $\mathcal{H}_D(F(-), -) : C^{\text{op}} \times D \to S$ as a left Kan extension of $\mathcal{H}_C$ along the functor $(\text{id} \times F) : C^{\text{op}} \times C \to C^{\text{op}} \times D$. 

• The natural transformation $\gamma$ exhibits the functor $\mathcal{H}_D(-, F(-)) : D^{\text{op}} \times C \to S$ as a left Kan extension of $\mathcal{H}_C$ along the functor $(F^{\text{op}} \times \text{id}) : C^{\text{op}} \times C \to D^{\text{op}} \times C$.

Proof. We will prove the second assertion; the second follows by a similar argument. By virtue of the commutative diagram (8.13) and the transitivity of left Kan extensions (Proposition 7.3.7.18), it will suffice to prove the following:

1. The natural transformation $\alpha$ exhibits $\mathcal{H}_C(-, -)$ as a left Kan extension of $\Delta_0^{T(w(C))}$ along the forgetful functor $T(w(C)) \to C^{\text{op}} \times C$.

2. The natural transformation $\beta|_{T(w(C))}$ exhibits the functor $\mathcal{H}_D(-, F(-))$ as a left Kan extension of $\Delta_0^{T(w(C))}$ along the composite functor $T(w(C)) \to C^{\text{op}} \times C \xrightarrow{F^{\text{op}} \times \text{id}} C^{\text{op}} \times D$.

Assertion (1) is a special case of Proposition 8.2.3.12. Assertion (2) follows from Proposition 8.2.6.13, since the natural transformation $\beta|_{T(w(C))}$ exhibits the profunctor $\mathcal{H}_D(-, F(-))$ as represented by $F$ (see the proof of Proposition 8.2.6.15).

Corollary 8.2.7.5. Let $F : C \to D$ be a functor between locally small $\infty$-categories. Then, for any functor $G : D \to C$, precomposition with the natural transformation $\gamma$ of Proposition 8.2.7.2 induces a homotopy equivalence

$$\text{Hom}_{\text{Fun}(C^{\text{op}} \times D, S)}(\mathcal{H}_D(F(-), -), \mathcal{H}_C(-, G(-))) \to \text{Hom}_{\text{Fun}(C^{\text{op}} \times C, S)}(\mathcal{H}_C(-, -), \mathcal{H}_C(-, (G \circ F)(-))).$$

Proof. Combine Propositions 8.2.7.4 and 7.3.6.1.

Remark 8.2.7.6. Let $F : C \to D$ and $G : D \to C$ be locally small $\infty$-categories, with Hom-functors

$$\mathcal{H}_C : C^{\text{op}} \times C \to S \quad \mathcal{H}_D : D^{\text{op}} \times D \to S.$$
Combining Corollary \[8.2.7.5\] and Proposition \[8.2.6.1\] we obtain homotopy equivalences

\[
\begin{align*}
\text{Hom}_{\text{Fun}(\mathcal{C},\mathcal{C})}(\text{id}_\mathcal{C}, G \circ F) \\
\downarrow \\
\text{Hom}_{\text{Fun}(\mathcal{C}^{\text{op}} \times \mathcal{C}, \mathcal{S})}(\mathcal{H}_\mathcal{C}(-,-), \mathcal{H}_\mathcal{C}(-, G \circ F)(-)) \\
\downarrow \\
\text{Hom}_{\text{Fun}(\mathcal{C}^{\text{op}} \times \mathcal{D}, \mathcal{S})}(\mathcal{H}_\mathcal{D}(F(-), -), \mathcal{H}_\mathcal{C}(-, G(-)))
\end{align*}
\]

In particular, every natural transformation of functors \(\eta : \text{id}_\mathcal{C} \to G \circ F\) determines a natural transformation of profunctors \(\eta' : \mathcal{H}_\mathcal{D}(F(-), -) \to \mathcal{H}_\mathcal{C}(-, G(-))\), which is characterized up to homotopy by the requirement that the diagram

\[
\begin{array}{ccc}
\mathcal{H}_\mathcal{C}(-,-) & \xrightarrow{[\gamma']} & \mathcal{H}_\mathcal{C}(-, G(-)) \\
\downarrow{[\gamma]} & & \downarrow{[\eta']} \\
\mathcal{H}_\mathcal{D}(F(-), F(-)) & \xrightarrow{[\eta']} & \mathcal{H}_\mathcal{C}(-, (G \circ F)(-))
\end{array}
\]

commutes in the homotopy category \(\text{hFun}(\mathcal{C}^{\text{op}} \times \mathcal{C}, \mathcal{S})\).

**Proposition 8.2.7.7.** Let \(F : \mathcal{C} \to \mathcal{D}\) and \(G : \mathcal{D} \to \mathcal{C}\) be functors between locally small \(\infty\)-categories and let \(\eta : \text{id}_\mathcal{C} \to G \circ F\) be a natural transformation. Then \(\eta\) exhibits \(G\) as a right adjoint to \(F\) if and only if the morphism \(\mathcal{H}_\mathcal{D}(F(-), -) \to \mathcal{H}_\mathcal{C}(-, G(-))\) of Remark \[8.2.7.6\] is an isomorphism of profunctors.

**Proof.** This is a reformulation of Corollary \[6.2.4.5\].

**Proof of Proposition 8.2.7.1** Let \(\mathcal{C}\) and \(\mathcal{D}\) be \(\infty\)-categories which admit Hom-functors

\[
\mathcal{H}_\mathcal{C} : \mathcal{C}^{\text{op}} \times \mathcal{C} \to \mathcal{S} \quad \mathcal{H}_\mathcal{D} : \mathcal{D}^{\text{op}} \times \mathcal{D} \to \mathcal{S}.
\]

Suppose we are given functors \(F : \mathcal{C} \to \mathcal{D}\) and \(G : \mathcal{D} \to \mathcal{C}\). It follows from Proposition \[8.2.7.4\] (and Remark \[8.2.7.6\]) that \(G\) is right adjoint to \(F\) if and only if the profunctors \(\mathcal{H}_\mathcal{D}(F(-), -)\) and \(\mathcal{H}_\mathcal{C}(-, G(-))\) are isomorphic (as objects of the \(\infty\)-category \(\text{Fun}(\mathcal{C}^{\text{op}} \times \mathcal{D}, \mathcal{S})\)). In particular, if a profunctor \(\mathcal{K} : \mathcal{C}^{\text{op}} \times \mathcal{D} \to \mathcal{S}\) is corepresented by \(F\), then it is represented by \(G\) if and only if \(G\) is right adjoint to \(F\).
8.3 Presheaf $\infty$-Categories

Let $\mathcal{C}$ be a small $\infty$-category. It is then very rare for $\mathcal{C}$ to admit small colimits: this is possible only if $\mathcal{C}$ is (equivalent to the nerve of) a partially ordered set (Proposition [?]). However, it is always possible to embed $\mathcal{C}$ into a larger $\infty$-category $\mathcal{C}$. For example, we can take $\mathcal{C}$ to be the $\infty$-category of functors $\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$. Theorem 8.2.5.5 implies that the covariant Yoneda embedding

$$h_\bullet : \mathcal{C} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}) \quad Y \mapsto h_Y$$

is fully faithful. Moreover, the $\infty$-category $\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$ admits small colimits, which can be computed levelwise: this is a special case of Proposition 7.1.6.1 since the $\infty$-category of spaces $\mathcal{S}$ admits small colimits (Corollary 7.4.5.6).

Our goal in this section is to show that the covariant Yoneda embedding $h_\bullet : \mathcal{C} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$ is universal among functors from $\mathcal{C}$ to $\infty$-categories which admit small colimits. More precisely, suppose that $\mathcal{D}$ is an $\infty$-category which admits small colimits, and let $\text{Fun}(\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}), \mathcal{D})$ denote the full subcategory of $\text{Fun}(\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}), \mathcal{D})$ spanned by those functors which preserve small colimits. In §8.3.3 we will show that precomposition with $h_\bullet$ induces an equivalence of $\infty$-categories

$$\text{Fun}(\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}), \mathcal{D}) \to \text{Fun}(\mathcal{C}, \mathcal{D})$$

(Theorem 8.3.3.1). Stated more informally, the $\infty$-category $\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$ can be obtained from $\mathcal{C}$ by freely adjoining colimits of small diagrams.

Let $f : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories, where $\mathcal{C}$ is small and $\mathcal{D}$ admits small colimits. Theorem 8.3.3.1 implies that $f$ admits an essentially unique extension to a colimit-preserving functor $F : \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}) \to \mathcal{D}$. This extension admits other useful characterizations:

(a) It is a left Kan extension of $f$ along the covariant Yoneda embedding $h_\bullet : \mathcal{C} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$ (see Example 8.3.3.11).

(b) If $\mathcal{D}$ is locally small, we will prove in §8.3.4 that $F$ is left adjoint to the composite functors

$$\mathcal{D} \xrightarrow{h_\bullet} \text{Fun}(\mathcal{D}^{\text{op}}, \mathcal{S}) \xrightarrow{\text{op}} \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$$

(Proposition 8.3.4.1).

To prove Theorem 8.3.3.1, the main step is to show that property (a) is satisfied by the identity functor $\text{id} : \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}) \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$. This is equivalent to the assertion that the covariant Yoneda embedding $h_\bullet : \mathcal{C} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$ is a dense functor: that is, it exhibits each object $\mathcal{F} \in \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$ as a colimit of the diagram

$$\mathcal{C} \times_{\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})} \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})_{/\mathcal{F}} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$$
CHAPTER 8. THE YONEDA EMBEDDING

(see Definition [8.3.1.15]). In §8.3.1 we discuss dense functors in general and provide a concrete criterion which can be used to show that a functor is dense (Proposition [8.3.1.23]). In §8.3.2 we apply this criterion to establish the density of the Yoneda embedding \( h_\bullet : \mathcal{C} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}) \).

Let us isolate another important feature of the covariant Yoneda embedding \( h_\bullet : \mathcal{C} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}) \). For every pair of objects \( X \in \mathcal{C} \) and \( \mathcal{F} \in \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}) \), the \( \infty \)-categorical analogue of Yoneda’s lemma supplies a homotopy equivalence

\[
\text{Hom}_{\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})}(h_X, \mathcal{F}) \simto \mathcal{F}(X)
\]

(Proposition [8.2.1.3]). It follows that \( h_X \) is an atomic object of the \( \infty \)-category \( \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}) \): that is, it corepresents a functor which preserves small colimits (Definition [8.3.5.1]). The Yoneda embedding is essentially characterized by this property, together with the fact that it is dense and fully faithful. More precisely, suppose that we are given a functor of \( \infty \)-categories \( f : \mathcal{C} \to \mathcal{D} \), where \( \mathcal{C} \) is small and \( \mathcal{D} \) admits small colimits. Theorem [8.3.3.1] then guarantees that \( f \) admits an essentially unique colimit-preserving extension \( F : \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}) \). In §8.3.5 we show that \( F \) is an equivalence of \( \infty \)-categories if and only if \( \mathcal{D} \) is locally small and the functor \( f \) is dense, fully faithful, and carries each object of \( \mathcal{C} \) to an atomic object of \( \mathcal{D} \) (Proposition [8.3.5.6]).

8.3.1 Dense Functors

To study the behavior of a (large) category \( \mathcal{D} \), it is often useful to approximate \( \mathcal{D} \) by well-chosen (small) subcategory \( \mathcal{C} \subseteq \mathcal{D} \). The following condition guarantees that, for some purposes, passage from \( \mathcal{D} \) to \( \mathcal{C} \) does not lose too much information:

**Definition 8.3.1.1.** Let \( \mathcal{D} \) be a (locally small) category. We say that a full subcategory \( \mathcal{C} \subseteq \mathcal{D} \) is dense if the functor

\[
\mathcal{D} \to \text{Fun}(\mathcal{C}^{\text{op}}, \text{Set}) \quad Y \mapsto \text{Hom}_\mathcal{D}(\bullet, Y)
\]

is fully faithful.

**Remark 8.3.1.2.** Definition [8.3.1.1] was introduced by Isbell in [28]. Beware that Isbell uses the term left adequate subcategory for what we refer to as a dense subcategory.

**Example 8.3.1.3.** Let \( \text{Cat} \) denote the ordinary category whose objects are small categories and whose morphisms are functors, and let \( \Delta \subset \text{Cat} \) be the simplex category. Proposition [1.2.2.1] asserts that the restricted Yoneda embedding

\[
\text{Cat} \to \text{Fun}(\Delta^{\text{op}}, \text{Set}) = \text{Set} \quad \mathcal{C} \mapsto \mathcal{N}_\bullet(\mathcal{C})
\]

is fully faithful, so that \( \Delta \) is a dense subcategory of \( \text{Cat} \).
8.3. PRESHEAF ∞-CATEGORIES

Exercise 8.3.1.4. Let \( C \) denote the category of partially ordered sets, and let \( \Delta_{\leq 1} \) denote the full subcategory of \( C \) spanned by the objects \([0]\) and \([1]\). Show that \( \Delta_{\leq 1} \) is a dense subcategory of \( C \).

We now introduce an ∞-categorical counterpart of Definition 8.3.1.1.

Definition 8.3.1.5. Let \( D \) be an ∞-category. We will say that a full subcategory \( C \subseteq D \) is dense if, for every object \( X \in D \), the composition

\[
(C \times_D D_{/X})^\circ \to D_{/X} \to D
\]

is a colimit diagram.

Remark 8.3.1.6. Let \( D \) be an ∞-category. Then a full subcategory \( C \subseteq D \) is dense if and only if the identity functor \( \text{id}_D \) is left Kan extended from \( C \).

Example 8.3.1.7. Let \( C \) be an ∞-category. Then \( C \) is a dense full subcategory of itself (see Example 7.3.3.6).

In the situation of Definition 8.3.1.5, suppose that the ∞-category \( D \) is locally small, and let \( h_\bullet : D \to \text{Fun}(D^{\text{op}}, S) \) be a covariant Yoneda embedding for \( D \) (see Definition 8.2.5.1). Composing with the restriction functor \( \text{Fun}(D^{\text{op}}, S) \to \text{Fun}(C^{\text{op}}, S) \), we obtain a functor

\[
D \to \text{Fun}(C^{\text{op}}, S) \quad Y \mapsto h_Y^C
\]

which we will refer to as the restricted Yoneda embedding.

Proposition 8.3.1.8. Let \( D \) be a locally small ∞-category. A full subcategory \( C \subseteq D \) is dense if and only if the restricted Yoneda embedding \( D \to \text{Fun}(C^{\text{op}}, S) \) is fully faithful.

We will deduce Proposition 8.3.1.8 from a more general result (Proposition 8.3.1.23), which we prove at the end of this section.

Corollary 8.3.1.9. Let \( D \) be a locally small category. Then a full subcategory \( C \subseteq D \) is dense (in the sense of Definition 8.3.1.1) if and only if \( N_\bullet(C) \) is a dense subcategory of the ∞-category \( N_\bullet(D) \) (in the sense of Definition 8.3.1.5).

Warning 8.3.1.10. Let \( D \) be an ∞-category. Consider the following conditions on a full subcategory \( C \subseteq D \):

1. The ∞-category \( C \subseteq D \) is dense, in the sense of Definition 8.3.1.5.
2. Every object \( X \in D \) can be realized as the colimit of a diagram taking values in the full subcategory \( C \subseteq D \).
(3) The ∞-category \( \mathcal{D} \) is generated by \( \mathcal{C} \) under colimits. That is, if \( \mathcal{D}_0 \subseteq \mathcal{D} \) is a full subcategory which contains \( \mathcal{C} \) and is closed under the formation of colimits in \( \mathcal{D} \), then \( \mathcal{D}_0 = \mathcal{D} \).

It follows immediately from the definitions that (1) \( \Rightarrow \) (2) \( \Rightarrow \) (3). Beware that neither of this implications is reversible. See Exercises 8.3.1.11 and 8.3.1.12.

Exercise 8.3.1.11. Let \( \mathcal{D} \) denote the category of free abelian groups, and let \( \mathcal{C} \subseteq \mathcal{D} \) denote the full subcategory spanned by object \( \mathbb{Z} \). Show that \( \mathcal{C} \) is not a dense subcategory of \( \mathcal{D} \). Consequently, the inclusion map \( N_* (\mathcal{C}) \subseteq N_* (\mathcal{D}) \) satisfies condition (2) of Warning 8.3.1.10, but does not satisfy condition (1).

Exercise 8.3.1.12. Let \( \text{Cat} \) denote the (ordinary) category of small categories, and let \( \Delta_{\leq 1} \subseteq \text{Cat} \) denote the full subcategory spanned by the objects \([0]\) and \([1]\). Show that:

- The full subcategory \( \Delta_{\leq 1} \) generates \( \text{Cat} \) under colimits.
- A small category \( \mathcal{C} \) realized as the colimit (in \( \text{Cat} \)) of a diagram \( \mathcal{K} \to \Delta_{\leq 1} \) if and only if the category \( \mathcal{C} \) is free, in the sense of Definition 1.2.6.7.

In particular, the inclusion \( N_* (\Delta_{\leq 1}) \subseteq N_* (\text{Cat}) \) satisfies condition (3) of Warning 8.3.1.10, but does not satisfy condition (2).

Warning 8.3.1.13 (Failure of Transitivity). Let \( \mathcal{E} \) be an ∞-category and let \( \mathcal{C} \subseteq \mathcal{D} \subseteq \mathcal{E} \) be full subcategories. Suppose that \( \mathcal{C} \) is a dense subcategory of \( \mathcal{E} \). Then \( \mathcal{C} \) is also a dense subcategory of \( \mathcal{D} \), and \( \mathcal{D} \) is a dense subcategory of \( \mathcal{E} \) (see Corollary 7.3.7.8). Beware that the converse is false (Example 8.3.1.14).

Example 8.3.1.14. Let \( \text{Cat} \) denote the (ordinary) category of small categories. Then the simplex category \( \Delta \) is a dense full subcategory of \( \text{Cat} \) (Example 8.3.1.3), and \( \Delta_{\leq 1} \) is a dense full subcategory of \( \Delta \) (Exercise 8.3.1.4). However, \( \Delta_{\leq 1} \) is not a dense full subcategory of \( \text{Cat} \) (Exercise 8.3.1.12).

For some applications, it will be useful to consider the following generalization of Definition 8.3.1.5.

Definition 8.3.1.15. Let \( \mathcal{D} \) be an ∞-category and let \( F : \mathcal{C} \to \mathcal{D} \) be a morphism of simplicial sets. We say that \( F \) is dense if the identity transformation \( \text{id}_F : F \to \text{id}_\mathcal{D} \circ F \) exhibits the identity functor \( \text{id}_\mathcal{D} \) as a left Kan extension of \( F \) along \( F \) (see Variant 7.3.1.5).

Example 8.3.1.16. Let \( \mathcal{D} \) be an ∞-category. Then a full subcategory \( \mathcal{C} \subseteq \mathcal{D} \) is dense (in the sense of Definition 8.3.1.5) if and only if the inclusion functor \( \mathcal{C} \hookrightarrow \mathcal{D} \) is dense (in the sense of Definition 8.3.1.15). See Proposition 7.3.2.5.
Remark 8.3.1.17. Let $F : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories, and let $\mathcal{C} \star_D \mathcal{D}$ denote the relative join of Construction 5.2.3.1. Then $F$ is dense if and only if the projection map $\mathcal{C} \star_D \mathcal{D} \to \mathcal{D}$ is left Kan extended from $\mathcal{C}$. See Proposition 7.3.2.10.

Remark 8.3.1.18 (Homotopy Invariance). Let $\mathcal{D}$ be an $\infty$-category, let $\mathcal{C}$ be a simplicial set, and let $F, F' : \mathcal{C} \to \mathcal{D}$ be diagrams which are isomorphic (when viewed as objects of the $\infty$-category $\text{Fun}(\mathcal{C}, \mathcal{D})$). Then $F$ is dense if and only if $F'$ is dense. This follows by combining Remarks 7.3.1.10 and 7.3.1.11.

Remark 8.3.1.19 (Change of Source). Let $\mathcal{D}$ be an $\infty$-category, let $\mathcal{F} : \mathcal{C} \to \mathcal{D}$ be a morphism of simplicial sets, and let $G : \mathcal{B} \to \mathcal{C}$ be a categorical equivalence of simplicial sets. Then $\mathcal{F}$ is dense if and only if $\mathcal{F} \circ G$ is dense. See Proposition 7.3.1.14.

Remark 8.3.1.20 (Change of Target). Let $G : \mathcal{D} \to \mathcal{E}$ be a functor of $\infty$-categories and let $\mathcal{F} : \mathcal{C} \to \mathcal{D}$ be a morphism of simplicial sets. Then:

- If $G$ is fully faithful and $G \circ \mathcal{F}$ is dense, then $\mathcal{F}$ is dense.
- If $G$ is an equivalence of $\infty$-categories and $\mathcal{F}$ is dense, then $G \circ \mathcal{F}$ is dense.

See Remark 7.3.1.13.

Remark 8.3.1.21. Let $\mathcal{D}$ be an $\infty$-category and let $\mathcal{F} : \mathcal{C} \to \mathcal{D}$ be a morphism of simplicial sets. Then $\mathcal{F}$ is dense if and only if, for every object $Y \in \mathcal{D}$, the composite map

$$(\mathcal{C} \times_D \mathcal{D}_{/Y})^\triangleright \to \mathcal{D}^\triangleright_{/Y} \to \mathcal{D}$$

is a colimit diagram in $\mathcal{D}$.

Remark 8.3.1.22. Let $\kappa$ be an uncountable regular cardinal and let $\mathcal{F} : \mathcal{C} \to \mathcal{D}$ be a morphism of simplicial sets. Assume that $\mathcal{C}$ is essentially $\kappa$-small and that $\mathcal{D}$ is a locally $\kappa$-small $\infty$-category. Then, for each object $X \in \mathcal{D}$, the fiber product $\mathcal{C} \times_D \mathcal{D}_{/X}$ is also essentially $\kappa$-small (Corollary 5.4.8.11). Let $\lambda$ be an infinite cardinal satisfying $\text{ecf}(\lambda) \geq \kappa$ (see Definition 5.4.3.16). Then $\mathcal{F}$ is dense if and only if, for every representable functor $h_Y : \mathcal{D}^\text{op} \to S^{<\lambda}$, the identity transformation $\text{id} : h_Y \circ F^\text{op} \to h_Y \circ F^\text{op}$ exhibits the functor $h_Y$ as a right Kan extension of $h_Y \circ F^\text{op}$ along $F^\text{op}$. This follows by combining Remark 8.3.1.21 with Proposition 7.4.5.13 (together with Remark 7.4.5.15).

Proposition 8.3.1.23. Let $\lambda$ be an uncountable cardinal, let $\mathcal{D}$ be an $\infty$-category which is locally $\lambda$-small, and let

$$h_* : \mathcal{D} \to \text{Fun}(\mathcal{D}^\text{op}, S^{<\lambda}) \quad Y \mapsto h_Y$$
be a covariant Yoneda embedding for \( D \) (Definition 8.2.5.1). If \( C \) is a simplicial set, then a diagram \( F : C \to D \) is dense if and only if the composite functor

\[
D \xrightarrow{h} \text{Fun}(D^{\text{op}}, S^{<\lambda}) \xrightarrow{\circ F^{\text{op}}} \text{Fun}(C^{\text{op}}, S^{<\lambda})
\]

is fully faithful.

**Proof.** Choose an uncountable cardinal \( \kappa \) such that \( C \) is essentially \( \kappa \)-small and \( D \) is locally \( \kappa \)-small. Enlarging \( \lambda \) if necessary, we may assume that the exponential cofinality of \( \lambda \) is \( \geq \kappa \) (see Remark 5.4.3.19). For each object \( Y \in D \), let \( h_Y : C^{\text{op}} \to S^{<\lambda} \) denote the composite functor \( h_Y \circ F^{\text{op}} \), given on objects by the construction \( C \mapsto \text{Hom}_D(F(C), Y) \). By virtue of Remark 8.3.1.22, it will suffice to show that the following conditions are equivalent:

1. The identity transformation \( \text{id} : h_Y \circ F^{\text{op}} \to h_Y \) exhibits \( h_Y \) as a right Kan extension of \( h_Y \) along the functor \( F^{\text{op}} \).
2. For each object \( X \in C \), the composite map

\[
\text{Hom}_D(X, Y) \to \text{Hom}_{\text{Fun}(D^{\text{op}}, S^{<\lambda})}(h_X, h_Y) \to \text{Hom}_{\text{Fun}(C^{\text{op}}, S^{<\lambda})}(h_X^{\text{op}}, h_Y^{\text{op}})
\]

is a homotopy equivalence of Kan complexes.

Since the covariant Yoneda embedding \( X \mapsto h_X \) is fully faithful (Theorem 8.2.5.5), we can reformulate (2) as follows:

3. The restriction map

\[
\text{Hom}_{\text{Fun}(D^{\text{op}}, S^{<\lambda})}(h_X, h_Y) \to \text{Hom}_{\text{Fun}(C^{\text{op}}, S^{<\lambda})}(h_X^{\text{op}}, h_Y^{\text{op}})
\]

is a homotopy equivalence of Kan complexes.

The inequality \( \kappa \leq \text{ecf}(\lambda) \) guarantees that the \( \infty \)-category \( S^{<\lambda} \) admits \( \kappa \)-small limits (Corollary 7.4.1.12). Using Proposition 7.6.7.12, we can choose a functor \( G : D^{\text{op}} \to S^{<\lambda} \) and a natural transformation \( \alpha : G \circ F^{\text{op}} \to h_Y^{\circ} \) which exhibits \( G \) as a right Kan extension of \( h_Y^{\circ} \) along the functor \( F^{\text{op}} \). Invoking the universal mapping property of \( G \) (Proposition 7.3.6.1), we see that there exists a natural transformation \( \beta : h_Y \to G \) and a commutative diagram

\[
\begin{array}{ccc}
G \circ F^{\text{op}} & \xrightarrow{\alpha} & h_Y^{\circ} \\
\downarrow{\beta} & & \downarrow{\text{id}} \\
h_Y \circ F^{\text{op}} & \xrightarrow{\text{id}} & h_Y^{\circ}
\end{array}
\]
in the ∞-category \( \text{Fun}(C^{\text{op}}, S^{<\lambda}) \). Using Remark 7.3.1.12, we see that condition (1_\text{Y}) is satisfied if and only if the natural transformation \( \beta \) is an isomorphism: that is, it induces a homotopy equivalence of Kan complexes \( \beta_X : h_Y(X) \to \mathcal{G}(X) \) for each object \( X \in D \) (Theorem 4.4.4.4). Combining this observation with Proposition 8.2.1.3, we can reformulate (1_\text{Y}) as follows:

\[(1'_\text{Y}) \text{ For each object } X \in C, \text{ precomposition with } \beta \text{ induces a homotopy equivalence } \]

\[
\begin{align*}
\text{Hom}_{\text{Fun}(D^{\text{op}}, S^{<\lambda})} (h_X, h_Y) & \xrightarrow{\circ[\beta]} \text{Hom}_{\text{Fun}(D^{\text{op}}, S^{<\lambda})} (h_X, \mathcal{G}). \\
\text{Hom}_{\text{Fun}(D^{\text{op}}, S^{<\lambda})} (h_X, h_Y) & \quad \text{Hom}_{\text{Fun}(C^{\text{op}}, S^{<\lambda})} (h^\circ_X, h^\circ_Y)
\end{align*}
\]

Using the commutativity of (8.14), we see that the diagram of Kan complexes

commutes up to homotopy, where the diagonal map on the right is the homotopy equivalence of Proposition 7.3.6.1. It follows that conditions (1'_\text{Y}) and (2'_\text{Y}) are equivalent.

\[\square\]

**Proof of Proposition 8.3.1.8** Let \( D \) be a locally small ∞-category and let \( C \subseteq D \) be a full subcategory. By virtue of Example 8.3.1.16, it will suffice to show that the inclusion functor \( C \leftarrow D \) is dense if and only if the restricted Yoneda embedding \( D \to \text{Fun}(C^{\text{op}}, S) \) is fully faithful. Following the convention of Remark 5.4.0.5, this is a special case of Proposition 8.3.1.23.

\[\square\]

**Proposition 8.3.1.24.** Let \( D \) be an ∞-category, let \( F : C \to D \) be a morphism of simplicial sets, and let \( D_0 \subseteq D \) be a full subcategory which contains the image of \( F \). If \( F \) is dense, then the subcategory \( D_0 \) is dense.

**Proof.** Using Proposition 4.1.3.2, we can factor \( F \) as a composition \( C \xrightarrow{F'} C' \xrightarrow{F''} D \), where \( F' \) is inner anodyne and \( F'' \) is an inner fibration. Using Remark 8.3.1.19, we see that the functor \( F'' \) is dense. Replacing \( F \) by \( F' \), we can reduce to proving Proposition 8.3.1.24 in the special case where \( C \) is an ∞-category.

Let \( \gamma \) denote the identity map \( \text{id}_F \), which we regard as a natural transformation from \( F \) to \( \text{id}_D \circ F \). Our assumption that \( F \) is dense guarantees that \( \gamma \) exhibits \( \text{id}_D \) as a left Kan extension of \( F \) along \( F \). To avoid confusion, let us write \( F_0 \) to denote the functor \( F \), regarded as a functor from \( C \) to \( D_0 \). Let \( \iota : D_0 \hookrightarrow D \) denote the inclusion map, so that \( F = \iota \circ F_0 \). We can therefore also regard the identity map \( \text{id}_F \) as a natural transformation
\( \alpha : F \to \iota \circ F_0 \). Our assumption that \( F \) is dense also guarantees that \( \alpha \) exhibits \( \iota \) as a left Kan extension of \( F \) along \( F_0 \). Note that \( \gamma = \text{id}_F \) is a composition of \( \alpha = \text{id}_F \) with \( \beta|_C \), where \( \beta = \text{id}_\iota \) is the identity transformation from \( \iota \) to itself. Invoking the transitivity of Kan extensions (Proposition 7.3.7.18), we deduce that \( \beta \) exhibits the identity functor \( \text{id}_D \) as a left Kan extension of \( \iota \) along itself: that is, the functor \( \iota \) is dense. Applying Example 8.3.1.16, we conclude that \( D_0 \) is a dense subcategory of \( D \).

**Remark 8.3.1.25.** Let \( D \) be an \( \infty \)-category and let \( F : C \to D \) be a dense diagram. Choose another diagram \( q : K \to D \) and set \( \tilde{D} = D/q \), so that the projection map \( \pi : \tilde{D} \to D \) is a right fibration. Then the projection map \( C \times_D \tilde{D} \to \tilde{D} \) is dense. To prove this, it will suffice to show that for every object \( Y \in \tilde{D} \), the induced map

\[
\theta : (C \times_D \tilde{D}_{/Y})^\rho \to \tilde{D}_{/Y} \to \tilde{D}
\]

is a colimit diagram in \( \tilde{D} \) (Remark 8.3.1.21). By virtue of Proposition 7.1.3.19, this is equivalent to the requirement that \( \pi \circ \theta \) is a colimit diagram in \( D \). Unwinding the definitions, we see that \( \pi \circ \theta \) is given by the composition

\[
(C \times_D \tilde{D}_{/Y})^\rho \to (C \times_D \mathcal{D}_{/\pi(Y)})^\rho \to \mathcal{D}_{/\pi(Y)}^\rho \to D.
\]

Since \( \pi \) is a right fibration, the map \( \tilde{D}_{/Y} \to \mathcal{D}_{/\pi(Y)} \) is a trivial Kan fibration (Proposition 4.3.7.12). Using Corollary 7.2.2.2, we are reduced to showing that the map \( (C \times_D \mathcal{D}_{/\pi(Y)})^\rho \to \mathcal{D}_{/\pi(Y)}^\rho \to D \) is a colimit diagram, which follows from our assumption that \( F \) is dense (Remark 8.3.1.21).

### 8.3.2 Density of Yoneda Embeddings

Our goal in this section is to prove the following result, which supplies an important source of examples of dense functors:

**Theorem 8.3.2.1.** Let \( C \) be a locally small \( \infty \)-category, and let \( h_\bullet : C \to \text{Fun}(\mathcal{C}^{\text{op}}, S) \) be a covariant Yoneda embedding (Definition 8.2.5.1). Then \( h_\bullet \) is a dense functor.

Since the covariant Yoneda embedding \( h_\bullet : C \to \text{Fun}(\mathcal{C}^{\text{op}}, S) \) is fully faithful, Theorem 8.3.2.1 can be reformulated as follows:

**Corollary 8.3.2.2.** Let \( C \) be a locally small \( \infty \)-category and let \( \text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, S) \subseteq \text{Fun}(\mathcal{C}^{\text{op}}, S) \) denote the full subcategory spanned by the representable functors. Then \( \text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, S) \) is a dense subcategory of \( \text{Fun}(\mathcal{C}^{\text{op}}, S) \).

**Proof.** By virtue of Example 8.3.1.16, it will suffice to show that the inclusion map \( \text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, S) \hookrightarrow \text{Fun}(\mathcal{C}^{\text{op}}, S) \) is a dense functor. Since the covariant Yoneda embedding
Example 8.3.2.3. Let $S_{\text{cont}}$ denote the full subcategory of $S$ spanned by the contractible Kan complexes. Then $S_{\text{cont}}$ is a dense subcategory of $S$. This follows by applying Corollary 8.3.2.2 in the special case $C = \Delta^0$. Moreover, the same assertion holds if we replace $S_{\text{cont}}$ by any nonempty subcategory of itself; for example, the full subcategory of $S$ spanned by the standard 0-simplex $\Delta^0$.

By virtue of the convention of Remark 5.4.0.5, Theorem 8.3.2.1 can be regarded as a special case of the following:

Variant 8.3.2.4. Let $\kappa$ be an uncountable cardinal and let $C$ be an $\infty$-category which is locally $\kappa$-small. Then the covariant Yoneda embedding $h_\bullet : C \to \text{Fun}(C^{\text{op}}, S)$ is a dense functor.

We will deduce Variant 8.3.2.4 from a more precise result. Recall that, if $X$ is an object of a (locally small) $\infty$-category $C$, then the representable functor $h_X \in \text{Fun}(C^{\text{op}}, S)$ corepresents the evaluation functor $ev_X : \text{Fun}(C^{\text{op}}, S) \to S$ (Remark 8.2.1.5). That is, for every functor $F : C^{\text{op}} \to S$, there is a canonical homotopy equivalence

$$\mathcal{F}(X) \sim Hom_{\text{Fun}(C^{\text{op}}, S)}(h_X, \mathcal{F}),$$

which depends functorially on $\mathcal{F}$. The following result guarantees that this homotopy equivalence can also be chosen to depend functorially on $X$:

Proposition 8.3.2.5. Let $\kappa$ be an uncountable cardinal and let $C$ be an $\infty$-category which is locally $\kappa$-small. Then the profunctor $ev : C^{\text{op}} \times \text{Fun}(C^{\text{op}}, S^{<\kappa}) \to S^{<\kappa}$ is corepresentable by the covariant Yoneda embedding $h_\bullet : C \to \text{Fun}(C^{\text{op}}, S^{<\kappa})$.

Proof. Let Tw($C$) denote the twisted arrow $\infty$-category of $C$, let $\lambda : \text{Tw}(C) \to C^{\text{op}} \times C$ be the left fibration of Proposition 8.1.1.10, and let $\Delta^0_{\text{Tw}(C)}$ denote the constant functor Tw($C$) $\to S^{<\kappa}$. Let $h : C^{\text{op}} \times C \to S^{<\kappa}$ denote the composition $ev \circ (id \times h_\bullet)$, so that $h$ is a Hom-functor for $C$. We can therefore choose a natural transformation

$$\alpha : \Delta^0_{\text{Tw}(C)} \to h \circ \lambda = ev \circ (id \times h_\bullet) \circ \lambda$$

which exhibits $h$ as a Hom-functor for $C$, in the sense of Remark 8.2.3.3. By virtue of Proposition 8.2.6.15, it will suffice to show that the natural transformation $\alpha$ also exhibits...
the profunctor ev as corepresented by the functor \( h \), in the sense of Variant 8.2.6.18. Fix an object \( X \in C \), so that \( \alpha \) carries the object \( \text{id}_X \in \text{Tw}(C) \) to a vertex \( \eta \in \mathcal{H}(X, X) = \text{ev}(X, h_X) \). We wish to show that \( \eta \) exhibits evaluation functor \( \text{ev}_X : \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \to S^{<\kappa} \) as corepresented by \( h_X \). This follows from Proposition 8.2.1.3, since \( \eta \) exhibits the functor \( h_X \) as represented by \( X \).

**Example 8.3.2.6.** Let \( C \) be a locally small category. Then the evaluation profunctor

\[
\text{ev} : \mathcal{C}^{\text{op}} \times \text{Fun}(\mathcal{C}^{\text{op}}, S) \to S \quad (X, \mathcal{F}) \mapsto \mathcal{F}(X)
\]

is corepresentable by the covariant Yoneda embedding \( h : C \to \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \).

**Proof of Variant 8.3.2.4.** Let \( \kappa \) be an uncountable cardinal and let \( C \) be an \( \infty \)-category which is locally \( \kappa \)-small. We wish to show that the covariant Yoneda embedding \( h^\bullet : C \to \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \) is dense. Choose a cardinal \( \lambda \geq \kappa \) for which the \( \infty \)-category \( D = \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \) is locally \( \lambda \)-small, and let \( h^\bullet_D : D \to \text{Fun}(\mathcal{D}^{\text{op}}, S^{<\lambda}) \) be a covariant Yoneda embedding for \( D \). By virtue of Proposition 8.3.1.23, it will suffice to show that the composite functor

\[
D \xrightarrow{h^\bullet_D} \text{Fun}(\mathcal{D}^{\text{op}}, S^{<\lambda}) \xrightarrow{\delta h^\bullet_C} \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\lambda})
\]

is fully faithful. Applying Proposition 8.3.2.5, we see that this functor is isomorphic to the inclusion of \( D = \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \) as a full subcategory of \( \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\lambda}) \).

### 8.3.3 The Universal Property of Presheaf \( \infty \)-Categories

When studying a small \( \infty \)-category \( C \), it is often useful to embed \( C \) into a larger \( \infty \)-category \( \hat{C} \) with better closure properties. For example, we can take \( \hat{C} \) to be the functor \( \infty \)-category \( \text{Fun}(\mathcal{C}^{\text{op}}, S) \). By virtue of Theorem 8.2.5.5, the covariant Yoneda embedding \( h^\bullet : C \to \text{Fun}(\mathcal{C}^{\text{op}}, S) \) is a fully faithful functor. Moreover, since the \( \infty \)-category of spaces \( S \) admits small limits and colimits (Corollary 7.4.5.6), the functor \( \infty \)-category \( \text{Fun}(\mathcal{C}^{\text{op}}, S) \) also admits small limits and colimits, which can be computed levelwise (Proposition 7.1.6.1).

Our goal in this section is to show that the Yoneda embedding \( h^\bullet \) can be characterized by a universal mapping property:

**Theorem 8.3.3.1.** Let \( C \) be an essentially small \( \infty \)-category and let \( h^\bullet : C \to \text{Fun}(\mathcal{C}^{\text{op}}, S) \) be a covariant Yoneda embedding for \( C \) (Definition 8.2.5.1). Let \( D \) be an \( \infty \)-category which admits small colimits, and let \( \text{Fun}'(\text{Fun}(\mathcal{C}^{\text{op}}, S), D) \) denote the full subcategory of \( \text{Fun}(\text{Fun}(\mathcal{C}^{\text{op}}, S), D) \) spanned by those functors \( F : \text{Fun}(\mathcal{C}^{\text{op}}, S) \to D \) which preserve small colimits. Then precomposition with \( h^\bullet \) induces an equivalence of \( \infty \)-categories

\[
\text{Fun}'(\text{Fun}(\mathcal{C}^{\text{op}}, S), D) \to \text{Fun}(C, D) \quad F \mapsto F \circ h^\bullet.
\]
Remark 8.3.3.2. Stated more informally, Theorem 8.3.3.1 asserts that the \( \infty \)-category \( \text{Fun}(C^{\text{op}}, S) \) can be obtained from \( C \) by “freely” adjoining small colimits.

Remark 8.3.3.3. Let \( f : C \to D \) be a functor of \( \infty \)-categories, where \( C \) is essentially small and \( D \) admits small colimits. Fix a covariant Yoneda embedding \( h_\bullet : C \to \text{Fun}(C^{\text{op}}, S) \). Theorem 8.3.3.1 implies that \( f \) is isomorphic to the composition \( F \circ h_\bullet \), for some functor \( F : \text{Fun}(C^{\text{op}}, S) \to D \) which preserves small colimits. Moreover, the functor \( F \) is uniquely determined up to isomorphism.

Example 8.3.3.4. Let \( D \) be an \( \infty \)-category which admits small colimits, and let \( \text{Fun}^\prime(S, D) \) denote the full subcategory of \( \text{Fun}(S, D) \) spanned by those functors which preserve small colimits. Then the evaluation functor

\[
\text{Fun}^\prime(S, D) \to D \quad F \mapsto F(\Delta^0)
\]

is an equivalence of \( \infty \)-categories (this follows by applying Theorem 8.3.3.1 in the special case \( C = \Delta^0 \)). Note that this property characterizes the \( \infty \)-category \( S \) up to equivalence: it is “freely generated” under small colimits by the object \( \Delta^0 \).

Remark 8.3.3.5. In the situation of Theorem 8.3.3.1, let \( \text{LFunc}(\text{Fun}(C^{\text{op}}, S), D) \) denote the full subcategory of \( \text{Fun}(\text{Fun}(C^{\text{op}}, S), D) \) spanned by those functors \( F : \text{Fun}(C^{\text{op}}, S) \to D \) which admit a right adjoint \( G : D \to \text{Fun}(C^{\text{op}}, S) \) (see Notation 6.2.1.3). By virtue of Corollary 7.1.3.21 this condition implies that \( F \) preserves small colimits: that is, we have an inclusion

\[
\text{LFunc}(\text{Fun}(C^{\text{op}}, S), D) \subseteq \text{Fun}^\prime(\text{Fun}(C^{\text{op}}, S), D).
\]

We will see later that equality holds if the \( \infty \)-category \( D \) is locally small (see Proposition [?])

Following the convention of Remark 5.4.0.5 we can regard Theorem 8.3.3.1 as a special case of the following more general assertion, which we will prove at the end of this section:

Variant 8.3.3.6. Let \( \kappa \) be an uncountable regular cardinal, let \( C \) be an \( \infty \)-category which is essentially \( \kappa \)-small, and let \( h_\bullet : C \to \text{Fun}(C^{\text{op}}, S^{<\kappa}) \) be a covariant Yoneda embedding for \( C \). Let \( D \) be an \( \infty \)-category which admits \( \kappa \)-small colimits and let \( \text{Fun}^\kappa(\text{Fun}(C^{\text{op}}, S^{<\kappa}), D) \) denote the full subcategory of \( \text{Fun}(\text{Fun}(C^{\text{op}}, S^{<\kappa}), D) \) spanned by those functors which preserve \( \kappa \)-small colimits. Then precomposition with \( h_\bullet \) determines an equivalence of \( \infty \)-categories

\[
\text{Fun}^\kappa(\text{Fun}(C^{\text{op}}, S^{<\kappa}), D) \to \text{Fun}(C, D) \quad F \mapsto F \circ h_\bullet.
\]

Warning 8.3.3.7. The conclusion of Variant 8.3.3.6 is not necessarily satisfied if we assume only that \( C \) is locally \( \kappa \)-small. For example, suppose that \( C = S \) is a set of cardinality \( \kappa \) (regarded as a discrete simplicial set), and let \( D \) be (the nerve of) the partially ordered set
Then we can identify objects of \( \text{Fun}(C^{\text{op}}, S^{<\kappa}) \) with collections of \( \kappa \)-small Kan complexes \( \{X_s\}_{s \in S} \). Define a functor \( \lambda : \text{Fun}(C^{\text{op}}, S^{<\kappa}) \to D \) by the formula

\[
\lambda(\{X_s\}_{s \in S}) = \begin{cases} 
0 & \text{if } |\{s \in S : X_s \neq \emptyset\}| < \kappa \\
1 & \text{otherwise,}
\end{cases}
\]

and let \( \lambda_0 : \text{Fun}(C^{\text{op}}, S^{<\kappa}) \to D \) be the constant functor taking the value 0. The functors \( \lambda \) and \( \lambda_0 \) both preserve \( \kappa \)-small colimits and coincide on the image of the Yoneda embedding \( h_* \), but do not coincide in general.

Let \( \kappa \) be an uncountable cardinal, and let \( C \) be an \( \infty \)-category which is locally \( \kappa \)-small. In what follows, we let \( \text{Fun}^{\text{rep}}(C^{\text{op}}, S^{<\kappa}) \) denote the full subcategory of \( \text{Fun}(C^{\text{op}}, S^{<\kappa}) \) spanned by the representable functors \( \mathcal{F} : C^{\text{op}} \to S^{<\kappa} \). We will need the following elementary observation:

**Lemma 8.3.3.8.** Let \( \kappa \) be an uncountable regular cardinal, let \( C \) be an \( \infty \)-category which is essentially \( \kappa \)-small, and let \( \mathcal{F} : C^{\text{op}} \to S^{<\kappa} \) be a functor. Then the \( \infty \)-category

\[
\text{Fun}^{\text{rep}}(C^{\text{op}}, S^{<\kappa})/\mathcal{F} = \text{Fun}^{\text{rep}}(C^{\text{op}}, S^{<\kappa}) \times_{\text{Fun}(C^{\text{op}}, S^{<\kappa})} \text{Fun}(C^{\text{op}}, S^{<\kappa})/\mathcal{F}
\]

is essentially \( \kappa \)-small.

**Proof.** The \( \infty \)-category \( \text{Fun}^{\text{rep}}(C^{\text{op}}, S^{<\kappa}) \) is equivalent to \( C \) (Theorem 8.2.5.5), and is therefore essentially \( \kappa \)-small. Since \( \kappa \) is regular, it will suffice to show that each fiber of the right fibration \( \text{Fun}^{\text{rep}}(C^{\text{op}}, S^{<\kappa})/\mathcal{F} \to \text{Fun}^{\text{rep}}(C^{\text{op}}, S^{<\kappa}) \) is an essentially \( \kappa \)-small Kan complex (Corollary 5.4.8.11). Equivalently, we must show that for each object \( \mathcal{G} \in \text{Fun}^{\text{rep}}(C^{\text{op}}, S^{<\kappa}) \), the mapping space \( X = \text{Hom}_{\text{Fun}(C^{\text{op}}, S^{<\kappa})}(\mathcal{G}, \mathcal{F}) \) is essentially \( \kappa \)-small. This follows from Proposition 8.2.1.3: if \( \mathcal{G} \) is representable by the object \( C \in C \), then \( X \) is homotopy equivalent to the \( \kappa \)-small Kan complex \( \mathcal{F}(C) \). \( \square \)

We will deduce Variant 8.3.3.6 from the following more precise assertion:

**Theorem 8.3.3.9.** Let \( \kappa \) be an uncountable regular cardinal, let \( C \) be an \( \infty \)-category which is essentially \( \kappa \)-small, and let \( T : \text{Fun}(C^{\text{op}}, S^{<\kappa}) \to D \) be a functor of \( \infty \)-categories. The following conditions are equivalent:

1. The functor \( T \) preserves \( \kappa \)-small colimits.

2. The functor \( T \) is left Kan extended from the full subcategory \( \text{Fun}^{\text{rep}}(C^{\text{op}}, S^{<\kappa}) \subseteq \text{Fun}(C^{\text{op}}, S^{<\kappa}) \).
Proof. We first show that (1) implies (2). Assume that the functor $T$ preserves \( \kappa \)-small colimits and let \( \mathscr{F} : \mathcal{C}^{\text{op}} \to \mathcal{S}^{<\kappa} \) be a functor; we wish to show that the composite functor

\[
\text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa})^{\mathcal{F}} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}) \xrightarrow{T} \mathcal{D}
\]

is a colimit diagram in the \( \infty \)-category \( \mathcal{D} \). Lemma \[8.3.3.8\] guarantees that the \( \infty \)-category \( \text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa})^{\mathcal{F}} \) is essentially \( \kappa \)-small. Since \( T \) preserves \( \kappa \)-small colimits, it will suffice to show that the map \( \text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa})^{\mathcal{F}} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}) \) is a colimit diagram (Remark \[7.6.7.5\]), which follows from Corollary \[8.3.2.2\].

We now show that (2) implies (1). Assume that \( T \) is left Kan extended from \( \text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}) \); we wish to show that it preserves \( \kappa \)-small colimits. Choose a cardinal \( \lambda \) such that \( \mathcal{D} \) is locally \( \lambda \)-small. Enlarging \( \lambda \) if necessary, we may assume that it has exponential cofinality \( \geq \kappa \) (Remark \[5.4.3.19\]). By virtue of Proposition \[7.4.5.13\] (and Remark \[7.4.5.15\]), it will suffice to show that for every representable functor \( H : \mathcal{D}^{\text{op}} \to \mathcal{S}^{<\lambda} \), the composition \( H^{\text{op}} \circ T \) preserves \( \kappa \)-small colimits. Since \( H^{\text{op}} \) preserves \( \kappa \)-small colimits (Proposition \[7.4.5.13\] and Remark \[7.4.5.15\]), the functor \( H^{\text{op}} \circ T \) is left Kan extended from \( \text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}) \). Consequently, to show that (2) implies (1), we may replace \( T \) by \( H^{\text{op}} \circ T \) and thereby reduce to the case where \( \mathcal{D} = (\mathcal{S}^{<\lambda})^{\text{op}} \), for some cardinal \( \lambda \) of exponential cofinality \( \geq \kappa \).

Let \( h_\bullet : \mathcal{C} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}) \) be a covariant Yoneda embedding for \( \mathcal{C} \), and let \( \mathscr{F} \) denote the composite functor

\[
\mathcal{C}^{\text{op}} \xrightarrow{h_\bullet^{\text{op}}} \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa})^{\text{op}} \xrightarrow{T^{\text{op}}} \mathcal{S}^{<\lambda}.
\]

Using Remark \[5.4.3.19\] again, we can choose a cardinal \( \lambda' \geq \lambda \) of exponential cofinality \( \geq \kappa \) such that \( \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\lambda'}) \) is locally \( \lambda' \)-small. In what follows, we abuse notation by identifying \( T \) with the composite functor \( \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}) \xrightarrow{T} (\mathcal{S}^{<\lambda'})^{\text{op}} \leftarrow (\mathcal{S}^{<\lambda})^{\text{op}} \). Note that, since the inclusion \( \mathcal{S}^{<\lambda} \hookrightarrow \mathcal{S}^{<\lambda'} \) preserves \( \kappa \)-small limits (see Variant \[7.4.5.8\]), this composite functor is also left Kan extended from \( \text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}) \).

Let \( H' : \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\lambda})^{\text{op}} \to \mathcal{S}^{<\lambda'} \) be a functor represented by \( \mathscr{F} \in \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\lambda}) \), and let \( U \) denote the composite functor

\[
\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}) \subseteq \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\lambda}) \xrightarrow{H'^{\text{op}}} (\mathcal{S}^{<\lambda'})^{\text{op}}.
\]

Applying Proposition \[8.3.2.5\], we see that the composition \( U \circ h_\bullet \) is isomorphic to the functor \( \mathscr{F} = T \circ h_\bullet \). Since the covariant Yoneda embedding \( h_\bullet : \mathcal{C} \to \text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}) \) is an equivalence of \( \infty \)-categories (Theorem \[8.2.5.5\]), it follows that the functors \( U \) and \( T \) are isomorphic when restricted to \( \text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}) \). Proposition \[7.4.5.13\] and Remark \[7.4.5.15\] guarantee that the functor \( U \) preserves \( \kappa \)-small colimits. Invoking the implication (1) \( \Rightarrow \) (2), we see that \( U \) is left Kan extended from \( \text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}) \). Applying the universal property of Kan extensions (Corollary \[7.3.6.11\]), we deduce that the functor \( T \) is isomorphic to \( U \), and therefore also preserves \( \kappa \)-small colimits. \( \square \)
Remark 8.3.3.10. In the statement of Theorem 8.3.3.9, it is not necessary to assume that the ∞-category $\mathcal{D}$ admits $\kappa$-small colimits (though we will primarily be interested in cases where this condition is satisfied).

Example 8.3.3.11. Let $\mathcal{C}$ be a small ∞-category and let $\text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S})$ denote the full subcategory of $\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$ spanned by the representable functors. Then a functor of ∞-categories $F : \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}) \to \mathcal{D}$ preserves small colimits if and only if it is left Kan extended from $\text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S})$.

Proof of Variant 8.3.3.6. Let $\kappa$ be an uncountable regular cardinal, let $\mathcal{C}$ be an ∞-category which is essentially $\kappa$-small, and let $\mathcal{D}$ be an ∞-category which admits $\kappa$-small colimits. We wish to show that the composite functor

$$\text{Fun}'(\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}), \mathcal{D}) \to \text{Fun}(\text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}), \mathcal{D}) \xrightarrow{\text{aff}} \text{Fun}(\mathcal{C}, \mathcal{D})$$

is an equivalence of ∞-categories. Theorem 8.2.5.5 guarantees that the covariant Yoneda embedding $\mathcal{C} \to \text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa})$ is an equivalence of ∞-categories. We are therefore reduced to showing that the restriction functor

$$U : \text{Fun}'(\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}), \mathcal{D}) \to \text{Fun}(\text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}), \mathcal{D}) \quad F \mapsto F|_{\text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa})}$$

is an equivalence of ∞-categories. By virtue of Theorem 8.3.3.9, $\text{Fun}'(\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}), \mathcal{D})$ is the full subcategory of $\text{Fun}(\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}), \mathcal{D})$ spanned by those functors which are left Kan extended from $\text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa})$. Applying Corollary 7.3.6.13, we see that $U$ restricts to a trivial Kan fibration

$$\text{Fun}'(\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}), \mathcal{D}) \to \text{Fun}'(\text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}), \mathcal{D}),$$

where $\text{Fun}'(\text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}), \mathcal{D})$ denotes the full subcategory of $\text{Fun}(\text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}), \mathcal{D})$ spanned by those functors which admit a left Kan extension to $\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa})$.

We will complete the proof by showing that every functor $f : \text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}) \to \mathcal{D}$ admits a left Kan extension to $\text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa})$. Fix an object $\mathcal{F} \in \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa})$ and let $\text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa})/\mathcal{F}$ be as in the statement of Lemma 8.3.3.8. By virtue of Corollary 7.3.5.6, it will suffice to show the diagram

$$\text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa})/\mathcal{F} \to \text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}) \xrightarrow{f} \mathcal{D}$$

admits a colimit in the ∞-category $\mathcal{D}$. Since $\mathcal{D}$ admits $\kappa$-small colimits, we are reduced to showing that the ∞-category $\text{Fun}^{\text{rep}}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa})/\mathcal{F}$ is essentially $\kappa$-small (see Remark 7.6.7.5), which follows from Lemma 8.3.3.8.\qed
Corollary 8.3.3.12. Let \( \kappa \) be an uncountable regular cardinal, let \( \mathcal{C} \) be an \( \infty \)-category which is essentially \( \kappa \)-small, and let \( h_\bullet : \mathcal{C} \to \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \) be a covariant Yoneda embedding for \( \mathcal{C} \). Then every object \( \mathcal{F} \in \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \) can be realized as the colimit of a diagram

\[
\mathcal{K} \to \mathcal{C} \overset{h_\bullet}{\to} \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}),
\]

where \( \mathcal{K} \) is a \( \kappa \)-small \( \infty \)-category.

Proof. Let \( \mathcal{K}' \) denote the fiber product \( \mathcal{C} \times_{\text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa})} \text{Fun}(\mathcal{C}^{\text{op}}, S)^{/\mathcal{F}} \). Combining Lemma 8.3.3.8 with Theorem 8.2.5.5, we deduce that \( \mathcal{K}' \) is essentially \( \kappa \)-small. We can therefore choose an equivalence of \( \infty \)-categories \( e : \mathcal{K} \to \mathcal{K}' \), where \( \mathcal{K} \) is \( \kappa \)-small. Applying Variant 8.3.3.6, we deduce that \( \mathcal{F} \) is a colimit of the composite functor

\[
\mathcal{K} \overset{e}{\to} \mathcal{K}' = \mathcal{C} \times_{\text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa})} \text{Fun}(\mathcal{C}^{\text{op}}, S)^{/\mathcal{F}} \to \mathcal{C} \overset{h_\bullet}{\to} \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}).
\]

8.3.4 Example: Extensions as Adjoints

Proposition 8.3.4.1. Let \( f : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories. Assume that \( \mathcal{C} \) is essentially small and that \( \mathcal{D} \) is locally small, and let

\[
h_\bullet^\mathcal{C} : \mathcal{C} \to \text{Fun}(\mathcal{C}^{\text{op}}, S) \quad h_\bullet^\mathcal{D} : \mathcal{D} \to \text{Fun}(\mathcal{D}^{\text{op}}, S)
\]

be covariant Yoneda embeddings for \( \mathcal{C} \) and \( \mathcal{D} \), respectively. Let \( G \) denote the composite functor

\[
\mathcal{D} \overset{h_\bullet^\mathcal{D}}{\to} \text{Fun}(\mathcal{D}^{\text{op}}, S) \overset{\circ f^{\text{op}}}{\longrightarrow} \text{Fun}(\mathcal{C}^{\text{op}}, S).
\]

If \( \mathcal{D} \) admits small colimits, then the functor \( G \) admits a left adjoint \( F : \text{Fun}(\mathcal{C}^{\text{op}}, S) \to \mathcal{D} \). Moreover, the composition \( F \circ h_\bullet^\mathcal{C} \) is isomorphic to \( f \).
Following the convention of Remark 5.4.0.5, we will deduce Proposition 8.3.4.1 from the following more general assertion:

**Variant 8.3.4.2.** Let $\kappa$ be an uncountable regular cardinal and let $f : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories. Assume that $\mathcal{C}$ is essentially $\kappa$-small, that $\mathcal{D}$ admits $\kappa$-small colimits, and that the morphism space $\text{Hom}_\mathcal{D}(f(C), D)$ is essentially $\kappa$-small for every pair of objects $C \in \mathcal{C}, D \in \mathcal{D}$. Then the functor

$$G : \mathcal{D} \to \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \quad D \mapsto \text{Hom}_\mathcal{D}(f(\bullet), D)$$

admits a left adjoint $F : \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \to \mathcal{D}$ which preserves $\kappa$-small colimits. Moreover, the composite functor

$$\mathcal{C} \xrightarrow{h^C \circ \bullet} \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \xrightarrow{F \circ \bullet} \mathcal{D}$$

is isomorphic to $f$.

**Proof.** We first prove the existence of the functor $F$. Fix a cardinal $\lambda$ of exponential cofinality $\geq \kappa$, so that the $\infty$-category $\text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa})$ is locally $\lambda$-small (see Corollary 5.4.8.9). By virtue of Proposition 6.2.4.1, it will suffice to show that for every functor $F : \mathcal{C}^{\text{op}} \to S^{<\kappa}$, the composite functor

$$\mathcal{D} \xrightarrow{G} \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \xrightarrow{\text{Hom}_{\text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa})}(F, \bullet)} S^{<\lambda}$$

is corepresentable by an object of $\mathcal{D}$. Since $\mathcal{D}$ admits $\kappa$-small colimits, the collection of functors $F$ which satisfy this condition is closed under $\kappa$-small colimits (Remark 8.2.5.11). Using Corollary 8.3.3.12, we can reduce to the case where the functor $F$ is representable by an object $C \in \mathcal{C}$. In this case, the object $\mathcal{F} \in \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa})$ corepresents the evaluation functor $\text{ev}_C : \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa})$ (Remark 8.2.1.5). It now follows from the definition of the functor $G$ that the composition $\text{ev}_C \circ G$ is corepresentable by the object $f(C) \in \mathcal{D}$.

Choose functor $F : \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \to \mathcal{D}$ and a natural transformation $\epsilon : (F \circ G) \to \text{id}_\mathcal{D}$ which exhibits $F$ as a left adjoint to the functor $G$. It follows from Corollary 7.1.3.21 that the functor $F$ preserves all colimits which exist in $\text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa})$; in particular, it preserves $\kappa$-small colimits. We will complete the proof by showing that $F \circ h^C$ is isomorphic to $f$.

For every pair of objects $X, Y \in \mathcal{C}$, let $\alpha_{X,Y}$ denote the morphism of Kan complexes

$$h^C_Y(X) = \text{Hom}_\mathcal{C}(X, Y) \to \text{Hom}_\mathcal{D}(f(X), f(Y)) = G(f(Y))(X).$$

By virtue of Proposition 8.2.7.2, we can promote the construction $(X, Y) \mapsto \alpha_{X,Y}$ to a natural transformation of functors $\alpha : h^C \to G \circ f$. Let $\beta$ denote a composition of the natural transformations

$$F \circ h^C \xrightarrow{F(\alpha)} F \circ G \circ f \xrightarrow{\epsilon} \text{id}_\mathcal{D} \circ f = f.$$

We claim that $\beta$ is an isomorphism in the $\infty$-category $\text{Fun}(\mathcal{C}, \mathcal{D})$. By virtue of Theorem 4.4.4.4 it will suffice to show that $\beta$ induces an isomorphism $\beta_X : F(h^C_X) \to f(X)$ for each
object \( X \in \mathcal{C} \). Fix an object \( D \in \mathcal{D} \); we wish to show that precomposition with \( \beta_X \) induces a homotopy equivalence of Kan complexes

\[
\beta_{X,D} : \text{Hom}_{\mathcal{D}}(f(X), D) \to \text{Hom}_{\mathcal{D}}(F(h^\mathcal{C}_X, D) \simeq \text{Hom}_{\text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa})}(h^\mathcal{C}_X, G(D))
\]

We conclude by observing that \( \beta_{X,D} \) is left homotopy inverse to the morphism

\[
\text{Hom}_{\text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa})}(h^\mathcal{C}_X, G(D)) \to G(D)(X) \simeq \text{Hom}_{\mathcal{D}}(f(X), D)
\]

given by evaluation at \( \text{id}_X \in h^\mathcal{C}_X(X) \), which is a homotopy equivalence by virtue of Proposition 8.2.1.3.

Example 8.3.4.3 (Functoriality of the Presheaf Construction). Let \( \kappa \) be an uncountable regular cardinal, let \( f : \mathcal{C} \to \mathcal{D} \) be a functor of \( \infty \)-categories. Assume that \( \mathcal{C} \) is essentially \( \kappa \)-small and that \( \mathcal{D} \) is locally \( \kappa \)-small, and fix covariant Yoneda embeddings

\[
h^\mathcal{C}_\bullet : \mathcal{C} \to \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \quad h^\mathcal{D}_\bullet : \mathcal{D} \to \text{Fun}(\mathcal{D}^{\text{op}}, S^{<\kappa}).
\]

Let \( G : \text{Fun}(\mathcal{D}^{\text{op}}, S^{<\kappa}) \to \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \) be given by precomposition with \( f \). Then the functor \( G \) admits a left adjoint \( F : \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \to \text{Fun}(\mathcal{D}^{\text{op}}, S^{<\kappa}) \). Moreover, the diagram of \( \infty \)-categories

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{h^\mathcal{C}_\bullet} & \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \\
| & f | & | F |
\mathcal{D} & \xrightarrow{h^\mathcal{D}_\bullet} & \text{Fun}(\mathcal{D}^{\text{op}}, S^{<\kappa}).
\end{array}
\]

commutes up to isomorphism. This follows by applying Variant 8.3.4.2 to the composite functor \((h^\mathcal{D}_\bullet \circ f) : \mathcal{C} \to \text{Fun}(\mathcal{D}^{\text{op}}, S^{<\kappa})\).

8.3.5 Characterization of Yoneda Embeddings

Let \( \mathcal{C} \) be an essentially small \( \infty \)-category, let \( \mathcal{C} \) denote the \( \infty \)-category \( \text{Fun}(\mathcal{C}^{\text{op}}, S) \), and let \( h : \mathcal{C} \to \mathcal{C} \) be a covariant Yoneda embedding for \( \mathcal{C} \). Then:

1. The functor \( h \) is fully faithful (Theorem 8.2.5.5).
2. For each object \( X \in \mathcal{C} \), the functor

\[
\text{Hom}^\mathcal{C}_\bullet(h(X), \bullet) : \mathcal{C} \to S
\]

preserves small colimits (see Example 8.3.5.2 below).
(3) The ∞-category $\hat{C}$ is generated (under small colimits) by the essential image of $h$ (in fact, the functor $h$ is dense: see Theorem 8.3.2.1).

Our goal in this section is to show that these properties characterize the ∞-category $\hat{C}$ (and the functor $h$) up to equivalence. First, let us introduce a bit of terminology.

**Definition 8.3.5.1.** Let $D$ be a locally small ∞-category which admits small colimits. We say that an object $X \in D$ is atomic if the corepresentable functor $h^X : D \to S$ $Y \mapsto \text{Hom}_D(X,Y)$ preserves small colimits.

**Example 8.3.5.2 (Representable Functors are Atomic).** Let $\mathcal{C}$ be an essentially small ∞-category. Then every representable functor $\mathcal{F} : \mathcal{C}^{\text{op}} \to S$ is atomic when regarded as an object of the ∞-category $\hat{\mathcal{C}} = \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$. To see this, suppose that $\mathcal{F}$ is representable by an object $C \in \mathcal{C}$. Using Remark 8.2.1.5, we see that $\mathcal{F}$ corepresents the evaluation functor $\text{ev}_C : \hat{\mathcal{C}} = \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}) \to S$ $\mathcal{G} \mapsto \mathcal{G}(C)$, and therefore preserves small colimits by virtue of Proposition 7.1.6.1.

**Definition 8.3.5.3.** Let $\hat{\mathcal{C}}$ be an ∞-category. We say that a full subcategory $\mathcal{C} \subseteq \hat{\mathcal{C}}$ is weakly dense if the following condition is satisfied:

- Let $f : Y \to Z$ be a morphism of $\hat{\mathcal{C}}$ such that, for every object $X \in \mathcal{C}$, the induced map

  $\text{Hom}_{\hat{\mathcal{C}}}(X,Y) \xrightarrow{[f]^\ast} \text{Hom}_{\hat{\mathcal{C}}}(X,Z)$

  is a homotopy equivalence of Kan complexes. Then $f$ is an isomorphism.

We say that a collection of objects $\{X_i\}_{i \in I}$ of $\hat{\mathcal{C}}$ is weakly dense if it spans a weakly dense full subcategory of $\hat{\mathcal{C}}$.

**Remark 8.3.5.4.** Let $\hat{\mathcal{C}}$ be a locally small ∞-category. A full subcategory $\mathcal{C} \subseteq \hat{\mathcal{C}}$ is weakly dense if and only if the restricted Yoneda embedding $\hat{\mathcal{C}} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S})$ is conservative.

**Example 8.3.5.5.** Let $\hat{\mathcal{C}}$ be an ∞-category and let $\mathcal{C} \subseteq \hat{\mathcal{C}}$ be a full subcategory which generates $\hat{\mathcal{C}}$ under colimits (see Warning 8.3.1.10). Then the full subcategory $\mathcal{C}$ is weakly dense. In particular, every dense subcategory of $\hat{\mathcal{C}}$ is weakly dense.

Let $h : \mathcal{C} \to \hat{\mathcal{C}}$ be a functor of ∞-categories. In what follows, we will say that another functor $f : \mathcal{C} \to \mathcal{D}$ is equivalent to $h$ if there is a diagram of ∞-categories

$$
\begin{array}{ccc}
\hat{\mathcal{C}} & \xrightarrow{h} & \mathcal{C} \\
\downarrow & & \downarrow f \\
\mathcal{D} & \xrightarrow{F} & \hat{\mathcal{C}}
\end{array}
$$
8.3. PRESHEAF $\infty$-CATEGORIES

which commutes up to isomorphism, where $F$ is an equivalence of $\infty$-categories. We will be primarily interested in the special case where $\hat{C} = \text{Fun}(C^{\text{op}}, S)$ and $h$ is a covariant Yoneda embedding for $C$.

**Proposition 8.3.5.6.** Let $f : C \to D$ be a functor of $\infty$-categories, where $C$ is essentially small. Then $f$ is equivalent to the covariant Yoneda embedding $h_\bullet : C \to \text{Fun}(C^{\text{op}}, S)$ if and only if it satisfies the following conditions:

(a) The $\infty$-category $D$ is locally small and admits small colimits.

(b) The $\infty$-category $D$ is locally small and admits small colimits. Moreover, it contains a small collection of atomic objects $\{X_i\}_{i \in I}$ which is weakly dense in $D$.

**Corollary 8.3.5.7.** Let $D$ be an $\infty$-category. The following conditions are equivalent:

(a) There exists an essentially small $\infty$-category $C$ and an equivalence of $\infty$-categories $F : \text{Fun}(C^{\text{op}}, S) \to D$.

(b) The $\infty$-category $D$ is locally small and admits small colimits. Moreover, it contains a small collection of atomic objects $\{X_i\}_{i \in I}$ which is weakly dense.

**Proof.** We first show that (a) implies (b). Without loss of generality, we may assume that $D = \text{Fun}(C^{\text{op}}, S)$, where $C$ is a small $\infty$-category. Since the $\infty$-category $S$ admits small colimits (Corollary 7.4.6.1), the $\infty$-category $D$ also admits small colimits (Proposition 7.1.6.1). Moreover, Corollary 5.4.8.10 guarantees that $D$ is locally small. For each object $X \in C$, let $h_X \in D$ be a functor represented by $X$. Then the collection of objects $\{h_X\}_{X \in C}$ span a full subcategory of $D$ which is dense (Corollary 8.3.2.2), and therefore weakly dense (Example 8.3.5.2). We conclude by observing that each of the representable functors $h_X$ is a atomic object of $D$ (Example 8.3.5.2).

We now show that (b) implies (a). Assume that $D$ is locally small and admits small colimits. Let $\{X_i\}_{i \in I}$ be a small collection of atomic objects of $D$, and let $D_0 \subseteq D$ be the full subcategory that they span. It follows from Proposition 5.4.8.8 that the $\infty$-category $D_0$ is essentially small. If $D_0$ is weakly dense in $D$, then the inclusion map $D_0 \hookrightarrow D$ satisfies the hypotheses of Proposition 8.3.5.6 and therefore induces an equivalence of $\infty$-categories $\text{Fun}(D_0^{\text{op}}, S) \to D$. 

Following the convention of Remark 5.4.0.5 we will deduce Proposition 8.3.5.6 from the following more precise assertion.
CHAPTER 8. THE YONEDA EMBEDDING

**Variant 8.3.5.8.** Let $\kappa$ be an uncountable regular cardinal and let $f : C \to D$ be a functor of $\infty$-categories, where $C$ is essentially $\kappa$-small. Then $f$ is equivalent to the covariant Yoneda embedding $h_\bullet : C \to \text{Fun}(C^{\text{op}}, S^{<\kappa})$ if and only if it satisfies the following conditions:

1. The $\infty$-category $D$ admits $\kappa$-small colimits.
2. The functor $f$ is fully faithful.
3. Let $C$ be an object of $C$. Then the image $f(C) \in D$ corepresents a functor

   \[ D \to S^{<\kappa} \quad Y \mapsto \text{Hom}_D(f(C), Y) \]

   which preserves $\kappa$-small colimits.
4. The collection of objects $\{f(X)\}_{X \in C}$ is weakly dense in $D$.

**Warning 8.3.5.9.** In the situation of Variant 8.3.5.8, it is not necessarily true that the $\infty$-category $D$ is locally $\kappa$-small. However, condition (2) requires that the morphism space $\text{Hom}_D(X, Y)$ is essentially $\kappa$-small whenever the object $X$ belongs to the essential image of the functor $f$.

**Proof of Proposition 8.3.5.6.** By virtue of Variant 8.3.5.8, the only nontrivial point is to verify that if $C$ is an essentially small $\infty$-category, then the $\infty$-category $\text{Fun}(C^{\text{op}}, S)$ is locally small. This follows from Corollary 5.4.8.10. \qed

We first prove a weak version of Variant 8.3.5.8.

**Lemma 8.3.5.10.** Let $\kappa$ be an uncountable regular cardinal and let $\lambda$ be an uncountable cardinal of exponential cofinality $\geq \kappa$. Let $C$ be an essentially $\kappa$-small $\infty$-category, let $D$ be a locally $\lambda$-small $\infty$-category, and let $f : C \to D$ be a functor which satisfies the following conditions:

1. The $\infty$-category $D$ admits $\kappa$-small colimits.
2. The functor $f$ is fully faithful.
3. Let $C$ be an object of $C$. Then the image $f(C) \in D$ corepresents a functor $D \to S^{<\lambda}$ which preserves $\kappa$-small colimits.

Then $f$ is isomorphic to the composition $T \circ h_\bullet$, for some fully faithful functor

\[ T : \text{Fun}(C^{\text{op}}, S^{<\kappa}) \to D \]

which preserves $\kappa$-small colimits. Moreover, the functor $T$ is uniquely determined up to isomorphism.
8.3. PRESHEAF $\infty$-CATEGORIES

Proof. It follows from Variant 8.3.3.6 that $f$ is isomorphic to a composition $F \circ h_\bullet$, for some functor $F : \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \to \mathcal{D}$ which preserves $\kappa$-small colimits (and that $F$ is uniquely determined up to isomorphism). To complete the proof, it will suffice to show that the functor $F$ is fully faithful. Since $\lambda$ has exponential cofinality $\geq \kappa$, the functor $\infty$-category $\text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa})$ is locally $\lambda$-small (Corollary 5.4.8.9). For every pair of functors $G, G' : \mathcal{C}^{\text{op}} \to S^{<\kappa}$, the functor $F$ induces a morphism of Kan complexes $\theta_{G, G'} : \text{Hom}_{\text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa})}(G, G') \to \text{Hom}_D(F(G), F(G'))$.

By virtue of Proposition 8.2.7.2 (and Remark 8.2.7.3), we can promote the construction $(G, G') \mapsto \theta_{G, G'}$ to a functor of $\infty$-categories $\theta : \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa})^{\text{op}} \times \text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \to \text{Fun}(\Delta^1, S^{<\lambda})$.

We wish to show that, for every pair of functors $G, G' : \mathcal{C}^{\text{op}} \to S^{<\kappa}$, the morphism $\theta_{G, G'}$ is a homotopy equivalence. Let us first regard the functor $G'$ as fixed. Since $T$ preserves $\kappa$-small colimits, it follows from Remark 7.4.5.15 that the functor $\text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa})^{\text{op}} \to \text{Fun}(\Delta^1, S^{<\lambda})$ preserves $\kappa$-small limits. By virtue of Corollary 8.3.3.12 it will suffice to show that $\theta_{G, G'}$ is a homotopy equivalence in the special case where $G = h_C$ for some object $C \in \mathcal{C}$. Let us now regard $G = h_C$ as fixed. Combining Example 8.3.5.2 with assumption (2), we deduce that the functor $\text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa}) \to \text{Fun}(\Delta^1, S^{<\lambda})$ preserves $\kappa$-small colimits. Invoking Corollary 8.3.3.12 again, we are reduced to proving that $\theta_{G, G'}$ is a homotopy equivalence in the special case where $G' = h_{C'}$ for some object $C' \in \mathcal{C}$. In this case, we have a commutative diagram of Kan complexes

$$
\begin{array}{ccc}
\text{Hom}_\mathcal{C}(C, C') & \xrightarrow{H} & \text{Hom}_\mathcal{D}(F(G), F(G')) \\
\downarrow \text{Hom}_{\text{Fun}(\mathcal{C}^{\text{op}}, S^{<\kappa})}(G, G') & & \\
\text{Hom}_\mathcal{D}(F(G), F(G'))
\end{array}
$$

where the left vertical map is a homotopy equivalence by virtue of Yoneda’s lemma (Theorem 8.2.5.5). It will therefore suffice to show that the right vertical map is a homotopy equivalence. Since $F \circ h_\bullet$ is isomorphic to $f$, this is equivalent to the assertion that the natural map $\text{Hom}_\mathcal{C}(C, C') \to \text{Hom}_\mathcal{D}(f(C), f(C'))$ is a homotopy equivalence, which follows from assumption (1). \qed
CHAPTER 8. THE YONEDA EMBEDDING

Proof of Variant 8.3.5.8. Let $\kappa$ be an uncountable regular cardinal, let $\mathcal{C}$ be an essentially $\kappa$-small $\infty$-category, and let $f : \mathcal{C} \to \mathcal{D}$ be a functor of $\infty$-categories which satisfies the hypotheses of Variant 8.3.5.8. By virtue of Lemma 8.3.5.10, there exists a fully faithful functor $F : \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}) \to \mathcal{D}$ which preserves $\kappa$-small colimits such that $f$ is isomorphic to the composite functor

$$\mathcal{C} \xrightarrow{h} \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa}) F \to \mathcal{D}.$$ 

To complete the proof, it will suffice to show that $F$ is an equivalence of $\infty$-categories. Using Variant 8.3.4.2, we see that the functor $F$ admits a right adjoint $G : \mathcal{D} \to \text{Fun}(\mathcal{C}^{\text{op}}, \mathcal{S}^{<\kappa})$, given on objects by the formula $G(D)(C) = \text{Hom}_{\mathcal{D}}(f(C), D)$. By virtue of Corollary 6.3.3.14, it will suffice to show that the functor $G$ is conservative. This follows from our assumption that the collection of objects $\{f(C)\}_{C \in \mathcal{C}}$ is weakly dense in $\mathcal{D}$ (Remark 8.3.5.4). \qed
