Proof. For every simplicial set \(X\), Corollary 4.4.5.7 guarantees that the induced map \(\operatorname{Fun}(X, \mathcal{C}) \simeq \operatorname{Fun}(X, \mathcal{D})^{\simeq}\) is a Kan fibration. Combining Proposition 4.5.2.14 with Example 3.4.1.3 we see that 4.13 is a categorical pullback square if and only if it induces a homotopy equivalence
\[
\rho_{X}: \operatorname{Fun}\left(X, \mathcal{C}^{\prime}\right)^{\simeq} \rightarrow \operatorname{Fun}(X, \mathcal{C})^{\simeq} \times_{\operatorname{Fun}(X, \mathcal{D}) \simeq \operatorname{Fun}\left(X, \mathcal{D}^{\prime}\right)^{\simeq},},
\]
for every simplicial set \(X\). Using Corollary 4.4.3.19, we can identify \(\rho_{X}\) with the map \(\operatorname{Fun}\left(X, \mathcal{C}^{\prime}\right) \simeq \rightarrow \operatorname{Fun}\left(X, \mathcal{C} \times_{\mathcal{D}} \mathcal{D}^{\prime}\right)^{\simeq}\) given by postcomposition with \(\theta\). The desired result now follows from the criterion of Proposition 4.5.1.22.

033R Corollary 4.5.2.27. Suppose we are given a pullback diagram of \(\infty\)-categories

If \(U\) is an isofibration, then (4.14) is a categorical pullback square.
033 C Corollary 4.5.2.28. Let \(F_{0}: \mathcal{C}_{0} \rightarrow \mathcal{C}\) and \(F_{1}: \mathcal{C}_{1} \rightarrow \mathcal{C}\) be functors of \(\infty\)-categories. If either \(F_{0}\) or \(F_{1}\) is an isofibration, then the comparison map
\[
\mathcal{C}_{0} \times{ }_{\mathcal{C}} \mathcal{C}_{1} \hookrightarrow \mathcal{C}_{0} \times{ }_{\mathcal{C}}^{\mathrm{h}} \mathcal{C}_{1} \quad\left(C_{0}, C_{1}\right) \mapsto\left(C_{0}, C_{1}, \mathrm{id}\right)
\]
is an equivalence of \(\infty\)-categories.
Proof. This is a restatement of Corollary 4.5.2.27.
01 HJ Corollary 4.5.2.29. Suppose we are given a pullback diagram of \(\infty\)-categories

where \(U\) is an isofibration. If \(F\) is an equivalence of \(\infty\)-categories, then \(F^{\prime}\) is also an equivalence of \(\infty\)-categories.

Proof. Combine Corollary 4.5.2.27 with Proposition 4.5.2.21.
Corollary 4.5.2.30. Suppose we are given a commutative diagram of \(\infty\)-categories

where the vertical maps are equivalences of \(\infty\)-categories. If \(U\) and \(V\) are isofibrations, then the induced map \(\mathcal{C}_{0} \times_{\mathcal{C}} \mathcal{C}_{1} \rightarrow \mathcal{D}_{0} \times{ }_{\mathcal{D}} \mathcal{D}_{1}\) is an equivalence of \(\infty\)-categories.

Proof. Combine Corollaries 4.5.2.20 and 4.5.2.28.
Corollary 4.5.2.31. Suppose we are given a categorical pullback square of \(\infty\)-categories

where \(U\) and \(V\) are isofibrations. Let \(C \in \mathcal{C}\) be an object having image \(D=F(C)\). Then the induced map
\[
\widetilde{\mathcal{C}}_{C}=\{C\} \times_{\mathcal{C}} \widetilde{\mathcal{C}} \rightarrow\{D\} \times_{\mathcal{D}} \widetilde{\mathcal{D}}=\widetilde{\mathcal{D}}_{D}
\]
is an equivalence of \(\infty\)-categories.
Proof. Apply Corollary 4.5.2.30 in the special case \(\mathcal{C}_{1}=\{C\}\) and \(\mathcal{D}_{1}=\{D\}\).
Corollary 4.5.2.32. Suppose we are given a diagram of \(\infty\)-categories

where \(U\) and \(V\) are isofibrations and the functors \(F\) and \(\widetilde{F}\) are equivalences of \(\infty\)-categories. Let \(C \in \mathcal{C}\) be an object having image \(D=F(C)\). Then the induced map
\[
\widetilde{\mathcal{C}}_{C}=\{C\} \times_{\mathcal{C}} \widetilde{\mathcal{C}} \rightarrow\{D\} \times_{\mathcal{D}} \widetilde{\mathcal{D}}=\widetilde{\mathcal{D}}_{D}
\]
is an equivalence of \(\infty\)-categories.

Proof. Combine Proposition 4.5.2.21 with Corollary 4.5.2.31.
01HL Warning 4.5.2.33. Suppose we are given a commutative diagram of Kan complexes

where \(q\) and \(q^{\prime}\) are Kan fibrations and \(f\) is a homotopy equivalence. By virtue of Proposition 3.2.8.1, the following conditions are equivalent:
(1) The morphism \(f^{\prime}\) is a homotopy equivalence of Kan complexes.
(2) For each vertex \(s^{\prime} \in S^{\prime}\) having image \(s=f\left(s^{\prime}\right) \in S\), the induced map of fibers \(X_{s^{\prime}}^{\prime} \rightarrow X_{s}\) is a homotopy equivalence of Kan complexes.
Corollary 4.5.2.32 can be regarded as a generalization of the implication (1) \(\Rightarrow(2)\), where we allow \(\infty\)-categories in place of Kan complexes and isofibrations in place of Kan fibrations. Beware that the implication \((2) \Rightarrow(1)\) does not generalize. For example, we have a commutative diagram of \(\infty\)-categories

where the vertical maps are isofibrations, the bottom horizontal map is an isomorphism, and the upper horizontal map restricts to an isomorphism on each fiber, but is nevertheless not an equivalence of \(\infty\)-categories.

033V Corollary 4.5.2.34. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an isofibration of \(\infty\)-categories, let \(B \rightarrow \mathcal{C}\) be a diagram, and let \(f: A \rightarrow B\) be a categorical equivalence of simplicial sets. Then precomposition with \(f\) induces an equivalence of \(\infty\)-categories Fun \(_{/ \mathcal{C}}(B, \mathcal{E}) \rightarrow \operatorname{Fun}_{/ \mathcal{C}}(A, \mathcal{E})\).
Proof. Apply Corollary 4.5.2.32 to the commutative diagram

note that the vertical maps are isofibrations (Corollary 4.4.5.6) and the horizontal maps are equivalences of \(\infty\)-categories (Proposition 4.5.3.8).

Corollary 4.5.2.35. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an equivalence of \(\infty\)-categories, let \(A \subseteq B\) be 02C5 simplicial sets, and suppose we are given a diagram \(A \rightarrow \mathcal{C}\). Then postcomposition with \(F\) induces an equivalence of \(\infty\)-categories \(\operatorname{Fun}_{A /}(B, \mathcal{C}) \rightarrow \operatorname{Fun}_{A /}(B, \mathcal{D})\).

Proof. Apply Corollary 4.5.2.32 to the commutative diagram

note that the vertical maps are isofibrations by virtue of Corollary 4.4.5.3 and the horizontal maps are equivalences by virtue of Remark 4.5.1.16

Remark 4.5.2.36 (Categorical Pullback Squares of Simplicial Sets). Suppose we are given a commutative diagram of simplicial sets

Applying Proposition 4.1.3.2 repeatedly, we can enlarge 4.15 to a cubical diagram

where the diagonal maps are inner anodyne and the front face

is a diagram of \(\infty\)-categories. Let us say that that the diagram of simplicial sets 4.15) is a categorical pullback square if the diagram of \(\infty\)-categories 4.16) is a categorical pullback square, in the sense of Definition 4.5.2.8. Using Proposition 4.5.2.19, it is not difficult to show that this condition depends only on the original diagram (for a more general statement, see Proposition 7.5.5.13). Beware that this more general notion of categorical pullback diagram can be badly behaved: for example, it does not satisfy the analogue of Proposition 4.5.2.26 (see Warning 4.5.5.12).

\subsection*{4.5.3 Categorical Equivalence}

01E7 Recall that a morphism of simplicial sets \(f: X \rightarrow Y\) is a weak homotopy equivalence if, for every Kan complex \(Z\), precomposition with \(f\) induces a bijection \(\pi_{0}(\operatorname{Fun}(Y, Z)) \rightarrow\) \(\pi_{0}(\operatorname{Fun}(X, Z))\) (Definition 3.1.6.12). If this condition is satisfied, then one should regard \(X\) and \(Y\) as indistinguishable from the perspective of classical homotopy theory. However, from the \(\infty\)-categorical perspective, the relation of weak homotopy equivalence is somewhat too coarse: it is possible for a functor of \(\infty\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\) to be a weak homotopy equivalence (or even a homotopy equivalence) without being an equivalence of \(\infty\)-categories (Warning 4.5.1.14). For this reason, it will be convenient to introduce a finer notion of equivalence.
01 E 8 Definition 4.5.3.1. Let \(f: X \rightarrow Y\) be a morphism of simplicial sets. We say that \(f\) is a categorical equivalence if, for every \(\infty\)-category \(\mathcal{C}\), the induced functor \(\operatorname{Fun}(Y, \mathcal{C}) \rightarrow \operatorname{Fun}(X, \mathcal{C})\) induces a bijection on isomorphism classes \(\pi_{0}\left(\operatorname{Fun}(Y, \mathcal{C})^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}(X, \mathcal{C})^{\simeq}\right)\).
01 E 9 Example 4.5.3.2. Every isomorphism of simplicial sets is a categorical equivalence.
01EA Example 4.5.3.3. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Then \(F\) is a categorical equivalence (in the sense of Definition 4.5.3.1) if and only if it is an equivalence of \(\infty\)-categories (in the sense of Definition 4.5.1.10). Both conditions are equivalent to the assertion that for every \(\infty\)-category \(\mathcal{E}\), precomposition with \(F\) induces a bijection \(\operatorname{Hom}_{\mathrm{hQCat}}(\mathcal{D}, \mathcal{E}) \rightarrow\) \(\operatorname{Hom}_{\mathrm{hQCat}}(\mathcal{C}, \mathcal{E})\).
01EB Remark 4.5.3.4. Let \(f: X \rightarrow Y\) be a categorical equivalence of simplicial sets. Then \(f\) is a weak homotopy equivalence (since every Kan complex is an \(\infty\)-category). Beware that the converse is generally false.

Remark 4.5.3.5 (Two-out-of-Three). Let \(f: X \rightarrow Y\) and \(g: Y \rightarrow Z\) be morphisms of simplicial sets. If any two of the morphisms \(f, g\), and \(g \circ f\) is a categorical equivalence, then so is the third. In particular, the collection of categorical equivalences is closed under composition.

Remark 4.5.3.6. The collection of categorical equivalences is closed under retracts. That
01ED
-

\(\square\) is, if there exists a commutative diagram of simplicial sets

where the horizontal compositions are the identity and \(f^{\prime}\) is a categorical equivalence, then \(f\) is also a categorical equivalence.

Remark 4.5.3.7. Let \(f: X \rightarrow Y\) be a categorical equivalence of simplicial sets. Then, for 01EE any simplicial set \(K\), the induced map \(f_{K}: X \times K \rightarrow Y \times K\) is also a categorical equivalence of simplicial sets. To prove this, we must show that for every \(\infty\)-category \(\mathcal{C}\), the restriction \(\operatorname{map} \theta: \operatorname{Fun}(Y \times K, \mathcal{C}) \rightarrow \operatorname{Fun}(X \times K, \mathcal{C})\) induces a bijection on isomorphism classes of objects. This follows from our assumption that \(f\) is a categorical equivalence, since \(\theta\) can be identified with the map \(\operatorname{Fun}(Y, \operatorname{Fun}(K, \mathcal{C})) \rightarrow \operatorname{Fun}(X, \operatorname{Fun}(K, \mathcal{C}))\) given by precomposition with \(f\).

Proposition 4.5.3.8. Let \(f: X \rightarrow Y\) be a morphism of simplicial sets. The following 01EF conditions are equivalent:
(1) The morphism \(f: X \rightarrow Y\) is a categorical equivalence. That is, for every \(\infty\)-category \(\mathcal{C}\), precomposition with \(f\) induces a bijection
\[
\pi_{0}\left(\operatorname{Fun}(Y, \mathcal{C})^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}(X, \mathcal{C})^{\simeq}\right)
\]
(2) For every \(\infty\)-category \(\mathcal{C}\), precomposition with \(f\) induces a homotopy equivalence of Kan complexes \(\operatorname{Fun}(Y, \mathcal{C})^{\simeq} \rightarrow \operatorname{Fun}(X, \mathcal{C})^{\simeq}\).
(3) For every \(\infty\)-category \(\mathcal{C}\), precomposition with \(f\) induces an equivalence of \(\infty\)-categories \(\operatorname{Fun}(Y, \mathcal{C}) \rightarrow \operatorname{Fun}(X, \mathcal{C})\).

Proof. The implication (2) \(\Rightarrow(1)\) follows from Remark 3.1.6.5, and the implication (3) \(\Rightarrow\) (2) follows from Remark 4.5.1.19. We will complete the proof by showing that (1) implies (3). Assume that \(f\) is a categorical equivalence of simplicial sets, let \(\mathcal{C}\) be an \(\infty\)-category, and let \(f^{*}: \operatorname{Fun}(Y, \mathcal{C}) \rightarrow \operatorname{Fun}(X, \mathcal{C})\) denote the functor given by precomposition with \(f\). We wish to
show that \(\left[f^{*}\right]\) is an isomorphism in the homotopy category hQCat. For this, it will suffice to show that for any \(\infty\)-category \(\mathcal{D}\), the induced map
\[
\theta: \pi_{0}\left(\operatorname{Fun}(\mathcal{D}, \operatorname{Fun}(Y, \mathcal{C}))^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}(\mathcal{D}, \operatorname{Fun}(X, \mathcal{C}))^{\simeq}\right)
\]
is bijective. We conclude by observing that \(\theta\) can be identified with the map
\[
\pi_{0}\left(\operatorname{Fun}(Y, \operatorname{Fun}(\mathcal{D}, \mathcal{C}))^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}(X, \operatorname{Fun}(\mathcal{D}, \mathcal{C}))^{\simeq}\right)
\]
given by precomposition with \(f\).
\(033 Z\) Corollary 4.5.3.9. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(K\) be a simplicial set, and let \(f, f^{\prime}: K \rightarrow \mathcal{C}\) be diagrams which are isomorphic (when viewed as objects of the \(\infty\)-category \(\operatorname{Fun}(K, \mathcal{C})\) ). Then \(f\) is a categorical equivalence if and only if \(f^{\prime}\) is a categorical equivalence.

023 C Corollary 4.5.3.10. Let \(\left\{f_{i}: X_{i} \rightarrow Y_{i}\right\}_{i \in I}\) be a collection of categorical equivalences indexed by a set \(I\). Then the coproduct map
\[
f: \coprod_{i \in I} X_{i} \rightarrow \coprod_{i \in I} Y_{i}
\]
is also a categorical equivalence.
Proof. By virtue of Proposition 4.5.3.8, it will suffice to show that for every \(\infty\)-category \(\mathcal{C}\), precomposition with \(f\) induces an equivalence of \(\infty\)-categories
\[
F: \operatorname{Fun}\left(\coprod_{i \in I} Y_{i}, \mathcal{C}\right) \rightarrow \operatorname{Fun}\left(\coprod_{i \in I} X_{i}, \mathcal{C}\right) .
\]

Note that \(F\) factors as a product of functors \(F_{i}: \operatorname{Fun}\left(Y_{i}, \mathcal{C}\right) \rightarrow \operatorname{Fun}\left(X_{i}, \mathcal{C}\right)\), each of which is induced by precomposition with \(f_{i}\). Since each \(f_{i}\) is a categorical equivalence, Proposition 4.5.3.8 guarantees that each \(F_{i}\) is an equivalence of \(\infty\)-categories. Applying Remark 4.5.1.17 we conclude that \(F\) is an equivalence of \(\infty\)-categories.

01EG Proposition 4.5.3.11. Let \(f: X \rightarrow Y\) be a trivial Kan fibration of simplicial sets. Then \(f\) is a categorical equivalence.

Proof. Let \(\mathcal{C}\) be an \(\infty\)-category. We wish to show that precomposition with \(f\) induces a bijection
\[
f^{*}: \pi_{0}\left(\operatorname{Fun}(Y, \mathcal{C})^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}(X, \mathcal{C})^{\simeq}\right) .
\]

Let \(s: Y \rightarrow X\) be a section of \(f\) (so that \(f \circ s=\operatorname{id}_{Y}\) ). Then precomposition with \(s\) induces a function \(s^{*}: \pi_{0}\left(\operatorname{Fun}(X, \mathcal{C})^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}(Y, \mathcal{C})^{\simeq}\right)\) for which the composition \(s^{*} \circ f^{*}\) is equal to the identity on the set \(\pi_{0}\left(\operatorname{Fun}(Y, \mathcal{C})^{\simeq}\right)\). We will complete the proof by showing that the
composition \(f^{*} \circ s^{*}\) is isomorphic to the identity on \(\pi_{0}\left(\operatorname{Fun}(X, \mathcal{C})^{\simeq}\right)\). Fix a map of simplicial sets \(g: X \rightarrow \mathcal{C}\); we wish to show that \(g\) is isomorphic to the composite map
\[
X \xrightarrow{f} Y \xrightarrow{s} X \xrightarrow{g} \mathcal{C}
\]
as an object of the \(\infty\)-category \(\operatorname{Fun}(X, \mathcal{C})\).
Since \(f\) is a trivial Kan fibration, the composition \(s \circ f\) is fiberwise homotopic to the identity map id \({ }_{X}\) : that is, we can choose a morphism of simplicial sets \(h: \Delta^{1} \times X \rightarrow X\) which is compatible with the projection to \(Y\) and which satisfies \(\left.h\right|_{\{0\} \times X}=s \circ f\) and \(\left.h\right|_{\{1\} \times X}=\mathrm{id}_{X}\). The composition \(g \circ h\) can then be regarded as a natural transformation \(u:(g \circ s \circ f) \rightarrow g\). We will complete the proof by showing that \(u\) is an isomorphism in the \(\infty\)-category \(\operatorname{Fun}(X, \mathcal{C})\). By virtue of Theorem 4.4.4.4, it will suffice to prove that for each vertex \(x \in X\), the composite map
\[
\Delta^{1} \simeq \Delta^{1} \times\{x\} \hookrightarrow \Delta^{1} \times X \xrightarrow{h} X \xrightarrow{g} \mathcal{C}
\]
describes an invertible morphism in \(\mathcal{C}\). Setting \(y=f(x)\), we note that this composite map factors through the (contractible) Kan complex \(X_{y}\), so the desired result follows from Proposition 1.4.6.10.

Corollary 4.5.3.12. Let \(\mathcal{C}\) and \(\mathcal{D}\) be \(\infty\)-categories, and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a trivial Kan 01EH fibration. Then \(F\) is an equivalence of \(\infty\)-categories.

Proof. Combine Proposition 4.5.3.11 with Example 4.5.3.3.
Corollary 4.5.3.13. Let \(\mathcal{C}\) be an \(\infty\)-category, and let \(\operatorname{Isom}(\mathcal{C})\) denote the full subcategory 02C4 of \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)\) spanned by the isomorphisms of \(\mathcal{C}\) (Example 4.4.1.14). Then the diagonal embedding
\[
\delta: \mathcal{C} \hookrightarrow \operatorname{Isom}(\mathcal{C}) \quad C \mapsto \operatorname{id}_{C}
\]
is an equivalence of \(\infty\)-categories.
Proof. Let \(\mathrm{ev}_{0}: \operatorname{Isom}(\mathcal{C}) \rightarrow \mathcal{C}\) denote the evaluation map
\[
\operatorname{Isom}(\mathcal{C}) \hookrightarrow \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right) \rightarrow \operatorname{Fun}(\{0\}, \mathcal{C}) \simeq \mathcal{C}
\]

Then \(\mathrm{ev}_{0} \circ \delta\) is the identity functor \(\mathrm{id}_{\mathcal{C}}\). Corollary 4.4.5.10 guarantees that \(\mathrm{ev}_{0}\) is a trivial Kan fibration, and therefore an equivalence of \(\infty\)-categories (Corollary 4.5.3.12). Applying the two-out-of-three property (Remark 4.5.1.18), we conclude that \(\delta\) is also an equivalence of \(\infty\)-categories.

Corollary 4.5.3.14. Let \(f: A \hookrightarrow B\) be an inner anodyne morphism of simplicial sets. Then 01EJ \(f\) is a categorical equivalence.

Proof. By virtue of Proposition 4.5.3.8, it will suffice to show that for every \(\infty\)-category \(\mathcal{C}\), the restriction map \(f^{*}: \operatorname{Fun}(B, \mathcal{C}) \rightarrow \operatorname{Fun}(A, \mathcal{C})\) is an equivalence of \(\infty\)-categories. This follows from Corollary 4.5.3.12, since \(f^{*}\) is a trivial Kan fibration (Proposition 1.5.7.6.

01EK Warning 4.5.3.15. Let \(f: A \rightarrow B\) be a morphism of simplicial sets. By virtue of Corollary 3.3.7.7, the morphism \(f\) is anodyne if and only if it is both a monomorphism and a weak homotopy equivalence. Beware that the analogous assertion for inner anodyne morphisms is false. If \(f\) is inner anodyne, then it is both a monomorphism (Remark 1.5.6.5) and a categorical equivalence (Corollary 4.5.3.14). However, the converse fails: a monomorphism \(A \hookrightarrow B\) which is a categorical equivalence need not be inner anodyne. For example, an inner anodyne morphism of simplicial sets is automatically bijective on vertices (Exercise 1.5.6.6). However, there can be other obstructions as well: see Example 4.5.3.16.

01 HD Example 4.5.3.16 ([8]). Let \(X=\Delta^{2} \amalg_{\mathrm{N} \cdot(\{1<2\})} \Delta^{0}\) be the simplicial set obtained from the standard 2 -simplex by collapsing the final edge to a point, which we represent by the diagram

Then \(X\) has exactly two nondegenerate edges \(e, e^{\prime}: \Delta^{1} \rightarrow X\), as indicated in the diagram. We now make the following observations:
- There is a pushout diagram of simplicial sets

Consequently, the morphism \(e^{\prime}: \Delta^{1} \rightarrow X\) is inner anodyne, and therefore a categorical equivalence (Corollary 4.5.3.14).
- There is a unique morphism of simplicial sets \(r: X \rightarrow \Delta^{1}\) satisfying \(r \circ e^{\prime}=\operatorname{id}_{\Delta^{1}}\); the composite map \(\Delta^{2} \rightarrow X \xrightarrow{r} \Delta^{1}\) is given on vertices by \(0 \mapsto 0,1 \mapsto 1\), and \(2 \mapsto 1\). Since \(e^{\prime}\) is a categorical equivalence, it follows that \(r\) is also a categorical equivalence (Remark 4.5.3.5).
- The composite map \(\Delta^{1} \xrightarrow{e} X \xrightarrow{r} \Delta^{1}\) is equal to the identity map \(\operatorname{id}_{\Delta^{1}}\). Since \(r\) is a categorical equivalence, it follows that \(e\) is also a categorical equivalence. Moreover, \(e\) is also a monomorphism of simplicial sets which is bijective on vertices.
- The morphism \(e: \Delta^{1} \hookrightarrow X\) is an inner fibration. This follows from Remark 4.1.1.5, since we have a pullback diagram of simplicial sets

where the horizontal maps are surjective and the inclusion \(\Lambda_{2}^{2} \hookrightarrow \Delta^{2}\) is an inner fibration (since can be realized as the nerve of a morphism between partially ordered sets).
- The morphism \(e\) is not inner anodyne, since the lifting problem

has no solution.
Remark 4.5.3.17 (Axioms for Categorical Equivalence). The collection of categorical 01EL equivalences of simplicial sets has the following properties:
(A) If \(\mathcal{C}\) and \(\mathcal{D}\) are \(\infty\)-categories, then a functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) is a categorical equivalence if and only if it is an equivalence of \(\infty\)-categories (Example 4.5.3.3).
(B) Every inner anodyne morphism of simplicial sets is a categorical equivalence (Corollary 4.5.3.14).
(C) If \(f: X \rightarrow Y\) and \(g: Y \rightarrow Z\) have the property that two of the morphisms \(f, g\), and \(g \circ f\) are categorical equivalences, then so is the third (Remark 4.5.3.5).

In fact, the collection of categorical equivalences is characterized by assertions \((A),(B)\) and \((C)\). Let \(f: X \rightarrow Y\) be a morphism of simplicial sets. Invoking Proposition 4.1.3.1 twice, we
can construct a commutative diagram of simplicial sets

where \(u\) and \(v\) are inner anodyne and \(\mathcal{C}\) and \(\mathcal{D}\) are \(\infty\)-categories. It follows from \((A),(B)\) and \((C)\) that the morphism \(f\) is a categorical equivalence if and only if the functor \(F\) is an equivalence of \(\infty\)-categories.

\subsection*{4.5.4 Categorical Pushout Squares}

01F6 Recall that a commutative diagram of simplicial sets

is a homotopy pushout square if, for every Kan complex \(X\), the diagram of Kan complexes

is a homotopy pullback square (Definition 3.4.2.1). In this section, we study a stronger version of this condition.

01 F7 Definition 4.5.4.1. A commutative diagram of simplicial sets

is a categorical pushout square if, for every \(\infty\)-category \(\mathcal{C}\), the diagram of Kan complexes

is a homotopy pullback square.
Remark 4.5.4.2. Every categorical pushout square of simplicial sets is also a homotopy 01F8 pushout square of simplicial sets (since every Kan complex \(X\) is an \(\infty\)-category which satisfies \(\operatorname{Fun}(K, X) \simeq=\operatorname{Fun}(K, X)\) for every simplicial set \(K)\).

Remark 4.5.4.3. Suppose we are given a categorical pushout square of simplicial sets

Then, for every simplicial set \(K\), the induced diagram

is also a categorical pushout square. That is, for every \(\infty\)-category \(\mathcal{C}\), the diagram of Kan complexes

is a homotopy pullback square. This follows by applying the requirement Definition 4.5.4.1 to the \(\infty\)-category \(\operatorname{Fun}(K, \mathcal{C})\).

0340 Proposition 4.5.4.4. A commutative diagram of simplicial sets

is a categorical pushout square if and only if it satisfies the following condition:
(*) For every \(\infty\)-category \(\mathcal{C}\), the diagram of \(\infty\)-categories

is a categorical pullback square.
Proof. Fix an \(\infty\)-category \(\mathcal{C}\). If the diagram of \(\infty\)-categories 4.18 is a categorical pullback square, then the diagram of cores

is a homotopy pullback square (Proposition 4.5.2.14). Allowing \(\mathcal{C}\) to vary, we see that if \((*)\) is satisfied, then (4.17) is a categorical pushout square. For the converse, assume that 4.17) is a categorical pullback square. For every simplicial set \(X\), the \(\operatorname{simplicial}\) set \(\operatorname{Fun}(X, \mathcal{C})\) is an \(\infty\)-category (Theorem 1.5.3.7), so the diagram of Kan complexes

is a homotopy pullback square. Identifying (4.19) with the diagram

and allowing \(X\) to vary, we conclude that the diagram (4.18) is a categorical pullback square (Proposition 4.5.2.14).

Corollary 4.5.4.5. Suppose we are given a categorical pushout square of simplicial sets 02VP

where the horizontal maps are monomorphisms. Let \(\mathcal{C}\) be an \(\infty\)-category. For every diagram \(A^{\prime} \rightarrow \mathcal{C}\), the restriction map \(\operatorname{Fun}_{A^{\prime} /}\left(B^{\prime}, \mathcal{C}\right) \rightarrow \operatorname{Fun}_{A /}(B, \mathcal{C})\) is an equivalence of \(\infty\)-categories.

Proof. Proposition 4.5.4.4 guarantees that the diagram

is a categorical pullback square, and Corollary 4.4.5.3 guarantees that the vertical maps are isofibrations. The desired result now follows from Corollary 4.5.2.31.

Proposition 4.5.4.6. A commutative diagram of simplicial sets

is a categorical pushout square if and only if the induced diagram of opposite simplicial sets

is a categorical pushout square.
Proof. Apply Remark 3.4.1.7
01F9 Proposition 4.5.4.7 (Symmetry). A commutative diagram of simplicial sets

is a categorical pushout square if and only if the transposed diagram

is a categorical pushout square.
Proof. Apply Proposition 3.4.1.9.
01FA Proposition 4.5.4.8 (Transitivity). Suppose we are given a commutative diagram of simplicial sets

where the left square is a categorical pushout. Then the right square is a categorical pushout if and only if the outer rectangle is a categorical pushout.

Proof. Apply Proposition 3.4.1.11.

Proposition 4.5.4.9 (Homotopy Invariance). Suppose we are given a commutative diagram 01FB of simplicial sets

where the morphisms \(w, w_{0}\), and \(w_{1}\) are categorical equivalences. Then any two of the following three conditions imply the third:
(1) The back face

is a categorical pushout square.
(2) The front face

is a categorical pushout square.
(3) The morphism \(w_{01}\) is a categorical equivalence of simplicial sets.

Proof. Combine Corollary 3.4.1.12 with Proposition 4.5.3.8.

01FC Proposition 4.5.4.10. Suppose we are given a commutative diagram of simplicial sets

01FD

where \(f\) is a categorical equivalence. Then (4.20) is a categorical pushout square if and only if \(f^{\prime}\) is a categorical equivalence.

Proof. For every \(\infty\)-category \(\mathcal{C}\), we obtain a commutative diagram of simplicial sets

01FE

where \(u\) is a homotopy equivalence of Kan complexes (Proposition 4.5.3.8). Applying Corollary 3.4.1.5, we conclude that (4.21) is a homotopy pullback square if and only if \(u^{\prime}\) is a homotopy equivalence of Kan complexes. Consequently, 4.20) is a categorical pushout square if and only if, for every \(\infty\)-category \(\mathcal{C}\), the composition with \(f^{\prime}\) induces a homotopy equivalence \(\operatorname{Fun}\left(A_{01}, \mathcal{C}\right)^{\simeq} \rightarrow \operatorname{Fun}\left(A_{1}, \mathcal{C}\right)^{\simeq}\). By virtue of Proposition 4.5.3.8, this is equivalent to the requirement that \(f^{\prime}\) is a categorical equivalence.

01FF Proposition 4.5.4.11. Suppose we are given a commutative diagram of simplicial sets

01FG

where \(f\) is a monomorphism. Then (4.2.2) is a categorical pushout square if and only if the induced map \(\rho: A_{0} \amalg_{A} A_{1} \rightarrow A_{01}\) is a categorical equivalence of simplicial sets.

Proof. For every \(\infty\)-category \(\mathcal{C}\), we obtain a commutative diagram of \(\infty\)-categories

where \(u\) is an isofibration (Corollary 4.4.5.3). It follows that the diagram 4.23) is a categorical pullback square if and only if the induced map
\[
\theta_{\mathcal{C}}: \operatorname{Fun}\left(A_{01}, \mathcal{C}\right) \rightarrow \operatorname{Fun}\left(A_{0}, \mathcal{C}\right) \times_{\operatorname{Fun}(A, \mathcal{C})} \operatorname{Fun}\left(A_{1}, \mathcal{C}\right) \simeq \operatorname{Fun}\left(A_{0} \coprod_{A} A_{1}, \mathcal{C}\right)
\]
is an equivalence of \(\infty\)-categories (Proposition 4.5.2.26). Using Proposition 4.5.4.4, we see that this condition is satisfied for every \(\infty\)-category \(\mathcal{C}\) if and only if (4.22) is a categorical pushout square. The desired result now follows from Proposition 4.5.3.8.

Example 4.5.4.12. Suppose we are given a pushout diagram of simplicial sets

If \(f\) is a monomorphism, then (4.24) is also a categorical pushout square.
Remark 4.5.4.13. Suppose we are given a pushout diagram of simplicial sets

where \(f\) is a monomorphism. If \(g\) is a categorical equivalence, then \(g^{\prime}\) is also a categorical equivalence. This follows by combining Example 4.5.4.12 with Proposition 4.5.4.10.

0345 Corollary 4.5.4.14. Suppose we are given a commutative diagram of simplicial sets

where \(f_{0}\) and \(g_{0}\) are monomorphisms and the vertical maps are categorical equivalences. Then the induced map
\[
A_{0} \coprod_{A} A_{1} \rightarrow B_{0} \coprod_{B} B_{1}
\]
is a categorical equivalence.
Proof. Combine Example 4.5.4.12 with Proposition 4.5.4.9.
01FL Corollary 4.5.4.15. Let \(i: A \rightarrow B\) and \(i^{\prime}: A^{\prime} \rightarrow B^{\prime}\) be morphisms of simplicial sets. Assume that \(i\) is a monomorphism and that either \(i\) or \(i^{\prime}\) is a categorical equivalence. Then the induced map
\[
\left(A \times B^{\prime}\right) \coprod_{\left(A \times A^{\prime}\right)}\left(B \times A^{\prime}\right) \rightarrow B \times B^{\prime}
\]
is a categorical equivalence.
Proof. By virtue of Proposition 4.5.4.11, it will suffice to show that the diagram

is a categorical pushout square. This follows from the criterion of Proposition 4.5.4.10 if \(i\) is a categorical equivalence, then the horizontal maps in the diagram (4.25) are categorical equivalences (Remark 4.5.3.7). Similarly, if \(i^{\prime}\) is a categorical equivalence, then the vertical maps in the diagram 4.25) are categorical equivalences.

\subsection*{4.5.5 Isofibrations of Simplicial Sets}

01 FU We now characterize isofibrations between \(\infty\)-categories by means of a lifting property.
01FR Proposition 4.5.5.1. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between \(\infty\)-categories. Then \(F\) is an isofibration if and only if it satisfies the following condition:
(*) Let \(B\) be a simplicial set and let \(A \subseteq B\) be a simplicial subset for which the inclusion \(A \hookrightarrow B\) is a categorical equivalence. Then every lifting problem

admits a solution.
We begin by proving a weak form of Proposition 4.5.5.1.
Lemma 4.5.5.2. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(B\) be a simplicial set, and let \(A \subseteq B\) be a 01FS simplicial subset with the property that the inclusion \(A \hookrightarrow B\) is a categorical equivalence. Then every diagram \(f_{0}: A \rightarrow \mathcal{C}\) can be extended to a diagram \(f: B \rightarrow \mathcal{C}\).

Proof. By virtue of Corollary 4.4.5.4 the restriction map \(\theta: \operatorname{Fun}(B, \mathcal{C})^{\simeq} \rightarrow \operatorname{Fun}(A, \mathcal{C})^{\simeq}\) is a Kan fibration. Since the inclusion \(A \hookrightarrow B\) is a categorical equivalence, the map \(\theta\) is a homotopy equivalence of Kan complexes (Proposition 4.5.3.8. Invoking Proposition 3.3.7.6. we conclude that \(\theta\) is a trivial Kan fibration. In particular, it is surjective on vertices.

Lemma 4.5.5.3. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(B\) be a simplicial set, let \(A \subseteq B\) be a simplicial subset, and suppose we are given a pair of diagrams \(f, g: B \rightarrow \mathcal{C}\) together with a natural transformation \(u_{0}:\left.\left.f\right|_{A} \rightarrow f^{\prime}\right|_{A}\). If the inclusion \(A \hookrightarrow B\) is a categorical equivalence, then \(u_{0}\) can be lifted to a natural transformation \(u: f \rightarrow g\). Moreover, if \(u_{0}\) is a natural isomorphism, then \(u\) is automatically a natural isomorphism.

Proof. The existence of the natural transformation \(u\) follows by applying Lemma 4.5.5.2 to the inclusion of simplicial sets
\[
\left(\Delta^{1} \times A\right) \coprod_{\left(\partial \Delta^{1} \times A\right)}\left(\partial \Delta^{1} \times B\right) \hookrightarrow \Delta^{1} \times B,
\]
which is a categorical equivalence by virtue of Corollary 4.5.4.15. We will complete the proof by showing that if \(u_{0}\) is a natural isomorphism, then \(u\) is a natural isomorphism.

Let us identify \(u\) with a morphism of simplicial sets \(v: B \rightarrow \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)\), and let \(\operatorname{Isom}(\mathcal{C})\) denote the full subcategory of \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)\) spanned by the isomorphisms in \(\mathcal{C}\). Since \(u_{0}\) is a natural isomorphism, the restriction \(\left.v\right|_{A}\) factors through the full subcategory \(\operatorname{Isom}(\mathcal{C})\). Invoking Lemma 4.5.5.2, we conclude that \(\left.v\right|_{A}\) extends to a diagram \(v^{\prime}: B \rightarrow \operatorname{Isom}(\mathcal{C})\). Since the inclusion \(A \hookrightarrow B\) is a categorical equivalence, the equality \(\left.v\right|_{A}=\left.v^{\prime}\right|_{A}\) guarantees that \(v\) and \(v^{\prime}\) are isomorphic as objects of the \(\infty\)-category \(\operatorname{Fun}\left(B, \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)\right)\). Since the
full subcategory \(\operatorname{Isom}(\mathcal{C}) \subseteq \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)\) is replete (Example 4.4.1.14), we conclude that \(v\) also factors through \(\operatorname{Isom}(\mathcal{C})\), so that \(u\) is a natural isomorphism by virtue of Theorem 4.4.4.4

Proof of Proposition 4.5.5.1. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Assume first that \(F\) satisfies condition (*) of Proposition 4.5.5.1, we will prove that \(F\) is an isofibration. For \(0<i<n\), the inner horn inclusion \(\Lambda_{i}^{n} \hookrightarrow \Delta^{n}\) is a categorical equivalence (Corollary 4.5.3.14, so condition ( \(*\) ) guarantees that \(F\) is an inner fibration. Fix an object \(C \in \mathcal{C}\) and an isomorphism \(u: D \rightarrow F(C)\) in the \(\infty\)-category \(\mathcal{D}\); we wish to show that \(u\) can be lifted to an isomorphism \(\bar{u}: \bar{D} \rightarrow C\) in the \(\infty\)-category \(\mathcal{C}\). By virtue of Corollary 4.4.3.14, we can assume that \(u=G(v)\) for some functor \(G: \mathcal{E} \rightarrow \mathcal{D}\), where \(\mathcal{E}\) is a contractible Kan complex and \(v: X \rightarrow Y\) is a morphism in \(\mathcal{E}\). Since the inclusion \(\{Y\} \hookrightarrow \mathcal{E}\) is a categorical equivalence (Example 4.5.1.13), condition (*) guarantees the existence of a solution to the lifting problem

Then \(\bar{u}=\bar{G}(v)\) is an isomorphism of \(\mathcal{C}\) having the desired property.
Now suppose that the functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) is an isofibration; we wish to show that condition \((*)\) is satisfied. Let \(B\) be a simplicial set and \(A \subseteq B\) a simplicial subset for which the inclusion \(A \hookrightarrow B\) is a categorical equivalence. We wish to show that every lifting problem

admits a solution. Invoking Lemma 4.5.5.2, we see that \(f_{0}\) can be extended to a morphism of simplicial sets \(f^{\prime}: B \rightarrow \mathcal{C}\). Let \(\bar{f}^{\prime}\) denote the composition \(B \xrightarrow{f^{\prime}} \mathcal{C} \xrightarrow{F} \mathcal{D}\), so that \(\left.\bar{f}\right|_{A}=\left.\bar{f}^{\prime}\right|_{A}\). Invoking Lemma 4.5.5.3, we conclude that there exists an isomorphism \(\bar{u}: \bar{f} \rightarrow \bar{f}^{\prime}\) in the diagram \(\infty\)-category \(\operatorname{Fun}(B, \mathcal{D})\) whose image in \(\operatorname{Fun}(A, \mathcal{D})\) is the identity transformation \(\operatorname{id}_{\left.\bar{f}\right|_{A}}\). Applying Corollary 4.4.5.9, we deduce that \(\bar{u}\) can be lifted to an isomorphism \(u: f \rightarrow f^{\prime}\) in the diagram \(\infty\)-category \(\operatorname{Fun}(B, \mathcal{C})\) whose image in \(\operatorname{Fun}(A, \mathcal{C})\) is the identity transformation \(\operatorname{id}_{f_{0}}\). The diagram \(f: B \rightarrow \mathcal{C}\) then satisfies \(\left.f\right|_{A}=f_{0}\) and \(F \circ f=\bar{f}\), as desired.

Proposition 4.5.5.1 has a converse:
Proposition 4.5.5.4. Let \(i: A \hookrightarrow B\) be a monomorphism of simplicial sets. Then \(i\) is a 02R2 categorical equivalence if and only if the following condition is satisfied:
(*) Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an isofibration of \(\infty\)-categories. Then every lifting problem

has a solution.
Proof. Assume that condition (*) is satisfied; we will show that the morphism \(i: A \hookrightarrow B\) is a categorical equivalence of simplicial sets (the converse follows from Proposition 4.5.5.1). Fix an \(\infty\)-category \(\mathcal{E}\); we wish to show that precomposition with \(i\) induces a bijection \(\theta: \pi_{0}\left(\operatorname{Fun}(B, \mathcal{E})^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}(A, \mathcal{E})^{\simeq}\right)\). The surjectivity of \(\theta\) follows by applying condition \((*)\) to the isofibration \(\mathcal{E} \rightarrow \Delta^{0}\), and the injectivity of \(\theta\) follows by applying \(\theta\) to the isofibration \(\operatorname{Isom}(\mathcal{E}) \rightarrow \mathcal{E} \times \mathcal{E}\) of Corollary 4.4.5.5.

We now use the characterization of Proposition 4.5.5.1 to generalize the notion of isofibration to arbitrary simplicial sets.

Definition 4.5.5.5. Let \(q: X \rightarrow S\) be a morphism of simplicial sets. We will say that \(q\) is 01 FV an isofibration if it satisfies the following condition:
\((*)\) Let \(B\) be a simplicial set and let \(A \subseteq B\) be a simplicial subset for which the inclusion \(A \hookrightarrow B\) is a categorical equivalence. Then every lifting problem

admits a solution.
Remark 4.5.5.6. Let \(\mathcal{C}\) and \(\mathcal{D}\) be \(\infty\)-categories. We have now given two a priori different 01 FW definitions of an isofibration from \(\mathcal{C}\) to \(\mathcal{D}\) :
- According to Definition 4.4.1.4 an isofibration \(F: \mathcal{C} \rightarrow \mathcal{D}\) is an inner fibration with the property that every isomorphism \(u: D \rightarrow F(C)\) in the \(\infty\)-category \(\mathcal{D}\) can be lifted to an isomorphism \(\bar{u}: \bar{D} \rightarrow C\) in the \(\infty\)-category \(\mathcal{C}\).
- According to Definition 4.5.5.5 an isofibration \(F: \mathcal{C} \rightarrow \mathcal{D}\) is a morphism of simplicial sets which has the right lifting property with respect to all monomorphisms \(A \hookrightarrow B\) which are categorical equivalences.

However, these definitions are equivalent: this is the content of Proposition 4.4.5.1.
01FX Remark 4.5.5.7. Let \(q: X \rightarrow S\) be an isofibration of simplicial sets. Then \(q\) is an inner fibration: that is, it has the right lifting property with respect to every horn inclusion \(\Lambda_{i}^{n} \hookrightarrow \Delta^{n}\) for \(0<i<n\) (such inclusions are categorical equivalences, by virtue of Corollary 4.5.3.14). In particular, for each vertex \(s \in S\), the fiber \(X_{s}=\{s\} \times_{S} X\) is an \(\infty\)-category (Remark 4.1.1.6). Moreover, if \(S\) is an \(\infty\)-category, then \(X\) is also an \(\infty\)-category (Remark 4.1.1.9.

01FY Example 4.5.5.8. Let \(q: X \rightarrow S\) be a Kan fibration of simplicial sets. Then \(q\) is an isofibration. To prove this, we note that if a monomorphism of simplicial sets \(i: A \hookrightarrow B\) is a categorical equivalence, then it is a weak homotopy equivalence (Remark 4.5.3.4) and therefore anodyne (Corollary 3.3.7.7), so that \(q\) has the right lifting property with respect to \(i\) (Remark 3.1.2.7).

01FZ Remark 4.5.5.9. Let \(q: X \rightarrow S\) be a morphism of simplicial sets. Then \(q\) is an isofibration if and only if the opposite morphism \(q^{\mathrm{op}}: X^{\mathrm{op}} \rightarrow S^{\mathrm{op}}\) is an isofibration.

01G0 Remark 4.5.5.10. The collection of isofibrations is closed under retracts. That is, given a diagram of simplicial sets

where both horizontal compositions are the identity, if \(q^{\prime}\) is an isofibration, then so is \(q\).
01G1 Remark 4.5.5.11. The collection of isofibrations is closed under pullback. That is, given a pullback diagram of simplicial sets

where \(q\) is an isofibration, the morphism \(q^{\prime}\) is also an isofibration.

Warning 4.5.5.12. Suppose we are given a pullback diagram of simplicial sets

where \(q\) is an isofibration. If \(f\) is an equivalence of \(\infty\)-categories, then \(f^{\prime}\) is also an equivalence of \(\infty\)-categories (Corollary 4.5.2.29). Beware that if \(f\) is merely assumed to be a categorical equivalence of simplicial sets, then it is not necessarily true that \(f^{\prime}\) is a categorical equivalence of simplicial sets.

Remark 4.5.5.13. Let \(p: X \rightarrow Y\) and \(q: Y \rightarrow Z\) be isofibrations of simplicial sets. Then 01G2 the composite map \((q \circ p): X \rightarrow Z\) is an isofibration of simplicial sets.

We have the following generalization of Proposition 4.4.5.1.
Proposition 4.5.5.14. Let \(q: X \rightarrow S\) be an isofibration of simplicial sets and let \(i: A \hookrightarrow B\) 01G3 be a monomorphism of simplicial sets. Then the restriction map
\[
q^{\prime}: \operatorname{Fun}(B, X) \rightarrow \operatorname{Fun}(A, X) \times_{\operatorname{Fun}(A, S)} \operatorname{Fun}(B, S)
\]
is also an isofibration of simplicial sets.
Proof. Let \(B^{\prime}\) be a simplicial set and let \(A^{\prime} \subseteq B^{\prime}\) be a simplicial subset for which the inclusion \(A^{\prime} \hookrightarrow B^{\prime}\) is a categorical equivalence. We wish to show that every lifting problem

admits a solution. Unwinding the definitions, we are reduced to the problem of solving an associated lifting problem

The left vertical map in this diagram is a categorical equivalence by virtue of Corollary 4.5.4.15, so the existence of the desired solution follows from our assumption that \(q\) is an isofibration.

01G4 Corollary 4.5.5.15. Let \(q: X \rightarrow S\) be an isofibration of simplicial sets. For every simplicial set \(B\), the induced map \(\operatorname{Fun}(B, X) \rightarrow \operatorname{Fun}(B, S)\) is also an isofibration.

Proof. Apply Proposition 4.5.5.14 in the special case \(A=\emptyset\).
02VQ Corollary 4.5.5.16. Let \(q: X \rightarrow S\) be an isofibration of simplicial sets. Suppose we are given a morphism of simplicial sets \(B \rightarrow S\) and a simplicial subset \(A \subseteq B\). Then the restriction map \(\theta: \operatorname{Fun}_{/ S}(B, X) \rightarrow \operatorname{Fun}_{/ S}(A, X)\) is an isofibration of \(\infty\)-categories.

Proof. The morphism \(\theta\) is a pullback of the isofibration \(\operatorname{Fun}(B, X) \rightarrow \operatorname{Fun}(A, X) \times \operatorname{Fun(A,S)}\) \(\operatorname{Fun}(B, S)\) of Proposition 4.5.5.14, and is therefore also an isofibration (Remark 4.5.5.11). We conclude by observing that since \(q\) is an inner fibration (Remark 4.5.5.7), the simplicial sets Fun \({ }_{/ S}(B, X)\) and Fun \({ }_{/ S}(A, X)\) are \(\infty\)-categories (Proposition 4.1.4.6).

02VR Remark 4.5.5.17. Suppose we are given a lifting problem in the category of simplicial sets

where \(q\) is an isofibration and \(i\) is a monomorphism. It follows from Corollary 4.5.5.16 that, if we regard the morphisms \(q, i\), and \(\bar{f}\) as fixed, then the existence of a solution to the lifting problem (4.26) depends only on the isomorphism class of \(f\) as an object of the \(\infty\)-category Fun \(_{/ S}(A, X)\).

01G5 Proposition 4.5.5.18. Let \(q: X \rightarrow S\) be an isofibration of simplicial sets and let \(i: A \hookrightarrow B\) be a monomorphism of simplicial sets. If \(i\) is a categorical equivalence, then the restriction map
\[
q^{\prime}: \operatorname{Fun}(B, X) \rightarrow \operatorname{Fun}(A, X) \times_{\operatorname{Fun}(A, S)} \operatorname{Fun}(B, S)
\]
is a trivial Kan fibration.
Proof. Let \(B^{\prime}\) be a simplicial set and let \(A^{\prime} \subseteq B^{\prime}\) be a simplicial subset. We wish to show that every lifting problem

admits a solution. Unwinding the definitions, we are reduced to the problem of solving an associated lifting problem

The left vertical map in this diagram is a categorical equivalence by virtue of Corollary 4.5 .4 .15 , so the existence of the desired solution follows from our assumption that \(q\) is an isofibration.

Corollary 4.5.5.19. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(i: A \hookrightarrow B\) be a monomorphism of 01G6 simplicial sets. If \(i\) is a categorical equivalence, then the restriction functor \(\operatorname{Fun}(B, \mathcal{C}) \rightarrow\) Fun \((A, \mathcal{C})\) is a trivial Kan fibration of simplicial sets.

Proof. Apply Proposition 4.5.5.18 in the special case \(S=\Delta^{0}\).
Proposition 4.5.5.20. Let \(q: X \rightarrow S\) be a morphism of simplicial sets. Then \(q\) is a trivial 01G7 Kan fibration if and only if it is both an isofibration and a categorical equivalence.

Proof. If \(q\) is a trivial Kan fibration, then it is an isofibration by virtue of Example 4.5.5.8 and a categorical equivalence by virtue of Proposition 4.5.3.11. Conversely, suppose that \(q\) is both an isofibration and a categorical equivalence. Using Exercise 3.1.7.11, we can write \(q\) as a composition \(X \xrightarrow{q^{\prime}} Y \xrightarrow{q^{\prime \prime}} S\), where \(q^{\prime}\) is a monomorphism and \(q^{\prime \prime}\) is a trivial Kan fibration. Then \(q^{\prime \prime}\) is a categorical equivalence (Proposition 4.5.3.11), so that \(q^{\prime}\) is also a categorical equivalence (Remark 4.5.3.5). Invoking our assumption that \(q\) is an isofibration, we conclude that the lifting problem

admits a solution. It follows that \(q\) is a retract of the morphism \(q^{\prime \prime}\), and is therefore also a trivial Kan fibration.

\subsection*{4.5.6 Isofibrant Diagrams}

Let \(\mathcal{C}\) be a small category. Every diagram of simplicial sets \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) has a limit in 0346 the category \(\operatorname{Set}_{\Delta}\), given concretely by the formula
\[
\lim _{\rightleftarrows}(\mathscr{F})(C)_{n}=\lim _{C \in \mathcal{C}} \mathscr{F}(C)_{n} ;
\]
see Remark 1.1.0.8. Beware that, when using simplicial sets as a framework for higher category theory, this operation is badly behaved in general:
- If each of the simplicial sets \(\mathscr{F}(C)\) is an \(\infty\)-category, then the limit \(\lim (\mathscr{F})\) need not be an \(\infty\)-category.
- If \(\alpha: \mathscr{F} \rightarrow \mathscr{G}\) be a natural transformation between functors \(\mathscr{F}, \mathscr{G}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) which is a levelwise categorical equivalence (Definition 4.5.6.1), then the induced map \(\lim _{\leftrightarrows}(\alpha): \lim _{\leftrightarrows}(\mathscr{F}) \rightarrow \lim _{\leftrightarrows}(\mathscr{G})\) need not be a categorical equivalence.

In this section, we will introduce the class of isofibrant diagrams \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) (Definition 4.5.6.3), and show that it does not suffer from these defects:
- If \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) is an isofibrant diagram of simplicial sets, then the limit \(\lim (\mathscr{F})\) is an \(\infty\)-category (Corollary 4.5.6.13).
- If \(\alpha: \mathscr{F} \rightarrow \mathscr{G}\) is a levelwise categorical equivalence between isofibrant diagrams \(\mathscr{F}, \mathscr{G}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\), then the induced map \(\lim _{\leftrightarrows}(\alpha): \lim _{\leftrightarrows}(\mathscr{F}) \rightarrow \lim _{\leftrightarrows}(\mathscr{G})\) is an equivalence of \(\infty\)-categories (Corollary 4.5.6.17).

We begin by introducing some terminology.
0347 Definition 4.5.6.1. Let \(\mathcal{C}\) be a category and let \(\alpha: \mathscr{F} \rightarrow \mathscr{G}\) be a natural transformation between diagrams \(\mathscr{F}, \mathscr{G}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\). We say that \(\alpha\) is a levelwise categorical equivalence if, for every object \(C \in \mathcal{C}\), the induced map \(\alpha_{C}: \mathscr{F}(C) \rightarrow \mathscr{G}(C)\) is a categorical equivalence of simplicial sets.
0348 Remark 4.5.6.2. Definition 4.5.6.1 is a special case of a general convention. If \(P\) is a property of morphisms of simplicial sets and \(\alpha: \mathscr{F} \rightarrow \mathscr{G}\) is a natural transformation between diagrams \(\mathscr{F}, \mathscr{G}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\), then we say that \(\alpha\) has the property \(P\) levelwise if, for every object \(C \in \mathcal{C}\), the morphism of simplicial sets \(\alpha_{C}: \mathscr{F}(C) \rightarrow \mathscr{G}(C)\) has the property \(P\). For example, we say that \(\alpha\) is a levelwise weak homotopy equivalence if, for every object \(C \in \mathcal{C}\), the morphism \(\alpha_{C}: \mathscr{F}(C) \rightarrow \mathscr{G}(C)\) is a weak homotopy equivalence of simplicial sets.

0349 Definition 4.5.6.3. Let \(\mathcal{C}\) be a small category. We say that a diagram \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) is isofibrant if it satisfies the following condition:
\((*)\) Let \(\mathscr{E}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a functor and let \(\mathscr{E}_{0} \subseteq \mathscr{E}\) be a subfunctor for which the inclusion \(\mathscr{E}_{0} \hookrightarrow \mathscr{E}\) is a levelwise categorical equivalence. Then every natural transformation \(\alpha_{0}: \mathscr{E}_{0} \rightarrow \mathscr{F}\) admits an extension \(\alpha: \mathscr{E} \rightarrow \mathscr{F}\).
034A Example 4.5.6.4. Let \(\mathcal{C}=\{X\}\) be a category having a single object and a single morphism. Then a diagram \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) is determined by the simplicial set \(\mathscr{F}(X)\). The diagram \(\mathscr{F}\) is isofibrant (in the sense of Definition 4.5.6.3) if and only if the simplicial set \(\mathscr{F}(X)\) is an \(\infty\)-category.

Remark 4.5.6.5. Let \(\mathcal{C}\) be a small category and \(\mathscr{F}: \mathcal{C} \rightarrow\) Set \(_{\Delta}\) be an isofibrant diagram. 034B Then, for each object \(C \in \mathcal{C}\), the simplicial set \(\mathscr{F}(C)\) is an \(\infty\)-category. That is, for \(0<i<n\), every morphism of simplicial sets \(\sigma_{0}: \Lambda_{i}^{n} \rightarrow \mathscr{F}(C)\) can be extended to an \(n\)-simplex of \(\mathscr{F}(C)\). This follows by applying condition \((*)\) of Definition 4.5.6.3 to the functor
\[
\mathscr{E}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta} \quad \mathscr{E}(D)=\Delta^{n} \times \operatorname{Hom}_{\mathcal{C}}(C, D)
\]
together with the subfunctor \(\mathscr{E}_{0} \subseteq \mathscr{E}\) given by \(\mathscr{E}_{0}(D)=\Lambda_{i}^{n} \times \operatorname{Hom}_{\mathcal{C}}(C, D)\).
We now give some more interesting examples of isofibrant diagrams.
Proposition 4.5.6.6. Let \((Q, \leq)\) be a well-founded partially ordered set (see Definition 034D 4.7.1.1). Then a diagram of simplicial sets \(\mathscr{F}: Q^{\mathrm{op}} \rightarrow \operatorname{Set}_{\Delta}\) is isofibrant if and only if, for each element \(q \in Q\), the map
\[
\theta_{q}: \mathscr{F}(q) \rightarrow \lim _{p<q} \mathscr{F}(p)
\]
is an isofibration of simplicial sets.
Example 4.5.6.7 (Isofibrant Squares). A square diagram of \(\infty\)-categories

is isofibrant (when regarded as a functor \([1] \times[1] \rightarrow \operatorname{Set}_{\Delta}\) ) if and only if it satisfies the following conditions:
- The functors \(F_{0}: \mathcal{E}_{0} \rightarrow \mathcal{E}\) and \(F_{1}: \mathcal{E}_{1} \rightarrow \mathcal{E}\) are isofibrations of \(\infty\)-categories.
- The functor \(\left(F_{1}^{\prime}, F_{0}^{\prime}\right): \mathcal{E}_{01} \rightarrow \mathcal{E}_{0} \times \mathcal{E} \mathcal{E}_{1}\) is an isofibration of \(\infty\)-categories.

Example 4.5.6.8 (Isofibrant Towers). Let \(\mathscr{F}: \mathbf{Z}_{\geq 0}^{\mathrm{op}} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram, which we identify 034E with a tower of simplicial sets
\[
\cdots \rightarrow \mathscr{F}(3) \rightarrow \mathscr{F}(2) \rightarrow \mathscr{F}(1) \rightarrow \mathscr{F}(0) .
\]

Then \(\mathscr{F}\) is isofibrant (in the sense of Definition 4.5.6.3) if and only if each of the simplicial sets \(\mathscr{F}(n)\) is an \(\infty\)-category and each of the transition functors \(\mathscr{F}(n+1) \rightarrow \mathscr{F}(n)\) is an isofibration of \(\infty\)-categories.

0571 Example 4.5.6.9 (The Postnikov Tower). Let \(X\) be a Kan complex. Then the tower of fundamental \(n\)-groupoids
\[
\cdots \rightarrow \pi_{\leq 3}(X) \rightarrow \pi_{\leq 2}(X) \rightarrow \pi_{\leq 1}(X) \rightarrow \pi_{0}(X)
\]
is an isofibrant diagram of Kan complexes (Corollary 3.5.8.9).
0572 Variant 4.5.6.10. If \(X\) is a Kan complex, then the weakly coskeletal tower
\[
\cdots \rightarrow \operatorname{cosk}_{3}^{\circ}(X) \rightarrow \operatorname{cosk}_{2}^{\circ}(X) \rightarrow \operatorname{cosk}_{1}^{\circ}(X) \rightarrow \operatorname{cosk}_{0}^{\circ}(X)
\]
of Example 3.5 .8 .5 is an isofibrant diagram (Variant 3.5.8.10). Beware that the coskeletal tower
\[
\cdots \rightarrow \operatorname{cosk}_{4}(X) \rightarrow \operatorname{cosk}_{3}(X) \rightarrow \operatorname{cosk}_{2}(X) \rightarrow \operatorname{cosk}_{1}(X)
\]
is generally not isofibrant (Warning 3.5.8.11).
Proof of Proposition 4.5.6.6. Suppose first that \(\mathscr{F}: Q^{\mathrm{op}} \rightarrow \operatorname{Set}_{\Delta}\) is an isofibrant diagram. We will show that, for each element \(q \in Q\), the induced map \(\theta_{q}: \mathscr{F}(q) \rightarrow \lim _{p<q} \mathscr{F}(p)\) is an isofibration of simplicial sets (for this step, we will not need to assume that \(Q\) is well-founded). Fix a simplicial set \(B\) and a simplicial subset \(A \subseteq B\) for which the inclusion map \(A \hookrightarrow B\) is a categorical equivalence; we wish to show that every lifting problem

admits a solution. Define \(\mathscr{B}: Q^{\mathrm{op}} \rightarrow \operatorname{Set}_{\Delta}\) by the formula \(\mathscr{B}(p)=\left\{\begin{array}{cl}B & \text { if } p \leq q \\ \emptyset & \text { otherwise, }\end{array}\right.\) and let \(\mathscr{B}_{0} \subseteq \mathscr{B}\) be the subfunctor given by the formula
\[
\mathscr{B}_{0}(p)= \begin{cases}B & \text { if } p<q \\ A & \text { if } p=q \\ \emptyset & \text { otherwise } .\end{cases}
\]

The lifting problem (4.27) can be identified with a natural transformation of functors \(\alpha_{0}: \mathscr{B}_{0} \rightarrow \mathscr{F}\). Since the inclusion \(\mathscr{B}_{0} \hookrightarrow \mathscr{B}\) is a levelwise categorical equivalence and \(\mathscr{F}\) is isofibrant, we can extend \(\alpha_{0}\) to a natural transformation \(\alpha: \mathscr{B} \rightarrow \mathscr{F}\), which determines a solution to the lifting problem (4.27).

Now suppose that the partially ordered set \((Q, \leq)\) is well-founded and that for each \(q \in Q\), the morphism \(\theta_{q}\) is an isofibration of simplicial sets. We wish to show that the diagram \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) is isofibrant. Let \(\mathscr{E}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a functor, let \(\mathscr{E}_{0} \subseteq \mathscr{E}\) be a subfunctor for which the inclusion \(\mathscr{E}_{0} \hookrightarrow \mathscr{E}\) is a levelwise categorical equivalence, and let \(\alpha_{0}: \mathscr{E}_{0} \rightarrow \mathscr{F}\) be a natural transformation; we wish to show that \(\alpha_{0}\) can be extended to a natural transformation \(\alpha: \mathscr{E} \rightarrow \mathscr{F}\).

For every downward-closed subset \(P \subseteq Q\), let \(\mathscr{E}^{P} \subseteq \mathscr{E}\) denote the subfunctor given by \(\mathscr{E}^{P}(q)=\left\{\begin{array}{rc}\mathscr{E}(q) & \text { if } q \in P \\ \emptyset & \text { otherwise, }\end{array}\right.\), and set \(\mathscr{E}_{0} P=\mathscr{E}^{P} \cap \mathscr{E}_{0}\). Let \(S\) denote the collection of pairs \(\left(P, \alpha^{P}\right)\), where \(P \subseteq Q\) is a downward-closed subset and \(\alpha^{P}: \mathscr{E}^{P} \rightarrow \mathscr{F}\) is a natural transformation satisfying \(\left.\alpha^{P}\right|_{\mathscr{E}_{0}^{P}}=\left.\alpha_{0}\right|_{\mathscr{E}_{0}^{P}}\). We regard \(S\) as a partially ordered set, where \(\left(P, \alpha^{P}\right) \leq\left(P^{\prime}, \alpha^{P^{\prime}}\right)\) if \(P\) is contained in \(P^{\prime}\) and \(\alpha^{P}\) is equal to the restriction \(\left.\alpha^{P^{\prime}}\right|_{\mathscr{E}^{P}}\). The partially ordered set \(S\) satisfies the hypotheses of Zorn's lemma, and therefore contains a maximal element \(\left(P, \alpha^{P}\right)\). To complete the proof, it will suffice to show that \(P=Q\), so that \(\alpha^{P}: \mathscr{E} \rightarrow \mathscr{F}\) is an extension of \(\alpha_{0}\). Assume otherwise. Since \(Q\) is well-founded, the complement \(Q \backslash P\) contains a minimal element \(q\). Set \(P^{\prime}=P \cup\{q\}\). Since \(\theta_{q}\) is an isofibration of simplicial sets, the lifting problem

admits a solution in the category of simplicial sets. This solution determines a natural transformation \(\alpha^{P^{\prime}}: \mathscr{E}^{P^{\prime}} \rightarrow \mathscr{F}\) satisfying \(\left.\alpha^{P^{\prime}}\right|_{\mathscr{E}^{P}}=\alpha^{P}\) and \(\left.\alpha^{P^{\prime}}\right|_{\mathscr{E}_{0}^{P^{\prime}}}=\left.\alpha_{0}\right|_{\mathscr{E}_{0}^{P^{\prime}}}\), contradicting the maximality of the pair \(\left(P, \alpha^{P}\right)\).

We now record some useful properties of isofibrant diagrams of simplicial sets. Fix a small category \(\mathcal{C}\), and let us regard \(\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)\) as equipped with the simplicial enrichment described in Example 2.4.2.2. For every simplicial set \(K\), we let \(\underline{K}\) denote the constant functor \(\mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) taking the value \(K\).
Proposition 4.5.6.11. Let \(\mathcal{C}\) be a small category and let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be an isofibrant 034H diagram of simplicial sets. For every functor \(\mathscr{E}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) and every subfunctor \(\mathscr{E}_{0} \subseteq \mathscr{E}\), the restriction map
\[
\theta: \operatorname{Hom}_{\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}(\mathscr{E}, \mathscr{F}) \bullet \rightarrow \operatorname{Hom}_{\text {Fun }\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}\left(\mathscr{E}_{0}, \mathscr{F}\right) \bullet
\]
is an isofibration of simplicial sets. If the inclusion \(\mathscr{E}_{0} \hookrightarrow \mathscr{E}\) is a levelwise categorical equivalence, then \(\theta\) is a trival Kan fibration.

Proof. Let \(B\) be a simplicial set and let \(A \subseteq B\) be a simplicial subset. We wish to show that every lifting problem

admits a solution, provided that either the inclusion map \(A \hookrightarrow B\) is a categorical equivalence or the inclusion \(\mathscr{E}_{0} \hookrightarrow \mathscr{E}\) is a levelwise categorical equivalence. Unwinding the definitions, we see that the diagram (4.28) determines a natural transformation
\[
\alpha_{0}:(\underline{A} \times \mathscr{E}) \coprod_{\left(\underline{\left.A \times \mathscr{E}_{0}\right)}\right.}\left(\underline{B} \times \mathscr{E}_{0}\right) \rightarrow \mathscr{F},
\]
and that solutions to 4.28) can be identified with extensions of \(\alpha_{0}\) to a natural transformation \(\alpha: \underline{B} \times \mathscr{E} \rightarrow \mathscr{F}\). By virtue of our assumption that \(\mathscr{F}\) is isofibrant, we are reduced to proving that the inclusion map
\[
(\underline{A} \times \mathscr{E}) \coprod_{\left(\underline{A} \times \mathscr{E}_{0}\right)}\left(\underline{B} \times \mathscr{E}_{0}\right) \hookrightarrow \underline{B} \times \mathscr{E}
\]
is a levelwise categorical equivalence, which follows from Corollary 4.5.4.15.
034 K Corollary 4.5.6.12. Let \(\mathcal{C}\) be a small category and let \(\mathscr{E}, \mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be diagrams of simplicial sets. If \(\mathscr{F}\) is isofibrant, then the simplicial set \(\operatorname{Hom}_{\text {Fun }\left(\mathcal{C}, \mathrm{Set}_{\Delta}\right)}(\mathscr{E}, \mathscr{F})\) • is an \(\infty\)-category.
Proof. Apply Proposition 4.5.6.11 in the special case \(\mathscr{E}_{0}=\emptyset\).
034L Corollary 4.5.6.13. Let \(\mathcal{C}\) be a small category and let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be an isofibrant

Proof. Apply Corollary 4.5.6.12 in the special case \(\mathscr{E}=\Delta^{0}\).
034M Proposition 4.5.6.14. Let \(\mathcal{C}\) be a small category, let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be an isofibrant diagram, and let \(\alpha: \mathscr{E} \rightarrow \mathscr{E}^{\prime}\) be a natural transformation between diagrams \(\mathscr{E}, \mathscr{E}^{\prime}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\). If \(\alpha\) is a levelwise categorical equivalence, then precomposition with \(\alpha\) induces an equivalence of \(\infty\)-categories
\[
\operatorname{Hom}_{\text {Fun }\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}\left(\mathscr{E}^{\prime}, \mathscr{F}\right)_{\bullet} \rightarrow \operatorname{Hom}_{\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}(\mathscr{E}, \mathscr{F})_{\bullet}
\]

Proof. Using Exercise 3.1.7.11, we can choose a contractible Kan complex \(X\) containing a pair of vertices \(x, y \in X\) with \(x \neq y\). Evaluation at the vertices \(x\) and \(y\) determine trivial Kan fibrations of \(\infty\)-categories
\[
\operatorname{ev}_{x}, \mathrm{ev}_{y}: \operatorname{Fun}\left(X, \operatorname{Hom}_{\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}(\mathscr{E}, \mathscr{F})_{\bullet}\right) \rightarrow \operatorname{Hom}_{\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}(\mathscr{E}, \mathscr{F})_{\bullet}
\]

Form a pullback diagram

so that \(U\) is also a trivial Kan fibration and therefore an equivalence of \(\infty\)-categories. It will therefore suffice to show that \(\mathrm{ev}_{x} \circ T\) is an equivalence of \(\infty\)-categories. Since the functors ev \(\mathrm{e}_{x}\) and \(\mathrm{ev}_{y}\) are isomorphic, this is equivalent to the requirement that \(\mathrm{ev}_{y} \circ T\) is an equivalence of \(\infty\)-categories. In fact, the functor \(\mathrm{ev}_{y} \circ T\) is a trivial Kan fibration: this follows by applying Proposition 4.5.6.11 to the levelwise categorical equivalence
\[
\underline{\{y\}} \times \mathscr{E} \hookrightarrow(\underline{X} \times \mathscr{E}) \coprod_{(\underline{\{x\}} \times \mathscr{E})} \mathscr{E}^{\prime} .
\]

Corollary 4.5.6.15. Let \(\mathcal{C}\) be a small category and let \(\alpha: \mathscr{E} \rightarrow \mathscr{F}\) be a levelwise categorical equivalence of isofibrant diagrams \(\mathscr{E}, \mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\). Then \(\alpha\) admits a homotopy inverse: that is, there is a natural transformation \(\beta: \mathscr{F} \rightarrow \mathscr{E}\) such that \(\alpha \circ \beta\) and \(\beta \circ \alpha\) are isomorphic to \(\mathrm{id}_{\mathscr{F}}\) and \(\mathrm{id}_{\mathscr{E}}\) as objects of the \(\infty\)-categories \(\operatorname{Hom}_{\text {Fun }\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}(\mathscr{F}, \mathscr{F}) \bullet\) and \(\operatorname{Hom}_{\text {Fun }\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}(\mathscr{E}, \mathscr{E}) \bullet\), respectively.

Proof. Since \(\mathscr{E}\) is isofibrant, Proposition 4.5.6.14 guarantees that the functor
\[
\operatorname{Hom}_{\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}(\mathscr{F}, \mathscr{E}) \bullet \xrightarrow{\circ \alpha} \operatorname{Hom}_{\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}(\mathscr{E}, \mathscr{E}) \bullet
\]
is an equivalence of \(\infty\)-categories. In particular, there exists a natural transformation \(\beta: \mathscr{F} \rightarrow \mathscr{E}\) such that \(\beta \circ \alpha\) is isomorphic to \(\mathrm{id}_{\mathscr{E}}\) (when viewed as an object of the \(\infty\)-category \(\left.\operatorname{Hom}_{\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}(\mathscr{E}, \mathscr{E}) \bullet\right)\). To complete the proof, it will suffice to show that \(\beta\) is also a right homotopy inverse to \(\alpha\) : that is, the composition \(\alpha \circ \beta\) is isomorphic to id \(\mathscr{F}\) (when viewed as an object of the \(\infty\)-category \(\operatorname{Hom}_{\text {Fun }\left(\mathcal{C}, \text { Set }_{\Delta}\right)}(\mathscr{F}, \mathscr{F}) \bullet\).

For each object \(C \in \mathcal{C}\), the functor \(\beta_{C}: \mathscr{F}(C) \rightarrow \mathscr{E}(C)\) is a left homotopy inverse of the functor \(\alpha_{C}: \mathscr{E}(C) \rightarrow \mathscr{F}(C)\). Since \(\alpha_{C}\) is an equivalence of \(\infty\)-categories, it follows that \(\beta_{C}\) is also an equivalence of \(\infty\)-categories. Allowing \(C\) to vary, we conclude that \(\beta\) is a levelwise categorical equivalence. We can therefore repeat the preceding argument to obtain a natural transformation \(\gamma: \mathscr{E} \rightarrow \mathscr{F}\) such that \(\gamma \circ \beta\) is isomorphic to id \(\mathscr{F}\). We then have isomorphisms
\[
\alpha \simeq(\gamma \circ \beta) \circ \alpha=\gamma \circ(\beta \circ \alpha) \simeq \gamma
\]
in the \(\infty\)-category \(\operatorname{Hom}_{\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}(\mathscr{E}, \mathscr{F})_{\bullet}\), so that \(\alpha \circ \beta\) is also isomorphic to id \(\mathscr{\mathscr { F }}\).

034P Corollary 4.5.6.16. Let \(\mathcal{C}\) be a small category, let \(\mathscr{E}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets, and let \(\alpha: \mathscr{F} \rightarrow \mathscr{G}\) be a levelwise categorical equivalence between diagrams \(\mathscr{F}, \mathscr{G}\) : \(\mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\). If \(\mathscr{F}\) and \(\mathscr{G}\) are isofibrant, then composition with \(\alpha\) induces an equivalence of \(\infty\)-categories
\[
\operatorname{Hom}_{\text {Fun }\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}(\mathscr{E}, \mathscr{F})_{\bullet} \rightarrow \operatorname{Hom}_{\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}(\mathscr{E}, \mathscr{G})_{\bullet}
\]

034Q Corollary 4.5.6.17. Let \(\mathcal{C}\) be a small category, and let \(\alpha: \mathscr{F} \rightarrow \mathscr{G}\) be a levelwise categorical equivalence between isofibrant diagrams \(\mathscr{F}, \mathscr{G}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\). Then the induced map \(\lim (\alpha)\) : \(\lim _{\rightleftarrows}(\mathscr{F}) \rightarrow \lim _{\rightleftarrows}(\mathscr{G})\) is an equivalence of \(\infty\)-categories.

Proof. Apply Corollary 4.5.6.16 in the special case \(\mathscr{E}=\underline{\Delta}^{0}\).
034R Example 4.5.6.18. Suppose we are given a commutative diagram of \(\infty\)-categories

where the horizontal maps are isofibrations and the vertical maps are equivalences of \(\infty\) categories. Then the induced map \(\varliminf_{\longleftarrow} \mathcal{C}(n) \rightarrow \varliminf_{幺} \mathcal{D}(n)\) is an equivalence of \(\infty\)-categories. This follows by combining Example 4.5.6.8, Corollary 4.5.6.13, and Corollary 4.5.6.17.

034S Proposition 4.5.6.19. Let \(\mathcal{C}\) be a small category and let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be an isofibrant diagram. Suppose that, for every object \(C \in \mathcal{C}\), the simplicial set \(\mathscr{F}(C)\) is a Kan complex. Then, for every diagram \(\mathscr{E}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\), the simplicial set \(X=\operatorname{Hom}_{\text {Fun }\left(\mathcal{C}, \mathrm{Set}_{\Delta}\right)}(\mathscr{E}, \mathscr{F})\). is a Kan complex.

Proof. By virtue of Corollary 4.5.6.12, the simplicial set \(X\) is an \(\infty\)-category. Define \(\mathscr{F} \Delta^{1}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) by the formula \(\mathscr{F}^{\Delta^{1}}(C)=\operatorname{Fun}\left(\Delta^{1}, \mathscr{F}(C)\right)\). Then \(\mathscr{F}^{\Delta^{1}}\) is also an isofibrant diagram. Moreover, our assumption that each \(\mathscr{F}(C)\) is a Kan complex guarantees that the diagonal embedding \(\mathscr{F} \hookrightarrow \mathscr{F}^{\Delta^{1}}\) is a levelwise categorical equivalence. Applying Corollary 4.5.6.16 we deduce that the diagonal map \(X \hookrightarrow \operatorname{Fun}\left(\Delta^{1}, X\right)\) is an equivalence of \(\infty\)-categories. In particular, every morphism of \(X\) is isomorphic (as an object of the \(\infty\)-category \(\operatorname{Fun}\left(\Delta^{1}, X\right)\) ) to an identity morphism, and is therefore an isomorphism (Example 4.4.1.14). Applying Proposition 4.4.2.1, we deduce that \(X\) is a Kan complex.

034 T Corollary 4.5.6.20. Let \(\mathcal{C}\) be a small category and let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be an isofibrant diagram. Suppose that, for every object \(C \in \mathcal{C}\), the simplicial set \(\mathscr{F}(C)\) is a Kan complex. Then the simplicial set \(\lim _{\leftrightarrows}(\mathscr{F})\) is a Kan complex.

Proof. Apply Proposition 4.5.6.19 in the special case \(\mathscr{E}=\underline{\Delta}^{0}\).

Corollary 4.5.6.21. Let \(\mathcal{C}\) be a small category, let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be an isofibrant diagram, 034U and define \(\mathscr{F} \simeq: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) by the formula \(\mathscr{F} \simeq(C)=\mathscr{F}(C) \simeq\). Then \(\mathscr{F} \simeq\) is also an isofibrant diagram. Moreover, the inclusion map \(\lim (\mathscr{F} \simeq) \hookrightarrow \lim (\mathscr{F})\) restricts to an isomorphism of \(\varliminf_{\rightleftarrows}(\mathscr{F} \sim)\) with the core of the \(\infty\)-category \(\underset{\rightleftarrows}{\varliminf}(\mathscr{F})\).

Proof. We first show that the diagram \(\mathscr{F} \simeq\) is isofibrant. Let \(\mathscr{E}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a functor and let \(\mathscr{E}_{0} \subseteq \mathscr{E}\) be a subfunctor for which the inclusion \(\mathscr{E}_{0} \hookrightarrow \mathscr{E}\) is a levelwise categorical equivalence. Suppose we are given a natural transformation \(\alpha_{0}: \mathscr{E}_{0} \rightarrow \mathscr{F} \simeq\). Our assumption that \(\mathscr{F}\) is isofibrant guarantees that \(\alpha_{0}\) can be extended to a natural transformation \(\alpha: \mathscr{E} \rightarrow \mathscr{F}\). We claim that \(\alpha\) automatically factors through the functor \(\mathscr{F} \simeq\) : that is, for every object \(C \in \mathcal{C}\), the map \(\alpha_{C}: \mathscr{E}(C) \rightarrow \mathscr{F}(C)\) factors through the core of \(\mathscr{F}(C)\). This follows from the observation that the lifting problem

has a (unique) solution, since the inclusion \(\mathscr{F}(C) \simeq \hookrightarrow \mathscr{F}(C)\) is an isofibration (Proposition 4.4.3.6).

We now prove the second assertion. Let \(X\) denote the core of the \(\infty\)-category \(\lim _{\leftrightarrows}(\mathscr{F})\). For every object \(C \in \mathcal{C}\), the projection map \(\lim (\mathscr{F}) \rightarrow \mathscr{F}(C)\) carries \(X\) into the core of \(\mathscr{F}(C)\). It follows that \(X\) is contained in the inverse limit \(\lim (\mathscr{F} \sim)\). The reverse inclusion follows from Corollary 4.4.3.18, since the simplicial set \(\varliminf \ll \mathscr{F}^{\sim}\) ) is a Kan complex (Corollary 4.5.6.20).

Corollary 4.5.6.22. Suppose we are given an inverse system of \(\infty\)-categories
\[
\cdots \rightarrow \mathcal{C}(3) \rightarrow \mathcal{C}(2) \rightarrow \mathcal{C}(1) \rightarrow \mathcal{C}(0)
\]
where each of the transition functors \(\mathcal{C}(n) \rightarrow \mathcal{C}(n-1)\) is an isofibration. Then the limit \(\mathcal{C}=\lim _{n} \mathcal{C}(n)\) is an \(\infty\)-category, whose core \(\mathcal{C}^{\simeq}\) is the inverse limit \(\lim _{n} \mathcal{C}(n)^{\simeq}\). In other words, a morphism of \(\mathcal{C}\) is an isomorphism if and only if its image in each \(\mathcal{C}(n)\) is an isomorphism.

Proof. Combine Example 4.5.6.8, Corollary 4.5.6.13, and Corollary 4.5.6.21.

\subsection*{4.5.7 Detecting Equivalences of \(\infty\)-Categories}
\(01 \mathrm{HF} \quad\) Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between \(\infty\)-categories. If \(F\) is an equivalence of \(\infty\)-categories, then the induced map \(F^{\simeq}: \mathcal{C}^{\simeq} \rightarrow \mathcal{D}^{\simeq}\) is a homotopy equivalence of Kan complexes (Remark 4.5.1.19. The converse assertion is not true in general. For example, the inclusion map \(\mathcal{C}^{\simeq} \hookrightarrow \mathcal{C}\) induces an isomorphism on cores, but is never an equivalence of \(\infty\)-categories unless \(\mathcal{C}\) is a Kan complex. However, we have the following slightly weaker result:

01HG Theorem 4.5.7.1. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Then \(F\) is an equivalence of \(\infty\)-categories if and only if the induced map of Kan complexes \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right) \simeq \rightarrow \operatorname{Fun}\left(\Delta^{1}, \mathcal{D}\right) \simeq\) is a homotopy equivalence.

Proof. For every simplicial set \(X\), let \(\theta_{X}: \operatorname{Fun}(X, \mathcal{C})^{\simeq} \rightarrow \operatorname{Fun}(X, \mathcal{D})^{\simeq}\) denote the map given by postcomposition with the functor \(F\). Let us say that \(X\) is good if the morphism \(\theta_{X}\) is a homotopy equivalence. By virtue of Proposition 4.5.1.22, the functor \(F\) is an equivalence of \(\infty\)-categories if and only if every simplicial set \(X\) is good. In particular, if \(F\) is an equivalence of \(\infty\)-categories, then \(\Delta^{1}\) is good. To prove the converse, we make the following observations:
(a) Let \(X\) be the colimit of a diagram of monomorphisms
\[
X(0) \hookrightarrow X(1) \hookrightarrow X(2) \hookrightarrow \cdots
\]

We then obtain a commutative diagram of Kan complexes

where the horizontal maps are Kan fibrations (Corollary 4.4.5.4). Moreover, the induced map of inverse limits can be identified with the map \(\theta_{X}: \operatorname{Fun}(X, \mathcal{C}) \simeq \rightarrow\) \(\operatorname{Fun}(X, \mathcal{D}) \simeq(\) Corollary 4.4.4.6). If each \(X(n)\) is good, then the vertical maps appearing in the diagram are homotopy equivalences, so that \(\theta_{X}\) is also a homotopy equivalence (Example 4.5.6.18). It follows that \(X\) is also good.
(b) Let \(X\) be a simplicial set which is given as a coproduct \(\coprod_{\alpha} X(\alpha)\) of a collection of simplicial sets \(X(\alpha)\). Then \(\theta_{X}\) can be identified with the product of the maps \(\theta_{X(\alpha)}\) (Corollary 4.4.4.6). Consequently, if each of the summands \(X(\alpha)\) is good, then \(X\) is also good (Remark 3.1.6.8).
(c) Let \(u: X \rightarrow Y\) be an inner anodyne morphism of simplicial sets. Then we have a commutative diagram of Kan complexes

where the horizontal maps are homotopy equivalences (Proposition 4.5.3.8). It follows that \(X\) is good if and only if \(Y\) is good.
(d) Suppose we are given a categorical pushout square of simplicial sets

If \(X, X^{\prime}\), and \(Y\) are good, then \(Y^{\prime}\) is also good (see Corollary 3.4.1.12).
(e) Let \(X\) be a retract of a simplicial set \(Y\). If \(Y\) is good, then \(X\) is also good.

Now suppose that the simplicial set \(\Delta^{1}\) is good. We will show that every simplicial set \(X\) is good, so that \(F\) is an equivalence of \(\infty\)-categories by virtue of Proposition 4.5.1.22, Writing \(X\) as the direct limit of its skeleta \(\left\{\operatorname{sk}_{n}(X)\right\}_{n \geq 0}\) and using (a), we can reduce to the case where \(X\) has dimension \(\leq n\) for some integer \(n\). We proceed by induction on \(n\). The case \(n=-1\) is trivial (in this case, the simplicial set \(X\) is empty and the morphism \(\theta_{X}\) is an isomorphism). We may therefore assume that \(n \geq 0\). Let \(S\) be the collection of nondegenerate \(n\)-simplices of \(X\), so that Proposition 1.1.4.12 supplies a pushout diagram

Since the horizontal maps in this diagram are monomorphisms, it is also a categorical pushout square (Example 4.5.4.12). Moreover, our inductive hypothesis guarantees that the
simplicial sets \(\mathrm{sk}_{n-1}(X)\) and \(\underset{\sigma \in S}{ } \partial \Delta^{n}\) are good. Applying (d), we are reduced to showing that the coproduct \(\underset{\sigma \in S}{ } \Delta^{n}\) is good. Using \((b)\), we are reduced to showing that the standard simplex \(\Delta^{n}\) is good. If \(n \geq 2\), then the inner horn inclusion \(\Lambda_{1}^{n} \hookrightarrow \Delta^{n}\) is a categorical equivalence, so that the desired result follows from our inductive hypothesis together with \((c)\). We are therefore reduced to showing that the standard simplices \(\Delta^{0}\) and \(\Delta^{1}\) are good. In the second case this follows from our assumption (4), and in the first case it follows from (e) (since the 0 -simplex \(\Delta^{0}\) is a retract of \(\Delta^{1}\) ).

01 HH Corollary 4.5.7.2. Let \(\mathcal{W}\) denote the full subcategory of Fun \(\left([1]\right.\), Set \(\left._{\Delta}\right)\) spanned by those morphisms of simplicial sets \(f: X \rightarrow Y\) which are categorical equivalences. Then \(\mathcal{W}\) is closed under the formation of filtered colimits in \(\operatorname{Fun}\left([1], \operatorname{Set}_{\Delta}\right)\).

Proof. By virtue of Corollary 4.1.3.3, there exists a functor \(Q: \operatorname{Set}_{\Delta} \rightarrow \operatorname{Set}_{\Delta}\) which commutes with filtered colimits and a natural transformation of functors \(u: \operatorname{id}_{\operatorname{Set}_{\Delta}} \rightarrow Q\) with the property that, for every simplicial set \(X\), the simplicial set \(Q(X)\) is an \(\infty\)-category and the morphism \(u_{X}: X \rightarrow Q(X)\) is inner anodyne. For every morphism of simplicial sets \(f: X \rightarrow Y\), we have a commutative diagram

where the vertical maps are categorical equivalences (Corollary 4.5.3.14). It follows from Remark 4.5.3.5 that \(f\) is a categorical equivalence if and only if the functor \(Q(f)\) is an equivalence of \(\infty\)-categories. Using the criterion of Theorem 4.5.7.1, we see that \(f\) is a categorical equivalence if and only if the induced map \(\operatorname{Fun}\left(\Delta^{1}, Q(X)\right)^{\simeq} \rightarrow \operatorname{Fun}\left(\Delta^{1}, Q(Y)\right)^{\simeq}\) is a homotopy equivalence of Kan complexes. The desired result now follows by observing that the construction \(X \mapsto \operatorname{Fun}\left(\Delta^{1}, Q(X)\right)^{\simeq}\) commutes with filtered colimits, since the collection of homotopy equivalences between Kan complexes is closed under filtered colimits (Proposition 3.2.8.3).

023D Corollary 4.5.7.3. Suppose we are given a commutative diagram of simplicial sets

with the following property: for every simplex \(\sigma: \Delta^{k} \rightarrow S\), the induced map \(f_{\sigma}: \Delta^{k} \times{ }_{S} X \rightarrow\) \(\Delta^{k} \times_{S} Y\) is a categorical equivalence of simplicial sets. Then \(f\) is a categorical equivalence of simplicial sets.

Proof. We will prove the following stronger assertion: for every morphism of simplicial sets \(S^{\prime} \rightarrow S\), the induced map
\[
f_{S^{\prime}}: S^{\prime} \times_{S} X \rightarrow S^{\prime} \times_{S} Y
\]
is a categorical equivalence of simplicial sets. By virtue of Corollary 4.5.7.2 (and Remark 1.1.4.4, we may assume without loss of generality that \(S^{\prime}\) has dimension \(\leq k\) for some integer \(k \geq-1\). We proceed by induction on \(k\). In the case \(k=-1\), the simplicial set \(S^{\prime}\) is empty and there is nothing to prove. Assume therefore that \(k \geq 0\). Let \(S^{\prime \prime}\) denote the \((k-1)\)-skeleton of \(S^{\prime}\) and let \(I\) be the set of nondegenerate \(d\)-simplices of \(S^{\prime}\), so that Proposition 1.1.4.12 supplies a pushout diagram of simplicial sets

where the horizontal maps are monomorphisms. It follows that the front and back faces of the diagram

are categorical pushout squares (Proposition 4.5.4.11). Consequently, to show that \(f_{S^{\prime}}\) is a categorical equivalence, it will suffice to show that \(f_{S^{\prime \prime}}, u\), and \(v\) are categorical equivalences (Proposition 4.5.4.9). In the first two cases, this follows from our inductive hypothesis. We may therefore replace \(S^{\prime}\) by the coproduct \(\coprod_{i \in I} \Delta^{k}\), and thereby reduce to the case of a coproduct of simplices. Using Corollary 4.5.3.10, we can further reduce to the case where \(S^{\prime} \simeq \Delta^{k}\) is a standard simplex, in which case the desired result follows from our hypothesis on \(f\).

034 V Corollary 4.5.7.4. A commutative diagram of \(\infty\)-categories

is a categorical pullback square if and only if the induced diagram of Kan complexes

is a homotopy pullback square.
Proof. We proceed as in the proof of Proposition 4.5.2.14. By definition, the diagram 4.29) is a categorical pullback square if and only if the induced map \(\theta: \mathcal{C}_{01} \rightarrow \mathcal{C}_{0} \times{ }_{\mathcal{C}} \mathcal{C}_{1}\) is an equivalence of \(\infty\)-categories. Using the criterion of Theorem 4.5.7.1, we see that this is equivalent to the requirement that \(\theta\) induces a homotopy equivalence of Kan complexes \(\rho: \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}_{01}\right)^{\simeq} \rightarrow \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}_{0} \times{ }_{\mathcal{C}}^{\mathrm{h}} \mathcal{C}_{1}\right)^{\simeq}\). Using Remarks 4.5.2.6 and 4.5.2.7 we can identify \(\rho\) with the map
\[
\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}_{01}\right) \simeq \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}_{0}\right) \simeq \times_{\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right) \simeq \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}_{1}\right) \simeq}^{\simeq}
\]
determined by the commutative diagram (4.30). The desired result now follows from the criterion of Corollary 3.4.1.6.

\subsection*{4.5.8 Application: Universal Property of the Join}

Let \(\mathcal{C}\) and \(\mathcal{D}\) be categories, and let \(\mathcal{C} \star \mathcal{D}\) denote their join (Definition 4.3.2.1). Proposition 4.3.2.13 (and Remark 4.3.2.14) supplies a pushout diagram of categories.

Passing to nerves, we obtain a commutative diagram of simplicial sets

Beware that this diagram is generally not a pushout square. However, we will show in this section that it is nevertheless a categorical pushout square, in the sense of Definition 4.5.4.1 Moreover, an analogous statement holds if we replace \(\mathrm{N}_{\bullet}(\mathcal{C})\) and \(\mathrm{N}_{\bullet}(\mathcal{D})\) by arbitrary simplicial sets \(X\) and \(Y\).
Construction 4.5.8.1. Let \(X\) and \(Y\) be simplicial sets, let \(\pi_{X}: X \times Y \rightarrow X\) and \(\pi_{Y}:\)
```

01HN

``` \(X \times Y \rightarrow Y\) denote the projection maps, and let \(\iota_{X}: X \hookrightarrow X \star Y\) and \(\iota_{Y}: Y \hookrightarrow X \star Y\) denote the inclusion maps. Then there is a unique map of simplicial sets \(c: X \times \Delta^{1} \times Y \rightarrow X \star Y\) with the property that \(\left.c\right|_{X \times\{0\} \times Y}=\iota_{X} \circ \pi_{X}\) and \(\left.c\right|_{X \times\{1\} \times Y}=\iota_{Y} \circ \pi_{Y}\). Concretely, if \(\sigma=\left(\sigma_{X}, \sigma_{\Delta^{1}}, \sigma_{Y}\right)\) is an \(n\)-simplex of the product \(X \times \Delta^{1} \times Y\), then \(c(\sigma)\) is the \(n\)-simplex of \(X \star Y\) given by the composition
\[
\Delta^{n} \simeq\left(\sigma_{\Delta^{1}}^{-1}\{0\}\right) \star\left(\sigma_{\Delta^{1}}^{-1}\{1\}\right) \xrightarrow{\sigma_{X} \star \sigma_{Y}} X \star Y .
\]

We will refer to \(c: X \times \Delta^{1} \times Y \rightarrow X \star Y\) as the collapse map.
Proposition 4.5.8.2. Let \(X\) and \(Y\) be simplicial sets, and let \(c: X \times \Delta^{1} \times Y \rightarrow X \star Y\) denote the collapse map of Construction 4.5.8.1. Then the commutative diagram of simplicial sets

is a categorical pushout square.

It will be convenient to state Proposition 4.5.8.2 in a slightly different form.
01 HR Notation 4.5.8.3 (The Blunt Join). Let \(X\) and \(Y\) be simplicial sets. We let \(X \diamond Y\) denote the simplicial set given by the iterated pushout
\[
X \underset{(X \times\{0\} \times Y)}{\coprod\left(X \times \Delta^{1} \times Y\right) \coprod_{(X \times\{1\} \times Y)} Y, ~}
\]
so that we have a pushout diagram of simplicial sets

We will refer \(X \diamond Y\) as the blunt join of \(X\) and \(Y\). The commutative diagram (4.31) determines a morphism of simplicial sets \(c_{X, Y}: X \diamond Y \rightarrow X \star Y\), which we will refer to as the comparison map.

01 HS Example 4.5.8.4. Let \(X\) and \(Y\) be simplicial sets. If \(X\) is empty, then the blunt join \(X \diamond Y\) can be identified with \(Y\). If \(Y\) is empty, then the blunt join \(X \diamond Y\) can be identified with \(X\). In either case, the comparison map \(c_{X, Y}: X \diamond Y \rightarrow X \star Y\) is an isomorphism of simplicial sets.

02GG Exercise 4.5.8.5. Let \(X\) and \(Y\) be simplicial sets. Show that the comparison map \(c_{X, Y}: X \diamond Y \rightarrow X \star Y\) of Notation 4.5.8.3 is an epimorphism of simplicial sets: that is, it is surjective at the level of \(n\)-simplices for each \(n \geq 0\).

01 HT Remark 4.5.8.6 (Functoriality). The blunt join construction \((X, Y) \mapsto X \diamond Y\) determines a functor \(\diamond: \operatorname{Set}_{\Delta} \times \operatorname{Set}_{\Delta} \rightarrow \operatorname{Set}_{\Delta}\). Moreover:
- For fixed \(X\), the functor
\[
\operatorname{Set}_{\Delta} \rightarrow \operatorname{Set}_{\Delta} \quad Y \mapsto X \diamond Y
\]
preserves monomorphisms, filtered colimits and pushout diagrams.
- For fixed \(Y\), the functor
\[
\operatorname{Set}_{\Delta} \rightarrow \operatorname{Set}_{\Delta} \quad X \mapsto X \diamond Y
\]
preserves monomorphisms, filtered colimits, and pushout diagrams.

Remark 4.5.8.7. Let \(f: X \rightarrow X^{\prime}\) and \(g: Y \rightarrow Y^{\prime}\) be categorical equivalences of simplicial 01HU sets. Then the induced map \((f \diamond g): X \diamond Y \rightarrow X^{\prime} \diamond Y^{\prime}\) is also a categorical equivalence. This follows by applying Proposition 4.5.4.9 to the diagram

By virtue of Proposition 4.5.4.11, Proposition 4.5.8.2 can be restated as follows:
Theorem 4.5.8.8. Let \(X\) and \(Y\) be simplicial sets. Then the comparison map \(c_{X, Y}: 01 \mathrm{HV}\) \(X \diamond Y \rightarrow X \star Y\) of Notation 4.5.8.3 is a categorical equivalence of simplicial sets.
Corollary 4.5.8.9. Let \(f: X \rightarrow X^{\prime}\) and \(g: Y \rightarrow Y^{\prime}\) be categorical equivalences of simplicial 01 HW sets. Then the induced map \((f \star g): X \star Y \rightarrow X^{\prime} \star Y^{\prime}\) is also a categorical equivalence of simplicial sets.

Proof. We have a commutative diagram of simplicial sets

where \(f \diamond g, c_{X, Y}\), and \(c_{X^{\prime}, Y^{\prime}}\) are categorical equivalences (Remark 4.5.8.7 and Theorem 4.5.8.8. Invoking the two-out-of-three property (Remark 4.5.3.5), we conclude that \(f \star g\) is also a categorical equivalence.

The proof of Theorem 4.5.8.8 will require some preliminaries. We begin by reducing to the special case where \(X=\Delta^{1}\).

01HX Lemma 4.5.8.10. Let \(Y\) be a simplicial set, and suppose that the comparison map \(c_{\Delta^{1}, Y}\) : \(\Delta^{1} \diamond Y \rightarrow \Delta^{1} \star Y\) is a categorical equivalence. Then, for every simplicial set \(X\), the comparison map \(c_{X, Y}: X \diamond Y \rightarrow X \star Y\) is a categorical equivalence.

Proof. Throughout the proof, we regard the simplicial set \(Y\) as fixed. Let us say that a simplicial set \(X\) is good if \(c_{X, Y}\) is a categorical equivalence. We begin with some elementary observations:
(a) The collection of good simplicial sets is closed under the formation of filtered colimits (since the collection of categorical equivalences is closed under filtered colimits, by virtue of Corollary 4.5.7.2.
(b) Suppose we are given a pushout diagram of simplicial sets

where \(f\) is a monomorphism. If \(X, X(0)\), and \(X(1)\) are good, then \(X(01)\) is good. This follows by applying Proposition 4.5.4.9 to the commutative diagram

noting that the front and back squares are categorical pushouts by virtue of Example 4.5.4.12,
(c) Let \(f: X \rightarrow X^{\prime}\) be an inner anodyne morphism of simplicial sets. Then \(X\) is good if and only if \(X^{\prime}\) is good. To prove this, we observe that there is a commutative diagram of simplicial sets

By the two-out-of-three property (Remark 4.5.3.5), it will suffice to show that the morphisms \(f \diamond \operatorname{id}_{Y}\) and \(f \star \operatorname{id}_{Y}\) are categorical equivalences. In the first case, this follows from Remark 4.5.8.7. For the second, we observe that \(f \star \operatorname{id}_{Y}\) is actually inner anodyne, since it factors as a composition
\[
X \star Y \xrightarrow{u} X^{\prime} \coprod_{X}(X \star Y) \xrightarrow{v} X^{\prime} \star Y,
\]
where \(u\) is a pushout of \(f\) (hence inner anodyne because \(f\) is inner anodyne) and \(v\) is inner anodyne by virtue of Proposition 4.3.6.4.

We wish to show that if the 1 -simplex \(\Delta^{1}\) is good, then every simplicial set \(X\) is good. Writing \(X\) as the filtered colimit of its finite simplicial subsets (Remark 3.6.1.8), we can use (a) to reduce to the case where \(X\) is finite. We now proceed by induction on the dimension of \(X\). If \(X=\emptyset\), then \(c_{X, Y}\) is an isomorphism (Example 4.5.8.4). Otherwise, the simplicial set \(X\) has dimension \(n \geq 0\). We now proceed by induction on the number of nondegenerate \(n\)-simplices of \(X\). Using Proposition 1.1.4.12, we can choose a pushout diagram of simplicial sets

where \(X^{\prime} \subseteq X\) is a simplicial subset having one fewer nondegenerate \(n\)-simplex. It then follows from our inductive hypothesis that \(\partial \Delta^{n}\) and \(X^{\prime}\) are good. By virtue of (b), it will suffice to show that \(\Delta^{n}\) is good. This holds for \(n=1\) by assumption, and also for \(n=0\) because \(\Delta^{0}\) is a retract of \(\Delta^{1}\). We may therefore assume that \(n \geq 2\), so that the horn inclusion \(\Lambda_{1}^{n} \hookrightarrow \Delta^{n}\) is inner anodyne. Our inductive hypothesis guarantees that \(\Lambda_{1}^{n}\) is good, so that \(\Delta^{n}\) is good by virtue of \((c)\).

Lemma 4.5.8.11. The comparison map \(c_{\Delta^{1}, \Delta^{0}}: \Delta^{1} \diamond \Delta^{0} \rightarrow \Delta^{1} \star \Delta^{0}\) is a categorical 01 HY equivalence.

Proof. Unwinding the definitions, we can identify the blunt join \(\Delta^{1} \diamond \Delta^{0}\) with the simplicial set \(\left(\Delta^{1} \times \Delta^{1}\right) \amalg_{\Delta^{1} \times\{1\}} \Delta^{0}\), which we represent informally by the diagram

Let \(X\) denote the simplicial set \(\Delta^{2} \amalg_{\mathrm{N} \cdot(\{1<2\})} \Delta^{0}\) obtained from the standard 2-simplex by collapsing the final edge to a point. We then have an inclusion map \(\iota: X \hookrightarrow \Delta^{1} \diamond \Delta^{0}\) (corresponding to the triangle in the upper right of the preceding diagram), which fits into a pushout diagram of simplicial sets

here \(u\) classifies to the "long edge" of the 2-simplex \(\Delta^{1} \star \Delta^{0} \simeq \Delta^{2}\). Since the vertical maps are monomorphisms and \(r\) is a categorical equivalence (see Example 4.5.3.16), it follows that \(c_{\Delta^{1}, \Delta^{0}}\) is also a categorical equivalence (Remark 4.5.4.13).

01 HZ Proposition 4.5.8.12. Let \(X\) be a simplicial set. Then the comparison map \(c_{X, \Delta^{0}}\) : \(X \diamond \Delta^{0} \rightarrow X \star \Delta^{0}=X^{\triangleright}\) is a categorical equivalence of simplicial sets.

Proof. Combine Lemmas 4.5.8.10 and 4.5.8.11.
023 E Remark 4.5.8.13. We will later prove a generalization of Proposition 4.5.8.12; see Proposition 5.2.4.5.

01J0 Corollary 4.5.8.14. Let \(f: A \hookrightarrow B\) be a right anodyne morphism of simplicial sets. Then the induced map
\[
\theta: B \coprod_{A}\left(A \diamond \Delta^{0}\right) \hookrightarrow B \diamond \Delta^{0}
\]
is a categorical equivalence of simplicial sets.
Proof. Proposition 4.3.6.4 guarantees that the natural map \(B \coprod_{A} A^{\triangleright} \hookrightarrow B^{\triangleright}\) is inner anodyne, and therefore a categorical equivalence (Corollary 4.5.3.14). Using Proposition 4.5.4.11, we
conclude that the diagram

is categorical pushout square. It then follows from Theorem 4.5.8.8 and Proposition 4.5.4.9 that the equivalent diagram

is also categorical pushout square, so that \(\theta\) is a categorical equivalence by virtue of Proposition 4.5.4.11.

Proof of Theorem 4.5.8.8. Let \(X\) and \(Y\) be arbitrary simplicial sets; we wish to show that the comparison map \(c_{X, Y}: X \diamond Y \rightarrow X \star Y\) is a categorical equivalence. By virtue of Lemma 4.5.8.10, we may assume without loss of generality that \(X=\Delta^{1}\). Note that the map the \(c_{X, Y}\) fits into a commutative diagram of simplicial sets

Note that the morphism \(c_{X, \Delta^{0}} \times \operatorname{id}_{Y}\) is a categorical equivalence by virtue of Proposition 4.5.8.12 and Remark 4.5.3.7. Consequently, to show that \(c_{X, Y}\) is a categorical equivalence, it will suffice to show that the square on the right is a categorical pushout (Proposition 4.5.4.10). Note that left part of the diagram is a pushout square in which the horizontal maps are monomorphisms, hence also a categorical pushout square (Proposition 4.5.4.11). We are therefore reduced to showing that the outer rectangle is a categorical pushout square (Proposition 4.5.4.8).

Specializing now to the case \(X=\Delta^{1}\), we wish to show that the lower part of the
commutative diagram

is a categorical pushout square. We first claim that the upper square is a categorical pushout: by virtue of Proposition 4.5.4.11, this is equivalent to the assertion that the induced map
\[
\theta:\left(\Delta^{1} \times Y\right) \coprod_{\{1\} \times Y}\left(\{1\}^{\triangleright} \times Y\right) \rightarrow\left(\Delta^{1}\right)^{\triangleright} \times Y
\]
is a categorical equivalence. This follows from Remark 4.5.3.7, since \(\theta\) factors as a product of the identity map \(\operatorname{id}_{Y}\) with the inner horn inclusion \(\Lambda_{1}^{2} \hookrightarrow \Delta^{2}\). To complete the proof, it will suffice to show that the outer rectangle is a categorical pushout square. Using the criterion of Proposition 4.5.4.11, we are reduced to showing that the map
\[
\rho: \Delta^{1} \coprod_{\{1\} \times Y}\left(\{1\}^{\triangleright} \times Y\right) \rightarrow \Delta^{1} \star Y
\]
is a categorical equivalence. Unwinding the definitions, we can identify \(\rho\) with the composition
\[
\Delta^{1} \coprod_{\{1\}}(\{1\} \diamond Y) \xrightarrow{\rho^{\prime}} \Delta^{1} \coprod_{\{1\}}(\{1\} \star Y) \xrightarrow{\rho^{\prime \prime}} \Delta^{1} \star Y .
\]

Here the map \(\rho^{\prime}\) is a categorical equivalence by virtue of Proposition 4.5.8.12 (together with Remark 4.5.4.13, and the map \(\rho^{\prime \prime}\) is inner anodyne by virtue of Proposition 4.3.6.4.

\subsection*{4.5.9 Relative Exponentiation}

Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be a morphism of simplicial sets. For every vertex \(B \in \mathcal{B}\), let \(\mathcal{C}_{B}=\) \(\{B\} \times{ }_{\mathcal{B}} \mathcal{C}\) denote the corresponding fiber of \(U\). If \(\mathcal{D}\) is an \(\infty\)-category, then Theorem 1.5.3.7 guarantees that the simplicial set \(\operatorname{Fun}\left(\mathcal{C}_{B}, \mathcal{D}\right)\) is also an \(\infty\)-category. Our goal in this section is to study the dependence of this construction on the vertex \(B \in \mathcal{B}\). We begin by introducing a relative version of Construction 1.5.3.1.

Construction 4.5.9.1. Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be a morphism of simplicial sets and let \(\mathcal{D}\) be another simplicial set. For every integer \(n \geq 0\), we let \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})_{n}\) denote the collection of pairs \((\sigma, f)\), where \(\sigma\) is an \(n\)-simplex of \(\mathcal{B}\) and \(f: \Delta^{n} \times_{\mathcal{B}} \mathcal{C} \rightarrow \mathcal{D}\) is a morphism of simplicial sets. Note that every nondecreasing function \(\alpha:[m] \rightarrow[n]\) induces a map
\[
\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})_{n} \rightarrow \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})_{m} \quad(\sigma, f) \mapsto\left(\alpha^{*}(\sigma), f^{\prime}\right),
\]
where \(f^{\prime}\) denotes the composite map
\[
\Delta^{m} \times_{\mathcal{B}} \mathcal{C} \xrightarrow{\alpha \times \text { id }} \Delta^{n} \times_{\mathcal{B}} \mathcal{C} \xrightarrow{f} \mathcal{D} .
\]

This construction is compatible with composition, and therefore endows \(\left.\{\operatorname{Fun}(\mathcal{C} / \mathcal{B}), \mathcal{D})_{n}\right\}_{n \geq 0}\) with the structure of a simplicial set \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{E})\).

Note that the assignment \((\sigma, f) \mapsto \sigma\) determines a morphism of simplicial sets \(\pi\) : \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D}) \rightarrow \mathcal{B}\). Moreover, there is an evaluation map ev: \(\mathcal{C} \times_{\mathcal{B}} \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{E}) \rightarrow \mathcal{D}\), which carries an \(n\)-simplex \((\widetilde{\sigma},(\sigma, f))\) of the fiber product \(\mathcal{C} \times_{\mathcal{B}} \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{E})\) to the \(n\)-simplex of \(\mathcal{D}\) given by the composite map \(\Delta^{n} \xrightarrow{\text { id } \times \widetilde{\sigma}} \Delta^{n} \times{ }_{\mathcal{B}} \mathcal{C} \xrightarrow{f} \mathcal{D}\).

Example 4.5.9.2. Let \(\mathcal{C}\) and \(\mathcal{D}\) be simplicial sets and let \(U: \mathcal{C} \rightarrow \Delta^{0}\) denote the projection
02TT map. Then the simplicial set \(\operatorname{Fun}\left(\mathcal{C} / \Delta^{0}, \mathcal{D}\right)\) of Construction 4.5.9.1 can be identified with the simplicial set \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\) of Construction 1.5.3.1.

Example 4.5.9.3. Let \(\mathcal{C}\) and \(\mathcal{D}\) be simplicial sets and let \(U: \mathcal{C} \rightarrow \mathcal{C}\) be the identity morphjism. Then the simplicial set \(\operatorname{Fun}(\mathcal{C} / \mathcal{C}, \mathcal{D})\) of Construction 4.5.9.1 can be identified with the product \(\mathcal{C} \times \mathcal{D}\).

Example 4.5.9.4. Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be a morphism of simplicial sets. Then the projection 02 TS map \(\pi: \operatorname{Fun}\left(\mathcal{C} / \mathcal{B}, \Delta^{0}\right) \rightarrow \mathcal{B}\) is an isomorphism.

The direct image \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\) of Construction 4.5.9.1 can be characterized by a universal mapping property:

Proposition 4.5.9.5. Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be a morphism of simplicial sets and let \(\mathcal{D}\) be a 02TP simplicial set. For every morphism of simplicial sets \(\mathcal{B}^{\prime} \rightarrow \mathcal{B}\), postcomposition with the evaluation map ev : \(\mathcal{C} \times{ }_{\mathcal{B}} \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{E}) \rightarrow \mathcal{D}\) induces a bijection
\[
\operatorname{Hom}_{\left(\operatorname{Set}_{\Delta}\right)_{/ \mathcal{B}}}\left(\mathcal{B}^{\prime}, \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\right) \rightarrow \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\mathcal{C} \times_{\mathcal{B}} \mathcal{B}^{\prime}, \mathcal{D}\right)
\]

Proof. Writing \(\mathcal{B}^{\prime}\) as a colimit of simplices, we may reduce to the case where \(\mathcal{B}^{\prime}=\Delta^{n}\), so that \(\sigma\) is an \(n\)-simplex of \(\mathcal{B}\). In this case, the desired result follows immediately from the definition of the simplicial set \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\).

02TQ Remark 4.5.9.6. In the situation of Proposition 4.5.9.5, postcomposition with the evaluation map ev : \(\mathcal{C} \times_{\mathcal{B}} \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D}) \rightarrow \mathcal{D}\) induces an isomorphism of simplicial sets
\[
\operatorname{Fun}_{/ \mathcal{B}}\left(\mathcal{B}^{\prime}, \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\right) \xrightarrow{\sim} \operatorname{Fun}\left(\mathcal{C} \times{ }_{\mathcal{B}} \mathcal{B}^{\prime}, \mathcal{D}\right) .
\]

The bijectivity of this map on \(n\)-simplices follows by applying Proposition 4.5.9.5 to the product \(\mathcal{B}^{\prime} \times \Delta^{n}\).

02TU Remark 4.5.9.7. Suppose we are given a pullback diagram of simplicial sets

For every simplicial set \(\mathcal{D}\), we have a canonical isomorphism of simplicial sets Fun \(\left(\mathcal{C}^{\prime} / \mathcal{B}^{\prime}, \mathcal{D}\right) \simeq\) \(\mathcal{B}^{\prime} \times_{\mathcal{B}} \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\).
02 TV Remark 4.5.9.8. Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be a morphism of simplicial sets, let \(\mathcal{D}\) be a simplicial set, and let \(\pi: \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D}) \rightarrow \mathcal{B}\) be the projection map of Construction 4.5.9.1. For every vertex \(B \in \mathcal{B}\), Remark 4.5.9.7 and Example 4.5.9.2 supply an isomorphism of simplicial sets
\[
\pi^{-1}\{B\}=\{B\} \times_{\mathcal{B}} \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D}) \simeq \operatorname{Fun}\left(\{B\} \times_{\mathcal{B}} \mathcal{C}, \mathcal{D}\right) .
\]

Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be a morphism of simplicial sets and let \(\mathcal{D}\) be an \(\infty\)-category. It follows from Remark 4.5.9.8 Theorem 1.5.3.7 that every fiber of the projection map \(\pi\) : \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D}) \rightarrow \mathcal{B}\) is an \(\infty\)-category. Beware that \(\pi\) is generally not an inner fibration.
02TW Exercise 4.5.9.9. Let \(\mathcal{B}=\Delta^{2}\) be the standard 2-simplex and let \(\mathcal{C}=\mathrm{N}_{\bullet}(\{0<2\})\) be the long edge of \(\mathcal{C}\). Show that \(\operatorname{Fun}\left(\mathcal{C} / \mathcal{B}, \Delta^{1}\right)\) is not an \(\infty\)-category.

To avoid the behavior described in Exercise 4.5.9.9, we need to impose an additional condition on the morphism \(U: \mathcal{C} \rightarrow \mathcal{B}\).

02TX Definition 4.5.9.10. Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be a morphism of simplicial sets. We will say that \(U\) is exponentiable if it satisfies the following condition:
(*) For every diagram of simplicial sets

in which both squares are pullbacks, if \(\bar{F}\) is a categorical equivalence, then \(F\) is also a categorical equivalence.

Remark 4.5.9.11. We will be primarily interested in the special case of Definition 4.5.9.10 where \(U\) is an inner fibration of simplicial sets. In this case, Definition 4.5.9.10 can be considerably simplified: to show that an inner fibration of simplicial sets \(U: \mathcal{C} \rightarrow \mathcal{B}\) is exponentiable, it suffices to verify condition \((*)\) in the special case where \(\bar{F}: \mathcal{B}^{\prime \prime} \rightarrow \mathcal{B}^{\prime}\) is the inner horn \(\Lambda_{1}^{2} \hookrightarrow \Delta^{2}\) (see Proposition [?]).
Remark 4.5.9.12. Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) and \(V: \mathcal{D} \rightarrow \mathcal{C}\) be exponentiable morphisms of simplicial 02 TZ sets. Then the composition \((U \circ V): \mathcal{D} \rightarrow \mathcal{B}\) is also exponentiable.
Remark 4.5.9.13. Suppose we are given a pullback diagram of simplicial sets

If \(U\) is exponentiable, then \(U^{\prime}\) is also exponentiable.
Remark 4.5.9.14. The collection of exponentiable morphisms of simplicial sets is closed
02U1 under retracts. That is, if we are given a commutative diagram of simplicial sets

where \(U^{\prime}\) is exponentiable and both horizontal compositions are the identity, then \(U\) is also exponentiable.
Example 4.5.9.15. Let \(\mathcal{C}\) be any simplicial set. Then the projection map \(\mathcal{C} \rightarrow \Delta^{0}\) is 02U2 exponentiable (this is a reformulation of Remark 4.5.3.7).
Example 4.5.9.16. The inclusion map \(\mathrm{N}_{\bullet}(\{0<2\}) \hookrightarrow \Delta^{2}\) is an isofibration of \(\infty\)-categories 02U4 which is not exponentiable. Note that there is a pullback diagram of simplicial sets

where the lower horizontal map is a categorical equivalence, but the upper horizontal map is not.

The terminology of Definition 4.5.9.10 is motivated by the following:
046Q Proposition 4.5.9.17. Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be a morphism of simplicial sets. The following conditions are equivalent:
(1) The morphism \(U\) is exponentiable (Definition 4.5.9.10).
(2) For every isofibration of simplicial sets \(V: \mathcal{D} \rightarrow \mathcal{E}\), the induced map
\[
\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D}) \xrightarrow{V_{0}} \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{E})
\]
is also an isofibration of simplicial sets.
(3) For every isofibration of \(\infty\)-categories \(V: \mathcal{D} \rightarrow \mathcal{E}\), the induced map
\[
\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D}) \xrightarrow{V_{0}} \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{E})
\]
is also an isofibration.
Proof. We first show that (1) implies (2). Assume that \(U\) is exponentiable, let \(V: \mathcal{D} \rightarrow \mathcal{E}\) be an isofibration of simplicial sets, and let \(i: A \hookrightarrow B\) be a monomorphism of simplicial sets which is a categorical equivalence; we wish to show that every lifting problem

admits a solution. Note that the lower horizontal map determines a morphism of simplicial sets \(B \rightarrow \mathcal{B}\). Invoking the universal property of Proposition 4.5.9.5, we can rewrite 4.32) as a lifting problem

Because \(U\) is exponentiable, the left vertical map is a categorical equivalence of simplicial sets. Our assumption that \(V\) is an isofibration then guarantees the existence of a solution.

The implication \((2) \Rightarrow(3)\) is immediate. We will complete the proof by showing that (3) implies (1). Assume that condition (3) is satisfied and suppose that we are given a commutative diagram of simplicial sets

where both squares are pullbacks and \(\bar{F}\) is a categorical equivalence; we wish to show that \(F\) is also a categorical equivalence. By virtue of Exercise 3.1.7.11, there exists a monomorphism of simplicial sets \(\iota: \mathcal{B}^{\prime \prime} \hookrightarrow Q\), where \(Q\) is a contractible Kan complex. Replacing \(\bar{F}\) by the morphism \((\iota, \bar{F}): \mathcal{B}^{\prime \prime} \hookrightarrow Q \times \mathcal{B}^{\prime}\) (and \(F\) by the morphism \((\iota, F): \mathcal{C}^{\prime \prime} \hookrightarrow Q \times \mathcal{C}^{\prime}\) ), we can reduce to the case where \(\bar{F}\) is a monomorphism of simplicial sets, so that \(F\) is also a monomorphism of simplicial sets. To show that \(F\) is a categorical equivalence, it will suffice to show that if \(V: \mathcal{D} \rightarrow \mathcal{E}\) is an isofibration of \(\infty\)-categories, then every lifting problem

admits a solution (Proposition 4.5.5.4). Invoking the universal property of direct images (Proposition 4.5.9.5), we can rewrite 4.34) as a lifting problem

Condition (3) guarantees that the right vertical map is an isofibration, so that the solution exists by virtue of our assumption that \(\bar{F}\) is a categorical equivalence.

Corollary 4.5.9.18. Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be an exponentiable morphism of simplicial sets. For 02U8 every \(\infty\)-category \(\mathcal{D}\), the projection map \(\pi: \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D}) \rightarrow \mathcal{B}\) is an isofibration of simplicial sets.

Proof. Apply Proposition 4.5.9.17 in the special case \(\mathcal{E}=\Delta^{0}\) (see Example 4.5.9.4).

\subsection*{4.6 Morphism Spaces}
\(01 \mathrm{~J} 3 \quad\) Let \(\mathcal{C}\) be an \(\infty\)-category containing a pair of objects \(X\) and \(Y\). Recall that a morphism from \(X\) to \(Y\) is an edge \(f\) of \(\mathcal{C}\) satisfying \(d_{1}^{1}(f)=X\) and \(d_{0}^{1}(f)=Y\) (Definition 1.4.1.1). Morphisms from \(X\) to \(Y\) can be identified with vertices of a \(\operatorname{simplicial}\) set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\), given by the iterated fiber product
\[
\{X\} \times_{\operatorname{Fun}(\{0\}, \mathcal{C})} \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right) \times \times_{\operatorname{Fun}(\{1\}, \mathcal{C})}\{Y\} .
\]

In \(\S 4.6 .1\), we show that the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is a Kan complex (Proposition 4.6.1.10, , which we refer to as the space of morphisms from \(X\) to \(Y\) (Construction 4.6.1.1).

Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. We say that \(F\) is fully faithful if, for every pair of objects \(X, Y \in \mathcal{C}\), the induced map \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\) is a homotopy equivalence of Kan complexes (Definition 4.6.2.1). We say that \(F\) is essentially surjective if it induces a surjection \(\pi_{0}\left(\mathcal{C}^{\simeq}\right) \rightarrow \pi_{0}\left(\mathcal{D}^{\simeq}\right)\) on isomorphism classes of objects. In 84.6 .2 , we show that \(F\) is an equivalence of \(\infty\)-categories if and only if it is both fully faithful and essentially surjective (Theorem 4.6.2.20). This is essentially a reformulation of the criterion of Theorem 4.5.7.1. Nevertheless, it can be quite useful: the mapping spaces \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) are often more amenable to calculation than the Kan complex \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right) \simeq\).

In practice, it is often useful to work with a variant of Construction 4.6.1.1. Let \(\mathcal{C}\) be an \(\infty\)-category containing a pair of objects \(X\) and \(Y\). We define simplicial sets \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) and \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) by the formulae
\[
\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)=\mathcal{C}_{X /} \times_{\mathcal{C}}\{Y\} \quad \operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)=\{X\} \times_{\mathcal{C}} \mathcal{C}_{/ Y}
\]

We will refer to \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) as the left-pinched space of morphisms from \(X\) to \(Y\), and to \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) as the right-pinched space of morphisms from \(X\) to \(Y\). These simplicial sets are also Kan complexes, which can often be described very explicitly:
- Let \(\mathcal{C}\) be a (2,1)-category containing objects \(X\) and \(Y\), and let \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{C})\) denote the Duskin nerve of \(\mathcal{C}\) (Construction 2.3.1.1). Then there are canonical isomorphisms of simplicial sets
\[
\operatorname{Hom}_{\mathrm{N} \mathrm{D}(\mathcal{C})}^{\mathrm{L}}(X, Y) \simeq \mathrm{N}_{\bullet}\left(\underline{\operatorname{Hom}}_{\mathcal{C}}(X, Y)\right) \simeq \operatorname{Hom}_{\mathrm{N} \mathrm{D}(\mathcal{C})}^{\mathrm{R}}(X, Y)^{\mathrm{op}} ;
\]
see Example 4.6.5.13.
- Let \(\mathcal{C}\) be a differential graded category containing objects \(X\) and \(Y\), and let \(\mathrm{N}_{\bullet}^{\mathrm{dg}}(\mathcal{C})\) denote the differential graded nerve of \(\mathcal{C}\) (Definition 2.5.3.7). Then there is a canonical isomorphism of simplicial sets
\[
\operatorname{Hom}_{\mathrm{N}_{\bullet}^{\mathrm{d}}(\mathcal{C})}^{\mathrm{L}}(X, Y) \simeq \mathrm{K}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}\right),
\]
where \(\mathrm{K}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}\right)\) denotes the Eilenberg-MacLane space associated to the chain complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}\) (Example 4.6.5.15).
- Let \(\mathcal{C}\) be a locally Kan simplicial category containing a pair of objects \(X\) and \(Y\), and let \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) denote the homotopy coherent nerve of \(\mathcal{C}\) (Definition 2.4.3.5). Then there are canonical homotopy equivalences
\[
\operatorname{Hom}_{\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})}^{\mathrm{L}}(X, Y) \leftarrow \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \bullet \operatorname{Hom}_{\mathrm{N}_{\bullet}}^{\mathrm{R}}(\mathcal{C})(X, Y)^{\mathrm{op}}
\]
see Theorem 4.6.8.5. This is a special case of a more general result (where the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) • is assumed to be an \(\infty\)-category rather than a Kan complex), which we prove in \(\$ 4.6 .8\).

In \(\S 4.6 .5\), we construct comparison maps
\[
\iota_{X, Y}^{\mathrm{L}}: \operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y) \hookrightarrow \operatorname{Hom}_{\mathcal{C}}(X, Y) \quad \iota_{X, Y}^{\mathrm{R}}: \operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y) \hookrightarrow \operatorname{Hom}_{\mathcal{C}}(X, Y),
\]
which we refer to as the pinch inclusion maps, and show that they are homotopy equivalences of Kan complexes (Proposition 4.6.5.10). This follows from a more general statement about the relationship between (co)slice \(\infty\)-categories and oriented fiber products (Theorem 4.6 .4 .17 , which we formulate and prove in \(\$ 4.6 .4\). Our proof will make use of a general detection principle for natural isomorphisms of diagrams (Theorem4.6.3.8), which we explain in \(\$ 4.6 .3\).

Let \(\mathcal{C}\) be an \(\infty\)-category. In \(\S 4.6 .9\), we associate to every triple of objects \(X, Y, Z \in \mathcal{C}\) a morphism of Kan complexes
\[
\circ: \operatorname{Hom}_{\mathcal{C}}(Y, Z) \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Z),
\]
which is well-defined up to homotopy (Construction 4.6.9.9). We show that this composition law is unital and associative up to homotopy (Propositions 4.6.9.11 and 4.6.9.12), and therefore determines an enrichment of the homotopy category hC over the homotopy category of Kan complexes hKan (Construction 4.6.9.13 and Remark 4.6.9.14).

\subsection*{4.6.1 Morphism Spaces}

Let \(\mathcal{C}\) be a category. To every pair of objects \(X, Y \in \operatorname{Ob}(\mathcal{C})\), one can associate a set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) of morphisms from \(X\) to \(Y\). Our goal in this section is to explain a counterpart of this construction in the setting of \(\infty\)-categories.

Construction 4.6.1.1. Let \(\mathcal{C}\) be a simplicial set containing a pair of vertices \(X\) and \(Y\). We 01J5 let \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) denote the simplicial set given by the fiber product
\[
\{X\} \times_{\text {Fun }(\{0\}, \mathcal{C})} \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right) \times_{\text {Fun }(\{1\}, \mathcal{C})}\{Y\} .
\]

We will typically be interested in this construction only in the case where \(\mathcal{C}\) is an \(\infty\)-category; if this condition is satisfied, we will refer to \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) as the space of morphisms from \(X\) to \(Y\).

01J6 Remark 4.6.1.2. Let \(\mathcal{C}\) be an \(\infty\)-category containing a pair of objects \(X\) and \(Y\). Recall that a morphism from \(X\) to \(Y\) is an edge \(e: \Delta^{1} \rightarrow \mathcal{C}\) satisfying \(e(0)=X\) and \(e(1)=Y\) (Definition 1.4.1.1). It follows that morphisms from \(X\) to \(Y\) can be identified with vertices of the morphism space \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) of Construction 4.6.1.1

03X9 Variant 4.6.1.3 (Endomorphism Spaces). Let \(\mathcal{C}\) be an \(\infty\)-category containing an object \(X\). We let \(\operatorname{End}_{\mathcal{C}}(X)\) denote the simplicial set
\[
\operatorname{Hom}_{\mathcal{C}}(X, X)=\{X\} \times_{\mathcal{C}} \operatorname{Fun}\left(\Delta^{1} / \partial \Delta^{1}, \mathcal{C}\right) .
\]

We will refer to \(\operatorname{End}_{\mathcal{C}}(X)\) as the space of endomorphisms of \(X\). Note that vertices of the simplicial set \(\operatorname{End}_{\mathcal{C}}(X)\) can be identified with endomorphisms of \(X\), in the sense of Definition 1.4.1.5

01 J 7 Example 4.6.1.4. Let \(\mathcal{C}\) be an ordinary category containing objects \(X\) and \(Y\), which we will identify with objects of the \(\infty\)-category \(\mathrm{N}_{\bullet}(\mathcal{C})\). Then the morphism space \(\operatorname{Hom}_{\mathrm{N}_{\bullet}(\mathcal{C})}(X, Y)\) of Construction 4.6.1.1 can be identified with the constant simplicial set having the value \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) (see Example4.6.4.6). In particular, when \(X=Y\) we can identify the simplicial set \(\operatorname{End}_{\mathrm{N}_{\mathbf{0}}(\mathcal{C})}(X)=\operatorname{Hom}_{\mathrm{N} \cdot(\mathcal{C})}(X, X)\) with the endomorphism monoid \(\operatorname{End}_{\mathcal{C}}(X)\) of Example 1.3.2.2.

01J8 Example 4.6.1.5. Let \(X\) be a topological space containing a pair of points \(x\) and \(y\), which we regard as objects of the \(\infty\)-category \(\operatorname{Sing}\). \((X)\). Then we have a canonical isomorphism of Kan complexes
\[
\operatorname{Hom}_{\text {Sing. }}(X)(x, y) \simeq \operatorname{Sing}_{\bullet}\left(P_{x, y}\right),
\]
where \(P_{x, y}\) denotes the topological space of continuous paths \(p:[0,1] \rightarrow X\) satisfying \(p(0)=x\) and \(p(1)=y\) (equipped with the compact-open topology). Setting \(x=y\), we obtain an isomorphism \(\operatorname{End}_{\operatorname{Sing} \bullet}(X)(x)=\operatorname{Sing}(\Omega(X))\), where \(\Omega(X)\) is the based loop space of \(X\). See Example 3.4.0.5.

01 J9 Example 4.6.1.6. Let \(\mathcal{C}\) and \(\mathcal{D}\) be \(\infty\)-categories, so that the join \(\mathcal{C} \star \mathcal{D}\) is also an \(\infty\)-category (Corollary 4.3.3.25). Then the morphism spaces in \(\mathcal{C} \star \mathcal{D}\) are described by the formula
\[
\operatorname{Hom}_{\mathcal{C} * \mathcal{D}}(X, Y) \simeq \begin{cases}\operatorname{Hom}_{\mathcal{C}}(X, Y) & \text { if } X, Y \in \mathcal{C} \\ \operatorname{Hom}_{\mathcal{D}}(X, Y) & \text { if } X, Y \in \mathcal{D} \\ \Delta^{0} & \text { if } X \in \mathcal{C}, Y \in \mathcal{D} \\ \emptyset & \text { if } X \in \mathcal{D}, Y \in \mathcal{C}\end{cases}
\]

Example 4.6.1.7. Let \(\mathcal{C}\) be a simplicial set containing vertices \(X\) and \(Y\). Let \(K\) be a 01JA simplicial set, and let \(\underline{X}, \underline{Y}: K \rightarrow \mathcal{C}\) be the constant maps taking the values \(X\) and \(Y\), respectively. Then there is a canonical isomorphism of simplicial sets
\[
\operatorname{Hom}_{\operatorname{Fun}(K, \mathcal{C})}(\underline{X}, \underline{Y}) \simeq \operatorname{Fun}\left(K, \operatorname{Hom}_{\mathcal{C}}(X, Y)\right) .
\]

Remark 4.6.1.8. Let \(\mathcal{C}\) be a simplicial set containing vertices \(X\) and \(Y\), which we also 01JB regard as vertices of the opposite simplicial set \(\mathcal{C}^{\text {op }}\). Then there is a canonical isomorphism of simplicial sets \(\operatorname{Hom}_{\mathcal{C}}{ }^{\circ \mathrm{p}}(X, Y) \simeq \operatorname{Hom}_{\mathcal{C}}(Y, X)^{\mathrm{op}}\).

Remark 4.6.1.9. Let \(\left\{\mathcal{C}_{i}\right\}_{i \in I}\) be a collection of \(\infty\)-categories having a product \(\mathcal{C}=\prod_{i \in I} \mathcal{C}_{i}\). 034Y Let \(X\) and \(Y\) be objects of \(\mathcal{C}\), which we identify with collections \(\left\{X_{i} \in \mathcal{C}_{i}\right\}_{i \in I}\) and \(\left\{Y_{i} \in \mathcal{C}_{i}\right\}_{i \in I}\), respectively. Then there is a canonical isomorphism of simplicial sets
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \simeq \prod_{i \in I} \operatorname{Hom}_{\mathcal{C}_{i}}\left(X_{i}, Y_{i}\right) .
\]

Proposition 4.6.1.10. Let \(\mathcal{C}\) be an \(\infty\)-category. For every pair of objects \(X, Y \in \mathcal{C}\), the 01 JC morphism space \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is a Kan complex.

Proposition 4.6.1.10 is a special case of the following more general assertion:
Proposition 4.6.1.11. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(B\) be a simplicial set, let \(A \subseteq B\) be a 01P1 simplicial subset which contains every vertex of \(B\), and let \(f: A \rightarrow \mathcal{C}\) be a diagram. Then the fiber product \(\operatorname{Fun}(B, \mathcal{C}) \times_{\operatorname{Fun}(A, \mathcal{C})}\{f\}\) is a Kan complex.

Proof. Corollary 4.4.5.3 guarantees the restriction map \(\theta: \operatorname{Fun}(B, \mathcal{C}) \rightarrow \operatorname{Fun}(A, \mathcal{C})\) is an isofibration, so that the fiber \(\operatorname{Fun}(B, \mathcal{C}) \times_{\operatorname{Fun}(A, \mathcal{C})}\{f\}\) is an \(\infty\)-category. To show that it is a Kan complex, it will suffice to show that every morphism \(u\) in \(\operatorname{Fun}(B, \mathcal{C}) \times_{\operatorname{Fun}(A, \mathcal{C})}\{f\}\) is an isomorphism (Proposition 4.4.2.1). By virtue of Corollary 4.4.3.20, this is equivalent to the assertion that the image of \(u\) in the \(\infty\)-category \(\operatorname{Fun}(B, \mathcal{C})\) is an isomorphism. This follows from Theorem 4.4.4.4, since for every vertex \(b \in B\), the evaluation functor
\[
\operatorname{ev}_{b}: \operatorname{Fun}(B, \mathcal{C}) \rightarrow \operatorname{Fun}(\{b\}, \mathcal{C}) \simeq \mathcal{C}
\]
factors through \(\operatorname{Fun}(A, \mathcal{C})\) and therefore carries \(u\) to the identity morphism \(\operatorname{id}_{f(b)}\).
Remark 4.6.1.12. Let \(\mathcal{C}\) be an \(\infty\)-category containing a pair of morphisms \(f, g: X \rightarrow Y\) 01JD having the same source and target. Then \(f\) and \(g\) are homotopic (Definition 1.4.3.1) if and only if they belong to the same connected component of the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) : this follows from the characterization of Corollary 1.4.3.7. Consequently, we obtain a bijection \(\operatorname{Hom}_{\mathrm{h}}(X, Y) \simeq \pi_{0}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)\right)\).

01JE Example 4.6.1.13 (Loop Spaces). Let ( \(X, x\) ) be a pointed Kan complex. The Kan complex \(\operatorname{Hom}_{X}(x, x)\) is often denoted by \(\Omega(X)\) and referred to as the based loop space of \(X\). Note that it can be identified with the fiber over \(x\) of the evaluation map
\[
q:\{x\} \times_{\operatorname{Fun}(\{0\}, X)} \operatorname{Fun}\left(\Delta^{1}, X\right) \rightarrow \operatorname{Fun}(\{1\}, X)=X .
\]

By virtue of Example 3.1.7.10, this map is a Kan fibration whose domain is a contractible Kan complex. It follows that the long exact sequence of Theorem 3.2.6.1 yields isomorphisms \(\pi_{n}\left(\operatorname{Hom}_{X}(x, x), \operatorname{id}_{x}\right) \simeq \pi_{n+1}(X, x)\) for \(n \geq 0\).

046R Remark 4.6.1.14 (Morphism Spaces in Homotopy Fiber Products). Let \(F_{0}: \mathcal{C}_{0} \rightarrow \mathcal{C}\) and \(F_{1}: \mathcal{C}_{1} \rightarrow \mathcal{C}\) be functors of \(\infty\)-categories. Let \(X_{0}, Y_{0} \in \mathcal{C}_{0}\) and \(X_{1}, Y_{1} \in \mathcal{C}_{1}\) be objects having the same images \(F_{0}\left(X_{0}\right)=X=F_{1}\left(X_{1}\right)\) and \(F_{0}\left(Y_{0}\right)=Y=F_{1}\left(Y_{1}\right)\) in \(\mathcal{C}\), so that \(X_{01}=\left(X_{0}, X_{1}, \mathrm{id}_{X}\right)\) and \(Y_{01}=\left(Y_{0}, Y_{1}, \mathrm{id}_{Y}\right)\) can be viewed as objects of the homotopy fiber product \(\mathcal{C}_{01}=\mathcal{C}_{0} \times{ }_{\mathcal{C}}^{\mathrm{h}} \mathcal{C}_{1}\) (see Construction 4.5.2.1). Then the mapping space \(\operatorname{Hom}_{\mathcal{C}_{01}}\left(X_{01}, Y_{01}\right)\) can be identified with the homotopy fiber product of Kan complexes
\[
\operatorname{Hom}_{\mathcal{C}_{0}}\left(X_{0}, Y_{0}\right) \times{ }_{\operatorname{Hom}_{\mathcal{C}}(X, Y)}^{\mathrm{h}} \operatorname{Hom}_{\mathcal{C}_{1}}\left(X_{1}, Y_{1}\right) .
\]

It will sometimes be convenient to work with a relative version of Construction 4.6.1.1
01P2 Construction 4.6.1.15. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets, let \(X\) and \(Y\) be vertices of \(\mathcal{C}\), and let \(e: q(X) \rightarrow q(Y)\) be an edge of the simplicial set \(\mathcal{D}\). We let \(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{e}\) denote the fiber product \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \times_{\operatorname{Hom}_{\mathcal{D}}(q(X), q(Y))}\{e\}\), which we regard as a simplicial subset of \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\).
01P3 Example 4.6.1.16. In the situation of Construction 4.6.1.15. suppose that the simplicial \(\operatorname{Hom}_{\mathcal{D}}(q(X), q(Y))\) is isomorphic to \(\Delta^{0}\) (this condition is satisfied, for example, if \(\mathcal{D}\) is the nerve of a partially ordered set). Then the inclusion map \(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{e} \hookrightarrow \operatorname{Hom}_{\mathcal{C}}(X, Y)\) is an isomorphism.

01P4 Example 4.6.1.17. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets and let \(X\) and \(Y\) be vertices of \(\mathcal{C}\) having the same image \(D=q(X)=q(Y)\) in \(\mathcal{D}\). Then we have a canonical isomorphism of simplicial sets
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y)_{\mathrm{id}_{D}} \simeq \operatorname{Hom}_{\mathcal{C}_{D}}(X, Y),
\]
where \(\mathcal{C}_{D}=\{D\} \times_{\mathcal{D}} \mathcal{C}\) denotes the fiber of \(q\) over the vertex \(D\).
01 P5 Remark 4.6.1.18. Suppose we are given a pullback diagram of simplicial sets

Let \(X\) and \(Y\) be vertices of \(\mathcal{C}\), and let \(e: q(X) \rightarrow q(Y)\) be an edge of the simplicial set \(\mathcal{D}\). Then composition with \(F\) induces an isomorphism of simplicial sets
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y)_{e} \rightarrow \operatorname{Hom}_{\mathcal{C}^{\prime}}(F(X), F(Y))_{\bar{F}(e)} .
\]

Remark 4.6.1.19. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets, let \(X\) and \(Y\) be vertices of \(\mathcal{C}\), and let \(e: q(X) \rightarrow q(Y)\) be an edge of \(\mathcal{D}\). Form a pullback diagram of simplicial sets

so that \(X\) lifts uniquely to a vertex \(\widetilde{X} \in \mathcal{C}^{\prime}\) lying over the vertex \(0 \in \Delta^{1}\), and \(Y\) lifts uniquely to a vertex \(\tilde{Y} \in \mathcal{C}^{\prime}\) lying over the vertex \(1 \in \Delta^{1}\). Remark 4.6.1.18 and Example 4.6.1.16 supply isomorphisms
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y)_{e} \simeq \operatorname{Hom}_{\mathcal{C}^{\prime}}(\tilde{X}, \tilde{Y})_{\mathrm{id}_{\Delta^{1}}}=\operatorname{Hom}_{\mathcal{C}^{\prime}}(\tilde{X}, \tilde{Y})
\]

Proposition 4.6.1.20. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of simplicial sets, let \(X\) and \(Y\) be 01P7 vertices of \(\mathcal{C}\), and let \(e: q(X) \rightarrow q(Y)\) be an edge of \(\mathcal{D}\). Then the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{e}\) is a Kan complex.

Proof. Form a pullback diagram of simplicial sets

Since \(q\) is an inner fibration, the morphism \(q^{\prime}\) is also an inner fibration (Remark 4.1.1.5), so that \(\mathcal{C}^{\prime}\) is an \(\infty\)-category (Remark 4.1.1.9). Remark 4.6.1.19 then supplies an isomorphism of \(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{e}\) with a simplicial set of the form \(\operatorname{Hom}_{\mathcal{C}^{\prime}}(\tilde{X}, \widetilde{Y})\), which is a Kan complex by virtue of Proposition 4.6.1.10.

In the special case where \(\mathcal{D}\) is an \(\infty\)-category, we can prove a slightly stronger assertion:
Proposition 4.6.1.21. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories and let \(X\) 01P8 and \(Y\) be objects of \(\mathcal{C}\). Then the induced map \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(q(X), q(Y))\) is a Kan fibration of simplicial sets.

01P9 Remark 4.6.1.22. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories, let \(X\) and \(Y\) be objects of \(\mathcal{C}\), and let \(e: q(X) \rightarrow q(Y)\) be a morphism in \(\mathcal{D}\). By construction, we have a pullback diagram of simplicial sets

It follows from Proposition 4.6.1.21 that the vertical maps in this diagram are Kan fibrations, so that 4.35 is also a homotopy pullback square. Stated more informally, we have a homotopy fiber sequence
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y)_{e} \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(q(X), q(Y)) .
\]

Proposition 4.6.1.21 is an immediate consequence of the following more general assertion:
01PC Proposition 4.6.1.23. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories, let \(B\) be \(a\) simplicial set, let \(A \subseteq B\) be a simplicial subset which contains every vertex of \(B\), and let \(f: A \rightarrow \mathcal{C}\) be a diagram. Then the induced map
\[
\operatorname{Fun}(B, \mathcal{C}) \times_{\operatorname{Fun}(A, \mathcal{C})}\{f\} \rightarrow \operatorname{Fun}(B, \mathcal{D}) \times_{\operatorname{Fun}(A, \mathcal{D})}\{q \circ f\}
\]
is a Kan fibration of simplicial sets.
Proof. It follows from Proposition 4.6.1.10 that the simplicial sets \(\operatorname{Fun}(B, \mathcal{C}) \times{ }_{\operatorname{Fun}(A, \mathcal{C})}\{f\}\) and \(\operatorname{Fun}(B, \mathcal{D}) \times_{\operatorname{Fun}(A, \mathcal{D})}\{q \circ f\}\) are Kan complexes. It will therefore suffice to show that \(\theta\) is an isofibration (Corollary 4.4.3.10). This follows from the observation that \(\theta\) is a pullback of the restriction map
\[
\operatorname{Fun}(B, \mathcal{C}) \rightarrow \operatorname{Fun}(B, \mathcal{D}) \times_{\operatorname{Fun}(A, \mathcal{D})} \operatorname{Fun}(A, \mathcal{C}),
\]
which is an isofibration by virtue of Variant 4.4.5.11.
Proof of Proposition 4.6.1.21. Apply Proposition 4.6.1.23 in the special case \(B=\Delta^{1}\) and \(A=\partial \Delta^{1}\).

01PB Exercise 4.6.1.24. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be an isofibration of simplicial sets, and let \(X\) and \(Y\) vertices of \(\mathcal{C}\). Show that the induced map \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(q(X), q(Y))\) is a Kan fibration.

\subsection*{4.6.2 Fully Faithful and Essentially Surjective Functors}

Let \(\mathcal{C}\) and \(\mathcal{D}\) be categories. Recall that a functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) is an equivalence of categories 01JG if and only if it satisfies the following pair of conditions:
(1) The functor \(F\) is fully faithful: that is, for every pair of objects \(X, Y \in \mathcal{C}\), the induced \(\operatorname{map} \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\) is bijective.
(2) The functor \(F\) is essentially surjective: that is, for every object \(X \in \mathcal{D}\), there exists an object \(Y \in \mathcal{C}\) and an isomorphism \(X \simeq F(Y)\) in the category \(\mathcal{D}\).

Our goal in this section is to give an analogous characterization of equivalences in the setting of \(\infty\)-categories (Theorem 4.6.2.20). We begin by formulating \(\infty\)-categorical analogues of conditions (1) and (2).

Definition 4.6.2.1. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. We say that \(F\) is fully faithful if, for every pair of objects \(X, Y \in \mathcal{C}\), the induced map of morphism spaces \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\) is a homotopy equivalence of Kan complexes.
Example 4.6.2.2. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a full subcategory (Definition
01JH -

01 JJ 4.1.2.15). Then the inclusion \(\operatorname{map} \iota: \mathcal{C}^{\prime} \hookrightarrow \mathcal{C}\) is fully faithful. In fact, for every pair of objects \(X, Y \in \mathcal{C}^{\prime}\), the inclusion \(\iota\) induces an isomorphism of simplicial sets \(\operatorname{Hom}_{\mathcal{C}^{\prime}}(X, Y) \simeq\) \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\).
Example 4.6.2.3. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between ordinary categories. Then \(F\) is fully faithful if and only if the induced map \(\mathrm{N}_{\bullet}(F): \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{D})\) is fully faithful (in the sense of Definition 4.6.2.1). Consequently, we can regard Definition 4.6.2.1 as a generalization of the classical notion of fully faithful functor.
Remark 4.6.2.4. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between \(\infty\)-categories, so that \(F\) induces a functor of homotopy categories \(f: \mathrm{hC} \rightarrow \mathrm{h} \mathcal{D}\). If \(F\) is fully faithful, then \(f\) is also fully faithful (see Remark 4.6.1.12). Beware that the converse is generally false.
Remark 4.6.2.5 (Transitivity). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories, 01JM where \(G\) is fully faithful. Then \(F\) is fully faithful if and only if \(G \circ F\) is fully faithful. In particular, the collection of fully faithful functors is closed under composition.
Remark 4.6.2.6. Suppose we are given a commutative diagram of \(\infty\)-categories

Combining Remark 4.6.1.14 with Corollary 3.4.1.6, we see that the following conditions are equivalent:
(1) The diagram (4.36) induces a fully faithful functor from \(\mathcal{C}_{01}\) to the homotopy fiber product \(\mathcal{C}_{0} \times{ }_{\mathcal{C}}^{\mathrm{h}} \mathcal{C}_{1}\).
(2) For every object \(X_{01} \in \mathcal{C}_{01}\) having images \(X_{0} \in \mathcal{C}_{0}, X_{1} \in \mathcal{C}_{1}, X \in \mathcal{C}\) and every object \(Y_{01} \in \mathcal{C}_{01}\) having images \(Y_{0} \in \mathcal{C}_{0}, Y_{1} \in \mathcal{C}_{1}, Y \in \mathcal{C}\), the diagram of Kan complexes

is a homotopy pullback square.
In particular, if (4.36) is a categorical pullback diagram, then it satisfies condition (2).
Remark 4.6.2.7. Suppose we are given a categorical pullback diagram of \(\infty\)-categories

If \(F^{\prime}\) is fully faithful, then \(F\) is fully faithful (see Remark 4.6.2.6 and Corollary 3.4.1.5.
01PD Proposition 4.6.2.8. Suppose we are given a commutative diagram of \(\infty\)-categories

Assume that the functors \(q\) and \(q^{\prime}\) are inner fibrations and that the functors \(F\) and \(\bar{F}\) are fully faithful. Then, for every object \(D \in \mathcal{D}\), the induced functor \(F_{D}: \mathcal{C}_{D} \rightarrow \mathcal{C}_{\bar{F}(D)}^{\prime}\) is fully faithful.

Proof. Let \(X\) and \(Y\) be objects of the \(\infty\)-category \(\mathcal{C}_{D}\). We then have a cubical diagram of

Kan complexes

The front and back faces of this diagram are homotopy pullback squares (Remark 4.6.1.22), the comparison maps
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y)) \quad \operatorname{Hom}_{\mathcal{D}}(D, D) \rightarrow \operatorname{Hom}_{\mathcal{D}}(\bar{F}(D), \bar{F}(D))
\]
are homotopy equivalences by virtue of our assumptions that \(F\) and \(\bar{F}\) are fully faithful, and the map of singletons \(\left\{\operatorname{id}_{D}\right\} \rightarrow\left\{\operatorname{id}_{\bar{F}(D)}\right\}\) is an isomorphism. Applying Corollary 3.4.1.12, we conclude that the comparison map \(\operatorname{Hom}_{\mathcal{C}_{D}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{C}_{\bar{F}(D)}^{\prime}}(F(X), F(Y))\) is also a homotopy equivalence.

Proposition 4.6.2.9. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a fully faithful functor of \(\infty\)-categories. Then \(F\) is 01 JN conservative (Definition 4.4.2.7). That is, if \(u: X \rightarrow Y\) is a morphism in \(\mathcal{C}\) for which \(F(u)\) is an isomorphism in the \(\infty\)-category \(\mathcal{D}\), then \(u\) is an isomorphism in the \(\infty\)-category \(\mathcal{C}\).

Proof. Let \(\bar{v}: F(Y) \rightarrow F(X)\) be a homotopy inverse to \(F(u)\). Since \(F\) is fully faithful, the natural map \(\operatorname{Hom}_{\mathcal{C}}(Y, X) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(Y), F(X))\) is a homotopy equivalence. We may therefore assume without loss of generality that \(\bar{v}=F(v)\), for some morphism \(v: Y \rightarrow X\) in the \(\infty\)-category \(\mathcal{C}\). Let \(v \circ u\) be a composition of \(u\) and \(v\) in the \(\infty\)-category \(\mathcal{C}\). Since \(F(u)\) is homotopy inverse to \(F(v)\), the morphism \(F(v \circ u)\) is homotopic to \(\mathrm{id}_{F(C)}=F\left(\mathrm{id}_{C}\right)\). Since the map \(\operatorname{Hom}_{\mathcal{C}}(X, X) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(X))\) is a homotopy equivalence, it follows that \(v \circ u\) is homotopic to \(\mathrm{id}_{C}\) : that is, \(v\) is a left homotopy inverse to \(u\). A similar argument (with the roles of \(u\) and \(v\) reversed) shows that \(v\) is also a right homotopy inverse to \(u\). It follows that \(u\) is an isomorphism.

01JP Corollary 4.6.2.10. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a fully faithful functor of \(\infty\)-categories. Then the induced map of cores \(\mathcal{C}^{\simeq} \rightarrow \mathcal{D}^{\simeq}\) is also fully faithful.

Proof. Fix objects \(X, Y \in \mathcal{C}^{\simeq}\). Our assumption that \(F\) is fully faithful guarantees that the induced map \(\theta: \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\) is a homotopy equivalence of Kan complexes. By virtue of Proposition 4.6.2.9, \(\theta\) restricts to a homotopy equivalence from the summand of \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) spanned by the isomorphisms from \(X\) to \(Y\) to the summand of \(\operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\) spanned by the isomorphisms from \(F(X)\) to \(F(Y)\). Unwinding the definitions, we conclude that \(F^{\simeq}\) induces a homotopy equivalence \(\operatorname{Hom}_{\mathcal{C}} \simeq(X, Y) \rightarrow\) \(\operatorname{Hom}_{\mathcal{D}} \simeq(F(X), F(Y))\).

01JQ Definition 4.6.2.11. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. The essential image of \(F\) is the full subcategory of \(\mathcal{D}\) spanned by those objects \(D \in \mathcal{D}\) for which there exists an object \(C \in \mathcal{C}\) and an isomorphism \(F(C) \simeq D\). We say that \(F\) is essentially surjective if its essential image is the entire \(\infty\)-category \(\mathcal{D}\) : that is, if the map of sets \(\pi_{0}\left(\mathcal{C}^{\simeq}\right) \rightarrow \pi_{0}\left(\mathcal{D}^{\simeq}\right)\) is surjective.

01JR Remark 4.6.2.12. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, and let \(\mathcal{D}^{\prime} \subseteq \mathcal{D}\) be the essential image of \(F\). Then \(\mathcal{D}^{\prime}\) is a replete full subcategory of \(\mathcal{D}\), and \(F\) can be regarded as an essentially surjective functor from \(\mathcal{C}\) to \(\mathcal{D}^{\prime}\). Moreover, the essential image \(\mathcal{D}^{\prime}\) is uniquely determined by these properties.

01JS Remark 4.6.2.13. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between \(\infty\)-categories. Then \(F\) is essentially surjective if and only if the induced functor of homotopy categories \(f: \mathrm{h} \mathcal{C} \rightarrow \mathrm{h} \mathcal{D}\) is essentially surjective (in the sense of classical category theory).

01JT Remark 4.6.2.14. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between \(\infty\)-categories. Then \(F\) is essentially surjective if and only if the induced map of Kan complexes \(F^{\simeq}: \mathcal{C}^{\simeq} \rightarrow \mathcal{D}^{\simeq}\) is essentially surjective.

01JU Example 4.6.2.15. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between ordinary categories. Then \(F\) is essentially surjective if and only if the induced map \(\mathrm{N}_{\bullet}(F): \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{D})\) is an essentially surjective functor of \(\infty\)-categories (in the sense of Definition 4.6.2.11).

01JV Example 4.6.2.16. Let \(f: X \rightarrow Y\) be a morphism of Kan complexes. Then \(f\) is essentially surjective (in the sense of Definition 4.6.2.11) if and only if the induced map \(\pi_{0}(f): \pi_{0}(X) \rightarrow \pi_{0}(Y)\) is a surjection.

01JW Remark 4.6.2.17 (Transitivity). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories. If \(F\) and \(G\) are essentially surjective, then the composition \(G \circ F\) is essentially surjective. Conversely, if \(G \circ F\) is essentially surjective, then \(G\) is essentially surjective.

Remark 4.6.2.18. Suppose we are given a categorical pullback diagram of \(\infty\)-categories 0573

If \(F\) is essentially surjective, then \(F^{\prime}\) is essentially surjective. This follows from Proposition 4.5.2.14 and Corollary 3.5.1.24

Remark 4.6.2.19. Suppose we are given a commutative diagram of \(\infty\)-categories

satisfying the following conditions:
(a) The functor \(q\) is an inner fibration and \(q^{\prime}\) is an isofibration.
(b) The functor \(\bar{F}\) is essentially surjective.
(c) For each object \(D \in \mathcal{D}\), the induced functor \(F_{D}: \mathcal{C}_{D} \rightarrow \mathcal{C}_{\bar{F}(D)}^{\prime}\) is essentially surjective.

Then the functor \(F\) is essentially surjective. To prove this, consider an arbitrary object \(Z \in \mathcal{C}^{\prime}\). Assumption (b) guarantees that there exists an object \(D \in \mathcal{D}\) and an isomorphism \(\bar{u}: \bar{F}(D) \rightarrow q^{\prime}(Z)\) in the \(\infty\)-category \(\mathcal{D}^{\prime}\). Assumption (a) guarantees that we can lift \(\bar{u}\) to an isomorphism \(u: Y \rightarrow Z\) in the \(\infty\)-category \(\mathcal{C}^{\prime}\), where \(Y\) belongs to the fiber \(\mathcal{C}_{\bar{F}(D)}^{\prime}\). Applying (c), we can choose an object \(X \in \mathcal{C}_{D}\) and an isomorphism \(v: F(X) \rightarrow Y\) in the \(\infty\)-category \(\mathcal{C}_{\bar{F}(D)}^{\prime}\). It follows that \(Z\) is isomorphic to \(F(X)\) in the \(\infty\)-category \(\mathcal{C}^{\prime}\).

Theorem 4.6.2.20. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be functor of \(\infty\)-categories. Then \(F\) is an equivalence 01JX of \(\infty\)-categories if and only if it is fully faithful and essentially surjective.

We begin by considering the special case of Theorem 4.6.2.20 where \(\mathcal{C}\) and \(\mathcal{D}\) are Kan complexes.

Lemma 4.6.2.21. Let \(f: X \rightarrow Y\) be a morphism of Kan complexes which is fully faithful 01JY and essentially surjective. Then \(f\) is a homotopy equivalence.

Proof. Since \(f\) is essentially surjective, the underlying map of connected components \(\pi_{0}(f)\) : \(\pi_{0}(X) \rightarrow \pi_{0}(Y)\) is surjective. We claim that it is also injective. To prove this, suppose that \(x\) and \(x^{\prime}\) are vertices of \(X\) such that \(f(x)\) and \(f\left(x^{\prime}\right)\) belong to the same connected component of \(Y\). Then the morphism space \(\operatorname{Hom}_{Y}\left(f(x), f\left(x^{\prime}\right)\right)\) is nonempty. Since \(f\) is fully faithful, it induces a homotopy equivalence \(\operatorname{Hom}_{X}\left(x, x^{\prime}\right) \rightarrow \operatorname{Hom}_{Y}\left(f(x), f\left(x^{\prime}\right)\right)\). It follows that \(\operatorname{Hom}_{X}\left(x, x^{\prime}\right)\) is nonempty, so that \(x\) and \(x^{\prime}\) belong to the same connected component of \(X\). This completes the proof that \(\pi_{0}(f)\) is a bijection.

By virtue of Whitehead's theorem (Theorem 3.2.7.1), it will suffice to show that for every vertex \(x \in X\) having image \(y=f(x) \in Y\) and every integer \(n \geq 0\), the induced map \(\theta\) : \(\pi_{n+1}(X, x) \rightarrow \pi_{n+1}(Y, y)\) is an isomorphism. Using Example 4.6.1.13. we can identify \(\theta\) with the natural map \(\pi_{n}\left(\operatorname{Hom}_{X}(x, x), \operatorname{id}_{x}\right) \rightarrow \pi_{n}\left(\operatorname{Hom}_{Y}(y, y), \operatorname{id}_{y}\right)\), which is bijective by virtue of our assumption that \(f\) induces a homotopy equivalence \(\operatorname{Hom}_{X}(x, x) \rightarrow \operatorname{Hom}_{Y}(y, y)\).

Proof of Theorem 4.6.2.20. Assume first that \(F: \mathcal{C} \rightarrow \mathcal{D}\) is an equivalence of \(\infty\)-categories. Then \(F\) induces a homotopy equivalence of Kan complexes \(F^{\simeq}: \mathcal{C}^{\simeq} \rightarrow \mathcal{D}^{\simeq}\) (Remark 4.5.1.19). Passing to connected components, we conclude that the induced map \(\pi_{0}\left(\mathcal{C}^{\simeq}\right) \rightarrow \pi_{0}\left(\mathcal{D}^{\simeq}\right)\) is bijective. In particular, \(F\) is essentially surjective. We have a commutative diagram of Kan complexes

where the horizontal maps are homotopy equivalences (Theorem 4.5.7.1) and the vertical maps are Kan fibrations (Corollary 4.4.5.4. Applying Proposition 3.2.8.1. we conclude that for every vertex \((X, Y) \in \operatorname{Fun}\left(\partial \Delta^{1}, \mathcal{C}\right)^{\simeq}\), the induced map of fibers
\[
\begin{aligned}
\operatorname{Hom}_{\mathcal{C}}(X, Y) & =\{(X, Y)\} \times_{\operatorname{Fun}\left(\partial \Delta^{1}, \mathcal{C}\right) \simeq} \simeq \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)^{\simeq} \\
& \rightarrow\{(X, Y)\} \times_{\operatorname{Fun}\left(\partial \Delta^{1}, \mathcal{D}\right) \simeq} \operatorname{Fun}\left(\Delta^{1}, \mathcal{D}\right)^{\simeq} \\
& =\operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))
\end{aligned}
\]
is a homotopy equivalence. It follows that \(F\) is fully faithful.
Now suppose that \(F: \mathcal{C} \rightarrow \mathcal{D}\) is a functor of \(\infty\)-categories which is fully faithful and essentially surjective. Using Corollary 4.6.2.10 and Remark 4.6.2.14 we see that the induced map \(F^{\simeq}: \mathcal{C}^{\simeq} \rightarrow \mathcal{D}^{\simeq}\) is also fully faithful and essentially surjective, and is therefore a homotopy equivalence of Kan complexes (Lemma 4.6.2.21). It follows that the morphism \(\theta_{0}\) in (4.37) is a homotopy equivalence of Kan complexes. Combining our assumption that \(F\) is fully faithful with Proposition 3.2.8.1, we conclude that \(\theta\) is also a homotopy equivalence. Applying Theorem 4.5.7.1, we conclude that \(F\) is an equivalence of \(\infty\)-categories.

Corollary 4.6.2.22. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, and let \(\mathcal{D}^{\prime} \subseteq \mathcal{D}\) be the 01 KO essential image of \(F\). Then \(F\) is fully faithful if and only if it induces an equivalence of \(\infty\)-categories \(\mathcal{C} \rightarrow \mathcal{D}^{\prime}\).

Corollary 4.6.2.23. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a fully faithful functor of \(\infty\)-categories. Then, for 04Q6 every simplicial set \(K\), the induced map \(\operatorname{Fun}(K, \mathcal{C}) \xrightarrow{F \circ} \operatorname{Fun}(K, \mathcal{D})\) is also fully faithful.

Proof. Using Corollary 4.6.2.22, we can replace \(\mathcal{C}\) by its essential image and thereby reduce to the case where \(F: \mathcal{C} \hookrightarrow \mathcal{D}\) is the inclusion of a full subcategory. In this case, the induced map \(\operatorname{Fun}(K, \mathcal{C}) \xrightarrow{F_{0}} \operatorname{Fun}(K, \mathcal{D})\) is also the inclusion of a full subcategory, and therefore automatically fully faithful (Example 4.6.2.2).

Corollary 4.6.2.24. Let \(f: X \rightarrow Y\) be a morphism of Kan complexes. Then \(f\) is fully 01 K 1 faithful (when regarded as a functor of \(\infty\)-categories) if and only if it induces a homotopy equivalence from \(X\) to a summand of \(Y\).

Proof. Combine Corollary 4.6.2.22 with Exercise 4.4.1.13.

\subsection*{4.6.3 Digression: Categorical Mapping Cylinders}

Let \(\mathcal{C}\) be an \(\infty\)-category, and let \(f_{0}, f_{1}: B \rightarrow \mathcal{C}\) be diagrams in \(\mathcal{C}\) indexed by a simplicial 01K2 set \(B\). Recall that \(f_{0}\) and \(f_{1}\) are naturally isomorphic if they are isomorphic as objects of the diagram \(\infty\)-category \(\operatorname{Fun}(B, \mathcal{C})\) (Definition 4.4.4.1). Our goal in this section is to establish a detection criterion for natural isomorphisms.
Proposition 4.6.3.1. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(f_{0}, f_{1}: B \rightarrow \mathcal{C}\) be a pair of diagrams. 01K3 The following conditions are equivalent:
(1) The diagrams \(f_{0}\) and \(f_{1}\) are isomorphic when regarded as objects of the \(\infty\)-category \(\operatorname{Fun}(B, \mathcal{C})\).
(2) There exists a factorization of the fold map \(\left(\mathrm{id}_{B}, \mathrm{id}_{B}\right): B \amalg B \rightarrow B\) as a composition
\[
B \coprod B \xrightarrow{\left(s_{0}, s_{1}\right)} \bar{B} \xrightarrow{\pi} B,
\]
where \(\pi\) is a categorical equivalence, and a diagram \(\bar{f}: \bar{B} \rightarrow \mathcal{C}\) satisfying \(f_{0}=\bar{f} \circ s_{0}\) and \(f_{1}=\bar{f} \circ s_{1}\).
(3) For every factorization of the fold map \(\left(\mathrm{id}_{B}, \mathrm{id}_{B}\right): B \amalg B \rightarrow B\) as a composition
\[
B \coprod B \xrightarrow{\left(s_{0}, s_{1}\right)} \bar{B} \xrightarrow{\pi} B,
\]
where \(s_{0}\) and \(s_{1}\) have disjoint images, there exists a diagram \(\bar{f}: \bar{B} \rightarrow \mathcal{C}\) satisfying \(f_{0}=\bar{f} \circ s_{0}\) and \(f_{1}=\bar{f} \circ s_{1}\).

We will deduce Proposition 4.6.3.1 from a more general statement (Theorem 4.6.3.8), which we prove at the end of this section.

01 K 4 Remark 4.6.3.2. Proposition 4.6 .3 .1 has an interpretation in the language of model categories. Let us regard the category \(\operatorname{Set}_{\Delta}\) of simplicial sets as equipped with the Joyal model structure of Remark [?]. Conditions (2) and (3) of Proposition 4.6.3.1 are equivalent to the requirement that the morphisms \(f_{0}, f_{1}: B \rightarrow \mathcal{C}\) are homotopic with respect to the Joyal model structure (in the sense of Definition [?]). Proposition 4.6.3.1 asserts that this is equivalent to the requirement that \(f_{0}\) and \(f_{1}\) are naturally isomorphic (in the sense of Definition 4.4.4.1).

Let us introduce a bit of terminology which is useful for exploiting Proposition 4.6.3.1
01K5 Definition 4.6.3.3. Let \(i: A \hookrightarrow B\) be a monomorphism of simplicial sets. A categorical mapping cylinder for \(B\) relative to \(A\) is a simplicial set \(\bar{B}\) equipped with a morphism \(\pi: \bar{B} \rightarrow B\) together with a pair of sections \(s_{0}, s_{1}: B \rightarrow \bar{B}\) having the following properties:
(1) The morphism \(\pi: \bar{B} \rightarrow B\) is a categorical equivalence of simplicial sets.
(2) The morphisms \(s_{0}, s_{1}: B \rightarrow \bar{B}\) satisfy \(s_{0} \circ i=s_{1} \circ i\), and the induced map ( \(s_{0}, s_{1}\) ): \(\left(B \amalg_{A} B\right) \rightarrow \bar{B}\) is a monomorphism.

If these conditions are satisfied in the special case \(A=\emptyset\), we will simply refer to \(\bar{B}\) (together with the morphisms \(\pi, s_{0}\), and \(s_{1}\) ) as a categorical mapping cylinder for \(B\).

01K6 Remark 4.6.3.4. In the situation of Definition 4.6.3.3. condition (2) is equivalent to the requirement that the diagram of simplicial sets

commutes and is a pullback square (note that the morphisms \(s_{0}\) and \(s_{1}\) are automatically monomorphisms, since they are right inverse to the map \(\pi: \bar{B} \rightarrow B)\).

01K7 Remark 4.6.3.5. Let \(i: A \hookrightarrow B\) be a monomorphism of simplicial sets, and let \(\left(\mathrm{id}_{B}, \mathrm{id}_{B}\right)\) : \(\left(B \amalg_{A} B\right) \rightarrow B\) be the fold map. Unwinding the definitions, we see that a categorical mapping cylinder for \(B\) relative to \(A\) can be identified with a factorization of \(\left(\mathrm{id}_{B}, \mathrm{id}_{B}\right)\) as a composition
\[
B \coprod_{A} B \xrightarrow{\iota} \bar{B} \xrightarrow{\pi} B,
\]
where \(\iota\) is a monomorphism of simplicial sets and \(\pi\) is a categorical equivalence. Such factorizations always exist: by virtue of Exercise 3.1.7.11, we can even arrange that \(\pi\) is a trivial Kan fibration of simplicial sets (hence a categorical equivalence by virtue of Proposition 4.5.3.11.

Example 4.6.3.6. Let \(i: A \hookrightarrow B\) be a monomorphism of simplicial sets, and let \(Q 01 \mathrm{~K} 8\) be a contractible Kan complex containing vertices \(x_{0}, x_{1} \in Q\) with \(x_{0} \neq x_{1}\). Set \(\bar{B}=\) \(A \amalg_{(Q \times A)}(Q \times B)\). The commutative diagram

is a categorical pushout square (since the vertical maps are categorical equivalences), and therefore induces a categorical equivalence \(\bar{\pi}: \bar{B} \rightarrow B\) (Proposition 4.5.4.11). Let \(s_{0}: B \rightarrow \bar{B}\) be the section of \(\pi\) given by the composition
\[
B \simeq\left\{x_{0}\right\} \times B \hookrightarrow Q \times B \rightarrow \bar{B},
\]
and define \(s_{1}: B \rightarrow \bar{B}\) similarly. Then the quadruple ( \(\bar{B}, \pi, s_{0}, s_{1}\) ) is a categorical mapping cylinder of \(B\) relative to \(A\).

Corollary 4.6.3.7. Let \(\mathcal{C}\) be an \(\infty\)-category, and let \(f_{0}, f_{1}: B \rightarrow \mathcal{C}\) be a pair of diagrams 01 K 9 indexed by a simplicial set \(B\). Let
\[
(B \coprod B) \xrightarrow{\left(s_{0}, s_{1}\right)} \bar{B} \xrightarrow{\pi} B
\]
be a categorical mapping cylinder for \(B\) (Definition 4.6.3.3). The following conditions are equivalent:
(a) The diagrams \(f_{0}\) and \(f_{1}\) are isomorphic when regarded as objects of the \(\infty\)-category \(\operatorname{Fun}(B, \mathcal{C})\).
(b) There exists a diagram \(\bar{f}: \bar{B} \rightarrow \mathcal{C}\) satisfying \(f_{0}=\bar{f} \circ s_{0}\) and \(f_{1}=\bar{f} \circ s_{1}\).

In particular, condition (b) does not depend on the choice of categorical mapping cylinder.
Proof. The implication \((a) \Rightarrow(b)\) follows from the implication (1) \(\Rightarrow\) (3) of Proposition 4.6.3.1, and the implication \((b) \Rightarrow(a)\) from the implication \((2) \Rightarrow(1)\) of Proposition 4.6.3.1

We will deduce Proposition 4.6.3.1 from a more general relative statement.
01KA Theorem 4.6.3.8. Let \(q: X \rightarrow S\) be an isofibration of simplicial sets, let \(g: B \rightarrow S\) be \(a\) morphism of simplicial sets, and let \(f_{0}, f_{1}: B \rightarrow X\) be morphisms satisfying \(q \circ f_{0}=g=q \circ f_{1}\). Let \(A \subseteq B\) be a simplicial subset satisfying \(\left.f_{0}\right|_{A}=\left.f_{1}\right|_{A}\). The following conditions are equivalent:
(1) The diagrams \(f_{0}\) and \(f_{1}\) are isomorphic when regarded as objects of the \(\infty\)-category \(\mathrm{Fun}_{A / / S}(B, X)\) (see Proposition 4.1.4.6).
(2) There exists a factorization of the fold map \(\left(\mathrm{id}_{B}, \mathrm{id}_{B}\right): B \amalg_{A} B \rightarrow B\) as a composition
\[
B \coprod_{A} B \xrightarrow{\left(s_{0}, s_{1}\right)} \bar{B} \xrightarrow{\pi} B,
\]
where \(\pi\) is a categorical equivalence and the lifting problem

admits a solution.
(3) For every factorization of the fold map \(\left(\mathrm{id}_{B}, \mathrm{id}_{B}\right): B \amalg_{A} B \rightarrow B\) as a composition
\[
B \coprod_{A} B \xrightarrow{\left(s_{0}, s_{1}\right)} \bar{B} \xrightarrow{\pi} B,
\]
where the map \(\left(s_{0}, s_{1}\right): B \amalg_{A} B \rightarrow \bar{B}\) is a monomorphism, the lifting problem

admits a solution.
Proof. By virtue of Corollary 4.4.3.15, condition (1) is satisfied if and only if there exists a morphism of simplicial sets \(u: Q \rightarrow \operatorname{Fun}_{A / / S}(B, X)\), where \(Q\) is a contractible Kan complex, and a pair of vertices \(x_{0}, x_{1} \in Q\) satisfying \(u\left(x_{0}\right)=f_{0}\) and \(u\left(x_{1}\right)=f_{1}\). Moreover, we may
assume (modifying \(Q\) if necessary) that the vertices \(x_{0}\) and \(x_{1}\) are distinct. In this case, let \(\bar{B}=A \coprod_{(Q \times A)}(Q \times B)\) and let
\[
B \coprod_{A} B \xrightarrow{\left(s_{0}, s_{1}\right)} \bar{B} \xrightarrow{\pi} B
\]
be the categorical mapping cylinder described in Example 4.6.3.6. Unwinding the definitions, we see that morphisms \(u: Q \rightarrow \operatorname{Fun}_{A / / S}(B, X)\) satisfying \(u\left(x_{0}\right)=f_{0}\) and \(u\left(x_{1}\right)=f_{1}\) can be identified with solutions to the lifting problem

This proves that \((3) \Rightarrow(1) \Rightarrow(2)\).
We will complete the proof by showing that \((2) \Rightarrow(3)\). Assume that (2) is satisfied, so that the fold map \(\left(\mathrm{id}_{B}, \mathrm{id}_{B}\right): B \coprod_{A} B \rightarrow B\) factors as a composition
\[
B \coprod_{A} B \xrightarrow{\left(s_{0}, s_{1}\right)} \bar{B} \xrightarrow{\pi} B
\]
where \(\pi\) is a categorical equivalence and there exists a morphism \(\bar{f}: \bar{B} \rightarrow X\) for which the diagram

commutes. Using Exercise 3.1.7.11, we can factor \(\pi\) as a composition
\[
\bar{B} \xrightarrow{j} \bar{B}^{\prime} \xrightarrow{\pi^{\prime}} B,
\]
where \(j\) is a monomorphism and \(\pi^{\prime}\) is a trivial Kan fibration. Then \(\pi^{\prime}\) is also a categorical equivalence (Proposition 4.5.3.11), so the morphism \(j\) is a categorical equivalence (Remark 4.5 .3 .5 . Our assumption that \(q\) is an isofibration guarantees that the lifting problem

admits a solution \(\bar{f}^{\prime}: \bar{B}^{\prime} \rightarrow X\).
We now show that condition (3) is satisfied. Suppose that we are given another factorization of the fold map \(\left(\mathrm{id}_{B}, \mathrm{id}_{B}\right):\left(\mathrm{id}_{B}, \mathrm{id}_{B}\right): B \coprod_{A} B \rightarrow B\) as a composition
\[
B \coprod_{A} B \xrightarrow{\iota} \bar{B}^{\prime \prime} \xrightarrow{\pi^{\prime \prime}} B,
\]
where \(\iota\) is a monomorphism. We wish to show that the lifting problem

admits a solution \(\bar{f}^{\prime \prime}: \bar{B}^{\prime \prime} \rightarrow X\). We first observe that the lifting problem

admits a solution \(v: \bar{B}^{\prime \prime} \rightarrow \bar{B}^{\prime}\), since \(\iota\) is a monomorphism and \(\pi^{\prime}\) is a trivial Kan fibration. We now conclude the proof by setting \(\bar{f}^{\prime \prime}=\bar{f}^{\prime} \circ v\).

01KB Corollary 4.6.3.9. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(f_{0}, f_{1}: B \rightarrow \mathcal{C}\) be a pair of diagrams indexed by a simplicial set \(B\), and let \(A \subseteq B\) be a simplicial subset satisfying \(\left.f_{0}\right|_{A}=\left.f_{1}\right|_{A}\). The following conditions are equivalent:
(1) The diagrams \(f_{0}\) and \(f_{1}\) are isomorphic when regarded as objects of the \(\infty\)-category \(\operatorname{Fun}_{A}(B, \mathcal{C})\).
(2) There exists a factorization of the fold map \(\left(\mathrm{id}_{B}, \mathrm{id}_{B}\right): B \amalg_{A} B \rightarrow B\) as a composition
\[
B \coprod_{A} B \xrightarrow{\left(s_{0}, s_{1}\right)} \bar{B} \xrightarrow{\pi} B,
\]
where \(\pi\) is a categorical equivalence, and a morphism \(\bar{f}: \bar{B} \rightarrow \mathcal{C}\) satisfying \(f_{0}=\bar{f} \circ s_{0}\) and \(f_{1}=\bar{f} \circ s_{1}\).
(3) For every factorization of the fold map \(\left(\mathrm{id}_{B}, \mathrm{id}_{B}\right): B \amalg_{A} B \rightarrow B\) as a composition
\[
B \coprod_{A} B \xrightarrow{\left(s_{0}, s_{1}\right)} \bar{B} \xrightarrow{\pi} B
\]
where the map \(\left(s_{0}, s_{1}\right): B \coprod_{A} B \rightarrow \bar{B}\) is a monomorphism, there exists a morphism \(\bar{f}: \bar{B} \rightarrow \mathcal{C}\) satisfying \(f_{0}=\bar{f} \circ s_{0}\) and \(f_{1}=\bar{f} \circ s_{1}\).

Proof. Apply Theorem 4.6.3.8 in the special case where \(S=\Delta^{0}\).
Proof of Proposition 4.6.3.1. Apply Corollary 4.6.3.9 in the special case \(A=\emptyset\).
For later use, we record a relative version of Corollary 4.6.3.7.
Corollary 4.6.3.10. Let \(q: X \rightarrow S\) be an isofibration of simplicial sets, let \(g: B \rightarrow S\) be \(a 01 \mathrm{KC}\) morphism of simplicial sets, and let \(f_{0}, f_{1}: B \rightarrow X\) be morphisms satisfying \(q \circ f_{0}=g=q \circ f_{1}\). Let \(A\) be a simplicial subset of \(B\) satisfying \(\left.f_{0}\right|_{A}=\left.f_{1}\right|_{A}\), and let
\[
\left(B \coprod_{A} B\right) \xrightarrow{\left(s_{0}, s_{1}\right)} \bar{B} \xrightarrow{\pi} B
\]
be a categorical mapping cylinder of \(B\) relative to \(A\). The following conditions are equivalent:
(a) The diagrams \(f_{0}\) and \(f_{1}\) are isomorphic when regarded as objects of the \(\infty\)-category
\(\operatorname{Fun}_{A / / S}(B, X)\).
(b) The lifting problem

admits a solution.
In particular, condition (b) does not depend on the choice of categorical mapping cylinder.
Proof. The implication \((a) \Rightarrow(b)\) follows from the implication \((1) \Rightarrow(3)\) of Theorem 4.6.3.8. and the implication \((b) \Rightarrow(a)\) from the implication \((2) \Rightarrow(1)\) of Theorem 4.6.3.8.

Corollary 4.6.3.11. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(f_{0}, f_{1}: B \rightarrow \mathcal{C}\) be a pair of diagrams 01 KD indexed by a simplicial set \(B\). Let \(A\) be a simplicial subset of \(B\) satisfying \(\left.f_{0}\right|_{A}=\left.f_{1}\right|_{A}\), and let
\[
\left(B \coprod_{A} B\right) \xrightarrow{\left(s_{0}, s_{1}\right)} \bar{B} \xrightarrow{\pi} B
\]
be a categorical mapping cylinder of \(B\) relative to \(A\). The following conditions are equivalent:
(a) The diagrams \(f_{0}\) and \(f_{1}\) are isomorphic when regarded as objects of the \(\infty\)-category \(\operatorname{Fun}_{A /}(B, \mathcal{C})\).
(b) There exists a diagram \(\bar{f}: \bar{B} \rightarrow \mathcal{C}\) satisfying \(f_{0}=\bar{f} \circ s_{0}\) and \(f_{1}=\bar{f} \circ s_{1}\).

In particular, condition (b) does not depend on the choice of categorical mapping cylinder.
Proof. Apply Corollary 4.6.3.10 in the special case \(S=\Delta^{0}\).

\subsection*{4.6.4 Oriented Fiber Products}

01KE Let \(\mathcal{C}, \mathcal{D}\), and \(\mathcal{E}\) be categories. To every pair of functors \(F: \mathcal{C} \rightarrow \mathcal{E}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\), one can associate the oriented fiber product \(\mathcal{C} \tilde{\times}_{\mathcal{E}} \mathcal{D}\), whose objects are triples \((C, D, \eta)\) where \(C\) is an object of \(\mathcal{C}, D\) is an object of \(\mathcal{D}\), and \(\eta: F(C) \rightarrow G(D)\) is a morphism in the category \(\mathcal{E}\) (Notation 2.1.4.19). This construction has a counterpart in the setting of \(\infty\)-categories.

01KF Definition 4.6.4.1 (The Oriented Fiber Product). Let \(F: \mathcal{C} \rightarrow \mathcal{E}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be morphisms of simplicial sets. We let \(\mathcal{C} \tilde{\times}_{\mathcal{E}} \mathcal{D}\) denote the simplicial set given by the iterated fiber product
\[
\mathcal{C} \times_{\operatorname{Fun}(\{0\}, \mathcal{E})} \operatorname{Fun}\left(\Delta^{1}, \mathcal{E}\right) \times_{\operatorname{Fun}(\{1\}, \mathcal{E})} \mathcal{D}
\]

We will refer to \(\mathcal{C} \tilde{x}_{\mathcal{E}} \mathcal{D}\) as the oriented fiber product of \(\mathcal{C}\) with \(\mathcal{D}\) over \(\mathcal{E}\).
As our notation suggests, we will be primarily interested in the special case of Definition 4.6.4.1 where the simplicial sets \(\mathcal{C}, \mathcal{D}\), and \(\mathcal{E}\) are \(\infty\)-categories.

01 KG Proposition 4.6.4.2. Let \(\mathcal{E}\) be an \(\infty\)-category, and suppose we are given morphisms of simplicial sets \(F: \mathcal{C} \rightarrow \mathcal{E}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\). Then the projection map \(\theta: \mathcal{C} \tilde{\times}_{\mathcal{E}} \mathcal{D} \rightarrow \mathcal{C} \times \mathcal{D}\) is an isofibration of simplicial sets.

Proof. By construction, we have a pullback diagram of simplicial sets

Since \(\mathcal{E}\) is an \(\infty\)-category, the restriction map \(\theta_{0}\) is an isofibration of \(\infty\)-categories (Corollary 4.4.5.3. Invoking Remark 4.5.5.11, we conclude that \(\theta\) is an isofibration of simplicial sets.

01KH Corollary 4.6.4.3. Let \(F: \mathcal{C} \rightarrow \mathcal{E}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories. Then the oriented fiber product \(\mathcal{C} \tilde{\times}_{\mathcal{E}} \mathcal{D}\) is also an \(\infty\)-category.

Proof. By virtue of Proposition 4.6.4.2, the projection \(\operatorname{map} \mathcal{C} \tilde{\wedge}_{\mathcal{E}} \mathcal{D} \rightarrow \mathcal{C} \times \mathcal{D}\) is an isofibration. Since \(\mathcal{C} \times \mathcal{D}\) is an \(\infty\)-category, it follows that \(\mathcal{C} \tilde{\times}_{\mathcal{E}} \mathcal{D}\) is also an \(\infty\)-category (Remark 4.5.5.7).

Remark 4.6.4.4 (Homotopy Invariance). Suppose we are given a commutative diagram of 03PN \(\infty\)-categories

where the vertical maps are equivalences of \(\infty\)-categories. Then the induced map
\[
\mathcal{C} \tilde{\times}_{\mathcal{E}} \mathcal{D} \rightarrow \mathcal{C}^{\prime} \tilde{\wedge}_{\mathcal{E}^{\prime}} \mathcal{D}^{\prime}
\]
is also an equivalence of \(\infty\)-categories. This follows by applying Corollary 4.5.2.30 to the diagram

Remark 4.6.4.5. Let \(F: \mathcal{C} \rightarrow \mathcal{E}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories. Then we can \(034 Z\) identify objects of the oriented fiber product \(\mathcal{C} \tilde{x}_{\mathcal{E}} \mathcal{D}\) with triples \((C, D, e)\), where \(C\) is an object of \(\mathcal{C}, D\) is an object of \(\mathcal{D}\), and \(e: F(C) \rightarrow G(D)\) is a morphism in the \(\infty\)-category \(\mathcal{E}\). Note that the homotopy fiber product \(\mathcal{C} \times{ }_{\mathcal{E}}^{\mathrm{h}} \mathcal{D}\) of Construction 4.5.2.1 can be identified with the full subcategory of \(\mathcal{C} \tilde{\times}_{\mathcal{E}} \mathcal{D}\) spanned by those triples ( \(C, D, e\) ) where the morphism \(e\) is an isomorphism.

Example 4.6.4.6. Let \(F: \mathcal{C} \rightarrow \mathcal{E}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors between ordinary categories, 01 KJ and let \(\mathcal{C} \tilde{x}_{\mathcal{E}} \mathcal{D}\) denote the oriented fiber product of Notation 2.1.4.19. Since the nerve construction is compatible with the formation of inverse limits and functor categories, we have a canonical isomorphism of simplicial sets
\[
\mathrm{N}_{\bullet}\left(\mathcal{C} \tilde{\times}_{\mathcal{E}} \mathcal{D}\right) \simeq\left(\mathrm{N}_{\bullet}(\mathcal{C}) \tilde{\times}_{\mathrm{N}_{\bullet}(\mathcal{E})} \mathrm{N}_{\bullet}(\mathcal{D})\right) .
\]

Consequently, Definition 4.6.4.1 can be viewed as a generalization of the classical oriented fiber product.

Example 4.6.4.7. Let \(\mathcal{C}\) and \(\mathcal{D}\) be simplicial sets. Then the oriented fiber product \(\mathcal{C} \tilde{x}_{\Delta^{0}} \mathcal{D} 02 \mathrm{C} 6\) can be identified with the cartesian product \(\mathcal{C} \times \mathcal{D}\).

01 KL Remark 4.6.4.8. Let \(F: \mathcal{C} \rightarrow \mathcal{E}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be morphisms of simplicial sets, and let \(F^{\mathrm{op}}: \mathcal{C}^{\mathrm{op}} \rightarrow \mathcal{E}^{\mathrm{op}}\) and \(G^{\mathrm{op}}: \mathcal{D}^{\mathrm{op}} \rightarrow \mathcal{E}^{\mathrm{op}}\) be the opposite morphisms. Then we have a canonical isomorphism of simplicial sets
\[
\left(\mathcal{C} \tilde{x}_{\mathcal{E}} \mathcal{D}\right)^{\mathrm{op}} \simeq\left(\mathcal{D}^{\mathrm{op}} \tilde{x}_{\mathcal{E}^{\mathrm{op}}} \mathcal{C}^{\mathrm{op}}\right) .
\]

01KN Remark 4.6.4.9. Let \(F: K \rightarrow \mathcal{C}\) be a morphism of simplicial sets, which we identify with a vertex of the simplicial set \(\operatorname{Fun}(K, \mathcal{C})\). For any simplicial set \(J\), we have canonical isomorphisms
\(\operatorname{Fun}\left(J, \mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{F\}\right) \simeq \operatorname{Fun}_{K /}(J \diamond K, \mathcal{C}) \quad \operatorname{Fun}\left(J,\{F\} \tilde{x}_{\operatorname{Fun}(K, \mathcal{C})} \mathcal{C}\right) \simeq \operatorname{Fun}_{K /}(K \diamond J, \mathcal{C})\),
where \(J \diamond K\) and \(K \diamond J\) denote the blunt joins introduced in Notation 4.5.8.3 Restricting to vertices, we obtain bijections
\[
\begin{aligned}
&\{\text { Morphisms } J\left.\rightarrow \mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{F\}\right\} \\
& \simeq\left\{\text { Morphisms } \bar{F}: J \diamond K \rightarrow \mathcal{C} \text { with }\left.\bar{F}\right|_{K}=F\right\} \\
&\left\{\text { Morphisms } J \rightarrow\{F\} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})} \mathcal{C}\right\} \simeq\left\{\text { Morphisms } \bar{F}^{\prime}: K \diamond J \rightarrow \mathcal{C} \text { with }\left.\bar{F}^{\prime}\right|_{K}=F\right\} .
\end{aligned}
\]

01 KP Example 4.6.4.10. Let \(\mathcal{C}\) be a simplicial set containing vertices \(X\) and \(Y\), which we identify with morphisms of simplicial sets \(X, Y: \Delta^{0} \rightarrow \mathcal{C}\). Then the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) of Construction 4.6.1.1 is the oriented fiber product \(\{X\} \tilde{x}_{\mathcal{C}}\{Y\}\).

The following result is a relative version of Proposition 4.6.1.10;
01 KQ Proposition 4.6.4.11. Let \(\mathcal{C}\) be an \(\infty\)-category containing an object \(X\). Then the projection \(\operatorname{map}\{X\} \tilde{x}_{\mathcal{C}} \mathcal{C} \rightarrow \mathcal{C}\) is a left fibration and the projection map \(\mathcal{C} \tilde{\times}_{\mathcal{C}}\{X\} \rightarrow \mathcal{C}\) is a right fibration.

Proof. We will prove the second assertion; the first follows by a similar argument. Let \(A \hookrightarrow B\) be a right anodyne morphism of simplicial sets; we wish to show that every lifting problem

admits a solution. Unwinding the definitions, we are reduced to showing that a map of simplicial sets
\[
\sigma_{0}: B \coprod_{A}(A \diamond\{X\}) \rightarrow \mathcal{C}
\]
can be extended to a map \(\sigma: B \diamond\{X\} \rightarrow \mathcal{C}\) (see Notation 4.5.8.3). By virtue of Lemma 4.5 .5 .2 , it will suffice to show that the inclusion map
\[
\iota: B \coprod_{A}(A \diamond\{X\}) \hookrightarrow B \diamond\{X\}
\]
is a categorical equivalence of simplicial sets, which follows from Corollary 4.5.8.14
Corollary 4.6.4.12. Let \(\mathcal{D}\) be an \(\infty\)-category containing an object \(X\), and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be 01KR a morphism of simplicial sets. Then the projection \(\operatorname{map}\{X\} \tilde{\times}_{\mathcal{D}} \mathcal{C} \rightarrow \mathcal{C}\) is a left fibration, and the projection map \(\mathcal{C} \tilde{\times}_{\mathcal{D}}\{X\} \rightarrow \mathcal{C}\) is a right fibration.

Proof. Unwinding the definition, we have pullback diagrams

The desired result now follows by combining Proposition 4.6.4.11 with Remark 4.2.1.8.
If \(F: \mathcal{K} \rightarrow \mathcal{C}\) is a functor between ordinary categories, then Remark 4.3.1.11 supplies canonical isomorphisms
\[
\mathcal{C}_{/ F} \simeq \mathcal{C} \tilde{\times}_{\operatorname{Fun}(\mathcal{K}, \mathcal{C})}\{F\} \quad \mathcal{C}_{F /} \simeq\{F\} \tilde{\times}_{\operatorname{Fun}(\mathcal{K}, \mathcal{C})} \mathcal{C}
\]

Our next goal is to establish a similar result in the setting of \(\infty\)-categories. Here the situation is a bit more subtle: if \(F: K \rightarrow \mathcal{C}\) is a diagram in an \(\infty\)-category \(\mathcal{C}\), then the simplicial sets \(\mathcal{C}{ }_{/ F}\) and \(\mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{F\}\) are generally not isomorphic. However, we will show that they are equivalent as \(\infty\)-categories.

Construction 4.6.4.13 (The Slice Diagonal Morphism). Let \(F: K \rightarrow \mathcal{C}\) be a morphism 02GH of simplicial sets, and let \(c: \mathcal{C}_{/ F} \diamond K \rightarrow \mathcal{C}_{/ F} \star K\) be the comparison morphism of Notation 4.5.8.3. By virtue of Remark 4.6.4.9, the composite map
\[
\mathcal{C}_{/ F} \diamond K \stackrel{c}{\rightarrow}_{\mathcal{C}}^{/ F} \text { } \star K \rightarrow \mathcal{C}
\]
determines a morphism of simplicial sets \(\delta_{/ F}: \mathcal{C} / F \rightarrow \mathcal{C} \tilde{\times}_{\text {Fun }(K, \mathcal{C})}\{F\}\), which we will refer to as the slice diagonal morphism. Similarly, the composition
\[
K \diamond \mathcal{C}_{F /} \rightarrow K \star \mathcal{C}_{F /} \rightarrow \mathcal{C}
\]
determines a morphism of simplicial sets \(\delta_{F /}: \mathcal{C}_{F /} \rightarrow\{F\} \tilde{\times}_{\text {Fun }(K, \mathcal{C})} \mathcal{C}\), which we will refer as the coslice diagonal morphism.

02GJ Remark 4.6.4.14. Let \(F: K \rightarrow \mathcal{C}\) be a morphism of simplicial sets. For every simplicial set \(J\), composition with the slice diagonal \(\delta_{/ F}\) of Construction 4.6.4.13 determines a map of sets
\[
\operatorname{Hom}_{\text {Set }_{\Delta}}\left(J, \mathcal{C}_{/ F}\right) \rightarrow \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(J, \mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{F\}\right) .
\]

Under the bijection of Remark 4.6.4.9, this identifies with the map
\[
\operatorname{Hom}_{\left(\operatorname{Set}_{\Delta}\right)_{K /}}(J \star K, \mathcal{C}) \rightarrow \operatorname{Hom}_{\left(\operatorname{Set}_{\Delta}\right)_{K /}}(J \diamond K, \mathcal{C})
\]
given by precomposition with the comparison map \(c_{J, K}: J \diamond K \rightarrow J \star K\) of Notation 4.5.8.3
01KT Remark 4.6.4.15. Let \(F: K \rightarrow \mathcal{C}\) be a morphism of simplicial sets. Then the slice and coslice diagonal morphisms
\[
\mathcal{C}_{/ F} \rightarrow \mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{F\} \quad \mathcal{C}_{F /} \rightarrow\{F\} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})} \mathcal{C}
\]
are monomorphisms of simplicial sets. This follows from Remark 4.6.4.14 together with the observation that for every simplicial set \(J\), the comparison maps
\[
c_{J, K}: J \diamond K \rightarrow J \star K \quad c_{K, J}: K \diamond J \rightarrow K \star J
\]
are epimorphisms (see Exercise 4.5.8.5)
02GK Exercise 4.6.4.16. Let \(f: K \rightarrow \mathcal{C}\) be a morphism of simplicial sets. Then \(f\) can be identified with a vertex of the simplicial set \(\operatorname{Fun}(K, \mathcal{C})\), which (to avoid confusion) we will temporarily denote by \(F\). Applying Construction 4.6.4.13 to the inclusion map \(\{F\} \hookrightarrow \operatorname{Fun}(K, \mathcal{C})\), we obtain a monomorphism of simplicial sets \(\operatorname{Fun}(K, \mathcal{C})_{/ F} \hookrightarrow \operatorname{Fun}(K, \mathcal{C}) \tilde{x}_{\operatorname{Fun}(K, \mathcal{C})}\{F\}\), which induces a monomorphism
\[
u: \mathcal{C} \times_{\operatorname{Fun}(K, \mathcal{C})} \operatorname{Fun}(K, \mathcal{C})_{/ F} \hookrightarrow \mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{F\} .
\]

Show that the slice diagonal morphism \(\delta_{/ f}: \mathcal{C}_{/ f} \rightarrow \mathcal{C} \tilde{x}_{\text {Fun }(K, \mathcal{C})}\{F\}\) of Construction 4.6.4.13 factors (uniquely) through \(u\). In particular, \(\delta_{/ f}\) determines a morphism of simplicial sets \(\mathcal{C}_{/ f} \rightarrow \mathcal{C} \times_{\operatorname{Fun}(K, \mathcal{C})} \operatorname{Fun}(K, \mathcal{C})_{/ F}\). Similarly, the coslice diagonal morphism \(\delta_{f /}\) induces a morphism of simplicial sets \(\mathcal{C}_{f /} \rightarrow \operatorname{Fun}(K, \mathcal{C})_{F /} \times_{\operatorname{Fun}(K, \mathcal{C})} \mathcal{C}\).

We can now formulate our main result, which we prove at the end of this section.
01 KU Theorem 4.6.4.17. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(F: K \rightarrow \mathcal{C}\) be a diagram. Then the slice and coslice diagonal maps
\[
\delta_{/ F}: \mathcal{C}_{/ F} \hookrightarrow \mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{F\} \quad \delta_{F /}: \mathcal{C}_{F /} \hookrightarrow\{F\} \tilde{x}_{\operatorname{Fun}(K, \mathcal{C})} \mathcal{C}
\]
are equivalences of \(\infty\)-categories.

Corollary 4.6.4.18. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(C \in \mathcal{C}\) be an object. Then the slice 02VT and coslice diagonal maps
\[
\delta_{/ C}: \mathcal{C} / C \hookrightarrow \mathcal{C} \tilde{x}_{\mathcal{C}}\{C\} \quad \delta_{C /}: \mathcal{C}_{C /} \hookrightarrow\{C\} \tilde{x}_{\mathcal{C}} \mathcal{C}
\]
are equivalences of \(\infty\)-categories.
Corollary 4.6.4.19. Let \(G: \mathcal{C} \rightarrow \mathcal{D}\) be an equivalence of \(\infty\)-categories and let \(F: K \rightarrow \mathcal{C}\) 02GL be a diagram in \(\mathcal{C}\). Then the induced functors
\[
G^{\prime}: \mathcal{C}_{/ F} \rightarrow \mathcal{D}_{/(G \circ F)} \quad G^{\prime \prime}: \mathcal{C}_{F /} \rightarrow \mathcal{D}_{(G \circ F) /}
\]
are equivalences of \(\infty\)-categories.
Proof. We will show that \(G^{\prime}\) is an equivalence of \(\infty\)-categories; the analogous statement for \(G^{\prime \prime}\) follows by a similar argument. Note that we have a commutative diagram

where the vertical maps are equivalences of \(\infty\)-categories by virtue of Theorem 4.6.4.17. It will therefore suffice to show that \(\bar{G}^{\prime}\) is an equivalence of \(\infty\)-categories, which is a special case of Remark 4.6.4.4

Corollary 4.6.4.20. Let \(G: \mathcal{C} \rightarrow \mathcal{D}\) be fully faithful functor of \(\infty\)-categories and let 02C8 \(F: K \rightarrow \mathcal{C}\) be a morphism of simplicial sets. Then the induced functors
\[
G^{\prime}: \mathcal{C}_{/ F} \rightarrow \mathcal{D}_{/(G \circ F)} \quad G^{\prime \prime}: \mathcal{C}_{F /} \rightarrow \mathcal{D}_{(G \circ F) /}
\]
are also fully faithful.
Proof. Let \(\mathcal{C}^{\prime} \subseteq \mathcal{D}\) be the essential image of \(G\) (Definition 4.6.2.11), so that \(G\) induces an equivalence of \(\infty\)-categories \(\mathcal{C} \rightarrow \mathcal{C}^{\prime}\) (Corollary 4.6.2.22). By virtue of Corollary 4.6.4.19, the functors \(G^{\prime}\) and \(G^{\prime \prime}\) restrict to equivalences
\[
\mathcal{C}_{/ F} \rightarrow \mathcal{C}_{/(G \circ F)}^{\prime} \quad \mathcal{C}_{F /} \rightarrow \mathcal{C}_{(G \circ F) /}^{\prime}
\]

We may therefore replace \(\mathcal{C}\) by \(\mathcal{C}^{\prime}\) and thereby reduce to the case where \(G: \mathcal{C} \hookrightarrow \mathcal{D}\) is the inclusion of a full subcategory. In this case, the functors \(G^{\prime}\) and \(G^{\prime \prime}\) are also the inclusions of full subcategories, hence fully faithful (Example 4.6.2.2).

We now turn to the proof of Theorem 4.6.4.17. As we will see, it is essentially a reformulation of Theorem 4.5.8.8.

01 KV Lemma 4.6.4.21. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(F: K \rightarrow \mathcal{C}\) be a diagram indexed by a simplicial set \(K\). Suppose we are given a pair of diagrams \(e_{0}, e_{1}: J \rightarrow \mathcal{C}_{/ F}\) indexed by a simplicial set \(J\), which we identify with diagrams \(F_{0}, F_{1}: J \star K \rightarrow \mathcal{C}\) satisfying \(\left.F_{0}\right|_{K}=F=\left.F_{1}\right|_{K}\). The following conditions are equivalent:
(1) The diagrams \(e_{0}\) and \(e_{1}\) are isomorphic when regarded as objects of the diagram \(\infty\) category \(\operatorname{Fun}\left(J, \mathcal{C}_{/ F}\right)\).
(2) The diagrams \(F_{0}\) and \(F_{1}\) are isomorphic when regarded as objects of the \(\infty\)-category \(\operatorname{Fun}_{K /}(J \star K, \mathcal{C})\).

Proof. Choose a categorical mapping cylinder
\[
J \coprod J \xrightarrow{\left(s_{0}, s_{1}\right)} \bar{J} \xrightarrow{\pi} J
\]
for the simplicial set \(J\) (Definition 4.6.3.3). Using Corollary 4.5.8.9, we deduce that the resulting diagram
\[
(J \star K) \coprod_{K}(J \star K) \xrightarrow{\left(s_{0}^{\prime}, s_{1}^{\prime}\right)} \bar{J} \star K \xrightarrow{\pi^{\prime}} J \star K
\]
is a categorical mapping cylinder for the join \(J \star K\) relative to \(K\). Using the criterion of Corollary 4.6.3.11, we see that (1) and (2) can be reformulated as follows:
(1') There exists a diagram \(\bar{e}: \bar{J} \rightarrow \mathcal{C}_{/ F}\) satisfying \(e_{0}=\bar{e} \circ s_{0}\) and \(e_{1}=\bar{e} \circ s_{1}\).
(2') There exists a diagram \(\bar{F}^{\prime}: \bar{J} \star K \rightarrow \mathcal{C}\) satisfying \(F_{0}=\bar{F} \circ s_{0}^{\prime}\) and \(F_{1}=\bar{F} \circ s_{1}^{\prime}\).
The equivalence of \(\left(1^{\prime}\right)\) and \(\left(2^{\prime}\right)\) follows immediately from the universal property of the slice \(\infty\)-category \(\mathcal{C}_{/ F}\).

Proof of Theorem 4.6.4.17, Let \(\mathcal{C}\) be an \(\infty\)-category and let \(F: K \rightarrow \mathcal{C}\) be a diagram, which we regard as an object of the \(\infty\)-category \(\operatorname{Fun}(K, \mathcal{C})\). We will show that the slice diagonal morphism
\[
\delta_{/ F}: \mathcal{C}_{/ F} \hookrightarrow \mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{F\}
\]
is an equivalence of \(\infty\)-categories; the corresponding assertion for the coslice diagonal morphism follows by a similar argument. Fix a simplicial set \(J\); we wish to show that the induced map of sets
\[
\theta: \pi_{0}\left(\operatorname{Fun}\left(J, \mathcal{C}_{/ F}\right) \simeq \pi_{0}\left(\operatorname{Fun}\left(J, \mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{F\}\right)^{\simeq}\right)\right.
\]
is a bijection. Using Lemma 4.6.4.21 and Remark 4.6.4.14 we can identify \(\theta\) with the map of sets
\[
\pi_{0}\left(\operatorname{Fun}_{K /}(J \star K, \mathcal{C})^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}_{K /}(J \diamond K, \mathcal{C})^{\simeq}\right)
\]
induced by precomposition with the comparison map \(c_{J, K}: J \diamond K \rightarrow J \star K\) of Notation 4.5.8.3. It will therefore suffice to show that composition with \(c_{J, K}\) induces an equivalence of \(\infty\)-categories \(\operatorname{Fun}_{K /}(J \star K, \mathcal{C}) \rightarrow \operatorname{Fun}_{K /}(J \diamond K, \mathcal{C})\). This follows by applying Corollary 4.5 .2 .32 to the commutative diagram

here the vertical maps are isofibrations (Corollary 4.4.5.3) and the upper horizontal map is an equivalence of \(\infty\)-categories because the morphism \(c_{J, K}\) is a categorical equivalence (Theorem 4.5.8.8).

\subsection*{4.6.5 Pinched Morphism Spaces}

Let \(\mathcal{C}\) be an \(\infty\)-category. In \(\S 4.6 .1\), we associated to every pair of objects \(X, Y \in \mathcal{C}\) a Kan complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\), which we refer to as the space of morphisms from \(X\) to \(Y\) (Construction 4.6.1.1). In this section, we discuss a variant of this construction which is often more technically convenient to work with.

Construction 4.6.5.1. Let \(\mathcal{C}\) be a simplicial set containing vertices \(X\) and \(Y\). We let \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) denote the fiber product \(\mathcal{C}_{X /} \times \mathcal{C}\{Y\}\), and we let \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) denote the fiber product \(\{X\} \times_{\mathcal{C}} \mathcal{C}_{/ Y}\). We will be primarily interested in these constructions in the situation where \(\mathcal{C}\) is an \(\infty\)-category. In this case, we refer to \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) as the left-pinched space of morphisms from \(X\) to \(Y\) and to \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) as the right-pinched space of morphisms from \(X\) to \(Y\).

Remark 4.6.5.2. Let \(\mathcal{C}\) be a simplicial set containing vertices \(X\) and \(Y\). For every integer \(n \geq 0\), one can identify \(n\)-simplices of the left-pinched morphism space \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) with \((n+1)\)-simplices \(\sigma: \Delta^{n+1} \rightarrow \mathcal{C}\) for which \(\sigma(0)=X\) and the face \(d_{0}^{n+1}(\sigma)\) is the constant map \(\Delta^{n} \rightarrow\{Y\} \hookrightarrow \mathcal{C}\). Similarly, one can identify \(n\)-simplices of the right-pinched morphism space \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) with \((n+1)\)-simplices \(\sigma^{\prime}: \Delta^{n+1} \rightarrow \mathcal{C}\) for which \(\sigma(n+1)=Y\) and the face \(d_{n+1}^{n+1}(\sigma)\) is the constant map \(\Delta^{n} \rightarrow\{X\} \hookrightarrow \mathcal{C}\). In particular, we have canonical bijections
\(\left\{\right.\) Vertices of \(\left.\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\right\} \simeq\{\) Edges \(f: X \rightarrow Y\) in \(\mathcal{C}\} \simeq\left\{\right.\) Vertices of \(\left.\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\right\}\).

01KZ Remark 4.6.5.3. Let \(\mathcal{C}\) be a simplicial set containing vertices \(X\) and \(Y\), which we also regard as vertices of the opposite simplicial set \(\mathcal{C}^{\text {op }}\). Then we have canonical isomorphisms of simplicial sets
\[
\operatorname{Hom}_{\mathcal{C}^{\mathrm{op}}}^{\mathrm{L}}(X, Y) \simeq \operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(Y, X)^{\mathrm{op}} \quad \operatorname{Hom}_{\mathcal{C}^{\mathrm{op}}}^{\mathrm{R}}(X, Y) \simeq \operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(Y, X)^{\mathrm{op}} .
\]

0574 Remark 4.6.5.4. Let \(\mathcal{C}\) be a simplicial set, let \(n \geq 0\) be an integer, and let \(\operatorname{cosk}_{n}(\mathcal{C})\) denote the \(n\)-coskeleton of \(\mathcal{C}\) (Notation 3.5.3.18). For every pair of vertices \(X, Y \in \mathcal{C}\), Remark 4.3.5.16 supplies canonical isomorphisms
\[
\begin{aligned}
& \operatorname{cosk}_{n}(\mathcal{C})_{X /} \simeq \operatorname{cosk}_{n-1}\left(\mathcal{C}_{X /}\right) \times_{\operatorname{cosk}_{n-1}(\mathcal{C})} \operatorname{cosk}_{n}(\mathcal{C}) \\
& \operatorname{cosk}_{n}(\mathcal{C})_{/ Y} \simeq \operatorname{cosk}_{n-1}\left(\mathcal{C}_{/ Y}\right) \times_{\operatorname{cosk}_{n-1}(\mathcal{C})} \operatorname{cosk}_{n}(\mathcal{C}) .
\end{aligned}
\]

Passing to fibers over the vertices \(Y\) and \(X\), we obtain isomorphisms of pinched morphism spaces
\(\operatorname{Hom}_{\operatorname{cosk}_{n}(\mathcal{C})}^{\mathrm{L}}(X, Y) \simeq \operatorname{cosk}_{n-1}\left(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\right) \quad \operatorname{Hom}_{\operatorname{cosk}_{n}(\mathcal{C})}^{\mathrm{R}}(X, Y) \simeq \operatorname{cosk}_{n-1}\left(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\right)\).
In particular, if \(\mathcal{C}\) is \(n\)-coskeletal, then the pinched morphism spaces \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) and \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) are \((n-1)\)-coskeletal.

01L0 Proposition 4.6.5.5. Let \(\mathcal{C}\) be an \(\infty\)-category. For every pair of objects \(X, Y \in \mathcal{C}\), the pinched morphism spaces \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) and \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) are Kan complexes.

Proof. By virtue of Proposition 4.3.6.1, the projection \(\operatorname{map} \mathcal{C}_{X /} \rightarrow \mathcal{C}\) is a left fibration. Applying Corollary 4.4.2.3, we deduce that the fiber \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)=\mathcal{C}_{X /} \times_{\mathcal{C}}\{Y\}\) is a Kan complex. A similar argument shows that \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) is a Kan complex.

01L1 Remark 4.6.5.6. Let \(\mathcal{C}\) be an \(\infty\)-category containing a pair of morphisms \(f, g: X \rightarrow Y\) having the same source and target. Then the datum of an edge \(e: f \rightarrow g\) in the left-pinched morphism space \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) is equivalent to the datum of a homotopy from \(f\) to \(g\), in the sense of Definition 1.4.3.1. In particular, \(f\) and \(g\) are homotopic if and only if they belong to the same connected component of \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\). We therefore have a canonical bijection \(\operatorname{Hom}_{\mathrm{hc}}(X, Y) \simeq \pi_{0}\left(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\right)\).

We now compare the pinched morphism spaces of Construction4.6.5.1 with the morphism spaces of Construction 4.6.1.1.

01 L 2 Construction 4.6.5.7. Let \(\mathcal{C}\) be a simplicial set containing vertices \(X\) and \(Y\), and let
\[
\delta_{X /}: \mathcal{C}_{X /} \hookrightarrow\{X\} \tilde{x}_{\mathcal{C}} \mathcal{C} \quad \delta_{/ Y}: \mathcal{C}_{/ Y} \hookrightarrow \mathcal{C} \tilde{x}_{\mathcal{C}}\{Y\}
\]
be the coslice and slice diagonal morphisms of Construction 4.6.4.13. Restricting to the fibers over the objects \(Y, X \in \mathcal{C}\), we obtain morphisms of Kan complexes
\[
\begin{aligned}
\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y) & =\mathcal{C}_{X /} \times_{\mathcal{C}}\{Y\} \rightarrow\{X\} \tilde{x}_{\mathcal{C}}\{Y\}=\operatorname{Hom}_{\mathcal{C}}(X, Y) \\
\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y) & =\{X\} \times_{\mathcal{C}} \mathcal{C} / Y \rightarrow\{X\} \tilde{\times}_{\mathcal{C}}\{Y\}=\operatorname{Hom}_{\mathcal{C}}(X, Y),
\end{aligned}
\]
which we will denote by \(\iota_{X, Y}^{\mathrm{L}}\) and \(\iota_{X, Y}^{\mathrm{R}}\), respectively. We will refer to \(\iota_{X, Y}^{\mathrm{L}}\) as the left-pinch inclusion map and to \(\iota_{X, Y}^{\mathrm{R}}\) as the right-pinch inclusion map.
Remark 4.6.5.8. Let \(\mathcal{C}\) be a simplicial set containing vertices \(X\) and \(Y\). Then the pinch 01L3 inclusion maps
\[
\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y) \xrightarrow{{c_{X, Y}^{\mathrm{L}}}_{\longrightarrow}^{\operatorname{Hom}_{\mathcal{C}}}(X, Y) \stackrel{\iota_{X, Y}^{\mathrm{R}}}{\Vdash} \operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y), ~}
\]
are monomorphisms (see Remark 4.6.4.15).
Remark 4.6.5.9. Let \(\mathcal{C}\) be an \(\infty\)-category containing objects \(X\) and \(Y\). Then the pinch 01L4 inclusion maps
\[
\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y) \xrightarrow{{\iota_{X, Y}^{\mathrm{L}}}_{\longrightarrow}^{\operatorname{Hom}_{\mathcal{C}}}(X, Y) \stackrel{\iota_{X, Y}^{\mathrm{R}}}{\Vdash} \operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y), ~}
\]
are bijective on vertices: vertices of each simplicial set can be identified with morphisms from \(X\) to \(Y\) in the \(\infty\)-category \(\mathcal{C}\) (Remarks 4.6.1.2 and 4.6.5.2. However, they are generally not bijective on edges. Note that edges of the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) can be identified with diagrams

in the \(\infty\)-category \(\mathcal{C}\). Such a diagram belongs to the image of the left-pinch inclusion map \(\iota_{X, Y}^{\mathrm{L}}\) if and only \(\tau=s_{0}(g)\) (so that the simplex \(\tau\) is degenerate, \(f^{\prime}=g\), and the entire diagram is determined by \(\sigma\) ). Similarly, the diagram belongs to the image of the right-pinch inclusion map \(\iota_{X, Y}^{\mathrm{R}}\) if and only if \(\sigma=s_{1}(g)\) (so that the simplex \(\sigma\) is degenerate, \(f=g\), and the entire diagram is determined by \(\tau\) ).
4.6. MORPHISM SPACES

01 L 5 Proposition 4.6.5.10. Let \(\mathcal{C}\) be an \(\infty\)-category. For every pair of objects \(X, Y \in \mathcal{C}\), the pinch inclusion morphisms
\[
\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y) \xrightarrow{{\iota_{X, Y}^{\mathrm{L}}}_{\longrightarrow}^{L}} \operatorname{Hom}_{\mathcal{C}}(X, Y) \stackrel{\iota_{X, Y}^{\mathrm{R}}}{\longleftarrow} \operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)
\]
are homotopy equivalences of Kan complexes.
Proof. We will prove that the left-pinch inclusion morphism \(\iota_{X, Y}^{\mathrm{L}}\) is a homotopy equivalence; the proof for the right-pinch inclusion morphism \(\iota_{X, Y}^{\mathrm{R}}\) is similar. Note that we have a commutative diagram of \(\infty\)-categories

where the horizontal maps are equivalences of \(\infty\)-categories (Corollary 4.6.4.18) and the vertical maps are left fibrations (Propositions 4.3.6.1 and 4.6.4.11), hence isofibrations (Example 4.4.1.11). Applying Corollary 4.5.2.32, we deduce that the induced map of fibers
\[
\iota_{X, Y}^{\mathrm{L}}: \operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)=\left(\mathcal{C}_{X /}\right) \times_{\mathcal{C}}\{Y\} \rightarrow\{X\} \tilde{\times}_{\mathcal{C}}\{Y\}=\operatorname{Hom}_{\mathcal{C}}(X, Y)
\]
is an equivalence of \(\infty\)-categories, hence a homotopy equivalence of Kan complexes (Remark 4.5.1.4.

01PX Corollary 4.6.5.11. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between \(\infty\)-categories. The following conditions are equivalent:
- The functor \(F\) is fully faithful. That is, for every pair of objects \(X, Y \in \mathcal{C}\), the functor \(F\) induces a homotopy equivalence of Kan complexes \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\).
- For every pair of objects \(X, Y \in \mathcal{C}\), the functor \(F\) induces a homotopy equivalence of left-pinched morphism spaces \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}^{\mathrm{L}}(F(X), F(Y))\).
- For every pair of objects \(X, Y \in \mathcal{C}\), the functor \(F\) induces a homotopy equivalence of right-pinched morphism spaces \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}^{\mathrm{R}}(F(X), F(Y))\).

01L6 Example 4.6.5.12. Let \(\mathcal{C}\) be an ordinary category containing objects \(X\) and \(Y\). Then the slice and coslice diagonal morphisms
\[
\delta_{X /}: \mathrm{N}_{\bullet}(\mathcal{C})_{X /} \rightarrow\{X\} \tilde{\times}_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}(\mathcal{C}) \quad \delta_{/ Y}: \mathrm{N}_{\bullet}(\mathcal{C})_{/ Y} \rightarrow\left(\mathrm{~N}_{\bullet}(\mathcal{C}) \tilde{x}_{\mathrm{N}_{\bullet}(\mathcal{C})}\{Y\}\right.
\]
are isomorphisms (see Remark 4.3.1.7). In particular, we can identify the pinched morphism spaces \(\operatorname{Hom}_{\mathrm{N} \bullet(\mathcal{C})}^{\mathrm{L}}(X, Y)\) and \(\operatorname{Hom}_{\mathrm{N} \bullet(\mathcal{C})}^{\mathrm{R}}(X, Y)\) with the constant simplicial set \(\operatorname{Hom}_{\mathrm{N}}(\mathcal{C})(X, Y)\) associated to the usual morphism set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\).

Let \(\mathcal{C}\) be an \(\infty\)-category containing a pair of objects \(X\) and \(Y\). By virtue of Proposition 4.6.5.10 the pinched morphism spaces \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) and \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) of Construction 4.6.5.1 contain the same homotopy-theoretic information as the morphism space \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) of Construction 4.6.1.1. However, they package this information in a more efficient way: an \(n\)-simplex of the Kan complex \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) can be identified with a single \((n+1)\)-simplex of the \(\infty\)-category \(\mathcal{C}\) (see Remark 4.6.5.2, but to specify an \(n\)-simplex of \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) one must supply \(n+1\) different \((n+1)\)-simplices of \(\mathcal{C}\) (see Remark 4.6.5.9 for the case \(n=1\) ).

Example 4.6.5.13 (Pinched Morphism Spaces in the Duskin Nerve). Let \(\mathcal{C}\) be a 2 -category 01L7 (Definition 2.2.1.1). For each integer \(n \geq 0\), we can use Remark 2.3.1.8 to identify \((n+1)\) simplices \(\sigma\) of the Duskin nerve \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{C})\) with the following data:
(0) A collection of objects \(\left\{Z_{i}\right\}_{0 \leq i \leq n+1}\) of the 2-category \(\mathcal{C}\).
(1) A collection of 1-morphisms \(\left\{f_{j, i}: Z_{i} \rightarrow Z_{j}\right\}_{0 \leq i \leq j \leq n+1}\) in the 2-category \(\mathcal{C}\), satisfying \(f_{j, i}=\operatorname{id}_{Z_{i}}\) when \(i=j\).
(2) A collection of 2-morphisms \(\left\{\mu_{k, j, i}: f_{k, j} \circ f_{j, i} \Rightarrow f_{k, i}\right\}_{0 \leq i \leq j \leq k \leq n+1}\) in the 2-category \(\mathcal{C}\), satisfying some additional constraints (see (b) and (c) of Proposition 2.3.1.9.

Fix a pair of objects \(X\) and \(Y\). Then \(\sigma\) represents an \(n\)-simplex of the right pinched morphism space \(\operatorname{Hom}_{\mathrm{N}_{\mathrm{D}}(\mathcal{C})}^{\mathrm{R}}(X, Y)\) if and only if the above data satisfies the following additional conditions:
- For \(0 \leq i \leq n\), the object \(Z_{i}\) is equal to \(X\). For \(i=n+1\), the object \(Z_{i}\) is equal to \(Y\).
- For \(0 \leq i \leq j \leq n\), the 1 -morphism \(f_{j, i}\) is equal to the identity 1 -morphism id \(X_{X}\).
- For \(0 \leq i \leq j \leq k \leq n\), the 2-morphism \(\mu_{k, j, i}\) is equal to the unit constraint \(v: \operatorname{id}_{X} \circ \operatorname{id}_{X} \Rightarrow \operatorname{id}_{X}\).

In this case, we can identify (1) with a collection of 1-morphisms \(\left\{g_{i}: X \rightarrow Y\right\}_{0 \leq i \leq n}\) given by \(g_{i}=f_{n+1, i}\), and (2) with a collection of 2-morphisms \(\left\{\nu_{j, i}: g_{j} \Rightarrow g_{i}\right\}_{0 \leq i \leq j \leq n}\), where \(\nu_{j, i}\) is given by the composition
\[
g_{j} \xlongequal{\Longrightarrow} g_{j} \circ \operatorname{id}_{X}=f_{n+1, j} \circ f_{j, i} \xrightarrow{\mu_{n+1, j, i}} f_{n+1, i}=g_{i} .
\]

Unwinding the definitions, condition (b) translates to the requirement that \(\nu_{j, i}\) is an identity 2-morphism when \(i=j\), and condition (c) translates to the identity \(\nu_{k, j} \circ \nu_{j, i}=\nu_{k, i}\) for \(0 \leq i \leq j \leq k \leq n\). In this case, we can identify the pair ( \(\left\{g_{i}\right\}_{0 \leq i \leq n},\left\{\nu_{j, i}\right\}_{0 \leq i \leq j \leq n}\) ) with a functor \([n] \rightarrow \underline{\operatorname{Hom}}_{\mathcal{C}}(X, Y)^{\mathrm{op}}\). These identifications depends functorially on \([n] \in \boldsymbol{\Delta}\), and therefore determine a canonical isomorphism of simplicial sets
\[
\operatorname{Hom}_{\mathrm{N}_{\bullet}(\mathcal{C})}^{\mathrm{R}}(X, Y) \simeq \mathrm{N}_{\bullet}\left(\underline{\operatorname{Hom}}_{\mathcal{C}}(X, Y)^{\mathrm{op}}\right) .
\]

Using similar reasoning, we obtain an isomorphism of simplicial sets
\[
\operatorname{Hom}_{\mathrm{N}_{\bullet}(\mathcal{C})}^{\mathrm{L}}(X, Y) \simeq \mathrm{N}_{\bullet}\left(\underline{\operatorname{Hom}}_{\mathcal{C}}(X, Y)\right)
\]

01L8 Example 4.6.5.14. Let \(X\) be a topological space containing a pair of points \(x\) and \(y\), which we regard as objects of the \(\infty\)-category Sing. \((X)\). Using Example 4.3.5.9, we obtain canonical isomorphisms of Kan complexes
\[
\operatorname{Hom}_{\text {Sing. }}^{\mathrm{L}}(X)(x, y) \simeq \operatorname{Sing}_{\bullet}\left(P_{x, y}\right) \simeq \operatorname{Hom}_{\operatorname{Sing}}^{\bullet}(X)(x, y),
\]
where \(P_{x, y}\) denotes the topological space of continuous paths \(p:[0,1] \rightarrow X\) satisfying \(p(0)=x\) and \(p(1)=y\) (equipped with the compact-open topology). Combining this observation with Example 4.6.1.5. we can identify the pinch inclusion maps \(\iota_{x, y}^{\mathrm{L}}\) and \(\iota_{x, y}^{\mathrm{R}}\) with monomorphisms from the simplicial set Sing. \(\left(P_{x, y}\right)\) to itself. Beware that these maps are not the identity (though one can show that they are homotopic to the identity).
\(01 \mathrm{L9}\) Example 4.6.5.15 (Pinched Morphism Spaces in the Differential Graded Nerve). Let \(\mathcal{C}\) be a differential graded category (Definition 2.5.2.1), let \(\mathrm{N}_{\bullet}^{\mathrm{dg}}(\mathcal{C})\) denote the differential graded nerve of \(\mathcal{C}\) (Definition 2.5.3.7), and let \(X\) and \(Y\) be objects of \(\mathcal{C}\) (which we also view as objects of the \(\infty\)-category \(\mathrm{N}_{\bullet}^{\mathrm{dg}}(\mathcal{C})\) ), and let \(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}\) denote the chain complex of morphisms from \(X\) to \(Y\). For \(n \geq 0\), we can identify \(n\)-simplices of the left-pinched morphism space \(\operatorname{Hom}_{\mathrm{N}_{\bullet} \mathrm{d}_{(\mathcal{C})}}^{\mathrm{L}}(X, Y)\) with \((n+1)\)-simplices \(\sigma: \Delta^{n+1} \rightarrow \mathrm{~N}_{\bullet}^{\mathrm{dg}}(\mathcal{C})\) for which \(\sigma(0)=X\) and \(d_{0}^{n+1}(\sigma)\) is the constant \(n\)-simplex with the value \(Y\) (Remark 4.6.5.2). Concretely, such a simplex can be described as a datum \(I \mapsto f_{I}\), defined for each subset \(I=\left\{i_{0}>i_{1}>i_{2}>\cdots>i_{k}>i_{k+1}\right\} \subseteq[n+1]\) having at least two elements, with the following properties:
(1) If \(i_{k+1}>0\), then \(f_{I}\) is an element of the abelian \(\operatorname{group} \operatorname{Hom}_{\mathcal{C}}(Y, Y)_{k}\), which is equal to \(\mathrm{id}_{Y}\) in the case \(k=0\) and vanishes for \(k>0\).
(2) If \(i_{k+1}=0\), then \(f_{I}\) is an element of the abelian \(\operatorname{group} \operatorname{Hom}_{\mathcal{C}}(X, Y)_{k}\) which satisfies the identity
\[
\partial f_{I}=\sum_{a=1}^{k}(-1)^{a}\left(f_{\left\{i_{0}>i_{1}>\cdots>i_{a}\right\}} \circ f_{\left\{i_{a}>\cdots>i_{k+1}\right\}}-f_{I \backslash\left\{i_{a}\right\}}\right) .
\]

Note that, by virtue of (1), we can rewrite this identity as
\[
\partial f_{I}= \begin{cases}0 & \text { if } k=0  \tag{4.38}\\ \sum_{a=0}^{k}(-1)^{a+1} f_{I \backslash\left\{i_{a}\right\}} & \text { if } k>0 .\end{cases}
\]

Let \(J=\left\{j_{0}<j_{1}<\cdots<j_{k}\right\}\) be a nonempty subset of \([n]\). For \(\left\{f_{I}\right\}\) as above, define \(g_{J} \in \operatorname{Hom}_{\mathcal{C}}(X, Y)_{k}\) by the formula \(g_{J}=(-1)^{k(k-1) / 2} f_{\left\{j_{k}+1>j_{k-1}+1>\cdots>0\right\}}\). We can then
rewrite the identity (4.38) as
\[
\partial g_{J}=\sum_{b=0}^{k}(-1)^{b} g_{J \backslash\left\{j_{b}\right\}} .
\]

The construction \(J \mapsto g_{J}\) can then be identified with a morphism from the normalized chain complex \(\mathrm{N}_{*}\left(\Delta^{n}\right)\) of Construction 2.5.5.9 to the chain complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\). This identification depends functorially on \(n\), and therefore determines an isomorphism of simplicial sets
\[
\operatorname{Hom}_{\mathrm{N}_{\bullet}^{\mathrm{dg}}(\mathcal{C})}^{\mathrm{L}}(X, Y) \simeq \mathrm{K}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}\right),
\]
where \(\mathrm{K}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}\right)\) denotes the Eilenberg-MacLane space associated to the chain complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}(\) Construction 2.5.6.3). In particular, the left-pinched morphism space \(\operatorname{Hom}_{\mathrm{N}_{0}{ }^{\mathrm{d}}(\mathcal{C})}^{\mathrm{L}}(X, Y)\) has the structure of a simplicial abelian group.

\subsection*{4.6.6 Digression: Diagrams in Slice \(\infty\)-Categories}

For some applications, it will be useful to combine the slice and coslice constructions
04HY introduced in \(\$ 4.3\).

Notation 4.6.6.1. Let \(K_{-}, K_{+}\), and \(\mathcal{C}\) be simplicial sets, and suppose we are given a morphism \(f_{ \pm}: K_{-} \star K_{+} \rightarrow \mathcal{C}\). Set \(f_{-}=\left.f_{ \pm}\right|_{K_{-}}\)and \(f_{+}=\left.f_{ \pm}\right|_{K_{+}}\), and let \(\pi: \mathcal{C}_{/ f_{+}} \rightarrow \mathcal{C}\) denote the projection map. Then \(f_{ \pm}\)determines a morphism of simplicial sets \(\widetilde{f}_{-}: K_{-} \rightarrow \mathcal{C}_{/ f_{+}}\)for which the diagram

is commutative. In this situation, we let \(\mathcal{C}_{f_{-} / / f_{+}}\)denote the coslice simplicial set \(\left(\mathcal{C}_{/ f_{+}}\right)_{\tilde{f}_{-} /}\).
Remark 4.6.6.2. In the situation of Notation 4.6.6.1, we can also identify \(f_{ \pm}\)with a 01 NR morphism of simplicial sets \(\tilde{f}_{+}: K_{+} \rightarrow \mathcal{C}_{f_{-} / \text {. }}\) Let \(Y\) be any simplicial set. Using Proposition 4.3 .5 .13 we see that the following data are equivalent:
(1) Morphisms from \(Y\) to \(\left(\mathcal{C}_{/ f_{+}}\right)_{\bar{f}_{-} /}\).
(2) Morphisms from \(Y\) to \(\left(\mathcal{C}_{f_{-} /}\right)_{/ \bar{f}_{+}}\).
(3) Morphisms \(f: K_{-} \star Y \star K_{+} \rightarrow \mathcal{C}\) satisfying \(\left.f\right|_{K_{-} \star K_{+}}=f_{ \pm}\).

It follows that the simplicial set \(\mathcal{C}_{f_{-} / / f_{+}}=\left(\mathcal{C}_{/ f_{+}}\right)_{\tilde{f}_{-} /}\)can also be identified with the slice simplicial set \(\left(\mathcal{C}_{f_{-} /}\right)_{/ \widetilde{f}_{+}}\).

04J0 Warning 4.6.6.3. In the situation of Notation 4.6.6.1. the simplicial set \(\mathcal{C}_{f_{-} / / f_{+}}\)depends on the morphism \(f_{ \pm}: K_{-} \star K_{+} \rightarrow \mathcal{C}\), and not only on the morphisms \(f_{-}=\left.f_{ \pm}\right|_{K_{-}}\)and \(f_{+}=\left.f_{ \pm}\right|_{K_{+}}\)indicated in the notation.

In the situation of Notation 4.6.6.1, suppose that the simplicial set \(\mathcal{C}\) is an \(\infty\)-category. Applying Proposition 4.3.6.1 twice, we deduce that the simplicial set \(\mathcal{C}_{f_{-} / / f_{+}}\)is also an \(\infty\)-category. We now exploit the relationship between slice constructions and oriented fiber products (Theorem 4.6.4.17) to give an alternative description of \(\mathcal{C}_{f_{-} / / f_{+}}\).
04 J 1 Construction 4.6.6.4. Let \(f_{ \pm}: K_{-} \star K_{+} \rightarrow \mathcal{C}\) be a morphism of simplicial sets, and set \(f_{-}=\left.f_{ \pm}\right|_{K_{-}}\)and \(f_{+}=\left.f_{ \pm}\right|_{K_{+}}\). Let \(K\) be another simplicial set, set \(M=\operatorname{Fun}\left(K, \mathcal{C}_{f_{-} / / f_{+}}\right)\). Let ev : \(M \times K \rightarrow \mathcal{C}_{f_{-} / / f_{+}}\)be the evaluation map, and let \(\pi_{-}: M \times K_{-} \rightarrow K_{-}\)and \(\pi_{+}: M \times K_{+} \rightarrow K_{+}\)be given by projection onto the second factor. Then the composition
\[
\begin{array}{lll}
M \times\left(K_{-} \star K \star K_{+}\right) & \rightarrow & \left(M \times K_{-}\right) \star(M \times K) \star\left(M \times K_{+}\right) \\
& \rightarrow & \mathcal{C}
\end{array}
\]
classifies a morphism of simplicial sets \(M \rightarrow \operatorname{Fun}\left(K_{-} \star K \star K_{+}, \mathcal{C}\right)\), whose composition with the restriction map \(\operatorname{Fun}\left(K_{-} \star K \star K_{+}, \mathcal{C}\right) \rightarrow \operatorname{Fun}\left(K_{-} \star K_{+}, \mathcal{C}\right)\) is the constant map taking the value \(f_{ \pm}\). We therefore obtain a comparison map
\[
\theta: \operatorname{Fun}\left(K, \mathcal{C}_{f_{-} / / f_{+}}\right) \rightarrow \operatorname{Fun}\left(K_{-} \star K \star K_{+}, \mathcal{C}\right) \times_{\operatorname{Fun}\left(K_{-\star} K_{+}, \mathcal{C}\right)}\left\{f_{ \pm}\right\} .
\]

04 J 2 Theorem 4.6.6.5. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(f_{ \pm}: K_{-} \star K_{+} \rightarrow \mathcal{C}\) be a diagram. Then, for any simplicial set \(K\), the comparison map
\[
\theta: \operatorname{Fun}\left(K, \mathcal{C}_{f_{-} / / f_{+}}\right) \rightarrow \operatorname{Fun}\left(K_{-} \star K \star K_{+}, \mathcal{C}\right) \times_{\operatorname{Fun}\left(K_{-\star} K_{+}, \mathcal{C}\right)}\left\{f_{ \pm}\right\}
\]
of Construction 4.6.6.4 is an equivalence of \(\infty\)-categories.
04J3 Example 4.6.6.6. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(f_{ \pm}: K_{-} \star K_{+} \rightarrow \mathcal{C}\) be a diagram. Applying Theorem 4.6.6.5 in the special case \(K=\Delta^{0}\), we obtain an equivalence of \(\infty\)-categories
\[
\mathcal{C}_{f_{-} / / f_{+}} \rightarrow \operatorname{Fun}\left(K_{-} \star \Delta^{0} \star K_{+}, \mathcal{C}\right) \times_{\operatorname{Fun}\left(K_{-} \star K_{+}, \mathcal{C}\right)}\left\{f_{ \pm}\right\} .
\]

We begin by proving Theorem 4.6.6.5 in the special case where \(K_{-}\)is empty.
04J4 Lemma 4.6.6.7. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(f_{+}: K_{+} \rightarrow \mathcal{C}\) be a diagram. Then, for every simplicial set \(K\), the comparison map
\[
\theta: \operatorname{Fun}\left(K, \mathcal{C}_{/ f_{+}}\right) \rightarrow \operatorname{Fun}\left(K \star K_{+}, \mathcal{C}\right) \times_{\left.K_{+}, \mathcal{C}\right)}\left\{f_{+}\right\}
\]
of Construction 4.6.6.4 is an equivalence of \(\infty\)-categories.

Proof. Let \(c: K \diamond K_{+} \rightarrow K \star K_{+}\)be as in Notation 4.5.8.3. We then have a commutative diagram

where the vertical maps are isofibrations (Corollary 4.4.5.3). Since \(c\) is a categorical equivalence of simplicial sets (Theorem 4.5.8.8), the upper horizontal map is an equivalence of \(\infty\)-categories. Applying Corollary 4.5.2.32, we conclude that composition with \(c\) induces an equivalence of \(\infty\)-categories
\[
\begin{aligned}
\operatorname{Fun}\left(K \star K_{+}, \mathcal{C}\right) \times_{\operatorname{Fun}\left(K_{+}, \mathcal{C}\right)}\left\{f_{+}\right\} & \xrightarrow{\theta^{\prime}} \operatorname{Fun}\left(K \diamond K_{+}, \mathcal{C}\right) \times \times_{\operatorname{Fun}\left(K_{+}, \mathcal{C}\right)}\left\{f_{+}\right\} \\
& \simeq \operatorname{Fun}\left(K, \mathcal{C} \tilde{\times}_{\operatorname{Fun}\left(K_{+}, \mathcal{C}\right)}\left\{f_{+}\right\}\right) .
\end{aligned}
\]

It will therefore suffice to show that \(\theta^{\prime} \circ \theta\) is an equivalence of \(\infty\)-categories. We conclude by observing that \(\theta^{\prime} \circ \theta\) is given by postcomposition with the slice diagonal \(\mathcal{C}_{/ f_{+}} \hookrightarrow\) \(\mathcal{C} \tilde{x}_{\operatorname{Fun}\left(K_{+}, \mathcal{C}\right)}\left\{f_{+}\right\}\), which is an equivalence of \(\infty\)-categories by virtue of Theorem 4.6.4.17

Example 4.6.6.8. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(f_{+}: K_{+} \rightarrow \mathcal{C}\) be a diagram. Applying 04J5 Lemma 4.6.6.7 in the special case \(K=\Delta^{0}\), we obtain an equivalence of \(\infty\)-categories \(\mathcal{C}_{/ f_{+}} \rightarrow \operatorname{Fun}\left(K_{+}^{\triangleleft}, \mathcal{C}\right) \times_{\operatorname{Fun}\left(K_{+}, \mathcal{C}\right)}\left\{f_{+}\right\}\).

Proof of Theorem 4.6.6.5. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(f_{ \pm}: K_{-} \star K_{+} \rightarrow \mathcal{C}\) be a diagram. Set \(f_{-}=\left.f_{ \pm}\right|_{K_{-}}\)and \(f_{+}=\left.f_{ \pm}\right|_{K_{+}}\), so that \(f_{ \pm}\)can be identified with a morphism \(\tilde{f}_{-}: K_{-} \rightarrow\) \(\mathcal{C}_{/ f_{+}}\). We then have a commutative diagram of simplicial sets

where the vertical maps are isofibrations (Corollary 4.4.5.3). It follows from Lemma 4.6.6.7 (and Proposition 4.5.2.26) that the lower right square and the outer right rectangle are categorical pullback squares, so the upper right corner is also a categorical pullback square (Proposition 4.5.2.18). Similarly, the dual of Lemma 4.6.6.7 guarantees that the upper left corner is a categorical pullback square. Applying Proposition 4.5.2.18, we conclude that the outer rectangle on the top of the diagram is a categorical pullback square, which is a restatement of Theorem 4.6.6.5 (Proposition 4.5.2.26).

04J6 Corollary 4.6.6.9. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(f_{ \pm}: K_{-} \star K_{+} \rightarrow \mathcal{C}\) be a diagram. Then, for any inclusion of simplicial sets \(A \hookrightarrow B\), the diagram of \(\infty\)-categories

is a categorical pullback square.

Proof. We can identify (4.39) with the upper half of a commutative diagram

By virtue of Proposition 4.5.2.18, it will suffice to show that the lower half and outer rectangle of the diagram are categorical pullback squares, which follows from Theorem 4.6.6.5

We conclude this section by recording a thematically related result, which characterizes slices of functor \(\infty\)-categories (rather than functors into a slice \(\infty\)-category).

02GN Variant 4.6.6.10. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(f: K \rightarrow \mathcal{C}\) be a diagram, which we identify with an object \(F\) of the \(\infty\)-category \(\operatorname{Fun}(K, \mathcal{C})\). Then the functors
\[
\mathcal{C}_{/ f} \rightarrow \mathcal{C} \times \times_{\operatorname{Fun}(K, \mathcal{C})} \operatorname{Fun}(K, \mathcal{C})_{/ F} \quad \mathcal{C}_{f /} \rightarrow \operatorname{Fun}(K, \mathcal{C})_{F /} \times_{\operatorname{Fun}(K, \mathcal{C})} \mathcal{C}
\]
of Exercise 4.6.4.16 are equivalences of \(\infty\)-categories.
Proof. We will show that the slice diagonal \(\delta_{/ f}\) induces an equivalence of \(\infty\)-categories \(\mathcal{C}_{/ f} \rightarrow \mathcal{C} \times_{\operatorname{Fun}(K, \mathcal{C})} \operatorname{Fun}(K, \mathcal{C})_{/ F}\); the analogous assertion for coslice \(\infty\)-categories follows by a similar argument. By virtue of Theorem 4.6.4.17, it will suffice to show that the inclusion map
\[
\mathcal{C} \times_{\operatorname{Fun}(K, \mathcal{C})} \operatorname{Fun}(K, \mathcal{C})_{/ F} \hookrightarrow \mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{F\}
\]
is an equivalence of \(\infty\)-categories. By construction, this map fits into a commutative diagram
of \(\infty\)-categories

where the upper square and lower square are both pullback diagrams. Note that the morphisms \(V\) and \(V \circ U\) are both right fibrations (Propositions 4.6.4.11 and 4.3.6.1), and therefore isofibrations (Example 4.4.1.11). Using Propositions 4.5.2.26 and 4.5.2.18, we see that the upper square is a categorical pullback. Theorem 4.6.4.17 guarantees that \(U\) is an equivalence of \(\infty\)-categories, so that \(\iota\) is an equivalence of \(\infty\)-categories by virtue of Proposition 4.5.2.21.

\subsection*{4.6.7 Initial and Final Objects}

Let \(\mathcal{C}\) be a category. Recall that an object \(Y \in \mathcal{C}\) is initial if, for every object \(Z \in \mathcal{C}\),
02H6 there is a unique morphism from \(Y\) to \(Z\). This definition has an obvious counterpart in the setting of \(\infty\)-categories.
Definition 4.6.7.1. Let \(\mathcal{C}\) be an \(\infty\)-category. We say that an object \(Y \in \mathcal{C}\) is initial if, for \(02 \mathrm{H7}\) every object \(Z \in \mathcal{C}\), the morphism space \(\operatorname{Hom}_{\mathcal{C}}(Y, Z)\) is a contractible Kan complex. We say that \(Y\) is final if, for every object \(X \in \mathcal{C}\), the morphism space \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is a contractible Kan complex.

Remark 4.6.7.2. Let \(\mathcal{C}\) be an \(\infty\)-category. Then an object \(Y \in \mathcal{C}\) is initial if and only if it 02H8 is final when viewed as an object of the opposite \(\infty\)-category \(\mathcal{C}^{\mathrm{op}}\).
Example 4.6.7.3. Let \(\mathcal{C}\) be a category. An object \(Y \in \mathcal{C}\) is initial if and only if it is initial when viewed as an object of the \(\infty\)-category \(\mathrm{N}_{\bullet}(\mathcal{C})\). Similarly, an object \(Y \in \mathcal{C}\) is final if and only if it is final when viewed as an object of the \(\infty\)-category \(\mathrm{N}_{\bullet}(\mathcal{C})\).
Example 4.6.7.4. Let \(\mathcal{C}\) and \(\mathcal{D}\) be \(\infty\)-categories, and \(\operatorname{let} \mathcal{C} \star \mathcal{D}\) denote their join (Construction 02MW 4.3.3.13). Then \(\mathcal{C} \star \mathcal{D}\) is also an \(\infty\)-category (Corollary 4.3.3.25). It follows from Example 4.6.1.6 that if \(X\) is an initial object of \(\mathcal{C}\), then it is also initial when regarded as an object of \(\mathcal{C} \star \mathcal{D}\). Similarly, if \(Y\) is a final object of \(\mathcal{D}\), then it is also final when regarded as an object of \(\mathcal{C} \star \mathcal{D}\).

02MX Example 4.6.7.5. Let \(\mathcal{C}\) be an \(\infty\)-category. Then the cone point of the \(\infty\)-category \(\mathcal{C}^{\triangleleft}\) is an initial object. Similarly, the cone point of \(\mathcal{C}^{\triangleright}\) is a final object.

02HA Remark 4.6.7.6. In the formulation of Definition 4.6.7.1, we can replace the Kan complexes \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) and \(\operatorname{Hom}_{\mathcal{C}}(Y, Z)\) by their left-pinched variants \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) and \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(Y, Z)\), or by their right-pinched variants \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) and \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(Y, Z)\) (see Proposition 4.6.5.10).

02HB Example 4.6.7.7. Let \(\mathcal{C}\) be a locally Kan simplicial category, so that the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) is an \(\infty\)-category (Theorem 2.4.5.1). Combining Remark 4.6.7.6 with Theorem 4.6.8.5, we deduce the following:
- An object \(Y \in \mathcal{C}\) is initial when viewed as an object of the \(\infty\)-category \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) if and only if, for every object \(Z \in \mathcal{C}\), the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(Y, Z)\). is contractible.
- An object \(Y \in \mathcal{C}\) final when viewed as an object of the \(\infty\)-category \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) if and only if, for every object \(X \in \mathcal{C}\), the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) • is contractible.

02HD Example 4.6.7.8. Let \(\mathcal{C}\) be a \((2,1)\)-category, so that the Duskin nerve \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{C})\) is an \(\infty\) category (Theorem 2.3.2.1). Combining Remark 4.6.7.6) with Example 4.6.5.13, we obtain the following:
- An object \(Y \in \mathcal{C}\) is initial when viewed as an object of the \(\infty\)-category \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{C})\) if and only if, for every object \(Z \in \mathcal{C}\), the groupoid \(\underline{\operatorname{Hom}}_{\mathcal{C}}(Y, Z)\) is contractible (that is, there exists a 1-morphism from \(Y\) to \(Z\) and for every pair of morphisms \(f, g: X \rightarrow Y\), there is a unique isomorphism \(\gamma: f \stackrel{\sim}{\Longrightarrow} g\) ).
- An object \(Y \in \mathcal{C}\) is final when viewed as an object of the \(\infty\)-category \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{C})\) if and only if, for every object \(X \in \mathcal{C}\), the groupoid \(\underline{\operatorname{Hom}}_{\mathcal{C}}(X, Y)\) is contractible.

02HE Proposition 4.6.7.9. Let \(\mathcal{C}\) be a differential graded category, so that the differential graded nerve \(\mathrm{N}_{\bullet}^{\mathrm{dg}}(\mathcal{C})\) is an \(\infty\)-category (Theorem 2.5.3.10). Let \(Y\) be an object of \(\mathcal{C}\). The following conditions are equivalent:
(1) The object \(Y\) is initial when viewed as an object of the \(\infty\)-category \(\mathrm{N}_{\bullet}^{\mathrm{dg}}(\mathcal{C})\).
(2) The object \(Y\) is final when viewed as an object of the \(\infty\)-category \(\mathrm{N}_{\bullet}^{\mathrm{dg}}(\mathcal{C})\).
(3) The identity morphism \(\operatorname{id}_{Y}: Y \rightarrow Y\) is nullhomologous: that is, there exists a 1-chain \(e \in \operatorname{Hom}_{\mathcal{C}}(Y, Y)_{1}\) satisfying \(\partial(e)=\operatorname{id}_{Y}\).

Proof. We will show that \((1) \Leftrightarrow(3)\); the proof that \((2) \Leftrightarrow(3)\) is similar. If condition (1) is satisfied, then there exists a 2 -simplex of \(\mathrm{N}_{\bullet}^{\mathrm{dg}}(\mathcal{C})\) with boundary as indicated in the diagram

which we can identify with a 1 -chain \(e \in \operatorname{Hom}_{\mathcal{C}}(Y, Y)_{1}\) satisfying \(\partial(e)=\mathrm{id}_{Y}\) (see Example 2.5.3.4). Conversely, suppose that there exists \(e \in \operatorname{Hom}_{\mathcal{C}}(Y, Y)_{1}\) satisfying \(\partial(e)=\operatorname{id}_{Y}\). For every object \(Z \in \mathcal{C}, e\) determines a chain homotopy from the identity map id : \(\operatorname{Hom}_{\mathcal{C}}(Y, Z)_{*} \rightarrow\) \(\operatorname{Hom}_{\mathcal{C}}(Y, Z)_{*}\) to the zero map. It follows that the homology of chain complex \(\operatorname{Hom}_{\mathcal{C}}(Y, Z)_{*}\) vanishes, so that the Eilenberg-MacLane space \(\mathrm{K}\left(\operatorname{Hom}_{\mathcal{C}}(Y, Z)_{*}\right)\) of Construction 2.5.6.3 is a contractible Kan complex. Example 4.6.5.15 supplies an isomorphism of Kan complexes \(\operatorname{Hom}_{\mathrm{N}^{\mathrm{d} g}}^{\mathrm{L}}(Y, Z) \simeq \mathrm{K}\left(\operatorname{Hom}_{\mathcal{C}}(Y, Z)_{*}\right)\). Allowing \(Z\) to vary and invoking Remark 4.6.7.6, we conclude that \(Y\) is an initial object of the \(\infty\)-category \(\mathrm{N}_{\bullet}^{\mathrm{dg}}(\mathcal{C})\).

Proposition 4.6.7.10. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(Y\) be an object of \(\mathcal{C}\). Then:
(1) The object \(Y\) is initial if and only if the projection map \(\mathcal{C}_{Y /} \rightarrow \mathcal{C}\) is a trivial Kan fibration of simplicial sets.
(2) The object \(Y\) is final if and only if the projection map \(\mathcal{C}_{/ Y} \rightarrow \mathcal{C}\) is a trivial Kan fibration of simplicial sets.

Proof. We will give the proof of (1); the proof of (2) is similar. Proposition 4.3.6.1 guarantees that the projection map \(q: \mathcal{C}_{Y /} \rightarrow \mathcal{C}\) is a left fibration of simplicial sets. Applying Proposition 4.4.2.14, we see that \(q\) is a trivial Kan fibration if and only if, for each object \(Z \in \mathcal{C}\), the left-pinched morphism space \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(Y, Z)=\mathcal{C}_{Y /} \times_{\mathcal{C}}\{Z\}\) is a contractible Kan complex. By virtue of Remark 4.6.7.6, this is equivalent to the assumption that \(Y\) is an initial object of \(\mathcal{C}\).

Corollary 4.6.7.11. Let \(X\) be a Kan complex and let \(x \in X\) be a vertex. The following 02HJ conditions are equivalent:
(1) The vertex \(x\) is initial when viewed as an object of the \(\infty\)-category \(X\).
(2) The vertex \(x\) is final when viewed as an object of the \(\infty\)-category \(X\).
(3) The Kan complex \(X\) is contractible.

In particular, these conditions are independent of the choice of vertex \(x \in X\).

Proof. If the Kan complex \(X\) is contractible, then the projection map \(X_{x /} \rightarrow X\) is a trivial Kan fibration (Corollary 4.3.7.19), so the object \(x \in X\) is initial by virtue of Proposition 4.6.7.10. Conversely, if the projection map \(X_{x /} \rightarrow X\) is a trivial Kan fibration, then it is a homotopy equivalence (Proposition 3.1.6.10). Since the Kan complex \(X_{x /}\) is contractible (Corollary 4.3.7.14), it follows that \(X\) is contractible. This proves the equivalence of (1) and (3); the equivalence of (2) and (3) follows by a similar argument.

02HG Corollary 4.6.7.12. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(f: K \rightarrow \mathcal{C}\) be a diagram, let \(U: \mathcal{C}{ }_{/ f} \rightarrow \mathcal{C}\) be the projection map, and let \(Y\) be an initial object of \(\mathcal{C}\). Then:
(1) There exists an object \(\widetilde{Y} \in \mathcal{C}_{/ f}\) satisfying \(U(\widetilde{Y})=Y\).
(2) If \(\tilde{Y}\) is any object of \(\mathcal{C}_{/ f}\) satisfying \(U(\tilde{Y})=Y\), then \(\tilde{Y}\) is an initial object of \(\mathcal{C}_{/ f}\).

Proof. Assertion (1) is equivalent to the statement that \(f\) can be lifted to a map \(\tilde{f}: K \rightarrow \mathcal{C}_{Y /}\). This is clear, since the projection \(\operatorname{map} \mathcal{C}_{Y /} \rightarrow \mathcal{C}\) is a trivial Kan fibration (Proposition 4.6.7.10). To prove (2), fix an object \(\widetilde{Y} \in \mathcal{C}_{/ f}\) satisfying \(U(\widetilde{Y})=Y\). By virtue of Proposition 4.6.7.10 it will suffice to show that the projection map \(\left(\mathcal{C}_{/ f}\right)_{\widetilde{Y} /} \rightarrow \mathcal{C}_{/ f}\) is a trivial Kan fibration. Equivalently, we wish to show that every lifting problem

02HH

admits a solution, provided that the left vertical map is a monomorphism. Unwinding the definitions, we can rewrite (4.40) as a lifting problem

Our assumption that the object \(Y \in \mathcal{C}\) is initial guarantees that this lifting problem has a solution (Proposition 4.6.7.10).

02HK Corollary 4.6.7.13. Let \(\mathcal{C}\) be an \(\infty\)-category. An object \(Y \in \mathcal{C}\) is initial if and only if, for every integer \(n \geq 1\) and every morphism of simplicial sets \(\sigma: \partial \Delta^{n} \rightarrow \mathcal{C}\) satisfying \(\sigma(0)=Y\), there exists an n-simplex \(\bar{\sigma}: \Delta^{n} \rightarrow \mathcal{C}\) satisfying \(\left.\bar{\sigma}\right|_{\partial \Delta^{n}}=\sigma\).

Proof. Let \(n\) be a positive integer. Using the isomorphism
\[
\partial \Delta^{n} \simeq\left(\emptyset \star \Delta^{n-1}\right) \coprod_{\left(\emptyset \star \partial \Delta^{n-1}\right)}\left(\Delta^{0} \star \partial \Delta^{n-1}\right)
\]
supplied by Variant 4.3.6.17, we see that a morphism of simplicial sets \(\sigma: \partial \Delta^{n} \rightarrow \mathcal{C}\) satisfying \(\sigma(0)=Y\) can be identified with a commutative diagram

and that an extension of \(\sigma\) to an \(n\)-simplex of \(\mathcal{C}\) can be identified with a dotted arrow which renders the diagram commutative. By virtue of Proposition 4.6.7.10, the object \(Y\) is initial if and only if every lifting problem of the form (4.41) admits a solution: that is, if and only if the projection map \(\mathcal{C}_{Y /} \rightarrow \mathcal{C}\) is a trivial Kan fibration of simplicial sets.

Let \(\mathcal{C}\) be an \(\infty\)-category which contains an initial object \(X\). This object is rarely unique: every object \(Y \in \mathcal{C}\) which is isomorphic to \(X\) is also initial (Corollary 4.6.7.15). However, the object \(X\) is essentially unique in the following sense:

Corollary 4.6.7.14. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(\mathcal{C}^{\text {init }} \subseteq \mathcal{C}\) be the full subcategory of \(\mathcal{C}\) 02HM spanned by the initial objects of \(\mathcal{C}\), and let \(\mathcal{C}^{\text {fin }} \subseteq \mathcal{C}\) be the full subcategory spanned by the final objects of \(\mathcal{C}\). If \(\mathcal{C}\) contains an initial object, then \(\mathcal{C}^{\text {init }}\) is a contractible Kan complex. If \(\mathcal{C}\) contains a final object, then \(\mathcal{C}^{\text {fin }}\) is a contractible Kan complex.

Proof. Assume that \(\mathcal{C}\) contains an initial object, we will show that \(\mathcal{C}^{\text {init }}\) is a contractible Kan complex (the analogous assertion for final objects follows by a similar argument). Suppose we are given a morphism of simplicial sets \(\sigma: \partial \Delta^{n} \rightarrow \mathcal{C}^{\text {init }}\); we wish to show that \(\sigma\) can be extended to a morphism \(\bar{\sigma}: \Delta^{n} \rightarrow \mathcal{C}^{\text {init }}\). If \(n=0\), this follows from our assumption that \(\mathcal{C}\) contains an initial object. If \(n>0\), then we can regard \(\sigma\) as a morphism from \(\partial \Delta^{n}\) to \(\mathcal{C}\) with the property that \(\sigma(i) \in \mathcal{C}\) is initial for \(0 \leq i \leq n\). Setting \(i=0\), we conclude that \(\sigma\) can be extended to a morphism \(\bar{\sigma}: \Delta^{n} \rightarrow \mathcal{C}\), which automatically factors through the full subcategory \(\mathcal{C}^{\text {init }} \subseteq \mathcal{C}\).

Corollary 4.6.7.15. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(X\) be an initial object of \(\mathcal{C}\). Then an 02HN object \(Y \in \mathcal{C}\) is initial if and only if it is isomorphic to \(X\).

Proof. If \(X\) and \(Y\) are initial objects of \(\mathcal{C}\), then they are contained in the contractible Kan complex \(\mathcal{C}^{\text {init }}\) of Corollary 4.6.7.14 and are therefore isomorphic when viewed as objects of
\(\mathcal{C}\). Conversely, suppose that \(X\) is initial and that there exists an isomorphism \(f: X \rightarrow Y\) in \(\mathcal{C}\); we wish to show that \(Y\) is also initial. Fix an object \(Z \in \mathcal{C}\); we wish to show that the mapping space \(\operatorname{Hom}_{\mathcal{C}}(Y, Z)\) is contractible. Let us regard the homotopy category hC as enriched over the homotopy category hKan of Kan complexes (see Construction 4.6.9.13). Since \(f\) an isomorphism in \(\mathcal{C}\), its homotopy class \([f]\) is an isomorphism in the homotopy category hC , so composition with \([f]\) induces an isomorphism \(\operatorname{Hom}_{\mathcal{C}}(Y, Z) \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Z)\) in the category hKan. Since the \(\operatorname{Kan}\) complex \(\operatorname{Hom}_{\mathcal{C}}(X, Z)\) is contractible, it follows that \(\operatorname{Hom}_{\mathcal{C}}(Y, Z)\) is also contractible.

02HP Notation 4.6.7.16. Let \(\mathcal{C}\) be an \(\infty\)-category. We will often use the symbol \(\emptyset_{\mathcal{C}}\) to denote an initial object of \(\mathcal{C}\), provided that such an object exists. In this case, we will sometimes abuse terminology by referring to \(\emptyset_{\mathcal{C}}\) as the initial object of \(\mathcal{C}\). This abuse is justified by Corollary 4.6.7.14, which guarantees that \(\emptyset_{\mathcal{C}}\) is uniquely determined up to a contractible space of choices (in particular, it is well-defined up to isomorphism). Similarly, we will often use the symbol \(\mathbf{1}_{\mathcal{C}}\) to denote a final object of \(\mathcal{C}\), provided that such an object exists, and will sometimes abuse terminology by referring to \(\mathbf{1}_{\mathcal{C}}\) as the final object of \(\mathcal{C}\). When it is unlikely to cause confusion, we will sometimes omit the subscripts and denote the objects \(\emptyset_{\mathcal{C}}\) and \(\mathbf{1}_{\mathcal{C}}\) by \(\emptyset\) and \(\mathbf{1}\), respectively.
\(02 H Q\) Corollary 4.6.7.17. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(X\) be an object of \(\mathcal{C}\). Then:
(1) If \(X\) is initial as an object of the \(\infty\)-category \(\mathcal{C}\), then it is also initial when viewed as an object of the homotopy category hC .
(2) If \(\mathcal{C}\) has an initial object and \(X\) is initial as an object of the homotopy category hC , then \(X\) is initial as an object of the \(\infty\)-category \(\mathcal{C}\).

Proof. Assertion (1) is immediate from the definition. To prove (2), assume that \(\mathcal{C}\) has an initial object \(Y\). Then \(Y\) is also initial when viewed as an object of the homotopy category hC . If \(X\) is an initial object of \(\mathrm{h} \mathrm{\mathcal{C}}\), then \(X\) and \(Y\) are isomorphic when viewed as objects of \(h \mathcal{C}\), hence also when viewed as objects of the \(\infty\)-category \(\mathcal{C}\). Invoking Corollary 4.6.7.15, we conclude that \(X\) is also an initial object of \(\mathcal{C}\).

02HR Warning 4.6.7.18. Let \(\mathcal{C}\) be an \(\infty\)-category containing an object \(X\) which is initial as an object of the homotopy category hC. Then \(X\) need not be initial when viewed as an object of \(\mathcal{C}\). For example, if \(\mathcal{C}\) is simply connected Kan complex, then every object \(X \in \mathcal{C}\) is initial when viewed as an object of the homotopy category hC \(=\pi_{\leq 1}(\mathcal{C})\). However, \(X\) is initial as an object of \(\mathcal{C}\) only if \(\mathcal{C}\) is contractible (Corollary 4.6.7.11).

02HS Proposition 4.6.7.19. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a fully faithful functor of \(\infty\)-categories and let \(Y\) be an object of \(\mathcal{C}\). Then:
(1) If \(F(Y)\) is an initial object of \(\mathcal{D}\), then \(Y\) is an initial object of \(\mathcal{C}\).
(2) If \(F(Y)\) is a final object of \(\mathcal{D}\), then \(Y\) is a final object of \(\mathcal{C}\).

Proof. Let \(Z\) be an object of \(\mathcal{C}\). If \(F(Y)\) is an initial object of the \(\infty\)-category \(\mathcal{D}\), then the mapping space \(\operatorname{Hom}_{\mathcal{D}}(F(Y), F(Z))\) is a contractible Kan complex. Since \(F\) is fully faithful, it follows that \(\operatorname{Hom}_{\mathcal{C}}(Y, Z)\) is also a contractible Kan complex. Allowing \(Z\) to vary, we conclude that \(Y\) is an initial object of \(\mathcal{C}\). This proves (1); the proof of (2) is similar.

Corollary 4.6.7.20. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an equivalence of \(\infty\)-categories, and let \(Y\) be an 02HT object of \(\mathcal{C}\). Then:
(1) The object \(Y\) is initial if and only if \(F(Y)\) is an initial object of \(\mathcal{D}\).
(2) The object \(Y\) is final if and only if \(F(Y)\) is a final object of \(\mathcal{D}\).

Proof. We will prove (1); the proof of (2) is similar. Note that since \(F\) is an equivalence of \(\infty\)-categories, it is fully faithful (Theorem 4.6.2.20). If \(F(Y)\) is an initial object of \(\mathcal{D}\), then Proposition 4.6.7.19 guarantees that the object \(Y \in \mathcal{C}\) is initial. To prove the converse, let \(G: \mathcal{D} \rightarrow \mathcal{C}\) be a homotopy inverse of the functor \(F\). Then \(G \circ F\) is isomorphic to the identity functor \(\mathrm{id}_{\mathcal{C}}\) as an object of the functor \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{C})\), so that \((G \circ F)(Y)\) is isomorphic to \(Y\) as an object of the \(\infty\)-category \(\mathcal{C}\). If \(Y\) is an initial object of \(\mathcal{C}\), then Corollary 4.6.7.15 guarantees that \((G \circ F)(Y)\) is also an initial object of \(\mathcal{C}\). Since the equivalence \(G\) is fully faithful (Theorem 4.6.2.20), Proposition 4.6.7.19 guarantees that \(F(Y)\) is an initial object of \(\mathcal{D}\).

Corollary 4.6.7.21. Let \(\mathcal{C}\) and \(\mathcal{D}\) be \(\infty\)-categories which are equivalent. Then:
- The \(\infty\)-category \(\mathcal{C}\) has an initial object if and only if the \(\infty\)-category \(\mathcal{D}\) has an initial object.
- The \(\infty\)-category \(\mathcal{C}\) has a final object if and only if the \(\infty\)-category \(\mathcal{D}\) has a final object.

Proposition 4.6.7.22. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(f: X \rightarrow Y\) be a morphism in \(\mathcal{C}\). 02J2 The following conditions are equivalent:
(1) The morphism \(f\) is an isomorphism from \(X\) to \(Y\) in the \(\infty\)-category \(\mathcal{C}\) (Definition 1.4.6.1).
(2) The morphism \(f\) is final when regarded as an object of the slice \(\infty\)-category \(\mathcal{C}_{/ Y}\).
(2') The morphism \(f\) is final when regarded as an object of the oriented fiber product \(\mathcal{C} \tilde{x}_{\mathcal{C}}\{Y\}\).
(3) The morphism \(f\) is initial when regarded as an object of the coslice \(\infty\)-category \(\mathcal{C}_{X /}\).
(3') The morphism \(f\) is initial when regarded as an object of the oriented fiber product \(\{X\} \tilde{x}_{\mathcal{C}} \mathcal{C}\).

Proof. The equivalences \((2) \Leftrightarrow\left(2^{\prime}\right)\) and \((3) \Leftrightarrow\left(3^{\prime}\right)\) follow from Corollaries 4.6.4.18 and 4.6.7.20. We will complete the proof by showing that \((1) \Leftrightarrow(3)\); the equivalence \((1) \Leftrightarrow(2)\) follows by applying the same argument in the \(\infty\)-category \(\mathcal{C}^{\text {op }}\). By virtue of Corollary 4.6.7.13. condition (3) is equivalent to the requirement that the restriction map \(\mathcal{C}_{f /} \rightarrow \mathcal{C}_{X /}\) is a trivial Kan fibration: that is, every lifting problem

admits a solution. Using the isomorphism of simplicial sets
\[
\left(\Delta^{1} \star \partial \Delta^{n}\right) \coprod_{\{0\} \star \partial \Delta^{n}}\left(\{0\} \star \Delta^{n}\right) \simeq \Lambda_{0}^{n+2}
\]
supplied by Lemma 4.3.6.15, we can identify (4.42) with a lifting problem

where \(\sigma_{0}\) carries the initial edge \(\Delta^{1} \simeq \mathrm{~N}_{\bullet}(\{0<1\}) \subseteq \Lambda_{0}^{n+2}\) to the morphism \(f\). The equivalence \((1) \Leftrightarrow(3)\) now follows from the criterion of Theorem 4.4.2.6.

02 J 4 Corollary 4.6.7.23. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(Y\) be an object of \(\mathcal{C}\). Then:
(1) The object \(Y\) is final if and only if the projection map \(F: \mathcal{C}_{/ Y} \rightarrow \mathcal{C}\) admits a section \(G\) satisfying \(G(Y)=\mathrm{id}_{Y}\).
(2) The object \(Y\) is initial if and only if the projection map \(F^{\prime}: \mathcal{C}_{Y /} \rightarrow \mathcal{C}\) admits a section \(G^{\prime}\) satisfying \(G^{\prime}(Y)=\mathrm{id}_{Y}\).

Proof. We will prove (1); the proof of (2) is similar. If \(Y\) is a final object, then the projection \(\operatorname{map} F: \mathcal{C}_{/ Y} \rightarrow \mathcal{C}\) is a trivial Kan fibration (Proposition 4.6.7.10), so the construction \(Y \mapsto \mathrm{id}_{Y}\) can be extended to a section of \(F\). Conversely, suppose that \(F\) admits a section
\(G: \mathcal{C} \rightarrow \mathcal{C}_{/ Y}\) satisfying \(G(Y)=\operatorname{id}_{Y}\). Let \(X\) be an object of \(\mathcal{C}\) : we wish to show that the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is contractible. The functors \(G\) and \(F\) induce morphisms of Kan complexes
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \xrightarrow{G} \operatorname{Hom}_{\mathcal{C} / Y}\left(G(X), \operatorname{id}_{Y}\right) \xrightarrow{F} \operatorname{Hom}_{\mathcal{C}}(X, Y),
\]
whose composition is the identity. In particular, the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is a retract of \(\operatorname{Hom}_{\mathcal{C}_{/ Y}}\left(G(X), \mathrm{id}_{Y}\right)\). It will therefore suffice to show that the Kan complex \(\operatorname{Hom}_{\mathcal{C}_{/ Y}}\left(G(X), \operatorname{id}_{Y}\right)\) is contractible. This is clear, since \(\operatorname{id}_{Y}\) is a final object of the slice \(\infty\)-category \(\mathcal{C}_{/ Y}\) (Proposition 4.6.7.22).
Corollary 4.6.7.24. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(Y\) be an object of \(\mathcal{C}\). The following 02J5 conditions are equivalent:
(1) The object \(Y \in \mathcal{C}\) is final.
(2) There exists a functor \(F: \mathcal{C}^{\triangleright} \rightarrow \mathcal{C}\) satisfying \(\left.F\right|_{\mathcal{C}}=\mathrm{id}_{\mathcal{C}}\) and for which the composition
\[
\Delta^{1} \simeq\{Y\}^{\triangleright} \hookrightarrow \mathcal{C}^{\triangleright} \xrightarrow{F} \mathcal{C}
\]
is the identity morphism \(\mathrm{id}_{Y}\) (in particular, \(F\) carries the cone point of \(\mathcal{C}^{\triangleright}\) to the object \(Y)\).
(3) The inclusion map \(\{Y\} \hookrightarrow \mathcal{C}\) is right anodyne.

Proof. The equivalence \((1) \Leftrightarrow(2)\) is a reformulation of Corollary 4.6.7.23. We next show that (2) implies (3). If condition (2) is satisfied, then we have a commutative diagram of simplicial sets

where the horizontal compositions are the identity. Since the inclusion \(\{Y\}^{\triangleright} \hookrightarrow \mathcal{C}^{\triangleright}\) is right anodyne (Lemma 4.3.7.8), it follows that the inclusion \(\{Y\} \hookrightarrow \mathcal{C}\) is also right anodyne.

We now complete the proof by showing that (3) implies (2). Suppose that the inclusion \(\{Y\} \hookrightarrow \mathcal{C}\) is right anodyne; we wish to show that there exists a functor \(F: \mathcal{C}^{\triangleright} \rightarrow \mathcal{C}\) satisfying \(\left.F\right|_{\mathcal{C}}=\operatorname{id}_{\mathcal{C}}\) and \(\left.F\right|_{\{Y\}^{\triangleright}}=\operatorname{id}_{Y}\). For this, it will suffice to show that the inclusion map
\[
\mathcal{C} \coprod_{\{Y\}}\{Y\}^{\triangleright} \hookrightarrow \mathcal{C}^{\triangleright}
\]
is inner anodyne, which is a special case of Proposition 4.3.6.4.

02P2 Corollary 4.6.7.25. Let \(\mathcal{C}\) be an \(\infty\)-category which has either an initial object or a final object. Then \(\mathcal{C}\) is weakly contractible.

Proof. We will assume that \(\mathcal{C}\) has a final object \(Y\); the case where \(\mathcal{C}\) has an initial object follows by a similar argument. Corollary 4.6.7.24 implies that the inclusion map \(\{Y\} \hookrightarrow \mathcal{C}\) is right anodyne. In particular, it is anodyne and therefore a weak homotopy equivalence.

\subsection*{4.6.8 Morphism Spaces in the Homotopy Coherent Nerve}

01 LA Let \(\mathcal{C}\) be a simplicial category and let \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\) denote the homotopy coherent nerve of \(\mathcal{C}\) (Definition 2.4.3.5). Suppose that \(\mathcal{C}\) is locally Kan, so that the simplicial set \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C}\) ) is an \(\infty\)-category (Theorem 2.4.5.1). Our goal in this section is to describe the morphism spaces in the \(\infty\)-category \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\). Our main result (Theorem 4.6.8.5) implies that, for every pair of objects \(X, Y \in \mathcal{C}\), there is a canonical homotopy equivalence
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \rightarrow \operatorname{Hom}_{\mathrm{Nhc}^{\mathrm{hc}}(\mathcal{C})}(X, Y),
\]
where \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\). denotes the Kan complex of morphisms from \(X\) to \(Y\) in \(\mathcal{C}\), and \(\operatorname{Hom}_{\mathrm{N}^{\mathrm{hc}}(\mathcal{C})}(X, Y)\) is given by Construction 4.6.1.1.

01LB Notation 4.6.8.1. Let \(K\) be a simplicial set. We define a simplicial category \(\mathcal{E}[K]\) as follows:
- The category \(\mathcal{E}[K]\) has exactly two objects, which we will denote by \(x\) and \(y\).
- The morphism spaces in \(\mathcal{E}[K]\) are given by the formulae
\[
\begin{aligned}
\operatorname{Hom}_{\mathcal{E}[K]}(x, x)_{\bullet}=\left\{\operatorname{id}_{x}\right\} & \operatorname{Hom}_{K}(y, y)_{\bullet}=\left\{\operatorname{id}_{y}\right\} \\
\operatorname{Hom}_{\mathcal{E}[K]}(x, y)_{\bullet}=K & \operatorname{Hom}_{K}(y, x)_{\bullet}=\emptyset .
\end{aligned}
\]

01LC Remark 4.6.8.2. The simplicial category \(\mathcal{E}[K]\) is characterized by the following universal property: if \(\mathcal{C}\) is any simplicial category containing a pair of objects \(X\) and \(Y\), then the natural map
\(\{\) Simplicial functors \(F: \mathcal{E}[K] \rightarrow \mathcal{C}\) with \(F(x)=X\) and \(F(y)=Y\}\)
is a bijection (see Proposition 2.4.5.9).

Construction 4.6.8.3. Fix an integer \(n \geq 0\), let [ \(n\) ] denote the linearly ordered set 01LD \(\{0<1<\cdots<n\}\), and let \(\{x\} \star[n]\) denote the linearly ordered set obtained from [ \(n\) ] by adjoining a new least element \(x\). Let \(\operatorname{Path}[\{x\} \star[n]]\) • denote the simplicial path category of Notation 2.4.3.1. We define a simplicial functor \(\pi: \operatorname{Path}[\{x\} \star[n]] \bullet \rightarrow \mathcal{E}\left[\Delta^{n}\right]\) as follows:
- On objects, the functor \(\pi\) is given by the formula
\[
\pi(i)= \begin{cases}x & \text { if } i=x \\ y & \text { if } 0 \leq i \leq n\end{cases}
\]
- For \(0 \leq m \leq n\), the morphism of simplicial sets
\[
\operatorname{Hom}_{\operatorname{Path}[\{x\} \star[n]]}(x, m)_{\bullet} \rightarrow \operatorname{Hom}_{\mathcal{E}\left[\Delta^{n}\right]}(x, y)_{\bullet}=\Delta^{n}
\]
is given by the map of partially ordered sets
\[
\left\{\text { Subsets } S=\left\{x<i_{0}<\cdots<i_{k}=m\right\} \subseteq\{x\} \star[n]\right\}^{\text {op }} \rightarrow[n] \quad S \mapsto i_{0} .
\]

Let \(\mathcal{C}\) be a simplicial category containing a pair of objects \(X\) and \(Y\). Then every \(n\)-simplex \(\sigma \in \operatorname{Hom}_{\mathcal{C}}(X, Y)_{n}\) determines a simplicial functor \(F_{\sigma}: \mathcal{E}\left[\Delta^{n}\right] \rightarrow \mathcal{C}\), given on objects by \(F_{\sigma}(x)=X\) and \(F_{\sigma}(y)=Y\). The composition \(F_{\sigma} \circ \pi\) is a simplicial functor from \(\operatorname{Path}[\{x\} \star[n]] \bullet\) to \(\mathcal{C}\), which (by Proposition 2.4.4.15) we can view as a map of simplicial sets \(f_{\sigma}:\{x\} \star \Delta^{n} \rightarrow \mathrm{~N}_{\bullet}^{\text {hc }}(\mathcal{C})\). By construction, \(f_{\sigma}\) carries \(x\) to \(X\), and the restriction \(\left.f_{\sigma}\right|_{\mathrm{N}}(\{0<1<\cdots<n\})\) is the constant map taking the value \(Y\). We can therefore identify \(f_{\sigma}\) with an \(n\)-simplex \(\theta(\sigma)\) of the left-pinched morphism space \(\operatorname{Hom}_{\mathrm{N}_{0}^{\mathrm{hc}}(\mathcal{C})}^{\mathrm{L}}(X, Y)\) introduced in Construction 4.6.5.1 (see Remark 4.6.5.2. The construction \(\sigma \mapsto \theta(\sigma)\) depends functorially on the object \([n] \in \boldsymbol{\Delta}\), and therefore determines a map of simplicial sets
\[
\theta: \operatorname{Hom}_{\mathcal{C}}(X, Y)_{\bullet} \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})}^{\mathrm{L}}(X, Y),
\]
which we will refer to as the comparison map.
Exercise 4.6.8.4. Let \(\mathcal{C}\) be a differential graded category containing a pair of objects \(X\) and \(Y\), and let \(\mathcal{C}^{\Delta}\) denote the associated simplicial category (Construction 2.5.9.2. Show that the isomorphism \(K\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}\right) \xrightarrow{\sim} \operatorname{Hom}_{\mathrm{N}_{0}^{\mathrm{dg}}(\mathcal{C})}^{\mathrm{L}}(X, Y)\) of Example 4.6 .5 .15 factors as a composition
\[
K\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}\right)=\operatorname{Hom}_{\mathcal{C}^{\Delta}}(X, Y) \bullet \xrightarrow{\theta} \operatorname{Hom}_{\mathrm{N}_{\bullet}\left(\mathcal{C}^{\Delta}\right)}^{\mathrm{L}}(X, Y) \xrightarrow{\rho} \operatorname{Hom}_{\mathrm{N}_{\bullet}}^{\mathrm{L}}(\mathcal{C})(X, Y),
\]
where \(\theta\) is the comparison map of Construction 4.6 .8 .3 and \(\rho\) is induced by the trivial Kan fibration \(\mathcal{Z}: \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}^{\Delta}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{dg}}(\mathcal{C})\) of Proposition 2.5.9.10. Beware that \(\theta\) and \(\rho\) are generally not isomorphisms.

Our comparison result can now be formulated as follows:
01LE Theorem 4.6.8.5. Let \(\mathcal{C}\) be a locally Kan simplicial category containing a pair of objects \(X, Y \in \mathcal{C}\). Then the comparison map
\[
\theta: \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet}(\mathcal{C})}^{\mathrm{L}}(X, Y)
\]
of Construction 4.6.8.3 is a homotopy equivalence of Kan complexes.
01 LF Remark 4.6.8.6. Let \(\mathcal{C}\) be a locally Kan simplicial category containing a pair of objects \(X, Y \in \mathcal{C}\). Combining Theorem 4.6.8.5 with Proposition 4.6.5.10, we obtain a homotopy equivalence of \(\operatorname{Kan}\) complexes \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet} \mathrm{C}(\mathcal{C})}(X, Y)\), given by composing the comparison map \(\theta\) of Construction 4.6.8.3 with the left-pinch inclusion map of Construction 4.6.5.7

Before giving the proof of Theorem 4.6.8.5, let us outline some applications.
01QO Definition 4.6.8.7. Let \(\mathcal{C}\) and \(\mathcal{D}\) be simplicial categories and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a simplicial functor.
- We say that \(F\) is weakly fully faithful if, for every pair of objects \(X, Y \in \operatorname{Ob}(\mathcal{C})\), the induced map \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\) • is a weak homotopy equivalence of simplicial sets.
- We say that \(F\) is weakly essentially surjective if the induced functor of homotopy categories \(\mathrm{h} F: \mathrm{hC} \rightarrow \mathrm{h} \mathcal{D}\) is essentially surjective (that is, every object of \(\mathcal{D}\) is homotopy equivalent to an object of the form \(F(X)\), for some \(X \in \operatorname{Ob}(\mathcal{C})\) ).
- We say that \(F\) is a weak equivalence of simplicial categories if it is weakly fully faithful and weakly essentially surjective.
\(01 Q 1\) Corollary 4.6.8.8. Let \(\mathcal{C}\) and \(\mathcal{D}\) be locally Kan simplicial categories, let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a simplicial functor, and let \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(F): \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{D})\) be the induced functor of \(\infty\)-categories. Then:
(1) The functor \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(F)\) is fully faithful (in the sense of Definition 4.6.2.1) if and only if the simplicial functor \(F\) is weakly fully faithful (in the sense of Definition 4.6.8.7).
(2) The functor \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(F)\) is essentially surjective (in the sense of Definition 4.6.2.11) if and only if the simplicial functor \(F\) is weakly essentially surjective (in the sense of Definition 4.6.8.7.
(3) The functor \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(F)\) is an equivalence of \(\infty\)-categories (in the sense of Definition 4.5.1.10) if and only if \(F\) is a weak equivalence of simplicial categories (in the sense of Definition 4.6.8.7.

Proof. For every pair of objects \(X, Y \in \mathrm{Ob}(\mathcal{C})\), we have a commutative diagram of simplicial sets

where the vertical maps are the homotopy equivalences supplied by Remark 4.6.8.6. It follows that the upper horizontal map is a homotopy equivalence if and only if the lower horizontal map is a homotopy equivalence. This proves (1). Assertion (2) follows from Proposition 2.4.6.9. Assertion (3) follows by combining (1) and (2) with the criterion of Theorem 4.6.2.20.

Theorem 4.6.8.5 is an immediate consequence of the following more general result:
Theorem 4.6.8.9. Let \(\mathcal{C}\) be a simplicial category containing a pair of objects \(X\) and \(Y\),
01LG and suppose that the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\). is an \(\infty\)-category. Then the left-pinched morphism space \(\operatorname{Hom}_{\mathrm{N}_{0}^{\mathrm{bc}}(\mathcal{C})}^{\mathrm{L}}(X, Y)\) is also an \(\infty\)-category, and the comparison map
\[
\theta: \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet} \mathrm{hc}(\mathcal{C})}^{\mathrm{L}}(X, Y)
\]
of Construction 4.6.8.3 is an equivalence of \(\infty\)-categories.
Remark 4.6.8.10. Let \(\mathcal{C}\) be a simplicial category containing a pair of objects \(X\) and \(Y\), and 01LH suppose that the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet\) is an \(\infty\)-category. Applying Theorem 4.6.8.9 to the opposite simplicial category \(\mathcal{C}^{\text {op }}\) (and using Remark 4.6.5.3), we obtain an equivalence of \(\infty\)-categories
\[
\theta^{\prime}: \operatorname{Hom}_{\mathcal{C}}(X, Y)_{\bullet}^{\mathrm{op}} \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})}^{\mathrm{R}}(X, Y),
\]
which can be described explicitly using a variant of Construction 4.6.8.3.
The remainder of this section is devoted to the proof of Theorem 4.6.8.9
Construction 4.6.8.11. Let \(K\) be a simplicial set. We let \(\Sigma(K)\) denote the pushout
01LJ \((\{x\} \star K) \coprod_{K}\{y\}\) (this is a model for the unreduced suspension of \(K\) ). Let Path \([\Sigma(K)]\) • denote the simplicial path category of \(\Sigma(K)\) (Notation 2.4.4.2). Then Path \([\Sigma(K)]\) • has exactly two objects, which we denote by \(x\) and \(y\). We let \(\Phi(K)\) denote the simplicial set \(\operatorname{Hom}_{\text {Path }[\Sigma(K)]}(x, y)\).
Example 4.6.8.12. If \(K=\Delta^{0}\), then the suspension \(\Sigma(K)\) can be identified with \(\Delta^{1}\). In this 01LK case, the simplicial path category Path \([\Sigma(K)] \bullet\) can be identified with the ordinary category [1], and the simplicial set \(\Phi(K)\) is isomorphic to \(\Delta^{0}\).

01LL Remark 4.6.8.13. Let \(K\) be a simplicial set, and let \(\mathcal{D}\) be another simplicial set containing vertices \(X\) and \(Y\). Unwinding the definitions, we have a canonical bijection

\(\{\) Morphisms \(F: \Sigma(K) \rightarrow \mathcal{D}\) with \(F(x)=X\) and \(F(y)=Y\}\).
01LM Remark 4.6.8.14. Let \(K\) be a simplicial set. Note that, for \(n>0\), every nondegenerate simplex \(\sigma: \Delta^{n} \rightarrow \Sigma(K)\) satisfies \(\sigma(0)=x\) and \(\sigma(n)=y\). Using Theorem 2.4.4.10, we see that for each \(m \geq 0\), \(\operatorname{Path}[\Sigma(K)]_{m}\) can be identified with the path category of a directed graph \(G_{m}\) with vertex set \(\operatorname{Vert}\left(G_{m}\right)=\{x, y\}\), where each edge of \(G_{m}\) has source \(x\) and target \(y\). These path categories are easy to describe: they satisfy
\[
\begin{aligned}
& \operatorname{Hom}_{\text {Path }\left[G_{m}\right]}(x, x)=\left\{\operatorname{id}_{x}\right\} \quad \operatorname{Hom}_{\text {Path }\left[G_{m}\right]}(y, y)=\left\{\operatorname{id}_{y}\right\} \\
& \operatorname{Hom}_{\operatorname{Path}\left[G_{m}\right]}(x, y)=\operatorname{Edge}\left(G_{m}\right) \quad \operatorname{Hom}_{\operatorname{Path}\left[G_{m}\right]}(y, x)=\emptyset .
\end{aligned}
\]

Allowing \(m\) to vary, we conclude that the simplicial category \(\operatorname{Path}[\Sigma(K)]\) • satisfies
\[
\operatorname{Hom}_{\operatorname{Path}[\Sigma(K)]}(x, x) \bullet=\left\{\operatorname{id}_{x}\right\} \quad \operatorname{Hom}_{\operatorname{Path}[\Sigma(K)]}(y, x) \bullet=\emptyset \quad \operatorname{Hom}_{\operatorname{Path}[\Sigma(K)]}(y, y) \bullet=\left\{\operatorname{id}_{y}\right\} .
\]

That is, \(\operatorname{Path}[\Sigma(K)]\) • can be identified with the simplicial category \(\mathcal{E}[\Phi(X)]\) of Notation 4.6.8.1. Moreover, we can identify \(m\)-simplices of \(\Phi(X)\) with elements of the set \(E(\Sigma(K), m)\) defined in Notation 2.4.4.9.

01LN Remark 4.6.8.15. Let \(u: K \rightarrow K^{\prime}\) be a monomorphism of simplicial sets. Then the induced map \(\Phi(u): \Phi(K) \rightarrow \Phi\left(K^{\prime}\right)\) is also a monomorphism (this follows immediately from the description given in Remark 4.6.8.14.).

01 LP Lemma 4.6.8.16. Let \(K\) be a simplicial set and let \(\mathcal{C}\) be a simplicial category containing objects \(X\) and \(Y\). Then the natural map

is a bijection.

Proof. Combine Remarks 4.6.8.2 and 4.6.8.14
Combining Remark 4.6.8.13 with Lemma 4.6.8.16 and invoking the universal property of simplicial path categories, we obtain the following:

Corollary 4.6.8.17. Let \(K\) be a simplicial set and let \(\mathcal{C}\) be a simplicial category containing 01LQ objects \(X\) and \(Y\). Then we have a canonical bijection
\[
\left\{\text { Morphisms } K \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet}(\mathcal{C})}^{\mathrm{L}}(X, Y)\right\} \simeq\left\{\operatorname{Morphisms} \Phi(K) \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet\right\}
\]

Remark 4.6.8.18. It follows from Corollary 4.6.8.17 that the left-pinched morphism space 03LK \(\operatorname{Hom}_{\mathrm{N}_{\bullet}(\mathcal{C})}^{\mathrm{L}}(X, Y)\) depends only on the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{\bullet}\), and not on any other features of the simplicial category \(\mathcal{C}\). In particular, there is a canonical isomorphism
\[
\operatorname{Hom}_{\mathrm{N}_{\bullet} \mathrm{C}(\mathcal{C})}^{\mathrm{L}}(X, Y) \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Set}_{\Delta}\right)}^{\mathrm{L}}\left(\Delta^{0}, \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet\right) .
\]

Corollary 4.6.8.19. Let \(A\) and \(B\) be simplicial sets, and let \(\mathcal{E}[B]\) be the simplicial category 01LR of Notation 4.6.8.1. Then we have a canonical bijection
\[
\left\{\text { Morphisms } A \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{E}[B])}^{\mathrm{L}}(x, y)\right\} \simeq\{\text { Morphisms } \Phi(A) \rightarrow B\} .
\]

Proof. Apply Corollary 4.6.8.17 in the special case \(\mathcal{C}=\mathcal{E}[B]\).
Corollary 4.6.8.20. The functor
\[
\operatorname{Set}_{\Delta} \rightarrow \operatorname{Set}_{\Delta} \quad B \mapsto \operatorname{Hom}_{\mathrm{N}_{\bullet} \mathrm{c}(\mathcal{E}[B])}^{\mathrm{L}}(x, y)
\]
has a left adjoint, given by the functor \(A \mapsto \Phi(A)\) of Construction 4.6.8.11.
Remark 4.6.8.21. The adjunction of Corollary 4.6.8.20 has an interpretation in the 01LT framework of Proposition 1.2.3.15. Let \(Q^{\bullet}\) denote the cosimplicial object of \(\operatorname{Set}_{\Delta}\) given by the construction \([n] \mapsto \Phi\left(\Delta^{n}\right)\). For every simplicial set \(B\), Corollary 4.6.8.19 supplies a canonical isomorphism of simplicial sets
\[
\operatorname{Hom}_{\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{E}[B])}^{\mathrm{L}}(x, y) \simeq \operatorname{Sing}_{\bullet}^{Q}(B),
\]
where \(\operatorname{Sing}_{\bullet}^{Q}(B)\) is the simplicial set defined in Variant 1.2.2.8. It follows that \(\Phi\) can be identified with the generalized geometric realization functor \(K \mapsto|K|^{Q}\) of Proposition 1.2.3.15

Corollary 4.6.8.22. The functor \(\Phi: \operatorname{Set}_{\Delta} \rightarrow \operatorname{Set}_{\Delta}\) of Construction 4.6.8.11 preserves 01LU colimits.
4.6. MORPHISM SPACES

01LV Construction 4.6.8.23. Let \(K\) be a simplicial set, let \(\mathcal{E}[K]\) be the simplicial category of Notation 4.6.8.1, and let
\[
\theta: K=\operatorname{Hom}_{\mathcal{E}[K]}(x, y)_{\bullet} \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet} \mathrm{L}(\mathcal{E}[K])}^{\mathrm{L}}(x, y)
\]
be the comparison map of Construction 4.6.8.3. We let \(\rho_{K}: \Phi(K) \rightarrow K\) denote the image of \(\theta\) under the bijection of Corollary 4.6.8.19.

We will deduce Theorem 4.6.8.9 from the following result, which we prove at the end of this section:

01LW Proposition 4.6.8.24. Let \(K\) be a simplicial set. Then the morphism \(\rho_{K}: \Phi(K) \rightarrow K\) of Construction 4.6.8.23 is a categorical equivalence of simplicial sets.

01LX Corollary 4.6.8.25. Let \(u: K \rightarrow K^{\prime}\) be a categorical equivalence of simplicial sets. Then the induced map \(\Phi(u): \Phi(K) \rightarrow \Phi\left(K^{\prime}\right)\) is also a categorial equivalence of simplicial sets.

Proof. We have a commutative diagram

where \(u\) is a categorical equivalence by hypothesis and the vertical maps are categorical equivalences by Proposition 4.6.8.24 Using Remark 4.5.3.5, we conclude that \(\Phi(u)\) is a categorical equivalence as well.

01 LY Corollary 4.6.8.26. Let \(\mathcal{C}\) be a simplicial category containing a pair of objects \(X\) and \(Y\), and assume that the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\). is an \(\infty\)-category. Then the simplicial set \(\operatorname{Hom}_{\mathrm{Nh}_{\bullet}(\mathcal{C})}^{\mathrm{L}}(X, Y)\) is also an \(\infty\)-category.

Proof. Let \(i: A \hookrightarrow B\) be an inner anodyne morphism of simplicial sets. We wish to show that every lifting problem

admits a solution. By virtue of Corollary 4.6.8.17, we can rephrase this as a lifting problem

Note that \(\Phi(i)\) is a monomorphism (Remark 4.6.8.15) and a categorical equivalence (Corollary 4.6.8.25), so the desired result follows from Lemma 4.5.5.2.

Corollary 4.6.8.27. Let \(\mathcal{C}\) be a simplicial category containing a pair of objects \(X\) and 01LZ \(Y\), and assume that the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) • is an \(\infty\)-category. Let \(K\) be another simplicial set, and suppose we are given a pair of morphisms \(f_{0}, f_{1}: K \rightarrow \operatorname{Hom}_{\mathrm{N}^{\mathrm{hc}}(\mathcal{C})}^{\mathrm{L}}(X, Y)\), which correspond (under the bijection of Corollary 4.6.8.17) to diagrams \(f_{0}^{\prime}, f_{1}^{\prime}: \Phi(K) \rightarrow\) \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\). The following conditions are equivalent:
(1) The diagrams \(f_{0}\) and \(f_{1}\) are isomorphic when regarded as objects of the \(\infty\)-category \(\operatorname{Fun}\left(K, \operatorname{Hom}_{\mathrm{N}_{0}(\mathcal{C})}^{\mathrm{L}}(X, Y)\right)\).
(2) The diagrams \(f_{0}^{\prime}\) and \(f_{1}^{\prime}\) are isomorphic when regarded as objects of the \(\infty\)-category \(\operatorname{Fun}\left(\Phi(K), \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet\right)\).

Proof. Choose a categorical mapping cylinder
\[
K \coprod K \xrightarrow{\left(s_{0}, s_{1}\right)} \bar{K} \xrightarrow{\pi} K
\]
for the simplicial set \(K\) (Definition 4.6.3.3). Using Remark 4.6.8.15. Corollary 4.6.8.22, and Corollary 4.6.8.25, we conclude that the induced diagram
\[
\Phi(K) \coprod \Phi(K) \xrightarrow{\left(\Phi\left(s_{0}\right), \Phi\left(s_{1}\right)\right)} \Phi(\bar{K}) \xrightarrow{\Phi(\pi)} \Phi(K)
\]
exhibits \(\Phi(\bar{K})\) as a categorical mapping cylinder of \(K\). Using Corollary 4.6.3.7, we see that (1) and (2) are equivalent to the following:
(1') There exists a diagram \(\bar{f}: \bar{K} \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})}^{\mathrm{L}}(X, Y)\) satisfying \(f_{0}=\bar{f} \circ s_{0}\) and \(f_{1}=\bar{f} \circ s_{1}\).
(2') There exists a diagram \(\bar{f}^{\prime}: \Phi(\bar{K}) \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Y)\) • satisfying \(f_{0}^{\prime}=\bar{f}^{\prime} \circ \Phi\left(s_{0}\right)\) and \(f_{1}^{\prime}=\bar{f}^{\prime} \circ \Phi\left(s_{1}\right)\).

The equivalence of \(\left(1^{\prime}\right)\) and ( \(2^{\prime}\) ) follows from Corollary 4.6.8.17

Proof of Theorem 4.6.8.9. Let \(\mathcal{C}\) be a simplicial category containing a pair of objects \(X, Y \in\) \(\mathcal{C}\) for which the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) • is an \(\infty\)-category. Applying Corollary 4.6.8.26, we deduce that the left-pinched morphism space \(\operatorname{Hom}_{\mathrm{N}_{0}(\mathcal{C})}^{\mathrm{L}}(X, Y)\) is also an \(\infty\)-category. We wish to show that the comparison map
\[
\theta: \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet} \mathrm{hc}(\mathcal{C})}^{\mathrm{L}}(X, Y)
\]
of Construction 4.6.8.3 is an equivalence of \(\infty\)-categories. To prove this, it will suffice to show that for every simplicial set \(K\), postcomposition with \(\theta\) induces a bijection
\[
\theta_{K}: \pi_{0}\left(\operatorname{Fun}\left(K, \operatorname{Hom}_{\mathcal{C}}(X, Y)_{\bullet}\right)^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}\left(K, \operatorname{Hom}_{\mathrm{N}_{\bullet}(\mathcal{C})}^{\mathrm{L}}(X, Y)\right)^{\simeq}\right) .
\]

By virtue of Corollary 4.6 .8 .27 , we can identify \(\pi_{0}\left(\operatorname{Fun}\left(K, \operatorname{Hom}_{\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})}^{\mathrm{L}}(X, Y)\right)^{\sim}\right)\) with the set \(\pi_{0}\left(\operatorname{Fun}\left(\Phi(K), \operatorname{Hom}_{\mathcal{C}}(X, Y)_{\bullet}\right)^{-}\right)\). Under this identification, \(\theta_{K}\) corresponds to the map
\[
\pi_{0}\left(\operatorname{Fun}\left(K, \operatorname{Hom}_{\mathcal{C}}(X, Y)_{\bullet}\right)^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}\left(\Phi(K), \operatorname{Hom}_{\mathcal{C}}(X, Y)_{\bullet}\right)^{\simeq}\right)
\]
given by precomposition with the map \(\rho_{K}: \Phi(K) \rightarrow K\) of Construction 4.6.8.23, which is bijective by virtue of the fact that \(\rho_{K}\) is a categorical equivalence of simplicial sets (Proposition 4.6.8.24).

We now turn to the proof of Proposition 4.6.8.24. Our strategy is to use formal arguments to reduce to the case where the simplicial set \(K\) is a standard simplex, which can be analyzed explicitly.

01MO Example 4.6.8.28. Let \(m\) and \(n\) be nonnegative integers. By virtue of Remark 4.6.8.14, we can identify \(m\)-simplices of the simplicial set \(\Phi\left(\Delta^{n}\right)\) with the set \(E\left(\Sigma\left(\Delta^{n}\right), m\right)\) defined in Notation 2.4.4.9. By definition, the elements of \(E\left(\Sigma\left(\Delta^{n}\right), m\right)\) are given by pairs \((\sigma, \vec{I})\), where \(\sigma: \Delta^{k} \rightarrow \Sigma\left(\Delta^{n}\right)\) is a nondegenerate simplex of dimension \(k>0\) and \(\vec{I}=\left(I_{0} \supseteq I_{1} \supseteq\right.\) \(\left.\cdots \supseteq I_{m}\right)\) is a chain of subsets of \([k]\) satisfying \(I_{0}=[k]\) and \(I_{m}=\{0, k\}\).

For each \(k>0\), there is a canonical bijection
\(\{\) Subsets \(S \subseteq[n]\) of cardinality \(k\} \simeq\left\{\right.\) Nondegenerate \(k\)-Simplices of \(\left.\Sigma\left(\Delta^{n}\right)\right\}\), which carries a subset \(S\) to the \(k\)-simplex \(\sigma_{S}\) given by the composite map
\[
\Delta^{k} \simeq\{x\} \star \mathrm{N}_{\bullet}(S) \hookrightarrow\{x\} \star \Delta^{n} \rightarrow \Sigma\left(\Delta^{n}\right)
\]

For every such subset \(S\), let \(\iota_{S}: \mathrm{N}_{\bullet}(S) \hookrightarrow \Delta^{k}\) be the inclusion map. Then the construction
\[
\left(\sigma_{S}, \vec{I}\right) \mapsto\left(\sigma_{S}^{-1}\left(I_{0}\right) \supseteq \sigma_{S}^{-1}\left(I_{1}\right) \supseteq \cdots \supseteq \sigma_{S}^{-1}\left(I_{m}\right)\right)
\]
induces a bijection from \(E\left(\Sigma\left(\Delta^{n}\right), m\right)\) to the collection of chains \(\vec{S}=\left(S_{0} \supseteq S_{1} \supseteq \cdots \supseteq S_{m}\right)\) of subsets of \([n]\) which satisfy the following pair of conditions:
(a) The set \(S_{m}\) contains exactly one element.
(b) For \(0 \leq i \leq m\), the unique element of \(S_{m}\) is the largest element of \(S_{i}\).

Let us henceforth use this bijection to identify \(m\)-simplices of \(\Phi\left(\Delta^{n}\right)\) with chains \(\vec{S}\) satisfying (a) and (b). In these terms, the face and degeneracy operators for the simplicial set \(\Phi\left(\Delta^{n}\right)=\Phi\left(\Delta^{n}\right)\). can be described explicitly as follows:
- For \(0 \leq i \leq m\), the degeneracy operator \(s_{i}^{m}: \Phi\left(\Delta^{n}\right)_{m} \rightarrow \Phi\left(\Delta^{n}\right)_{m+1}\) is given by
\[
s_{i}^{m}\left(S_{0} \supseteq \cdots \supseteq S_{m}\right)=\left(S_{0} \supseteq \cdots \supseteq S_{i-1} \supseteq S_{i} \supseteq S_{i} \supseteq S_{i+1} \supseteq \cdots \supseteq S_{m}\right)
\]
- For \(0 \leq i<m\), the face operator \(d_{i}^{m}: \Phi\left(\Delta^{n}\right)_{m} \rightarrow \Phi\left(\Delta^{n}\right)_{m-1}\) is given by the construction
\[
d_{i}^{m}\left(S_{0} \supseteq \cdots \supseteq S_{m}\right)=\left(S_{0} \supseteq \cdots \supseteq S_{i-1} \supseteq S_{i+1} \supseteq \cdots \supseteq S_{m}\right) .
\]
- For \(m>0\), the face operator \(d_{m}^{m}: \Phi\left(\Delta^{n}\right)_{m} \rightarrow \Phi\left(\Delta^{n}\right)_{m-1}\) is given by
\[
d_{m}^{m}\left(S_{0} \supseteq \cdots \supseteq S_{m}\right)=\left(S_{0}^{\prime} \supseteq S_{1}^{\prime} \supseteq \cdots \supseteq S_{m-1}^{\prime}\right),
\]
where \(S_{i}^{\prime}=\left\{j \in S_{i}: j \leq \min \left(S_{m-1}\right)\right\}\).
See Remark 2.4.4.17.
Construction 4.6.8.29. Let \(m\) and \(n\) be nonnegative integers. Suppose we are given 01M1 an \(m\)-simplex of \(\Phi\left(\Delta^{n}\right)\), which we identify with a chain of subsets \(\vec{S}=\left(S_{0} \supseteq \cdots \supseteq S_{m}\right)\) satisfying conditions (a) and (b) of Example 4.6.8.28. Let \(\tau:[m] \rightarrow[1]\) be a nondecreasing function. Let \(\vec{S}^{\prime}=\left(S_{0}^{\prime} \supseteq \cdots \supseteq S_{m}^{\prime}\right)\) be the chain of subsets of \([n+1]\) given by the formula
\[
S_{i}^{\prime}= \begin{cases}\left\{s+1: s \in S_{i}\right\} \text { if } \tau(i)=1 & \\ \{0\} & \text { if } \tau(m)=0 \\ \{0\} \cup\left\{s+1: s \in S_{i}\right\} & \text { otherwise. }\end{cases}
\]

The construction \((\vec{S}, \tau) \mapsto \vec{S}^{\prime}\) is compatible with the formation of face and degeneracy operators, and therefore determines a morphism of simplicial sets \(\pi: \Phi\left(\Delta^{n}\right) \times \Delta^{1} \rightarrow \Phi\left(\Delta^{n+1}\right)\).
Lemma 4.6.8.30. Let \(n \geq 0\) be an integer, and let \(\pi: \Phi\left(\Delta^{n}\right) \times \Delta^{1} \rightarrow \Phi\left(\Delta^{n+1}\right)\) be the 01M2 morphism of simplicial sets defined in Construction 4.6.8.29. Then \(\pi\) fits into a pushout diagram of simplicial sets

01M3 Remark 4.6.8.31. It follows from Lemma 4.6.8.30 that the morphism \(\pi\) of Construction 4.6 .8 .29 induces an isomorphism of simplicial sets \(\Delta^{0} \diamond \Phi\left(\Delta^{n}\right) \rightarrow \Phi\left(\Delta^{n+1}\right)\), where \(\diamond\) denotes the blunt join of Notation 4.5.8.3.

Proof of Lemma 4.6.8.30. Fix an integer \(m \geq 0\). By construction, the restriction \(\left.\pi\right|_{\Phi\left(\Delta^{n}\right) \times\{0\}}\) is the constant map which carries each \(m\)-simplex of \(\Phi\left(\Delta^{n}\right)\) to the element of \(\Phi\left(\Delta^{n+1}\right)\) given by the constant chain \(\vec{S}_{0}=(\{0\} \subseteq\{0\} \subseteq \cdots \subseteq\{0\})\). To complete the proof, we must show that for each \(m \geq 0\), the map \(\pi\) induces a bijection

The inverse bijection can be described explicitly as follows: it carries an \(m\)-simplex ( \(S_{0}^{\prime} \supseteq\) \(\left.\cdots \supseteq S_{m}^{\prime}\right) \neq \vec{S}_{0}\) of \(\Phi\left(\Delta^{n+1}\right)\) to the pair \((\vec{S}, \tau)\), where \(\vec{S}=\left(S_{0} \supseteq \cdots \supseteq S_{m}\right)\) is the \(m\)-simplex of \(\Phi\left(\Delta^{n}\right)\) given by
\[
S_{i}=\left\{s-1: s \in S_{i}^{\prime}, s>0\right\} \quad \tau(i)= \begin{cases}0 & \text { if } 0 \in S_{i}^{\prime} \\ 1 & \text { if } 0 \notin S_{i}^{\prime} .\end{cases}
\]

Proof of Proposition 4.6.8.24. Let \(K\) be a simplicial set. We wish to show that the map \(\rho_{K}: \Phi(K) \rightarrow K\) of Construction 4.6.8.23 is a categorical equivalence of simplicial sets. Using Corollary 4.6.8.22, we can write \(\rho_{K}\) as a filtered colimit of morphisms \(\rho_{K_{\alpha}}: \Phi\left(K_{\alpha}\right) \rightarrow K_{\alpha}\), where \(K_{\alpha}\) ranges over the collection of all finite simplicial subsets of \(K\) (Remark 3.6.1.8). Since the collection of categorical equivalences is closed under the formation of filtered colimits (Corollary 4.5.7.2), it will suffice to show that each \(\rho_{K_{\alpha}}\) is a categorical equivalence. We may therefore replace \(K\) by \(K_{\alpha}\) and thereby reduce to the case where the simplicial set \(K\) is finite.

Since \(K\) is a finite simplicial set, it has dimension \(\leq n\) for some integer \(n \geq-1\). We proceed by induction on \(n\). If \(n=-1\), then both \(K\) and \(\Phi(K)\) are empty, and there is nothing to prove. We may therefore assume that \(n \geq 0\) and that \(\rho_{K^{\prime}}\) is a categorical equivalence for every simplicial set \(K^{\prime}\) of dimension \(<n\). We now proceed by induction on the number \(m\) of nondegenerate \(n\)-simplices of \(K\). If \(m=0\), then \(K\) has dimension \(\leq n-1\) and the desired result holds by virtue of our inductive hypothesis. We may therefore assume that \(K\) has at least one nondegenerate \(n\)-simplex \(\sigma: \Delta^{n} \rightarrow K\). Using Proposition 1.1.4.12,
we see that there is a pushout diagram of simplicial sets

where \(S^{\prime}\) is a simplicial set of dimension \(\leq n\) with exactly ( \(m-1\) )-nondegenerate \(m\)-simplices. We then have a commutative diagram of simplicial sets

where the front and back faces are pushout squares (Corollary 4.6.8.22) in which the horizontal maps are monomorphisms (Remark 4.6.8.15), and are therefore categorical pushout squares (Example 4.5.4.12). Our inductive hypotheses guarantees that the maps \(\rho_{K^{\prime}}\) and \(\rho_{\partial \Delta^{n}}\) are categorical equivalences. Consequently, to show that \(\rho_{K}\) is a categorical equivalence, it will suffice to show that \(\rho_{\Delta^{n}}\) is a categorical equivalence (Proposition 4.5.4.9). We may therefore replace \(K\) by \(\Delta^{n}\) and thereby reduce to the case where \(K\) is a standard simplex.

If \(n=0\), then the map \(\rho_{\Delta^{n}}: \Phi\left(\Delta^{n}\right) \rightarrow \Delta^{n}\) is an isomorphism (Example 4.6.8.12). We may therefore assume without loss of generality that \(n>0\), so that Lemma 4.6.8.30 supplies an isomorphism of simplicial sets \(\Phi\left(\Delta^{n}\right) \simeq \Delta^{0} \diamond \Phi\left(\Delta^{n-1}\right)\). Using this isomorphism, we can identify \(\rho_{\Delta^{n}}\) with the composite map
\[
\Delta^{0} \diamond \Phi\left(\Delta^{n-1}\right) \xrightarrow{\mathrm{idd} \diamond \rho_{\Delta^{n-1}}} \Delta^{0} \diamond \Delta^{n-1} \xrightarrow{c} \Delta^{0} \star \Delta^{n-1} \simeq \Delta^{n},
\]
where \(c\) is the comparison map of Notation 4.5.8.3 (to check this, it suffices to observe that they agree on vertices). Our inductive hypothesis guarantees that \(\rho_{\Delta^{n-1}}\) is a categorical
equivalence of simplicial sets, so that the induced map \(\Delta^{0} \diamond \Phi\left(\Delta^{n-1}\right) \xrightarrow{\text { id } \diamond \rho_{\Delta^{n-1}}} \Delta^{0} \diamond \Delta^{n-1}\) is also a categorical equivalence by virtue of Remark 4.5.8.7. We are therefore reduced to showing that \(c\) is a categorical equivalence, which is a special case of Proposition 4.5.8.12.

\subsection*{4.6.9 Composition of Morphisms}

01 PF Let \(\mathcal{C}\) be an ordinary category. For every triple of objects \(X, Y, Z \in \mathrm{Ob}(\mathcal{C})\), the composition of morphisms in \(\mathcal{C}\) determines a map
\[
\circ: \operatorname{Hom}_{\mathcal{C}}(Y, Z) \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Z) .
\]

Our goal in this section is to construct an analogous operation in the \(\infty\)-categorical setting. Here the situation is more subtle: as we saw in §1.4.4, a pair of morphisms \(f: X \rightarrow Y\) and \(g: Y \rightarrow Z\) in an \(\infty\)-category \(\mathcal{C}\) generally do not have a unique composition. Nevertheless, we will show that the mapping spaces of Construction 4.6.1.1 can be endowed with a composition law which is well-defined up to homotopy (and even up to a contractible space of choices). To describe this composition law, it will be convenient to introduce a generalization of Construction 4.6.1.1.

01PG Notation 4.6.9.1. Let \(\mathcal{C}\) be a simplicial set containing a (nonempty) finite sequence of vertices \(X_{0}, X_{1}, \ldots, X_{n}\). We let \(\operatorname{Hom}_{\mathcal{C}}\left(X_{0}, X_{1}, \cdots, X_{n}\right)\) denote the simplicial set given by the fiber product
\[
\operatorname{Fun}\left(\Delta^{n}, \mathcal{C}\right) \times_{\operatorname{Fun}(\{0,1, \cdots, n\}, \mathcal{C})}\left\{\left(X_{0}, X_{1}, \cdots, X_{n}\right)\right\}
\]

01PH Example 4.6.9.2. Let \(\mathcal{C}\) be a simplicial set containing vertices \(X_{0}\) and \(X_{1}\). Then the simplicial set \(\operatorname{Hom}_{\mathcal{C}}\left(X_{0}, X_{1}\right)\) of Notation 4.6.9.1 agrees with the morphism space \(\operatorname{Hom}_{\mathcal{C}}\left(X_{0}, X_{1}\right)\) of Construction 4.6.1.1. In particular, if \(\mathcal{C}\) is an \(\infty\)-category, then \(\operatorname{Hom}_{\mathcal{C}}\left(X_{0}, X_{1}\right)\) is a Kan complex (Proposition 4.6.1.10).

01PJ Example 4.6.9.3. Let \(\mathcal{C}\) be a simplicial set and let \(X_{0}\) be a vertex of \(\mathcal{C}\). Then the simplicial set \(\operatorname{Hom}_{\mathcal{C}}\left(X_{0}\right)\) of Notation 4.6.9.1 is isomorphic to \(\Delta^{0}\).

Let \(\mathcal{C}\) be a simplicial set containing a sequence of vertices \(X_{0}, X_{1}, \ldots, X_{n}\). For every pair of integers \(0 \leq i<j \leq n\), precomposition with the edge \(\Delta^{1} \simeq \mathrm{~N}_{\bullet}(\{i<j\}) \hookrightarrow \Delta^{n}\) determines a restriction map \(\operatorname{Hom}_{\mathcal{C}}\left(X_{0}, X_{1}, \cdots, X_{n}\right) \rightarrow \operatorname{Hom}_{\mathcal{C}}\left(X_{i}, X_{j}\right)\).

01PK Proposition 4.6.9.4. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of simplicial sets, and let \(X_{0}, X_{1}, \ldots, X_{n}\) be vertices of \(\mathcal{C}\) having images \(\bar{X}_{0}, \bar{X}_{1}, \ldots, \bar{X}_{n} \in \mathcal{D}\). Then the restriction
map

is a trivial Kan fibration of simplicial sets.
Proof. Let Spine \([n]\) denote the spine of the standard \(n\)-simplex \(\Delta^{n}\) (see Example 1.5.7.7). Unwinding the definitions, we see that \(\theta\) is a pullback of the restriction map
\[
\theta^{\prime}: \operatorname{Fun}\left(\Delta^{n}, \mathcal{C}\right) \rightarrow \operatorname{Fun}(\text { Spine }[n], \mathcal{C}) \times_{\text {Fun }(\text { Spine }[n], \mathcal{D})} \operatorname{Fun}\left(\Delta^{n}, \mathcal{D}\right) .
\]

Since \(q\) is an inner fibration and the inclusion Spine \([n] \hookrightarrow \Delta^{n}\) is inner anodyne (Example 1.5.7.7), the morphism \(\theta^{\prime}\) is a trivial Kan fibration (Proposition 4.1.4.4.

Corollary 4.6.9.5. Let \(\mathcal{C}\) be an \(\infty\)-category containing objects \(X_{0}, X_{1}, \ldots, X_{n}\). Then the 01PL restriction map
\[
\operatorname{Hom}_{\mathcal{C}}\left(X_{0}, X_{1}, \cdots, X_{n}\right) \rightarrow \prod_{i=1}^{n} \operatorname{Hom}_{\mathcal{C}}\left(X_{i-1}, X_{i}\right)
\]
is a trivial Kan fibration of simplicial sets.
Example 4.6.9.6. Let \(\mathcal{C}\) be an ordinary category containing objects \(X_{0}, X_{1}, \ldots, X_{n}\), which 01PM we also regard as objects of the \(\infty\)-category \(\mathrm{N}_{\bullet}(\mathcal{C})\). Then the restriction map
\[
\theta: \operatorname{Hom}_{\mathrm{N}_{\bullet}(\mathcal{C})}\left(X_{0}, X_{1}, \cdots, X_{n}\right) \rightarrow \prod_{i=1}^{n} \operatorname{Hom}_{\mathrm{N}_{\bullet}(\mathcal{C})}\left(X_{i-1}, X_{i}\right)
\]
is an isomorphism of (discrete) simplicial sets.
Remark 4.6.9.7. It follows from Corollary 4.6.9.5 that the construction
\[
\left(X_{0}, X_{1}, \cdots, X_{n}\right) \mapsto \operatorname{Hom}_{\mathcal{C}}\left(X_{0}, X_{1}, \cdots, X_{n}\right)
\]
endows the collection of objects of \(\mathcal{C}\) with the structure of a Segal category (see Definition [?]). We will return to this point in §[?].
Corollary 4.6.9.8. Let \(\mathcal{C}\) be an \(\infty\)-category. For every sequence of objects \(X_{0}, X_{1}, \cdots, X_{n} \in 01 \mathrm{PP}\) \(\mathcal{C}\), the simplicial set \(\operatorname{Hom}_{\mathcal{C}}\left(X_{0}, X_{1}, \cdots, X_{n}\right)\) is a Kan complex.

Proof. Combine Corollary 4.6.9.5 with Proposition 4.6.1.10.

01 PQ Construction 4.6.9.9. Let \(\mathcal{C}\) be an \(\infty\)-category containing objects \(X, Y\), and \(Z\). By virtue of Corollary 4.6.9.5 the restriction map
\[
\theta: \operatorname{Hom}_{\mathcal{C}}(X, Y, Z) \rightarrow \operatorname{Hom}_{\mathcal{C}}(Y, Z) \times \operatorname{Hom}_{\mathcal{C}}(X, Y)
\]
is a trivial Kan fibration, so its homotopy class \([\theta]\) is an isomorphism in the homotopy category hKan. We let
\[
\circ: \operatorname{Hom}_{\mathcal{C}}(Y, Z) \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Z)
\]
denote the morphism in hKan obtained by composing \([\theta]^{-1}\) with (the homotopy class of) the restriction map \(\operatorname{Hom}_{\mathcal{C}}(X, Y, Z) \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Z)\). We will refer to \(\circ\) as the composition law on the \(\infty\)-category \(\mathcal{C}\).

01 PR Remark 4.6.9.10. Let \(\mathcal{C}\) be an \(\infty\)-category containing objects \(X, Y\), and \(Z\). Then the composition law
\[
\circ: \operatorname{Hom}_{\mathcal{C}}(Y, Z) \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Z)
\]
of Construction 4.6.9.9 induces a map of sets
\[
\pi_{0}\left(\operatorname{Hom}_{\mathcal{C}}(Y, Z)\right) \times \pi_{0}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)\right) \rightarrow \pi_{0}\left(\operatorname{Hom}_{\mathcal{C}}(X, Z)\right)
\]

Concretely, this map is given by the construction \(([g],[f]) \mapsto[h]\), where \(h\) is a composition of \(f\) and \(g\) in the sense of Definition 1.4.4.1.

01PS Proposition 4.6.9.11 (Unitality). Let \(\mathcal{C}\) be an \(\infty\)-category containing a pair of objects \(X\) and \(Y\). Then:
(1) The composition
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \simeq \operatorname{Hom}_{\mathcal{C}}(X, Y) \times\left\{\operatorname{id}_{X}\right\} \hookrightarrow \operatorname{Hom}_{\mathcal{C}}(X, Y) \times \operatorname{Hom}_{\mathcal{C}}(X, X) \xrightarrow{\circ} \operatorname{Hom}_{\mathcal{C}}(X, Y)
\] is equal to the identity (in the homotopy category of Kan complexes hKan).
(2) The composition
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \simeq\left\{\operatorname{id}_{Y}\right\} \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \hookrightarrow \operatorname{Hom}_{\mathcal{C}}(Y, Y) \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \xrightarrow{\circ} \operatorname{Hom}_{\mathcal{C}}(X, Y)
\]
is equal to the identity (in the homotopy category of Kan complexes hKan).
Proof. There is a diagram of Kan complexes

where the left diagonal arrow is induced by the map \(\sigma_{1}^{0}:[2] \rightarrow[1]\) of Construction 1.1.2.1 and the right diagonal arrow is induced by the map \(\delta_{2}^{1}:[1] \rightarrow[2]\) of Construction 1.1.1.4. Here the solid arrows are well-defined as morphisms of simplicial sets, while the dotted arrow is well-defined only as a morphism in the homotopy category hKan. We now observe that the triangle on the left is strictly commutative, the triangle on the right commutes up to homotopy (by the construction of the composition law o). Assertion (1) follows from the observation that the composition of the diagonal arrows is the identity on the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) (since \(\sigma_{1}^{0} \circ \delta_{2}^{1}\) is the identity on the object \([1] \in \boldsymbol{\Delta}\) ). Assertion (2) follows by a similar argument.

Proposition 4.6.9.12 (Associativity). Let \(\mathcal{C}\) be an \(\infty\)-category containing objects \(W, X, 01 \mathrm{PT}\) \(Y\), and \(Z\). Then the diagram

commutes (in the homotopy category of Kan complexes hKan).
Proof. By virtue of Corollary 4.6.9.5, 4.43) is isomorphic to the diagram of restriction maps

which commutes in the category of simplicial sets (and therefore also in the homotopy category hKan).

Construction 4.6.9.13 (The Enriched Homotopy Category). Let hKan denote the homo- 01PV topy category of Kan complexes, which we endow with the monoidal structure given by cartesian products. To every \(\infty\)-category \(\mathcal{C}\), we define an hKan-enriched category hC as follows:
- The objects of hC are the objects of \(\mathcal{C}\).
- For every pair of objects \(X, Y \in \mathcal{C}\), the Kan complex \(\underline{\operatorname{Hom}}_{\mathrm{h} \mathcal{C}}(X, Y)\) is the morphism space \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) of Construction 4.6.1.1.
- For every object \(X \in \mathcal{C}\), the unit map \(\Delta^{0} \rightarrow \underline{\operatorname{Hom}}_{\mathrm{hC}}(X, X)\) is the homotopy class of the inclusion \(\left\{\operatorname{id}_{X}\right\} \hookrightarrow \operatorname{Hom}_{\mathcal{C}}(X, X)\).
- For every triple of objects \(X, Y, Z \in \mathcal{C}\), the composition law
\[
\circ: \underline{\operatorname{Hom}}_{\mathrm{hC}}(Y, Z) \times \underline{\operatorname{Hom}}_{\mathrm{h} \mathcal{C}}(X, Y) \rightarrow \underline{\operatorname{Hom}}_{\mathrm{h} \mathcal{C}}(X, Z)
\]
is given by Construction 4.6.9.9.
Note that this definition satisfies the axiomatics of Definition 2.1.7.1 by virtue of Propositions 4.6.9.11 and 4.6.9.12 We will refer to hC as the enriched homotopy category of the \(\infty\)-category \(\mathcal{C}\).

01 PW Remark 4.6.9.14. Let \(\mathcal{C}\) be an \(\infty\)-category and let hC denote the enriched homotopy category of \(\mathcal{C}\). Then hC has an underlying category (Example 2.1.7.5), which we will also denote by hC. Concretely, this category can be described as follows:
- The objects of hC are the objects of \(\mathcal{C}\).
- For every pair of objects \(X, Y \in \mathcal{C}\), we have
\[
\operatorname{Hom}_{\mathrm{h} \mathcal{C}}(X, Y)=\operatorname{Hom}_{\mathrm{hKan}}\left(\Delta^{0}, \underline{\operatorname{Hom}}_{\mathrm{h} \mathcal{C}}(X, Y)\right) \simeq \pi_{0}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)\right) .
\]

In other words, \(\operatorname{Hom}_{\mathrm{hc}}(X, Y)\) can be identified with the set of homotopy classes of morphisms from \(X\) to \(Y\) in the \(\infty\)-category \(\mathcal{C}\).

By virtue of Remark 4.6.9.10, the composition of morphisms in the category hC agrees with the composition law of Construction 1.4.5.1. In other words, we can identify hC with the homotopy category constructed in \(\$ 1.4 .5\)

01 TP Notation 4.6.9.15. Let \(\mathcal{C}\) be an \(\infty\)-category containing objects \(X, Y\), and \(Z\). For every morphism \(f: X \rightarrow Y\) in \(\mathcal{C}\), the composition law of Construction 4.6.9.9 restricts to a morphism of Kan complexes
\[
\operatorname{Hom}_{\mathcal{C}}(Y, Z) \simeq \operatorname{Hom}_{\mathcal{C}}(Y, Z) \times\{f\} \hookrightarrow \operatorname{Hom}_{\mathcal{C}}(Y, Z) \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \xrightarrow{\circ} \operatorname{Hom}_{\mathcal{C}}(X, Z),
\]
which is well-defined up to homotopy. Note that this morphism depends only on the homotopy class \([f]\) of the morphism \(f\). We will denote this map by \(\operatorname{Hom}_{\mathcal{C}}(Y, Z) \xrightarrow{\circ[f]}\) \(\operatorname{Hom}_{\mathcal{C}}(X, Z)\) and refer to it as precomposition with \(f\). Similarly, for every morphism \(g\) : \(Y \rightarrow Z\), the composition law of Remark 4.6.9.10 determines a homotopy class of morphisms \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \xrightarrow{[g] 0} \operatorname{Hom}_{\mathcal{C}}(X, Z)\), which we will refer to as postcomposition with \(g\).

To describe the precomposition morphism of Notation 4.6.9.15 concretely, it is convenient to replace the morphism spaces \(\operatorname{Hom}_{\mathcal{C}}(X, Z)\) and \(\operatorname{Hom}_{\mathcal{C}}(Y, Z)\) by their right-pinched variants \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Z)=\mathcal{C}_{X /} \times_{\mathcal{C}}\{Z\}\) and \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(Y, Z)=\mathcal{C}_{Y /} \times_{\mathcal{C}}\{Z\}\), respectively (see Construction 4.6.5.1.

Proposition 4.6.9.16. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(f: X \rightarrow Y\) be a morphism of \(\mathcal{C}\). 02LL For every object \(Z \in \mathcal{C}\), the diagram of Kan complexes

commutes up to homotopy, where the vertical maps are the right-pinch inclusion morphisms of Construction 4.6.5.7.
Remark 4.6.9.17. In the situation of Proposition 4.6.9.16, the morphisms
\[
\iota_{Y, Z}^{\mathrm{R}}: \mathcal{C}_{Y /} \times \times_{\mathcal{C}}\{Z\} \rightarrow \operatorname{Hom}_{\mathcal{C}}(Y, Z) \quad \iota_{X, Z}^{\mathrm{R}}: \mathcal{C}_{X /} \times \times_{\mathcal{C}}\{Z\} \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Z)
\]
are homotopy equivalences, by virtue of Proposition 4.6.5.10. Moreover, the restriction map \(\mathcal{C}_{f /} \times_{\mathcal{C}}\{Z\} \rightarrow \mathcal{C}_{Y /} \times_{\mathcal{C}}\{Z\}\) is a trivial Kan fibration (Corollary 4.3.6.13). Consequently, the precomposition map \(\operatorname{Hom}_{\mathcal{C}}(Y, Z) \xrightarrow{\circ[f]} \operatorname{Hom}_{\mathcal{C}}(X, Z)\) is characterized (up to homotopy) by the conclusion of Proposition 4.6.9.16.

Proof of Proposition 4.6.9.16. It will suffice to show that there exists a morphism of Kan complexes
\[
\iota_{X, Y, Z}^{\mathrm{R}}: \mathcal{C}_{f /} \times \times_{\mathcal{C}}\{Z\} \rightarrow\{f\} \times_{\operatorname{Hom}_{\mathcal{C}}(X, Y)} \operatorname{Hom}_{\mathcal{C}}(X, Y, Z)
\]
for which the diagram

commutes (in the category of simplicial sets).
We first observe that there is a unique morphism of simplicial sets e : \(\Delta^{2} \times \mathcal{C}_{f /} \rightarrow \Delta^{1} \star \mathcal{C}_{f /}\) with the property that \(\left.e\right|_{\Delta^{1} \times \mathcal{C}_{f /}}\) is given by projection onto the first factor, and \(\left.e\right|_{\{2\} \times \mathcal{C}_{f /}}\) is given by projection onto the second factor. Note that the composite map
\[
\Delta^{2} \times \mathcal{C}_{f /} \xrightarrow{e} \Delta^{1} \star \mathcal{C}_{f /} \rightarrow \mathcal{C}
\]
can be identified with a morphism of simplicial sets \(e^{\prime}: \mathcal{C}_{f /} \rightarrow \operatorname{Fun}\left(\Delta^{2}, \mathcal{C}\right)\). Unwinding the definition, we see that \(e^{\prime}\) restricts to a morphism of simplicial subsets
\[
\iota_{X, Y, Z}^{\mathrm{R}}: \mathcal{C}_{f /} \times_{\mathcal{C}}\{Z\} \rightarrow\{f\} \times_{\operatorname{Hom}_{\mathcal{C}}(X, Y)} \operatorname{Hom}_{\mathcal{C}}(X, Y, Z) \subseteq \operatorname{Fun}\left(\Delta^{2}, \mathcal{C}\right)
\]
having the desired properties.
02R3 Corollary 4.6.9.18. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(f: X \rightarrow Y\) and \(g: X \rightarrow Z\) be morphisms of \(\mathcal{C}\), which we identify with objects of the coslice \(\infty\)-category \(\mathcal{C}_{X /}\). Then the morphism space \(\operatorname{Hom}_{\mathcal{C}_{X /}}(f, g)\) can be identified with the homotopy fiber of the composition map \(\operatorname{Hom}_{\mathcal{C}}(Y, Z) \xrightarrow{\circ[f]} \operatorname{Hom}_{\mathcal{C}}(X, Z)\) over the vertex \(g \in \operatorname{Hom}_{\mathcal{C}}(X, Z)\).

Proof. Using Proposition 4.6.9.16, we can replace the composition map \(\operatorname{Hom}_{\mathcal{C}}(Y, Z) \xrightarrow{\circ[f]}\) \(\operatorname{Hom}_{\mathcal{C}}(X, Z)\) with the restriction map \(\theta: \mathcal{C}_{f /} \times_{\mathcal{C}}\{Z\} \rightarrow \mathcal{C}_{X /} \times_{\mathcal{C}}\{Z\}\). The morphism \(\theta\) is a left fibration (Corollary 4.3.6.11). Since the left-pinched morphism space \(\mathcal{C}_{X /} \times{ }_{\mathcal{C}}\{Z\}=\) \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Z)\) is a Kan complex (Proposition 4.6.5.5), it follows that \(\theta\) is a Kan fibration (Corollary 4.4.3.8. In particular, the homotopy fiber of the composition map \(\operatorname{Hom}_{\mathcal{C}}(Y, Z) \xrightarrow{\circ[f]}\) \(\operatorname{Hom}_{\mathcal{C}}(X, Z)\) over the vertex \(g\) can be identified with the fiber
\[
\theta^{-1}\{g\} \simeq \mathcal{C}_{f /} \times_{\mathcal{C}_{X /}}\{g\}=\operatorname{Hom}_{\mathcal{C}_{X /}}^{\mathrm{L}}(f, g),
\]
which is homotopy equivalent to \(\operatorname{Hom}_{\mathcal{C}_{X /}}(f, g)\) by virtue of Proposition 4.6.5.10.
Let \(\mathcal{C}\) be a locally Kan simplicial category, so that the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) is an \(\infty\)-category (Theorem 2.4.5.1). In this case, the composition law of Construction 4.6.9.9 has a direct description:

02LN Proposition 4.6.9.19. Let \(\mathcal{C}\) be a locally Kan simplicial category. For every pair of objects \(X, Y \in \mathcal{C}\), let \(\theta_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \rightarrow \operatorname{Hom}_{\mathrm{Nh}_{\bullet}}(X, Y)\) denote the homotopy equivalence of Kan complexes supplied by Remark 4.6.8.6. Then, for every triple of objects \(X, Y, Z \in \mathcal{C}\), the diagram

commutes in the homotopy category hKan; here the lower horizontal map is the composition law of Construction 4.6.9.9.

Proof. We will show that there exists a morphism of Kan complexes
\[
\theta_{X, Y, Z}: \operatorname{Hom}_{\mathcal{C}}(Y, Z) \bullet \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet} \mathrm{c}(\mathcal{C})}(X, Y, Z)
\]
for which the diagram

is commutative.
Fix an integer \(n \geq 0\). Let \(\mathcal{E}\) denote the simplicial category with object set \(\operatorname{Ob}(\mathcal{E})=\) \(\{x, y, z\}\) and morphism spaces given by
\[
\begin{gathered}
\operatorname{Hom}_{\mathcal{E}}(x, x)_{\bullet}=\left\{\operatorname{id}_{x}\right\} \\
\operatorname{Hom}_{\mathcal{E}}(y, y)_{\bullet}=\left\{\operatorname{id}_{y}\right\} \quad \operatorname{Hom}_{\mathcal{E}}(z, z)_{\bullet}=\left\{\operatorname{id}_{z}\right\} \\
\operatorname{Hom}_{\mathcal{E}}(y, x)_{\bullet}=\emptyset \\
\operatorname{Hom}_{\mathcal{E}}(z, x)_{\bullet}=\emptyset \quad \operatorname{Hom}_{\mathcal{E}}(z, y)_{\bullet}=\emptyset \\
\operatorname{Hom}_{\mathcal{E}}(x, y)_{\bullet}=\Delta^{n} \quad \operatorname{Hom}_{\mathcal{E}}(y, z)_{\bullet}=\Delta^{n}
\end{gathered}
\]
where the composition law \(\operatorname{Hom}_{\mathcal{E}}(y, z)_{\bullet} \times \operatorname{Hom}_{\mathcal{E}}(x, y)_{\bullet} \rightarrow \operatorname{Hom}_{\mathcal{E}}(x, z)_{\bullet}\) is an isomorphism (so that \(\operatorname{Hom}_{\mathcal{E}}(x, z)\). can be identified with the product \(\Delta^{n} \times \Delta^{n}\) ). Note that there is a unique simplicial functor \(F: \operatorname{Path}\left[\Delta^{2} \times \Delta^{n}\right] \bullet \rightarrow \mathcal{E}\) satisfying the following conditions:
- On objects, the functor \(F\) is given by the formula
\[
F(i, j)= \begin{cases}x & \text { if } i=0 \\ y & \text { if } i=1 \\ z & \text { if } i=2\end{cases}
\]
- Let \((i, j)\) and \(\left(i^{\prime}, j^{\prime}\right)\) be vertices of \(\Delta^{2} \times \Delta^{n}\) satisfying \(i<i^{\prime}\) and \(j \leq j^{\prime}\), so that there is a unique indecomposable morphism \(u\) from \((i, j)\) to \(\left(i^{\prime}, j^{\prime}\right)\) in the path category \(\operatorname{Path}\left[\Delta^{2} \times \Delta^{n}\right]\) (given by the chain \(\left\{(i, j)<\left(i^{\prime}, j^{\prime}\right)\right\}\) ). If \(i=0\) and \(i^{\prime}=1\), then \(F(u)\) is the vertex \(j^{\prime}\) of \(\Delta^{n}=\operatorname{Hom}_{\mathcal{E}}(x, y)\). If \(i=1\) and \(i^{\prime}=2\), then \(F(u)\) is the vertex \(j^{\prime}\) of \(\Delta^{n}=\operatorname{Hom}_{\mathcal{E}}(y, z)_{\bullet}\). If \(i=0\) and \(i^{\prime}=2\), then \(F(u)\) is the vertex \(\left(j^{\prime}, j^{\prime}\right)\) of \(\Delta^{n} \times \Delta^{n}=\operatorname{Hom}_{\mathcal{E}}(x, z)\).

Let \(\sigma\) and \(\tau\) be \(n\)-simplices of the Kan complexes \(\operatorname{Hom}_{\mathcal{C}}(Y, Z)\) • and \(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{\bullet}\), respectively. Then there is a unique simplicial functor \(G_{\sigma, \tau}: \mathcal{E} \rightarrow \mathcal{C}\) satisfying the following conditions:
- On objects, the functor \(G_{\sigma, \tau}\) is given by \(G_{\sigma, \tau}(x)=X, G_{\sigma, \tau}(y)=Y\), and \(G_{\sigma, \tau}(z)=Z\).
- The induced map \(\Delta^{n}=\operatorname{Hom}_{\mathcal{E}}(x, y) \bullet \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Y)\) • is the \(n\)-simplex \(\tau\).
- The induced map \(\Delta^{n}=\operatorname{Hom}_{\mathcal{E}}(y, z) \bullet \rightarrow \operatorname{Hom}_{\mathcal{C}}(Y, Z)\) • is the \(n\)-simplex \(\sigma\).

The composite simplicial functor
\[
\operatorname{Path}\left[\Delta^{2} \times \Delta^{n}\right] \bullet \xrightarrow{F} \mathcal{E} \xrightarrow{G_{\sigma, \tau}} \mathcal{C}
\]
determines a morphism from \(\Delta^{2} \times \Delta^{n}\) to the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\), which can be identified with an \(n\)-simplex \(\theta_{X, Y, Z}(\sigma, \tau)\) of the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y, Z)\). Allowing \(n\) to vary, the construction \((\sigma, \tau) \mapsto \theta_{X, Y, Z}(\sigma, \tau)\) determines a morphism of simplicial sets \(\theta_{X, Y, Z}\) : \(\operatorname{Hom}_{\mathcal{C}}(Y, Z) \bullet \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet}(\mathcal{C})}(X, Y, Z)\) having the desired properties.

02LP Corollary 4.6.9.20. Let \(\mathcal{C}\) be a locally Kan simplicial category, and let \(U: \mathrm{hC} \rightarrow \mathrm{hN}{ }_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) be the isomorphism of homotopy categories supplied by Proposition 2.4.6.9. Then the homotopy equivalences \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet}^{\mathrm{hc}}}(X, Y)\) of Remark 4.6.8.6 promote \(U\) to an isomorphism of hKan-enriched categories. Here hC is endowed with the hKan-enrichment of Remark 3.1.5.12 and \(\mathrm{hN}_{\bullet}^{\text {hc }}(\mathcal{C})\) is endowed with the hKan-enrichment of Construction 4.6.9.13.

Let \(\mathcal{C}\) be a differential graded category. For every pair of objects \(X, Y \in \mathcal{C}\), we let \(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}\) denote the chain complex of morphisms from \(X\) to \(Y\) and \(\mathrm{K}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}\right)\) the associated Eilenberg-MacLane space (Construction 2.5.6.3). In what follows, let us write
\[
\rho_{Y, X}: \mathrm{K}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}\right) \hookrightarrow \operatorname{Hom}_{\mathrm{N}_{0}^{\mathrm{d}}(\mathcal{C})}(X, Y)
\]
for the composition of the isomorphism \(\mathrm{K}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}\right) \simeq \operatorname{Hom}_{\mathrm{N}_{\bullet}{ }_{(\mathcal{C})}}^{\mathrm{L}}(X, Y)\) of Example 4.6.5.15 with the pinch inclusion morphism \(\operatorname{Hom}_{\mathrm{N}^{\mathrm{dg}}(\mathcal{C})}^{\mathrm{L}}(X, Y) \hookrightarrow \operatorname{Hom}_{\mathrm{N}_{\cdot}{ }^{\mathrm{dg}}(\mathcal{C})}(X, Y)\) of Construction 4.6.5.7. We then have the following:

03EO Proposition 4.6.9.21. Let \(\mathcal{C}\) be a differential graded category containing objects \(X, Y\), and \(Z\), so that the composition law
\[
\circ: \operatorname{Hom}_{\mathcal{C}}(Y, Z)_{*} \otimes \operatorname{Hom}_{\mathcal{C}}(X, Y)_{*} \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Z)_{*}
\]
induces a bilinear map of simplicial abelian groups
\[
\mu: \mathrm{K}\left(\operatorname{Hom}_{\mathcal{C}}(Y, Z)_{*}\right) \times \mathrm{K}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}\right) \rightarrow \mathrm{K}\left(\operatorname{Hom}_{\mathcal{C}}(X, Z)_{*}\right)
\]
(see Proposition 2.5.9.1). Then the diagram of Kan complexes

commutes up to homotopy, where the bottom horizontal map is the composition law of Construction 4.6.9.9.

Remark 4.6.9.22. In the situation of Proposition 4.6.9.21, the morphisms \(\rho_{Y, X}, \rho_{Z, Y}\), and \(\rho_{Z, X}\) are homotopy equivalences (Proposition 4.6.5.10). Consequently, Proposition 4.6.9.21 determines the composition law on the hKan-enriched homotopy category of \(\mathrm{N}_{\bullet}^{\mathrm{dg}}(\mathcal{C})\).

Proof of Proposition 4.6.9.21. Let \(\mathcal{C}^{\Delta}\) denote the underlying simplicial category of the differential graded category \(\mathcal{C}\) (Construction 2.5.9.2). By virtue of Exercise 4.6.8.4 we can identify (4.44) with the outer rectangle of a larger diagram

where middle horizontal map is given by the composition law of the \(\infty\)-category \(\mathrm{N}_{\bullet}^{\text {hc }}\left(\mathcal{C}^{\Delta}\right)\). We now observe that the upper square commutes up to homotopy by virtue of Proposition 4.6.9.19, and the lower square commutes up to homotopy by the functoriality of Construction 4.6.9.9

\subsection*{4.7 Size Conditions on \(\infty\)-Categories}

Recall that a small category \(\mathcal{C}\) consists of the following data:
- A set \(\operatorname{Ob}(\mathcal{C})\), whose elements are referred to as objects of \(\mathcal{C}\).
- For every pair of objects \(X, Y \in \mathcal{C}\), a set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\), whose elements are referred to as morphisms from \(X\) to \(Y\).
- For every triple of objects \(X, Y, Z \in \mathcal{C}\), a composition law
\[
\circ: \operatorname{Hom}_{\mathcal{C}}(Y, Z) \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Z)
\]
which is required to be unital and associative.
This definition treats categories as algebraic objects akin to groups (though somewhat more general), which is perfectly adequate for many purposes. However, it is often useful to apply the theory to categories which are not small, such as the category of sets \(\mathcal{C}=\) Set. In this case, \(\operatorname{Ob}(\mathcal{C})\) is the collection of all sets, and must be treated with a bit of care to avoid paradoxes.

03PQ Example 4.7.0.1. When speaking informally, it is common to say that the category Set has all limits and colimits. A more precise statement is that the category Set has all small limits and colimits; that is, every diagram \(F: \mathcal{J} \rightarrow\) Set indexed by a small category \(\mathcal{J}\) has a limit and colimit. Here the size restriction on \(\mathcal{J}\) cannot be omitted. For example, if \(\left\{S_{j}\right\}_{j \in J}\) is a collection of sets indexed by another set \(J\), then it is permissible to form the coproduct \(\amalg_{j \in J} S_{j}\). However, it is not permissible to form the coproduct \(\amalg_{S \in \mathrm{Ob}(\mathrm{Set})} S\) of all sets.

In the setting of higher category theory, one encounters similar issues. In \(\S 1.4\), we defined an \(\infty\)-category to be a simplicial set \(\mathcal{C}\) • which satisfies a filling condition for inner horns (Definition 1.4.0.1). By analogy with the discussion above, we might be better to refer to such objects as small \(\infty\)-categories. However, we will often want to apply the ideas developed in this book to \(\infty\)-categories \(\mathcal{C} \bullet\) which are not small, because the collections \(n\)-simplices \(\mathcal{C}_{n}\) are "too big" to be sets (this situation arises, for example, if \(\mathcal{C}\). is the nerve of a large category). For the most part, we will ignore the set-theoretic issues which are raised by allowing such objects into our discourse. However, this is not always possible: as Example 4.7 .0 .1 illustrates, it is sometimes important to track the distinction between "large" and "small."

The first goal of this section is to introduce some language for quantifying the sizes of category-theoretic objects. Let \(\kappa\) be an infinite cardinal. We will say that a set is \(\kappa\)-small if its cardinality is strictly smaller than \(\kappa\) (Definition 4.7.3.1). We will say that a simplicial set \(S\) is \(\kappa\)-small if the collection of nondegenerate simplices of \(S\) is \(\kappa\)-small (Definition 4.7.4.1). We summarize the basic properties of \(\kappa\)-small sets and simplicial sets in \(\$ 4.7 .3\) and \(\S 4.7 .4\), respectively. Beware that \(\kappa\)-smallness is not a homotopy invariant condition: that is, it is possible for a \(\kappa\)-small \(\infty\)-category to be equivalent to an \(\infty\)-category which is not \(\kappa\)-small. In \(\S 4.7 .5\), we address this point by introducing the notion of essential smallness. If \(\kappa\) is an uncountable cardinal, we say that an \(\infty\)-category \(\mathcal{C}\) is essentially \(\kappa\)-small if it is equivalent to a \(\kappa\)-small \(\infty\)-category (Definition 4.7.5.1). One can formulate this condition also in the case \(\kappa=\aleph_{0}\), but it is poorly behaved: it is very rare for finite simplicial sets to be \(\infty\)-categories (see Warning 4.7.5.6).

The second goal of this section is to provide a concrete criterion which can be used to test if an \(\infty\)-category is essentially \(\kappa\)-small. For simplicity, let us assume that \(\kappa\) is an (uncountable) regular cardinal. We say that an \(\infty\)-category \(\mathcal{C}\) is locally \(\kappa\)-small if, for every pair of objects \(C, D \in \mathcal{C}\), the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(C, D)\) is essentially \(\kappa\)-small (Definition 4.7.8.1. In \(\S 4.7 .8\), we show that \(\mathcal{C}\) is essentially \(\kappa\)-small if and only if it locally \(\kappa\)-small and the set of isomorphism classes \(\pi_{0}\left(\mathcal{C}^{\simeq}\right)\) is \(\kappa\)-small (Proposition 4.7.8.7). We are therefore reduced to the problem of testing essential \(\kappa\)-smallness of Kan complexes. In \(\S 44.7 .7\), we address this problem by showing that a Kan complex \(X\) is essentially \(\kappa\)-small if and only if the set \(\pi_{0}(X)\) is \(\kappa\)-small and the homotopy groups \(\left\{\pi_{n}(X, x)\right\}_{n>0}\) are \(\kappa\)-small for every vertex \(x \in X\) (Proposition 4.7.7.1).

The proofs of Propositions 4.7.8.7 and 4.7.7.1 will use a common strategy. In both cases, the hard part is to show that if \(\mathcal{C}\) is an \(\infty\)-category for which certain homotopy-invariant quantities are bounded in size, then \(\mathcal{C}\) is equivalent to an \(\infty\)-category \(\mathcal{C}_{0}\) for which the collection of simplices is bounded in size. We will prove this using the theory of minimal models. We say that an \(\infty\)-category \(\mathcal{C}_{0}\) is minimal if the datum of a simplex \(\sigma: \Delta^{n} \rightarrow \mathcal{C}\) is determined by its homotopy class relative to the boundary \(\partial \Delta^{n}\) (see Definition 4.7.6.4). In \(\$ 4.7 .6\), we will prove the following:
- For every \(\infty\)-category \(\mathcal{C}\), there exists an equivalence of \(\infty\)-categories \(\mathcal{C}_{0} \rightarrow \mathcal{C}\), where \(\mathcal{C}_{0}\) is minimal (Proposition 4.7.6.15). Moreover, \(\mathcal{C}_{0}\) is uniquely determined up to isomorphism (Corollary 4.7.6.14).
- If \(\mathcal{C}_{0}\) is a minimal \(\infty\)-category, then every equivalence of \(\infty\)-categories \(\mathcal{C}_{0} \rightarrow \mathcal{C}\) is a monomorphism of simplicial sets (Lemma 4.7.6.11). Consequently, \(\mathcal{C}_{0}\) is essentially \(\kappa\)-small if and only if it is \(\kappa\)-small (Corollary 4.7.6.12).

Remark 4.7.0.2. Throughout this section, we will need some elementary properties of cardinals and cardinal arithmetic. For the reader's convenience, we briefly review the set-theoretic prerequisites in \(\S 4.7 .1\) and \(\S 4.7 .2\).

Remark 4.7.0.3. The notion of minimal \(\infty\)-category was introduced by Joyal in [30]. In the setting of Kan complexes, the theory of minimal models is much older (see [2]).

Remark 4.7.0.4. Let \(\kappa\) be an uncountable regular cardinal. We will see later that the 03PT essentially \(\kappa\)-small \(\infty\)-categories admit a more intrinsic characterization: they are precisely the \(\kappa\)-compact objects of the \(\infty\)-category \(\mathcal{Q C}\) of \(\infty\)-categories (see Proposition [?]).
Remark 4.7.0.5. Throughout this book, we will make reference to a dichotomy between 03PU "small" and "large" mathematical objects. We will generally take a somewhat informal view of this dichotomy, taking care only to avoid maneuvers which are obviously illegitimate (see Example 4.7.0.1. However, the reader who wishes to adopt a more scrupulous approach could proceed (within the framework of Zermelo-Fraenkel set theory) as follows:
- Assume the existence of an uncountable strongly inaccessible cardinal \(\kappa\) (see Definition 4.7.3.20.
- Declare that an \(\infty\)-category \(\mathcal{C}\) is small (essentially small, locally small) if it is \(\kappa\) small (essentially \(\kappa\)-small, locally \(\kappa\)-small), and apply similar conventions to other mathematical objects of interest (such as sets and categories).

\subsection*{4.7.1 Ordinals and Well-Orderings}

In this section, we review some standard facts about ordinals and well-ordered sets.
4.7. SIZE CONDITIONS ON \(\infty\)-CATEGORIES

034C Definition 4.7.1.1. Let \((S, \leq)\) be a partially ordered set. We say that ( \(S, \leq\) ) is well-founded if every nonempty subset \(S_{0} \subseteq S\) contains a minimal element: that is, an element \(s \in S_{0}\) for which the set \(\left\{t \in S_{0}: t<s\right\}\) is empty.

03PW Exercise 4.7.1.2. Let \((S, \leq)\) be a partially ordered set. Show that the following conditions are equivalent:
(1) The partial order \(\leq\) is well-founded: that is, every nonempty subset of \(S\) contains a minimal element.
(2) The set \(S\) does not contain an infinite descending sequence \(s_{0}>s_{1}>s_{2}>\cdots\).

03PX Example 4.7.1.3. Every finite partially ordered set \((S, \leq)\) is well-founded.
\(03 P Y\) Example 4.7.1.4. Let \(S\) be any set, and let \(\leq\) be the discrete partial ordering of \(S\) : that is, we have \(s \leq t\) if and only if \(s=t\). Then \((S, \leq)\) is well-founded.

03PZ Remark 4.7.1.5. Let \((S, \leq)\) be a well-founded partially ordered set. Then every subset \(S_{0} \subseteq S\) is also well-founded (when endowed with the partial order given by the restriction of \(\leq)\).
\(03 Q 0\) Definition 4.7.1.6. Let \((S, \leq)\) be a linearly ordered set. We say that \((S, \leq)\) is well-ordered if it is well-founded when regarded as a partially ordered set: that is, if every nonempty subset \(S_{0} \subseteq S\) contains a smallest element. In this case, we will refer to the relation \(\leq\) as a well-ordering of the set \(S\).
\(03 Q 1\) Definition 4.7.1.7 (Ordinals). An ordinal is an isomorphism class of well-ordered sets. If ( \(S, \leq\) ) is a well-ordered set, then its isomorphism class is an ordinal which we will refer to as the order type of \(S\).
\(03 Q 2\) Notation 4.7.1.8. We will typically use lower-case Greek letters to denote ordinals.
03Q3 Example 4.7.1.9 (Finite Ordinals). Let \(n\) be a nonnegative integer. Up to isomorphism, there is a unique linearly ordered set \(S\) having exactly \(n\) elements, which we can identify with the set \(\{0<1<\cdots<n-1\}\). We will abuse notation by identifying \(n\) with the order type of the linearly ordered set \(S\). By means of this convention, we can view every nonnegative integer as an ordinal. We say that an ordinal \(\alpha\) is finite it arises in this way (that is, if it is the order type of a finite linearly ordered set), and infinite if it does not.

03 Q4 Example 4.7.1.10. The set of nonnegative integers \(\mathbf{Z}_{\geq 0}=\{0<1<2<\cdots\}\) is well-ordered (with respect to its usual ordering). Its order type is an infinite ordinal, which we denote by \(\omega\).

By definition, well-ordered sets \((S, \leq)\) and \((T, \leq)\) have the same order type if there is an order-preserving bijection \(f: S \xrightarrow{\sim} T\). We will show in a moment that in this case, the bijection \(f\) is uniquely determined (Corollary 4.7.1.16). First, let us introduce a bit of additional terminology.

Definition 4.7.1.11. Let \((S, \leq)\) be a linearly ordered set. We say that a subset \(S_{0} \subseteq S\) is an initial segment if it is closed downwards: that is, for every pair of elements \(s \leq s^{\prime}\) of \(S\), if \(s^{\prime}\) is contained in \(S_{0}\), then \(s\) is also contained in \(S_{0}\). If \((T, \leq)\) is another linearly ordered set, we say that a function \(f: S \hookrightarrow T\) is an initial segment embedding if it is an isomorphism (of linearly ordered sets) from \(S\) to an initial segment of \(T\).

Example 4.7.1.12. Let \((S, \leq)\) be a linearly ordered set. Then the identity morphism 03Q6 \(\mathrm{id}_{S}: S \xrightarrow{\sim} S\) is an initial segment embedding.

Remark 4.7.1.13 (Transitivity). Let \((R, \leq),(S, \leq)\), and \((T, \leq)\) be linearly ordered set Suppose that \(f: R \hookrightarrow S\) and \(g: S \hookrightarrow T\) are initial segment embeddings. Then the composition \((g \circ f): R \hookrightarrow T\) is also an initial segment embedding.

Proposition 4.7.1.14. Let \((S, \leq)\) and \((T, \leq)\) be linearly ordered sets, and let \(f, f^{\prime}: S \hookrightarrow T\) 03Q8 be strictly increasing functions. Suppose that \(S\) is well-ordered and that \(f\) is an initial segment embedding. Then, for each \(s \in S\), we have \(f(s) \leq f^{\prime}(s)\).

Proof. Set \(S_{0}=\left\{s \in S: f^{\prime}(s)<f(s)\right\}\). We wish to show that \(S_{0}\) is empty. Assume otherwise. Since \(S\) is well-ordered, there is a least element \(s \in S_{0}\). Since \(f\) is an initial segment embedding, the inequality \(f^{\prime}(s)<f(s)\) implies that we can write \(f^{\prime}(s)=f(t)\) for some \(t<s\). Then \(t \notin S_{0}\), so we must have \(f(t) \leq f^{\prime}(t)\). It follows that \(f^{\prime}(s) \leq f^{\prime}(t)\), contradicting our assumption that the function \(f^{\prime}\) is strictly increasing.

Corollary 4.7.1.15 (Rigidity). Let \((S, \leq)\) and \((T, \leq)\) be linearly ordered sets, and let 03Q9 \(f, f^{\prime}: S \hookrightarrow T\) be initial segment embeddings. If \(S\) is well-ordered, then \(f=f^{\prime}\).

Corollary 4.7.1.16. Let \((S, \leq)\) and \((T, \leq)\) be well-ordered sets. If there exists an order- 03QA preserving bijection \(f: S \xrightarrow{\sim} T\), then \(f\) is unique.

Corollary 4.7.1.17. Let \((S, \leq)\) and \((T, \leq)\) be well-ordered sets. Then one of the following 03QB conditions is satisfied:
(1) There exists an initial segment embedding \(f: S \hookrightarrow T\).
(2) There exists an initial segment embedding \(g: T \hookrightarrow S\).

Proof. For each element \(s \in S\), let \(S_{\leq s}\) denote the initial segment \(\left\{s^{\prime} \in S: s^{\prime} \leq s\right\}\). Let \(S_{0} \subseteq S\) denote the collection of elements \(s \in S\) for which there exists an initial segment
embedding \(f_{\leq s}: S_{\leq s} \hookrightarrow T\). Note that, if this condition is satisfied, then the morphism \(f_{\leq s}\) is uniquely determined (Corollary 4.7.1.15). Moreover, if \(s^{\prime} \leq s\), then composite map \(S_{\leq s^{\prime}} \subseteq S_{\leq s} \xrightarrow{f_{\leq s}} T\) is also an initial segment embedding; it follows that \(s^{\prime}\) belongs to \(S_{0}\), and \(\left.f\right|_{\leq s^{\prime}}\) is the restriction of \(\left.f\right|_{\leq s}\) to \(S_{\leq s^{\prime}}\). Consequently, the construction \(s \mapsto f_{s}(s)\) determines a function \(f: S_{0} \rightarrow T\), which is an isomorphism of \(S_{0}\) with an initial segment \(T_{0} \subseteq T\). If \(S_{0}=S\), then \(f\) is an initial segment embedding from \(S\) to \(T\). If \(T_{0}=T\), then \(g=f^{-1}\) is an initial segment embedding from \(T\) to \(S\). Assume that neither of these conditions is satisfied: that is, the sets \(S \backslash S_{0}\) and \(T \backslash T_{0}\) are both nonempty. Let \(s\) be a least element of \(S \backslash S_{0}\), and let \(t\) be a least element of \(T \backslash T_{0}\). Then \(f\) extends uniquely to an initial segment embedding
\[
f_{\leq s}: S_{\leq s}=S_{0} \cup\{s\} \xrightarrow{\sim} T_{0} \cup\{t\} \subseteq T \quad s \mapsto t .
\]

The existence of \(f_{\leq s}\) shows that \(s\) belongs to \(S_{0}\), which is a contradiction.
03QC Remark 4.7.1.18. In the situation of Corollary 4.7.1.17, suppose that conditions (1) and (2) are both satisfied: that is, there exist initial segment embeddings \(f: S \hookrightarrow T\) and \(g: T \hookrightarrow S\). Then \(g \circ f\) is an initial segment embedding of \(S\) into itself, and therefore coincides with \(\mathrm{id}_{S}\) (Corollary 4.7.1.16). The same argument shows that \(f \circ g=\mathrm{id}_{T}\), so that \(f\) and \(g\) are mutually inverse bijections. In particular, \(S\) and \(T\) have the same order type.

O3QD Definition 4.7.1.19. Let \(\alpha\) and \(\beta\) be ordinals, given by the order types of well-ordered sets \((S, \leq)\) and \((T, \leq)\). We write \(\alpha \leq \beta\) if there exists an initial segment embedding from \((S, \leq)\) to ( \(T, \leq\) ) (note that this condition depends only on the order types of \(S\) and \(T\) ).

03QE Proposition 4.7.1.20. The relation \(\leq\) of Definition 4.7.1.19 determines a linear ordering on the collection of ordinals.

Proof. The reflexivity of the relation \(\leq\) follows from Example 4.7.1.12, and the transitivity follows from Remark 4.7.1.13, Let \(\alpha\) and \(\beta\) be ordinals, which we identify with the order types of well-ordered sets \((S, \leq)\) and \((T, \leq)\), respectively. Invoking Corollary 4.7.1.17, we deduce that \(\alpha \leq \beta\) or \(\beta \leq \alpha\). Moreover, if both conditions are satisfied, then Remark 4.7.1.18 shows that \(\alpha=\beta\).

03QF Remark 4.7.1.21. Let \((S, \leq)\) and \((T, \leq)\) be well-ordered sets. The following conditions are equivalent:
(1) There exists an initial segment embedding \(f: S \hookrightarrow T\).
(2) There exists a strictly increasing function \(f: S \hookrightarrow T\).

The implication \((1) \Rightarrow(2)\) is immediate from the definitions. To prove the converse, let \(f: S \hookrightarrow T\) be a strictly increasing function, and suppose that there is no initial segment
embedding from \(S\) to \(T\). Invoking Corollary 4.7.1.17, we deduce that there is an initial segment embedding \(g: T \hookrightarrow S\). The composition \((g \circ f): S \hookrightarrow S\) is strictly increasing, and therefore satisfies \((g \circ f)(s) \geq s\) for each \(s \in S\) (Proposition 4.7.1.14). Since the image of \(g\) is an initial segment \(S_{0} \subseteq S\), we must have \(S_{0}=S\). It follows that \(g^{-1}: S \xrightarrow{\sim} T\) is an isomorphism of linearly ordered sets, contradicting our assumption.

We now show that, for every ordinal \(\alpha\), there is a preferred candidate for a well-ordered set of order type \(\alpha\) : namely, the collection \(\operatorname{Ord}_{<\alpha}\) of ordinals smaller than \(\alpha\).

Proposition 4.7.1.22. Let \((S, \leq)\) be a well-ordered set, and let \(\alpha\) denote its order type. Then there is a unique order-preserving bijection \(S \rightarrow \mathrm{Ord}_{<\alpha}\), which carries each element \(s \in S\) to the order type of the well-ordered set \(S_{<s}=\left\{s^{\prime} \in S: s^{\prime}<s\right\}\).

Proof. We will prove existence; uniqueness then follows from Corollary 4.7.1.16. For each \(s \in S\), let \(\alpha_{s}\) denote the order type of the set \(S_{<s}\) (which is well-ordered, by virtue of Remark 4.7.1.5). Note that, since there is an initial segment embedding \(S_{<s} \hookrightarrow S\) which is not bijective, we must have \(\alpha_{s}<\alpha\) (Remark 4.7.1.18). Consequently, the construction \(s \mapsto \alpha_{s}\) determines a function \(S \rightarrow \operatorname{Ord}_{<\alpha}\). If \(s<t\) in \(S\), then there is an initial segment embedding from \(S_{<s}\) to \(S_{<t}\) which is not bijective, so that \(\alpha_{s}<\alpha_{t}\) (again by Remark 4.7.1.18). To complete the proof, it will suffice to show that the function \(s \mapsto \alpha_{s}\) is surjective. Let \(\beta\) be an ordinal which is strictly smaller than \(\alpha\). Then \(\beta\) is the order type of some initial segment \(S_{0} \subsetneq S\). Since \(S\) is well-ordered, the set \(S \backslash S_{0}\) has a smallest element \(s\). It follows that \(S_{0}=S_{<s}\), so that \(\beta=\alpha_{s}\).

Corollary 4.7.1.23. For every ordinal \(\alpha, \mathrm{Ord}_{<\alpha}\) is a well-ordered set of order type \(\alpha\).
Corollary 4.7.1.24. Let \(S\) be any nonempty collection of ordinals. Then \(S\) has a least 03QJ element.

Proof. Choose an ordinal \(\alpha \in S\). If \(\alpha\) is a least element of \(S\), then we are done. Otherwise, we can replace \(S\) by the nonempty subset \(S_{<\alpha}=\{\beta \in S: \beta<\alpha\}\). Note that \(S_{<\alpha}\) is a nonempty subset of \(\mathrm{Ord}_{<\alpha}\), and therefore has a smallest element by virtue of Corollary 4.7.1.23,

Warning 4.7.1.25 (The Burali-Forti Paradox). One can informally summarize Corollary 4.7.1.24 by saying that the collection Ord of all ordinals is well-ordered (with respect to the order relation of Definition 4.7.1.19). Beware that one must treat this statement with some care to avoid paradoxes. The proof of Proposition 4.7.1.22 shows that the order type of Ord is strictly larger than \(\alpha\), for each ordinal \(\alpha \in\) Ord. This paradox has a standard remedy: we regard the collection Ord as "too large" to form a set (so that its order type is not regarded as an ordinal).

03QL Definition 4.7.1.26. Let \((S, \leq)\) and \((T, \leq)\) be linearly ordered sets. We say that a function \(f: S \rightarrow T\) is cofinal if it is nondecreasing and, for every element \(t \in T\), there exists an element \(s \in S\) satisfying \(f(s) \geq t\).

03QM Proposition 4.7.1.27. Let \((T, \leq)\) be a linearly ordered set. There exists a well-ordered subset \(S \subseteq T\) for which the inclusion map \(S \hookrightarrow T\) is cofinal.

Proof. Let \(\left\{S_{q}\right\}_{q \in Q}\) be the collection of all well-ordered subsets of \(T\). We regard \(Q\) as a partially ordered set, where \(q \leq q^{\prime}\) if the set \(S_{q}\) is an initial segment of \(S_{q^{\prime}}\). This partial ordering satisfies the hypotheses of Zorn's lemma, and therefore contains a maximal element \(S_{\max }\). To complete the proof, it will suffice to show that the inclusion \(S_{\max } \hookrightarrow T\) is cofinal. Assume otherwise: then there exists an element \(t \in T\) satisfying \(s<t\) for each \(s \in S_{\max }\). Then \(S_{\max }\) is an initial segment of the well-ordered subset \(S_{\max } \cup\{t\} \subseteq T\), contradicting the maximality of \(S_{\max }\).

03QN Definition 4.7.1.28 (Cofinality). Let \((T, \leq)\) be a linearly ordered set. We let \(\operatorname{cf}(T)\) denote the smallest ordinal \(\alpha\) for which there exists a well-ordered set \((S, \leq)\) of order type \(\alpha\) and a cofinal function \(f: S \rightarrow T\). We refer to \(\operatorname{cf}(T)\) as the cofinality of the linearly ordered set \(T\).

If \(\beta\) is an ordinal, let \(\operatorname{cf}(\beta)\) denote the cofinality \(\operatorname{cf}(T)\), where \((T, \leq)\) is any well-ordered set of order type \(\beta\). We refer to \(\operatorname{cf}(\beta)\) as the cofinality of \(\beta\).

03QP Remark 4.7.1.29. For any linearly ordered set ( \(T, \leq\) ), the identity map id : \(T \rightarrow T\) is cofinal. Consequently, if \(T\) is well-ordered set of order type \(\alpha\), then we have \(\operatorname{cf}(\alpha)=\operatorname{cf}(T) \leq \alpha\). Beware that the inequality is often strict.

03QQ Example 4.7.1.30. Let \((T, \leq)\) be a linearly ordered set. Then \(\operatorname{cf}(T)=0\) if and only if \(T\) is empty.

03QR Example 4.7.1.31. Let \((T, \leq)\) be a nonempty linearly ordered set. The following conditions are equivalent:
- The cofinality \(\operatorname{cf}(T)\) is a positive integer.
- The cofinality \(\operatorname{cf}(T)\) is equal to 1 .
- The linearly ordered set \(T\) contains a largest element.

03QS Example 4.7.1.32. Let \((T, \leq)\) be a linearly ordered set. Then the cofinality \(\operatorname{cf}(T)\) is equal to \(\omega\) if and only if \(T\) contains an unbounded increasing sequence \(\left\{t_{0}<t_{1}<t_{2}<\cdots\right\}\).

03QT Proposition 4.7.1.33. Let \((T, \leq)\) be a linearly ordered set. Then the cofinality \(\operatorname{cf}(T)\) is the smallest ordinal \(\alpha\) with the following property:
(*) There exists a well-ordered set ( \(S, \leq\) ) of order type \(\alpha\) and a function \(f: S \rightarrow T\) which is unbounded (that is, every element \(t \in T\) satisfies \(t \leq f(s)\) for some \(s \in S\) ). Here we do not require \(f\) to be nondecreasing.

Proof. It is clear that the cofinality \(\operatorname{cf}(T)\) satisfies condition (*). For the converse, assume that \((S, \leq)\) is a well-ordered set of order type \(\alpha\) and that \(f: S \rightarrow T\) is an unbounded function. Let us say that an element \(s \in S\) is good if, for every element \(s^{\prime}<s\) of \(S\), we have \(f\left(s^{\prime}\right)<f(s)\). Let \(S_{0}\) be the collection of good elements of \(S\), and set \(f_{0}=\left.f\right|_{S_{0}}\). By construction, the function \(f_{0}\) is strictly increasing. Moreover, the order type of \(S_{0}\) is \(\leq \alpha\) (Remark 4.7.1.21). To complete the proof, it will suffice to show that \(f_{0}: S_{0} \hookrightarrow T\) is cofinal. Fix an element \(t \in T\), and set \(S_{\geq t}=\{s \in S: t \leq f(s)\}\). We wish to show that the intersection \(S_{\geq t} \cap S_{0}\) is nonempty. We first observe that \(S_{\geq t}\) is nonempty (by virtue of our assumption that \(f\) is unbounded). Since ( \(S, \leq\) ) is well-ordered, the set \(S_{\geq t}\) contains a least element \(s\). We claim that \(s\) belongs to \(S_{0}\). Assume otherwise: then there exists some \(s^{\prime}<s\) satisfying \(f\left(s^{\prime}\right) \geq f(s)\). It follows that \(s^{\prime}\) belongs to \(S_{\geq t}\), contradicting the minimality of \(s\).

We conclude this section by observing that well-orderings exist in abundance.
Theorem 4.7.1.34 (The Well-Ordering Theorem). Every set \(S\) admits a well-ordering.
By virtue of Example 4.7.1.4, Theorem 4.7.1.34 is a special case of the following more refined result:

Proposition 4.7.1.35. Let \((S, \preceq)\) be a well-founded partially ordered set. Then there exists 03QV a well-ordering \(\leq\) on \(S\) which refines \(\preceq\) in the following sense: for every pair of elements \(s, t \in S\) satisfying \(s \preceq t\), we also have \(s \leq t\).

Proof. Let \(Q\) denote the set of ordered pairs \(\left(T, \leq_{T}\right)\), where \(T\) is a subset of \(S\) which is closed downward with respect to \(\preceq\) and \(\leq_{T}\) is a well-ordering of \(T\) which refines \(\preceq\). We regard \(Q\) as a partially ordered set, where \(\left(T, \leq_{T}\right) \leq\left(T^{\prime}, \leq_{T^{\prime}}\right)\) if \(T\) is an initial segment of \(T^{\prime}\) (with respect to the ordering \(\leq_{T^{\prime}}\) ), and the ordering \(\leq_{T}\) coincides with the restriction of \(\leq_{T^{\prime}}\). The partially ordered set \(Q\) satisfies the hypotheses of Zorn's lemma, and therefore contains a maximal element \(\left(T_{\max }, \leq_{T_{\max }}\right)\). To complete the proof, it will suffice to show that \(T_{\max }=S\). Suppose otherwise. Then the set \(S \backslash T_{\max }\) is nonempty, and therefore contains an element \(s\) which is minimal with respect to the ordering \(\preceq\). Set \(T^{\prime}=T_{\max } \cup\{s\}\), and extend \(\leq_{T_{\max }}\) to a linear ordering \(\leq_{T^{\prime}}\) of \(T^{\prime}\) by declaring \(s\) to be a largest element. Then \(\left(T^{\prime}, \leq_{T^{\prime}}\right)\) is an element of \(Q\), contradicting the maximality of the pair \(\left(T_{\max }, \leq_{T_{\max }}\right)\).

\subsection*{4.7.2 Cardinals and Cardinality}

Let \(S\) and \(T\) be sets. We say that \(S\) and \(T\) have the same cardinality if there exists a bijection \(S \xrightarrow{\sim} T\). This is an equivalence relation on the collection of sets, whose equivalence classes are called cardinals. Following a standard convention in set theory, it will be convenient to view a cardinal as a special type of ordinal.

03QX Definition 4.7.2.1. Let \(S\) be a set. We let \(|S|\) denote the smallest ordinal \(\alpha\) for which there exists a well-ordering of \(S\) having order type \(\alpha\). We will refer to \(|S|\) as the cardinality of the set \(S\). A cardinal is an ordinal \(\kappa\) which has the form \(|S|\), for some set \(S\).

03QY Remark 4.7.2.2. Let \(S\) be a set, and let \(A\) be the collection of all ordinals which arise as the order types of well-orderings on \(S\). The collection \(A\) is nonempty (Theorem 4.7.1.34), and therefore contains a smallest element (Corollary 4.7.1.24). It follows that the cardinality \(|S|\) is well-defined.

03QZ Proposition 4.7.2.3. Let \(S\) and \(T\) be sets. Then \(|S| \leq|T|\) if and only if there exists a monomorphism \(f: S \hookrightarrow T\).

Proof. Choose well-orderings \(\left(S, \leq_{S}\right)\) and \(\left(T, \leq_{T}\right)\) having order types \(|S|\) and \(|T|\), respectively. If \(|S| \leq|T|\), then there is an isomorphism of \(\left(S, \leq_{S}\right)\) with an initial segment of \(\left(T, \leq_{T}\right)\); this isomorphism in particular gives a monomorphism of sets \(S \hookrightarrow T\). For the converse, suppose that there exists a monomorphism \(f: S \hookrightarrow T\). Then there is a unique linear ordering \(\leq_{S}^{\prime}\) on the set \(S\) for which \(f\) defines a strictly increasing function \(\left(S, \leq_{S}^{\prime}\right) \rightarrow\left(T, \leq_{T}\right)\). Then \(\leq_{S}^{\prime}\) is a well-ordering (Remark 4.7.1.5); let \(\alpha\) denote its order type. We then have \(|S| \leq \alpha \leq|T|\), where the second inequality follows from Remark 4.7.1.21.

03R0 Corollary 4.7.2.4. Let \(S\) and \(T\) be sets. Then \(S\) and \(T\) have the same cardinality if and only if there exists a bijection \(S \xrightarrow{\sim} T\).

Proof. Choose well-orderings \(\left(S, \leq_{S}\right)\) and \(\left(T, \leq_{T}\right)\) having order types \(|S|\) and \(|T|\), respectively. If \(|S|=|T|\), then there is an isomorphism of linearly ordered sets \(\left(S, \leq_{S}\right) \simeq\left(T, \leq_{T}\right)\), and therefore a bijection \(S \xrightarrow{\sim} T\). The converse follows from Proposition 4.7.2.3.

03R1 Corollary 4.7.2.5. Let \((S, \leq)\) be a well-ordered set of order type \(\alpha\). Then the cardinality \(\kappa=|S|\) is the largest cardinal which satisfies \(\kappa \leq \alpha\).

Proof. The inequality \(\kappa \leq \alpha\) follows immediately from the definition of \(|S|\). Let \(\lambda\) be another cardinal satisfying \(\lambda \leq \alpha\). Then \(\lambda\) is the order type of an initial segment \(S_{0} \subseteq S\), so we have \(\lambda=\left|S_{0}\right| \leq|S|=\kappa\).

03R2 Remark 4.7.2.6. Let \(\kappa\) be an ordinal. The following conditions are equivalent:
(1) The ordinal \(\kappa\) is a cardinal. That is, there exists a set \(S\) such that \(\kappa=|S|\).
(2) For every well-ordered set \((S, \leq)\) of order type \(\kappa\), we have \(\kappa=|S|\).
(3) The set of ordinals \(\operatorname{Ord}_{<\kappa}\) has cardinality \(\kappa\).

See Corollary 4.7.1.23

Example 4.7.2.7 (Finite Cardinals). Let \(n\) be a nonnegative integer. Then a set \(S\) has
03R3 cardinality \(n\) (in the sense of Definition 4.7.2.1) if and only if it has exactly \(n\) elements: that is, there exists a bijection \(S \simeq\{0<1<\cdots<n-1\}\). In particular, \(n\) is a cardinal. We will say that a cardinal \(\kappa\) is finite if it arises in this way (that is, if it is the cardinality of a finite set); otherwise, we say that \(\kappa\) is infinite.

Proposition 4.7.2.8 (Cantor's Diagonal Argument). Let \(S\) be a set, and let \(P(S)\) denote 03R4 the collection of all subsets of \(S\). Then \(|S|<|P(S)|\).

Proof. The construction \(s \mapsto\{s\}\) determines an injection from \(S\) to \(P(S)\), which shows that \(|S| \leq|P(S)|\). To show that the inequality is strict, it suffices to observe that no function \(f: S \rightarrow P(S)\) can be surjective, since the set \(T=\{s \in S: s \notin f(s)\}\) is an element of \(P(S)\) which does not belong to the image of \(f\).

Remark 4.7.2.9. The collection of cardinals is well-ordered. That is, if \(S\) is any nonempty collection of cardinals, then \(S\) contains a smallest element (see Corollary 4.7.1.24).

Example 4.7.2.10 (The First Infinite Cardinal). We let \(\aleph_{0}\) denote the smallest infinite cardinal. Alternatively, \(\aleph_{0}\) can be defined as the ordinal \(\omega\) of Example 4.7.1.10 (the order type of the linearly ordered set \(\{0<1<2<\cdots\}\) ). A set \(S\) has cardinality \(\aleph_{0}\) if and only if it is countably infinite.

Example 4.7.2.11 (Successor Cardinals). Let \(\kappa\) be a cardinal. Proposition 4.7.2.8 implies that there exists another cardinal \(\lambda\) such that \(\kappa<\lambda\). By virtue of Remark 4.7.2.9, there is a smallest cardinal with this property. We denote this cardinal by \(\kappa^{+}\)and refer to it as the successor of \(\kappa\).
Example 4.7.2.12 (The First Uncountable Cardinal). We say that a cardinal \(\kappa\) is uncountable if it is strictly larger than \(\aleph_{0}\). By virtue of Remark 4.7.2.9, there is a smallest uncountable cardinal, which we denote by \(\aleph_{1}\). In other words, \(\aleph_{1}\) is the successor cardinal \(\aleph_{0}^{+}\).
Remark 4.7.2.13 (The Continuum Hypothesis). Let \(\mathbf{R}\) be the set of real numbers. Then 03R5 \(03 R 6\)  03R7 03R8 \(|\mathbf{R}|\) is an uncountable cardinal (it is also the cardinality of the power set \(P(\mathbf{Z})\) ). The continuum hypothesis is the assertion that \(|\mathbf{R}|\) coincides with the smallest uncountable cardinal \(\aleph_{1}\). This was a central question in the early days of set theory (and first of Hilbert's celebrated list of problems for the mathematics of the 20th century). It is now known to be neither provable nor disprovable from the axioms of Zermelo-Fraenkel set theory (assuming that they are consistent), thanks to the work of Gödel ([26]) and Cohen ([9], [10]).
4.7. SIZE CONDITIONS ON \(\infty\)-CATEGORIES

03RA Proposition 4.7.2.14. Let \((T, \leq)\) be a linearly ordered set and let \(\kappa=\operatorname{cf}(T)\) be its cofinality (Definition 4.7.1.28). Then \(\kappa\) is a cardinal.

Proof. Choose a well-ordered set ( \(S, \leq\) ) of order type \(\kappa\) and a cofinal function \(f: S \rightarrow T\). If \(\kappa\) is not a cardinal, then we can choose another well-ordering \(\leq^{\prime}\) of \(S\) having order type \(\alpha<\kappa\). Applying Proposition 4.7.1.33, we obtain \(\operatorname{cf}(T) \leq \alpha<\kappa\), which is a contradiction.

\subsection*{4.7.3 Small Sets}

03RB We now introduce some terminology which will be useful for measuring the sizes of various mathematical objects.

03RC Definition 4.7.3.1. Let \(\kappa\) be a cardinal. We say that a set \(S\) is \(\kappa\)-small if the cardinality \(|S|\) is strictly smaller than \(\kappa\).
03RD Example 4.7.3.2. Let \(\aleph_{0}\) denote the first infinite cardinal (Example 4.7.2.10. Then a set \(S\) is \(\aleph_{0}\)-small if and only if it is finite.

03RE Example 4.7.3.3. Let \(\aleph_{1}\) denote the first uncountable cardinal (Example 4.7.2.12. Then a set \(S\) is \(\aleph_{1}\)-small if and only if it is countable.
03RF Remark 4.7.3.4. Let \(\kappa\) be a cardinal and let \(T\) be a \(\kappa\)-small set. Then:
- Any subset of \(T\) is also \(\kappa\)-small (see Proposition 4.7.2.3).
- The set \(T\) is \(\lambda\)-small for every cardinal \(\lambda \geq \kappa\).
- For every surjective morphism of sets \(T \rightarrow S\), the set \(S\) is also \(\kappa\)-small.

03RG Proposition 4.7.3.5. Let \(\kappa\) be an infinite cardinal. Then the collection of \(\kappa\)-small sets is closed under finite products.

Proof. We first note that the collection of finite sets is closed under finite products. It will therefore suffice to show that, for every infinite cardinal \(\lambda\), the following condition is satisfied:
\(\left(*_{\lambda}\right)\) If \(S\) and \(T\) are sets of cardinality \(\leq \lambda\), then the product \(S \times T\) has cardinality \(\leq \lambda\).
By virtue of Remark 4.7.2.9, we may assume that condition \(\left(*_{\mu}\right)\) is satisfied for every cardinal \(\mu<\lambda\). Without loss of generality, we may assume that \(S=\operatorname{Ord}_{<\lambda}=T\), where \(\operatorname{Ord}_{<\lambda}\) denotes the collection of ordinals smaller than \(\lambda\). Given a pair of elements \((\alpha, \beta),\left(\alpha^{\prime}, \beta^{\prime}\right) \in S \times T\), let us write \(\left(\alpha^{\prime}, \beta^{\prime}\right) \preceq(\alpha, \beta)\) if either \(\max \left(\alpha^{\prime}, \beta^{\prime}\right)<\max (\alpha, \beta)\), or \(\max \left(\alpha^{\prime}, \beta^{\prime}\right)=\max (\alpha, \beta)\) and \(\alpha^{\prime}<\alpha\), or \(\max \left(\alpha^{\prime}, \beta^{\prime}\right)=\max (\alpha, \beta)\) and \(\alpha^{\prime}=\alpha\) and \(\beta^{\prime} \leq \beta\). The relation \(\preceq\) defines a well-ordering of the set \(S \times T\). To prove \(\left(*_{\lambda}\right)\), it will suffice to show this well ordering has order type \(\leq \lambda\). Assume otherwise. Then there exists an element \((\alpha, \beta) \in S \times T\) such that \(\lambda\) is the order type of the initial segment \(K=\left\{\left(\alpha^{\prime}, \beta^{\prime}\right) \in S \times T:\left(\alpha^{\prime}, \beta^{\prime}\right) \prec(\alpha, \beta)\right\}\). Note that \(K\) is a subset of the product \(\operatorname{Ord}_{\leq \gamma}\) and \(\operatorname{Ord}_{\leq \gamma}\), where \(\gamma=\max (\alpha, \beta)\). Our inductive hypothesis guarantees that \(K\) has cardinality \(<\lambda\), contradicting Corollary 4.7.2.5.

Corollary 4.7.3.6. Let \(\kappa\) be an infinite cardinal. Then the collection of \(\kappa\)-small sets is 03RH closed under finite coproducts.

Proof. Let \(\left\{S_{i}\right\}_{i \in I}\) be a finite collection of \(\kappa\)-small sets. Then the disjoint union \(\coprod_{i \in I} S_{i}\) can be identified with a subset of the product \(\prod_{i \in I}\left(S_{i} \amalg\{i\}\right)\), which is \(\kappa\)-small by virtue of Proposition 4.7.3.5.

We will need the following generalization of Corollary 4.7.3.6.
Proposition 4.7.3.7. Let \(\kappa\) and \(\lambda\) be cardinals, where \(\lambda\) is infinite. The following conditions 03RJ are equivalent:
(1) The cardinal \(\kappa\) is strictly smaller than the cofinality \(\operatorname{cf}(\lambda)\) (see Definition 4.7.1.28).
(2) Let \(\left\{T_{s}\right\}_{s \in S}\) be a collection of \(\lambda\)-small sets indexed by a set \(S\) of cardinality \(\leq \kappa\). Then the coproduct \(\coprod_{s \in S} T_{s}\) is \(\lambda\)-small.

Proof. Assume first that condition (1) is satisfied. Let \(\left\{T_{s}\right\}_{s \in S}\) be a collection of \(\lambda\)-small sets indexed by a set \(S\) of cardinality \(\leq \kappa\); we wish to show that the coproduct \(T=\coprod_{s \in S} T_{s}\) is \(\lambda\)-small. Using Theorem 4.7.1.34, we can choose a well-ordering \(\leq_{S}\) on the set \(S\), and a well-ordering \(\leq_{s}\) on the set \(T_{s}\) for each \(s \in S\). For elements \(t \in T_{s}\) and \(t^{\prime} \in T_{s^{\prime}}\), write \(t \leq_{T} t^{\prime}\) if either \(s<_{S} s^{\prime}\), or \(s=s^{\prime}\) and \(t \leq_{s} t^{\prime}\). Then \(\leq_{T}\) is a well-ordering of the set \(T\). If \(T\) is not \(\lambda\)-small, then it has an initial segment of order type \(\lambda\). Passing to subsets, we may assume without loss of generality that \(T\) itself has order type \(\lambda\). Moreover, we may assume without loss of generality that each of the sets \(T_{s}\) is nonempty, and therefore contains a smallest element \(t_{s}\). We consider two cases:
- Suppose that \(S\) contains a largest element \(s\). In this case, we can write \(T\) as the disjoint union of the initial segment \(T^{\prime}=\coprod_{s^{\prime}<s} T_{s^{\prime}}\) with the set \(T_{s}\). Since \(T_{s}\) is nonempty, \(T^{\prime}\) has order type smaller than \(\lambda\), and is therefore \(\lambda\)-small. Applying Corollary 4.7.3.6, we deduce that \(T=T^{\prime} \coprod T_{s}\) is also \(\lambda\)-small.
- Suppose that \(S\) does not have a largest element. In this case, the construction \((s \in S) \mapsto\left(t_{s} \in T\right)\) is a cofinal function from \(S\) to \(T\). It follows that the order type of \(\left(S, \leq_{S}\right)\) is greater than or equal to the cofinality \(\operatorname{cf}(T)=\operatorname{cf}(\lambda)\), contradicting assumption (1).

We now prove the reverse implication. Assume that condition (2) is satisfied. Choose a well-ordering \(\left(S, \leq_{S}\right)\) of order type \(\operatorname{cf}(\lambda)\) and a cofinal map \(f: S \rightarrow \operatorname{Ord}_{<\lambda}\). If \(\kappa \geq \operatorname{cf}(\lambda)\), then condition (2) implies that the disjoint union \(\coprod_{s \in S} \operatorname{Ord}_{<f(s)}\) is \(\lambda\)-small. Since \(f\) is cofinal, the tautological map \(\coprod_{s \in S} \operatorname{Ord}_{<f(s)} \rightarrow \operatorname{Ord}_{<\lambda}\) is surjective. It follows that \(\operatorname{Ord}_{<\lambda}\) is \(\lambda\)-small, which is a contradiction.

03RK Corollary 4.7.3.8. Let \(\lambda\) be an infinite cardinal. Then \(\kappa=\operatorname{cf}(\lambda)\) is the smallest cardinal for which there exists a set \(S\) of cardinality \(\kappa\) and a collection of \(\lambda\)-small sets \(\left\{T_{s}\right\}_{s \in S}\), where the coproduct \(\amalg_{s \in S} T_{s}\) is not \(\lambda\)-small.

Proof. Proposition 4.7.2.14 guarantees that \(\kappa\) is a cardinal. The characterization is a restatement of Proposition 4.7.3.7.

03RL Corollary 4.7.3.9. Let \(\lambda\) be an infinite cardinal and let \(\kappa=\operatorname{cf}(\lambda)\) be its cofinality. Suppose we are given a collection of \(\lambda\)-small sets \(\left\{T_{s}\right\}_{s \in S}\). If the index set \(S\) is \(\kappa\)-small, then coproduct \(\amalg_{s \in S} T_{s}\) is \(\lambda\)-small.

03RM Definition 4.7.3.10 (Regular Cardinals). Let \(\kappa\) be a cardinal. We say that \(\kappa\) is regular if it is infinite and \(\operatorname{cf}(\kappa)=\kappa\). Here \(\operatorname{cf}(\kappa)\) denotes the cofinality of \(\kappa\) (Definition 4.7.1.28). We say that \(\kappa\) is singular if it is infinite but not regular.

03RN Remark 4.7.3.11. Let \(\kappa\) be an infinite cardinal. Then \(\kappa\) is regular if and only if the collection of \(\kappa\)-small sets is closed under \(\kappa\)-small coproducts (this is a special case of Corollary 4.7.3.8).

03RP Example 4.7.3.12. Let \(\aleph_{0}\) denote the first infinite cardinal (Example 4.7.2.10. Then \(\aleph_{0}\) is regular: that is, the collection of finite sets is closed under finite coproducts.

03RQ Example 4.7.3.13 (Successor Cardinals). Let \(\kappa\) be an infinite cardinal and let \(\kappa^{+}\)be its successor (Example 4.7.2.11). Then a set \(S\) is \(\kappa^{+}\)-small if and only if it has cardinality \(\leq \kappa\). It follows that \(\kappa^{+}\)is a regular cardinal. That is, if \(\left\{T_{s}\right\}_{s \in S}\) is a collection of sets of cardinality \(\leq \kappa\) indexed by a set \(S\) of cardinality \(\leq \kappa\), then the disjoint union \(\amalg_{s \in S} T_{s}\) also has cardinality \(\leq \kappa\). To prove this, choose a collection of monomorphisms \(\left\{i_{s}: T_{s} \hookrightarrow T\right\}_{s \in S}\), where \(T\) is a set of cardinality \(\kappa\). We then obtain a monomorphism
\[
\coprod_{s \in S} T_{s} \hookrightarrow S \times T \quad\left(x \in T_{s}\right) \mapsto\left(s, i_{s}(x)\right)
\]
where the set \(S \times T\) has cardinality \(\leq \kappa\) by virtue of Proposition 4.7.3.5.
03RR Example 4.7.3.14. Let \(\aleph_{1}\) denote the first uncountable cardinal (Example 4.7.2.12). Then \(\aleph_{1}\) is regular: that is, the collection of countable sets is closed under the formation of countable disjoint unions. This is a special case of Example 4.7.3.13, since \(\aleph_{1}=\aleph_{0}^{+}\).

03RS Example 4.7.3.15. Let \((T, \leq)\) be a nonempty linearly ordered set with no largest element. Then the cofinality \(\kappa=\operatorname{cf}(T)\) is a regular cardinal. To see this, choose a well-ordered set ( \(S, \leq\) ) of order type \(\kappa\) and a cofinal function \(f: S \rightarrow T\). Proposition 4.7.2.14 guarantees that \(\kappa\) is a cardinal, and Example 4.7.1.31 shows that \(\kappa\) is infinite. If it is not regular, then there exists a cofinal map \(g: R \rightarrow S\), where ( \(R, \leq\) ) is a well-ordered set of order type \(\alpha<\kappa\). This contradicts the definition of \(\kappa=\operatorname{cf}(T)\), since the composite map \((f \circ g): R \rightarrow T\) is cofinal.

It will be convenient to introduce the following bit of nonstandard terminology:
Definition 4.7.3.16. Let \(\lambda\) be an infinite cardinal. We let \(\operatorname{ecf}(\lambda)\) denote the least cardinal 03RT \(\kappa\) with the following property: there exists a set \(S\) of cardinality \(\kappa\) and a collection of \(\lambda\)-small sets \(\left\{T_{s}\right\}_{s \in S}\) for which the product \(\prod_{s \in S} T_{s}\) is not \(\lambda\)-small. We will refer to \(\operatorname{ecf}(\lambda)\) as the exponential cofinality of \(\lambda\).
Remark 4.7.3.17. Let \(\lambda\) be an infinite cardinal. Then the exponential cofinality \(\operatorname{ecf}(\lambda)\) satisfies \(\aleph_{0} \leq \operatorname{ecf}(\lambda) \leq \operatorname{cf}(\lambda)\). In particular, we have \(\operatorname{ecf}(\lambda) \leq \lambda\). The inequality \(\aleph_{0} \leq \operatorname{ecf}(\lambda)\) is a reformulation of the fact that the collection of \(\lambda\)-small sets is closed under finite products (Proposition 4.7.3.5). To prove the other inequality, choose a set \(S\) of cardinality \(\operatorname{cf}(\lambda)\) and a collection of \(\lambda\)-small sets \(\left\{T_{s}\right\}_{s \in S}\) for which the coproduct \(T=\coprod_{s \in S} T_{s}\) is not \(\lambda\)-small. We now observe that \(T\) can be identified with a subset of the product \(\prod_{s \in S}\left(T_{s} \amalg\{s\}\right)\). Since each of the sets \(T_{s} \amalg\{s\}\) is also \(\lambda\)-small, we obtain \(\operatorname{ecf}(\lambda) \leq \operatorname{cf}(\lambda)\).
Remark 4.7.3.18. Let \(\kappa\) and \(\lambda\) be infinite cardinals. Then \(\kappa \leq \operatorname{ecf}(\lambda)\) if and only if the 03RV following condition is satisfied: for every collection of \(\lambda\)-small sets \(\left\{T_{s}\right\}_{s \in S}\) indexed by a \(\kappa\)-small set \(S\), the product \(\prod_{s \in S} T_{s}\) is also \(\lambda\)-small.
Remark 4.7.3.19. Let \(\kappa\) be an infinite cardinal. Then there are arbitrarily large regular 03UQ cardinals \(\lambda\) satisfying \(\operatorname{ecf}(\lambda)>\kappa\). To see this, it will suffice (by enlarging \(\kappa\) ) to show that there exists some regular cardinal \(\lambda\) of exponential cofinality \(\geq \kappa\). Let \(S\) be a set of cardinality \(\kappa\) and let \(2^{\kappa}\) denote the cardinality of the power set \(P(S)=\left\{S_{0}: S_{0} \subseteq S\right\}\). Proposition 4.7.3.5 implies that the product \(S \times S\) also has cardinality \(\kappa\), so that \(P(S \times S) \simeq \prod_{s \in S} P(S)\) also has cardinality \(2^{\kappa}\). It follows that the collection of sets of cardinality \(\leq 2^{\kappa}\) is closed under the formation of products indexed by sets of cardinality \(\leq \kappa\), so that \(\lambda=\left(2^{\kappa}\right)^{+}\)has exponential cofinality \(>\kappa\).
Definition 4.7.3.20. Let \(\kappa\) be an infinite cardinal. We say that \(\kappa\) is strongly inaccessible 03RW if \(\kappa=\operatorname{ecf}(\kappa)\). In other words, \(\kappa\) is strongly inaccessible if the collection of \(\kappa\)-small sets is closed under the formation of \(\kappa\)-small products.

Example 4.7.3.21. Let \(\aleph_{0}\) be the least infinite cardinal. Then \(\aleph_{0}\) is strongly inaccessible. 03 RX That is, the collection of finite sets is closed under finite products.
Remark 4.7.3.22. Let \(\kappa\) be a strongly inaccessible cardinal. Then \(\kappa\) is regular: this follows 03RY immediately from the inequality \(\operatorname{ecf}(\kappa) \leq \operatorname{cf}(\kappa)\) of Remark 4.7.3.17.
Warning 4.7.3.23. The existence of uncountable strongly inaccessible cardinals cannot 03RZ be proven from the axioms of Zermelo-Fraenkel set theory (assuming those axioms are consistent).
Proposition 4.7.3.24. Let \(\lambda\) be an infinite cardinal and let \(\kappa=\operatorname{ecf}(\lambda)\) be the exponential 03S0 cofinality of \(\lambda\). Then \(\kappa\) is a regular cardinal.

Proof. Suppose that \(\kappa\) is not regular: that is, there is a collection of \(\kappa\)-small sets \(\left\{T_{s}\right\}_{s \in S}\) indexed by a \(\kappa\)-small set \(S\) such that \(T=\coprod_{s \in S} T_{s}\) has cardinality \(\geq \kappa\). Choose a collection of \(\lambda\)-small sets \(\left\{U_{t}\right\}_{t \in T}\) for which the product \(U=\prod_{t \in T} U_{t}\) is not \(\lambda\)-small. For each \(s \in S\), let \(U_{s}\) denote the product \(\prod_{t \in T_{s}} U_{t}\). Since \(T_{s}\) is \(\operatorname{ecf}(\lambda)\)-small, the set \(U_{s}\) is \(\lambda\)-small. Since \(S\) is also \(\operatorname{ecf}(\lambda)\)-small, it follows that \(U \simeq \prod_{s \in S} U_{s}\) is also \(\lambda\)-small, which is a contradiction.

\subsection*{4.7.4 Small Simplicial Sets}

03S1 Definition 4.7.3.1 has a counterpart in the setting of simplicial sets.
03S2 Definition 4.7.4.1. Let \(\kappa\) be an infinite cardinal. We say that a simplicial set \(S\) is \(\kappa\)-small if the collection of nondegenerate simplices of \(S\) is \(\kappa\)-small.

03S3 Remark 4.7.4.2. In the situation of Definition 4.7.4.1 the dimension of the simplices under consideration is not fixed. That is, a simplicial set \(S_{\bullet}\) is \(\kappa\)-small if and only if the disjoint union \(\coprod_{m \geq 0} S_{m}^{\text {nd }}\) is a \(\kappa\)-small set, where \(S_{m}^{\text {nd }} \subseteq S_{m}\) denotes the set of nondegenerate \(m\)-simplices of \(S_{\bullet}\).

03S4 Remark 4.7.4.3. Let \(\kappa\) be an infinite cardinal. Then a simplicial set \(S\) is \(\kappa\)-small if and only if the opposite simplicial set \(S^{\mathrm{op}}\) is \(\kappa\)-small.

03 S5 Example 4.7.4.4. A simplicial set \(S\) is \(\aleph_{0}\)-small (in the sense of Definition 4.7.4.1) if and only if it is finite (Definition 3.6.1.1).

03S6 Remark 4.7.4.5 (Coproducts). Let \(\kappa\) be an infinite cardinal and let \(\left\{S_{i}\right\}_{i \in I}\) be a collection of \(\kappa\)-small simplicial sets. Suppose that the cardinality of the index set \(I\) is smaller than the cofinality \(\operatorname{cf}(\kappa)\). Then the coproduct \(\coprod_{i \in I} S_{i}\) is also \(\kappa\)-small (see Corollary 4.7.3.9). In particular:
- The collection of \(\kappa\)-small simplicial sets is closed under finite coproducts.
- If \(\kappa\) is regular, then the collection of \(\kappa\)-small simplicial sets is closed under \(\kappa\)-small coproducts.

03S7 Remark 4.7.4.6 (Colimits). Let \(\kappa\) be an infinite cardinal and let \(\left\{S_{i}\right\}_{i \in \mathcal{I}}\) be a diagram of simplicial sets indexed by a category \(\mathcal{I}\). Suppose that the set of objects \(\operatorname{Ob}(\mathcal{I})\) has cardinality smaller than the cofinality of \(\kappa\). Then the colimit \(\lim _{i \in \mathcal{I}} S_{i}\) is also \(\kappa\)-small (since it can be realized as a quotient of the coproduct \(\amalg S_{i}\), which is \(\kappa\)-small by virtue of Remark 4.7.4.5).

03S8 Remark 4.7.4.7. Let \(S\) be a simplicial set. Then there is a least infinite cardinal \(\kappa\) for which \(S\) is \(\kappa\)-small. If \(S\) is finite, then \(\kappa=\aleph_{0}\). If \(S\) is not finite, then \(\kappa=\lambda^{+}\), where \(\lambda\) is the cardinality of the set of all nondegenerate simplices of \(S\). In particular, \(\kappa\) is always a regular cardinal.

Remark 4.7.4.8. Let \(\kappa\) be an infinite cardinal and let \(T\) be a \(\kappa\)-small simplicial set. Then: 03S9
- Every simplicial subset of \(T\) is \(\kappa\)-small.
- The simplicial set \(T\) is \(\lambda\)-small for each \(\lambda \geq \kappa\).
- For every epimorphism of simplicial sets \(T \rightarrow S\), the simplicial set \(S\) is also \(\kappa\)-small.

See Remark 4.7.3.4
Proposition 4.7.4.9. Let \(\kappa\) be an infinite cardinal and \(S_{\bullet}\) be a simplicial set. Assume that the cofinality of \(\kappa\) is larger than \(\aleph_{0}\) (this condition is satisfied, for example, if \(\kappa\) is uncountable and regular). The following conditions are equivalent:
(1) The simplicial set \(S_{\bullet}\) is \(\kappa\)-small.
(2) For every integer \(n \geq 0\), the set \(S_{n}\) is \(\kappa\)-small.
(3) For every finite simplicial set \(K\), the set \(\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(K, S_{\bullet}\right)\) is \(\kappa\)-small.

Proof. We first show that (1) implies (2). Assume that \(S_{\bullet}\) is \(\kappa\)-small and let \(n \geq 0\) be an integer. For each integer \(m \geq 0\), let \(S_{m}^{\text {nd }}\) denote the set of nondegenerate \(m\)-simplices of \(S_{\bullet}\). Using Proposition 1.1 .3 .8 , we can identify \(S_{n}\) with the coproduct \(\coprod_{\alpha:[n] \rightarrow[m]} S_{m}^{\text {nd }}\), where \(\alpha\) ranges over all surjective maps of linearly ordered sets \([n] \rightarrow[m]\). Our assumption that \(S_{\bullet}\) is \(\kappa\)-small guarantees that each of the sets \(S_{m}^{\text {nd }}\) is \(\kappa\)-small, so that \(S_{n}\) is also \(\kappa\)-small (Corollary 4.7.3.6).

We now show that (2) implies (1). Assume that, for each \(n \geq 0\), the set \(S_{n}\) is \(\kappa\)-small. Since \(\kappa\) has cofinality \(>\aleph_{0}\) it follows that the coproduct \(\coprod_{n \geq 0} S_{n}\) is also \(\kappa\)-small. In particular, the coproduct \(\coprod_{n \geq 0} S_{n}^{\text {nd }}\) is \(\kappa\)-small: that is, the simplicial set \(S_{\bullet}\) is \(\kappa\)-small.

The implication \((3) \Rightarrow(2)\) is immediate from the definition. We will complete the proof by showing that \((2) \Rightarrow(3)\). Assume that, for each \(n \geq 0\), the set \(S_{n}\) is \(\kappa\)-small, and let \(K\) be a finite simplicial set. By virtue of Proposition 3.6.1.7, there exists an epimorphism \(f: K^{\prime} \rightarrow K\), where \(K^{\prime}=\coprod_{i \in I} \Delta^{n_{i}}\) is a disjoint union of finitely many standard simplices. Then precomposition with \(f\) induces a monomorphism
\[
\operatorname{Hom}_{\text {Set }_{\Delta}}\left(K, S_{\bullet}\right) \hookrightarrow \operatorname{Hom}_{\text {Set }_{\Delta}}\left(K^{\prime}, S_{\bullet}\right) \simeq \prod_{i \in I} S_{n_{i}}
\]

Since the collection of \(\kappa\)-small sets is closed under finite products and passage to subsets (Proposition 4.7.3.5 and Remark 4.7.3.4), it follows that the set \(\operatorname{Hom}_{\text {Set }_{\Delta}}\left(K, S_{\bullet}\right)\) is also \(\kappa\)-small.

Warning 4.7.4.10. The implications \((1) \Rightarrow(2) \Leftrightarrow(3)\) of Proposition 4.7.4.9 are valid for an arbitrary infinite cardinal \(\kappa\). However, the implication \((2) \Rightarrow(1)\) is false if \(\kappa\) has countable cofinality (for example, if \(\kappa=\aleph_{0}\) ).

03SC Corollary 4.7.4.11. Let \(\kappa\) be an infinite cardinal. Then the collection of \(\kappa\)-small simplicial sets is closed under finite products.

Proof. Let \(\left\{S_{i}\right\}_{i \in I}\) be a collection of \(\kappa\)-small simplicial sets indexed by a finite set \(I\); we wish to show that the product \(S=\prod_{i \in I} S_{i}\) is \(\kappa\)-small. Without loss of generality, we may assume that \(\kappa\) is the least infinite cardinal for which each of the simplicial sets \(S_{i}\) is \(\kappa\)-small. Then \(\kappa\) is regular (Remark 4.7.4.7). If \(\kappa=\aleph_{0}\), then the desired result follows from Remark 3.6.1.6. We may therefore assume that \(\kappa\) is uncountable. In this case, the desired result follows from the criterion of Proposition 4.7.4.9, since the collection of \(\kappa\)-small sets is closed under finite products (Proposition 4.7.3.5).

03SD Corollary 4.7.4.12. Let \(\kappa\) be an uncountable cardinal, let \(S\) be a \(\kappa\)-small simplicial set, and let \(K\) be a finite simplicial set. Then the simplicial set \(\operatorname{Fun}(K, S)\) is \(\kappa\)-small.

Proof. Without loss of generality, we may assume that \(\kappa\) is the least uncountable cardinal for which \(S\) is \(\kappa\)-small. In particular, \(\kappa\) is regular (Remark 4.7.4.7). By virtue of Proposition 4.7.4.9, it will suffice to show that for every finite simplicial set \(L\), the set \(\operatorname{Hom}_{\text {Set }_{\Delta}}(L, \operatorname{Fun}(K, S)) \simeq \operatorname{Hom}_{\text {Set }_{\Delta}}(K \times L, S)\) is \(\kappa\)-small. This is a special case of Proposition 4.7.4.9, since the simplicial set \(K \times L\) is finite (Remark 3.6.1.6).

03SE Warning 4.7.4.13. The assertion of Corollary 4.7.4.12 is false in the case \(\kappa=\aleph_{0}\). That is, if \(K\) and \(S\) are finite simplicial sets, then the simplicial set \(\operatorname{Fun}(K, S)\) need not be finite.

We close by recording stronger forms of Corollaries 4.7.4.11 abnd 4.7.4.12.
03SF Corollary 4.7.4.14. Let \(\lambda\) be an infinite cardinal and let \(\kappa=\operatorname{ecf}(\lambda)\) be its exponential cofinality (Definition 4.7.3.16). Then the collection of \(\lambda\)-small simplicial sets is closed under \(\kappa\)-small products.

Proof. Let \(\left\{S_{i}\right\}_{i \in I}\) be a collection of \(\lambda\)-small simplicial sets indexed by a \(\kappa\)-small set \(I\); we wish to show that the product \(S=\prod_{i \in I} S_{i}\) is \(\lambda\)-small. If \(\kappa=\aleph_{0}\), this follows from Corollary 4.7.4.11. We may therefore assume that \(\kappa\) is uncountable. Then the cofinality \(\operatorname{cf}(\lambda)\) is also uncountable (Remark 4.7.3.17). The desired result now follows from the criterion of Proposition 4.7.4.9. since the collection of \(\lambda\)-small sets is closed under \(\kappa\)-small products.

03SG Corollary 4.7.4.15. Let \(\lambda\) be an uncountable cardinal and let \(\kappa=\operatorname{ecf}(\lambda)\) be its exponential cofinality. If \(S\) is a \(\lambda\)-small simplicial set and \(K\) be a \(\kappa\)-small simplicial set. Then \(\operatorname{Fun}(K, S)\) is \(\lambda\)-small.

Proof. Since \(K\) is \(\kappa\)-small, we can choose an epimorphism of simplicial sets \(\coprod_{i \in I} \Delta^{n_{i}} \rightarrow K\), where \(I\) is a \(\kappa\)-small set. It follows that \(\operatorname{Fun}(K, S)\) can be identified with a simplicial subset of the product \(\prod_{i \in I} \operatorname{Fun}\left(\Delta^{n_{i}}, S\right)\). Corollary 4.7.4.12 guarantees that each factor \(\operatorname{Fun}\left(\Delta^{n_{i}}, S\right)\) is \(\lambda\)-small, so that the product \(\prod_{i \in I} \operatorname{Fun}\left(\Delta^{n_{i}}, S\right)\) is \(\lambda\)-small by virtue of Corollary 4.7.4.14.

\subsection*{4.7.5 Essential Smallness}

Let \(\kappa\) be an infinite cardinal. Beware that the condition that a simplicial set is \(\kappa\)-small is not invariant under categorical equivalence. For this reason, it is useful to consider the following variant of Definition 4.7.4.1.

Definition 4.7.5.1. Let \(\kappa\) be an uncountable cardinal. We will say that a simplicial set \(\mathcal{C}\) is essentially \(\kappa\)-small if there exists a categorical equivalence of simplicial sets \(\mathcal{C} \rightarrow \mathcal{D}\), where \(\mathcal{D}\) is a \(\kappa\)-small \(\infty\)-category.
Remark 4.7.5.2. Let \(\kappa\) be an uncountable cardinal, and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a categorical equivalence of simplicial sets. Then \(\mathcal{C}\) is essentially \(\kappa\)-small if and only if \(\mathcal{D}\) is essentially \(\kappa\)-small.
Remark 4.7.5.3. Let \(\kappa\) be an uncountable cardinal. Then a simplicial set \(\mathcal{C}\) is essentially \(\kappa\)-small if and only if the opposite simplicial set \(\mathcal{C}^{\text {op }}\) is essentially \(\kappa\)-small. See Remark 4.7.4.3

Variant 4.7.5.4. Let \(\mathcal{C}\) be a simplicial set. We say that \(\mathcal{C}\) is essentially small if there exists 03SM a categorical equivalence \(\mathcal{C} \rightarrow \mathcal{D}\), where \(\mathcal{D}\) is a small \(\infty\)-category.
Proposition 4.7.5.5. Let \(\kappa\) be an uncountable cardinal and let \(\mathcal{C}\) be a \(\kappa\)-small simplicial set. 03SN Then there exists an inner anodyne morphism \(\mathcal{C} \hookrightarrow \mathcal{D}\), where \(\mathcal{D}\) is a \(\kappa\)-small \(\infty\)-category. In particular, \(\mathcal{C}\) is essentially \(\kappa\)-small.
Proof. Without loss of generality, we may assume that \(\kappa\) is the least uncountable cardinal for which \(\mathcal{C}\) is \(\kappa\)-small, so that \(\kappa\) is regular (Remark 4.7.4.7). We proceed as in the proof of Proposition 4.1.3.2. We will construct \(\mathcal{D}\) as the colimit of a diagram of inner anodyne morphisms
\[
\mathcal{C}=\mathcal{C}(0) \hookrightarrow \mathcal{C}(1) \hookrightarrow \mathcal{C}(2) \hookrightarrow \mathcal{C}(3) \hookrightarrow \cdots
\]
where each transition map fits into a pushout diagram

here the coproducts are indexed by the collection \(\left\{u_{s}: \Lambda_{i_{s}}^{n_{s}} \rightarrow \mathcal{C}(n)\right\}_{s \in S(n)}\) of all inner horns in the simplicial set \(\mathcal{C}(n)\). Note that if the simplicial set \(\mathcal{C}(n)\) is \(\kappa\)-small, then the set \(S(n)\) is also \(\kappa\)-small (Proposition 4.7.4.9), so that \(\mathcal{C}(n+1\) ) is also \(\kappa\)-small. Since \(\kappa\) is regular and uncountable, it follows that the colimit \(\mathcal{C}=\underset{\longrightarrow}{\lim } \mathcal{C}(n)\) is \(\kappa\)-small (Remark 4.7.4.6.

03SP Warning 4.7.5.6. The statement of Proposition 4.7.5.5 is false in the case \(\kappa=\aleph_{0}\). If \(S\) is a finite simplicial set, we generally cannot choose a categorical equivalence \(f: S \rightarrow \mathcal{D}\), where \(\mathcal{D}\) is an \(\infty\)-category which is also a finite simplicial set. For example, take \(S=\Delta^{2} / \partial \Delta^{2}\), so that the geometric realization \(|S|\) is homeomorphic to a sphere of dimension 2. Since every edge of \(S\) is degenerate, the homotopy category \(\mathrm{h} S\) is a groupoid. Consequently, if \(f\) is a categorical equivalence from \(S\) to an \(\infty\)-category \(\mathcal{D}\), then \(\mathcal{D}\) is a Kan complex (Proposition 4.4.2.1), which is homotopy equivalent to the singular simplicial set Sing. \((|S|)\) (Theorem 3.6.4.1. It follows that \(\pi_{2}(\mathcal{D})\) is an infinite cyclic group (generated by the homotopy class \([f]\) ), so that the Kan complex \(\mathcal{D}\) must contain infinitely many 2 -simplices.

03SQ Remark 4.7.5.7 (Coproducts). Let \(\kappa\) be an uncountable cardinal and let \(\left\{\mathcal{C}_{i}\right\}_{i \in I}\) be a collection of essentially \(\kappa\)-small simplicial sets. Suppose that the cardinality of the index set \(I\) is smaller than the cofinality \(\operatorname{cf}(\kappa)\). Then the coproduct \(\coprod_{i \in I} \mathcal{C}_{i}\) is also essentially \(\kappa\)-small. This follows by combining Remark 4.7.4.5 with Corollary 4.5.3.10. In particular:
- The collection of essentially \(\kappa\)-small simplicial sets is closed under finite coproducts.
- If \(\kappa\) is regular, then the collection of essentially \(\kappa\)-small simplicial sets is closed under \(\kappa\)-small coproducts.

03SR Remark 4.7.5.8 (Products). Let \(\kappa\) be an uncountable cardinal and let \(\left\{\mathcal{C}_{i}\right\}_{i \in I}\) be a finite collection of simplicial sets which are essentially \(\kappa\)-small. Then the product \(\prod_{i \in I} \mathcal{C}_{i}\) is essentially \(\kappa\)-small. This follows by combining Corollary 4.7.4.14, since the collection of categorical equivalences is stable under the formation of finite products (Remark 4.5.3.7).

03SS Variant 4.7.5.9. Let \(\kappa\) be an uncountable cardinal and let \(\left\{\mathcal{C}_{i}\right\}_{i \in I}\) be a collection of essentially \(\kappa\)-small \(\infty\)-categories. Suppose that the cardinality of the index set \(I\) has smaller than the exponential cofinality \(\operatorname{ecf}(\kappa)\). Then the product \(\prod_{i \in I} \mathcal{C}_{i}\) is also essentially \(\kappa\)-small. This follows by combining Corollary 4.7.4.14 with Remark 4.5.1.17.

03ST Remark 4.7.5.10. Let \(\lambda\) be an uncountable cardinal, let \(\mathcal{C}\) be an \(\infty\)-category which is essentially \(\lambda\)-small, and let \(K\) be a simplicial set. Suppose that \(K\) is \(\kappa\)-small, where \(\kappa=\operatorname{ecf}(\lambda)\) is the exponential cofinality of \(\lambda\). Then the \(\infty\)-category \(\operatorname{Fun}(K, \mathcal{C})\) is essentially \(\lambda\)-small. To prove this, we can use Remark 4.5 .1 .16 to reduce to the case where \(\mathcal{C}\) is \(\lambda\)-small, in which case it follows from Corollary 4.7.4.12. Moreover, if \(\kappa\) is uncountable, then it suffices to assume that \(K\) is essentially \(\kappa\)-small.

03SU Proposition 4.7.5.11. Let \(\kappa\) be an uncountable cardinal and let \(\mathcal{C}\) be an \(\infty\)-category which is essentially \(\kappa\)-small. Then any replete subcategory \(\mathcal{C}_{0} \subseteq \mathcal{C}\) is also essentially \(\kappa\)-small.

Proof. Choose an equivalence of \(\infty\)-categories \(F: \mathcal{D} \rightarrow \mathcal{C}\), where \(\mathcal{D}\) is \(\kappa\)-small. Then the inverse image \(\mathcal{D}_{0}=F^{-1}\left(\mathcal{C}_{0}\right)\) is \(\kappa\)-small (Remark 4.7.4.8), and the functor \(F\) restricts to an equivalence of \(\infty\)-categories \(\mathcal{D}_{0} \rightarrow \mathcal{C}_{0}\) (Corollary 4.5.2.29).

Corollary 4.7.5.12. Let \(\kappa\) be an uncountable cardinal and let \(\mathcal{C}\) be an \(\infty\)-category which is 03SV essentially \(\kappa\)-small. Then the core \(\mathcal{C}^{\simeq}\) is an essentially \(\kappa\)-small Kan complex.

Proof. Since \(\mathcal{C}^{\simeq}\) is a replete subcategory of \(\mathcal{C}\) (Proposition 4.4.3.6), this is a special case of Proposition 4.7.5.11.

Corollary 4.7.5.13. Let \(\kappa\) be an uncountable cardinal and let \(\mathcal{C}\) be an \(\infty\)-category which is 03SW essentially \(\kappa\)-small. Then any full subcategory \(\mathcal{C}_{0} \subseteq \mathcal{C}\) is essentially \(\kappa\)-small.

Proof. Let \(\mathcal{C}_{1} \subseteq \mathcal{C}\) be the full subcategory spanned by those objects \(X \in \mathcal{C}\) which are isomorphic to an object of \(\mathcal{C}_{0}\). Proposition 4.7.5.11 guarantees that \(\mathcal{C}_{1}\) is essentially \(\kappa\)-small. Since the inclusion \(\mathcal{C}_{0} \hookrightarrow \mathcal{C}_{1}\) is an equivalence of \(\infty\)-categories, it follows that \(\mathcal{C}_{0}\) is also essentially \(\kappa\)-small (Remark 4.7.5.2).

Proposition 4.7.5.14. Let \(F_{0}: \mathcal{C}_{0} \rightarrow \mathcal{C}\) and \(F_{1}: \mathcal{C}_{1} \rightarrow \mathcal{C}\) be functors of \(\infty\)-categories and 03SX let \(\kappa\) be an uncountable cardinal. If \(\mathcal{C}_{0}, \mathcal{C}_{1}\), and \(\mathcal{C}\) are essentially \(\kappa\)-small, then the oriented fiber product \(\mathcal{C}_{0} \tilde{\times}_{\mathcal{C}} \mathcal{C}_{1}\) is also essentially \(\kappa\)-small.

Proof. Choose equivalences of \(\infty\)-categories
\[
\mathcal{D}_{0} \rightarrow \mathcal{C}_{0} \quad \mathcal{C} \rightarrow \mathcal{D} \quad \mathcal{D}_{1} \rightarrow \mathcal{C}_{1}
\]
where \(\mathcal{D}_{0}, \mathcal{D}_{1}\), and \(\mathcal{D}\) are \(\kappa\)-small. By virtue of Remark 4.6.4.4 the induced maps
\[
\mathcal{C}_{0} \tilde{\times}_{\mathcal{C}} \mathcal{C}_{1} \leftarrow \mathcal{D}_{0} \tilde{\times}_{\mathcal{C}} \mathcal{D}_{1} \rightarrow \mathcal{D}_{0} \tilde{\times}_{\mathcal{D}} \mathcal{D}_{1}
\]
are equivalences of \(\infty\)-categories. It will therefore suffice to show that the \(\infty\)-category \(\mathcal{D}_{0} \tilde{\times}_{\mathcal{D}} \mathcal{D}_{1}\) is \(\kappa\)-small. This follows from Corollaries 4.7.4.12 and 4.7.4.11, since \(\mathcal{D}_{0} \tilde{\times}_{\mathcal{D}} \mathcal{D}_{1}\) can be identified with a simplicial subset of the product \(\mathcal{D}_{0} \times \operatorname{Fun}\left(\Delta^{1}, \mathcal{D}\right) \times \mathcal{D}_{1}\).

Corollary 4.7.5.15. Let \(F_{0}: \mathcal{C}_{0} \rightarrow \mathcal{C}\) and \(F_{1}: \mathcal{C}_{1} \rightarrow \mathcal{C}\) be functors of \(\infty\)-categories and let 03SY \(\kappa\) be an uncountable cardinal. If \(\mathcal{C}_{0}, \mathcal{C}_{1}\), and \(\mathcal{C}\) are essentially \(\kappa\)-small, then the homotopy fiber product \(\mathcal{C}_{0} \times{ }_{\mathcal{C}}^{\mathrm{h}} \mathcal{C}_{1}\) is essentially \(\kappa\)-small.

Proof. Since \(\mathcal{C}_{0} \times{ }_{\mathcal{C}}^{\mathrm{h}} \mathcal{C}_{1}\) is a full subcategory of the oriented fiber product \(\mathcal{C}_{0} \tilde{\times}_{\mathcal{C}} \mathcal{C}_{1}\), this follows from Proposition 4.7.5.14 and Corollary 4.7.5.13.

Corollary 4.7.5.16. Let \(\kappa\) be an uncountable cardinal and suppose we are given a categorical 03SZ pullback diagram of \(\infty\)-categories

If \(\mathcal{C}_{0}, \mathcal{C}\), and \(\mathcal{C}_{1}\) are essentially \(\kappa\)-small, then \(\mathcal{C}_{01}\) is essentially \(\kappa\)-small.
Proof. Combine Remark 4.7.5.2 with Corollary 4.7.5.15.
04J8 Corollary 4.7.5.17. Let \(\lambda\) be an uncountable cardinal, let \(\mathcal{C}\) be an \(\infty\)-category which is essentially \(\lambda\)-small, and let \(K\) be a simplicial set. Suppose that \(K\) is \(\kappa\)-small, where \(\kappa=\operatorname{ecf}(\lambda)\) is the exponential cofinality of \(\lambda\). Then, for any diagram \(f: K \rightarrow \mathcal{C}\), the \(\infty\)-categories \(\mathcal{C}_{f /}\) and \(\mathcal{C}_{/ f}\) are essentially \(\lambda\)-small. Moreover, if \(\kappa\) is uncountable, then it suffices to assume that \(K\) is essentially \(\kappa\)-small.

Proof. We will show that the \(\infty\)-category \(\mathcal{C}_{/ f}\) is essentially \(\lambda\)-small; the corresponding assertion for \(\mathcal{C}_{f /}\) follows by a similar argument. Theorem 4.6.4.17 supplies an equivalence of \(\infty\)-categories \(\mathcal{C}_{/ f} \hookrightarrow \mathcal{C} \tilde{\times}_{\text {Fun }(K, \mathcal{C})}\{f\}\). By virtue of Proposition 4.7.5.14 it will suffice to show that \(\operatorname{Fun}(K, \mathcal{C})\) is essentially \(\lambda\)-small, which follows from Remark 4.7.5.10.

04J9 Example 4.7.5.18. Let \(\lambda\) be an uncountable cardinal and let \(\mathcal{C}\) be an \(\infty\)-category which is essentially \(\lambda\)-small. Then, for every object \(X \in \mathcal{C}\), the \(\infty\)-categories \(\mathcal{C}_{/ X}\) and \(\mathcal{C}_{X /}\) are essentially \(\lambda\)-small.

\subsection*{4.7.6 Minimal \(\infty\)-Categories}
\(03 T 1\) Let \(\kappa\) be an uncountable cardinal. An \(\infty\)-category \(\mathcal{D}\) is essentially \(\kappa\)-small if and only if there exists an equivalence \(\mathcal{C} \rightarrow \mathcal{D}\), where \(\mathcal{C}\) is a \(\kappa\)-small \(\infty\)-category. Our goal in this section is to show that, if this condition is satisfied, then there is a preferred choice for the \(\infty\)-category \(\mathcal{C}\) which is characterized (up to noncanonical isomorphism) by the requirement that it is minimal. We will need some terminology.

0575 Definition 4.7.6.1. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(B\) be a simplicial set, and let \(A \subseteq B\) be a simplicial subset. Suppose we are given a pair of diagrams \(f_{0}, f_{1}: B \rightarrow \mathcal{C}\). An isomorphism of \(f_{0}\) with \(f_{1}\) relative to \(A\) is an isomorphism \(u: f_{0} \rightarrow f_{1}\) in the \(\infty\)-category \(\operatorname{Fun}(B, \mathcal{C})\) for which the image of \(u\) in \(\operatorname{Fun}(A, \mathcal{C})\) is an identity morphism. We say that \(f_{0}\) is isomorphic to \(f_{1}\) relative to \(A\) if there exists an isomorphism of \(f_{0}\) with \(f_{1}\) relative to \(A\).

0576 Remark 4.7.6.2. In the situation of Definition 4.7.6.1, two diagrams \(f_{0}, f_{1}: B \rightarrow \mathcal{C}\) are isomorphic relative to \(A\) if and only if they satisfy the following pair of conditions:
- The diagrams \(f_{0}\) and \(f_{1}\) have the same restriction to \(A\) : that is, we have \(\left.f_{0}\right|_{A}=\bar{f}=\left.f_{1}\right|_{A}\) for some diagram \(\bar{f}: A \rightarrow \mathcal{C}\).
- The diagrams \(f_{0}\) and \(f_{1}\) are isomorphic when viewed as objects of the \(\infty\)-category \(\operatorname{Fun}(B, \mathcal{C}) \times_{\operatorname{Fun}(A, \mathcal{C})}\{\bar{f}\}\).

Remark 4.7.6.3. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(f_{0}, f_{1}: B \rightarrow \mathcal{C}\) be a pair of diagrams, and
0577 let \(A \subseteq B\) be a simplicial subset. If \(f_{0}\) and \(f_{1}\) are isomorphic relative to \(A\) (in the sense of Definition 4.7.6.1, then they are homotopic relative to \(A\) (in the sense of Definition 3.2.1.1). The converse holds if the restriction functor \(\operatorname{Fun}(B, \mathcal{C}) \rightarrow \operatorname{Fun}(A, \mathcal{C})\) is conservative. In particular, the converse holds if \(\mathcal{C}\) is a Kan complex, or if \(A\) contains every vertex of \(B\).

Definition 4.7.6.4. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n \geq 0\) be an integer. We say that \(\mathcal{C}\) is 03T2 minimal in dimension \(n\) if it satisfies the following condition:
\(\left(*_{n}\right)\) Let \(\sigma_{0}, \sigma_{1}: \Delta^{n} \rightarrow \mathcal{C}\) be \(n\)-simplices of \(\mathcal{C}\). If \(\sigma_{0}\) is isomorphic to \(\sigma_{1}\) relative to \(\partial \Delta^{n}\), then \(\sigma_{0}=\sigma_{1}\).

We say that \(\mathcal{C}\) is minimal if it is minimal in dimension \(n\) for every integer \(n\).
Example 4.7.6.5. Let \(\mathcal{C}\) be an \(\infty\)-category. Then \(\mathcal{C}\) is minimal in dimension 0 if and only 03T3 if, for every pair of isomorphic objects \(X, Y \in \mathcal{C}\), we have \(X=Y\).

Example 4.7.6.6. Let \(\mathcal{C}\) be an \(\infty\)-category. Then \(\mathcal{C}\) is minimal in dimension 1 if and only 03T4 if, for every pair of objects \(X, Y \in \mathcal{C}\) and every pair of morphisms \(f, g: X \rightarrow Y\) which are homotopic, we have \(f=g\) (see Corollary 1.4.3.7).
Exercise 4.7.6.7. Let \(\mathcal{C}\) be a category. Show that the nerve \(\mathrm{N}_{\bullet}(\mathcal{C})\) is minimal in dimension \(n 03 \mathrm{~T} 5\) for every integer \(n>0\) (see Proposition 4.8.3.1 for a more general statement). Consequently, the \(\infty\)-category \(\mathrm{N}_{\bullet}(\mathcal{C})\) is minimal if and only if, for every pair of isomorphic objects \(X, Y \in \mathcal{C}\), we have \(X=Y\).

Remark 4.7.6.8. Let \(\mathcal{C}\) be a minimal \(\infty\)-category, and let \(\mathcal{C}_{0} \subseteq \mathcal{C}\) be a simplicial subset. If \(03 T 6\) \(\mathcal{C}_{0}\) is an \(\infty\)-category, then it is also minimal.

Remark 4.7.6.9. Let \(\left\{\mathcal{C}_{i}\right\}_{i \in I}\) be a collection of minimal \(\infty\)-categories. Then the product 0377 \(\prod_{i \in I} \mathcal{C}_{i}\) and the coproduct \(\coprod_{i \in I} \mathcal{C}_{i}\) are also minimal \(\infty\)-categories.

Warning 4.7.6.10. The collection of minimal \(\infty\)-categories has poor closure properties:
- If \(\mathcal{C}\) is a minimal \(\infty\)-category and \(K\) is a simplicial set, then the \(\infty\)-category \(\operatorname{Fun}(K, \mathcal{C})\) need not be minimal (even in the case \(K=\Delta^{1}\) ).
- If \(\mathcal{C}\) is a minimal \(\infty\)-category and \(q: K \rightarrow \mathcal{C}\) is a diagram, then the \(\infty\)-categories \(\mathcal{C}_{/ q}\) and \(\mathcal{C}_{q /}\) need not be minimal (even in the case \(K=\Delta^{0}\) ).
- If \(\mathcal{C}\) is a minimal \(\infty\)-category and \(\mathcal{D}\) is equivalent to \(\mathcal{C}\), then \(\mathcal{D}\) need not be minimal.

The goal of this section is to show that every \(\infty\)-category \(\mathcal{D}\) admits a minimal model: that is, a minimal \(\infty\)-category \(\mathcal{C}\) equipped with an equivalence \(F: \mathcal{C} \rightarrow \mathcal{D}\). Moreover, the \(\infty\)-category \(\mathcal{C}\) is uniquely determined up to isomorphism (Corollary 4.7.6.16). Our first step is to show that, in this case, the functor \(F\) is automatically a monomorphism.

03T9 Lemma 4.7.6.11. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an equivalence of \(\infty\)-categories. If \(\mathcal{C}\) is minimal, then \(F\) is a monomorphism of simplicial sets.

Proof. Let \(\sigma, \sigma^{\prime}: \Delta^{n} \rightarrow \mathcal{C}\) be \(n\)-simplices of \(\mathcal{C}\) satisfying \(F(\sigma)=F\left(\sigma^{\prime}\right)\); we wish to show that \(\sigma=\sigma^{\prime}\). Our proof proceeds by induction on \(n\). Set \(\tau=F(\sigma)=F\left(\sigma^{\prime}\right)\) and \(\sigma_{0}=\left.\sigma\right|_{\partial \Delta^{n}}\), so that our inductive hypothesis guarantees that \(\sigma_{0}=\left.\sigma^{\prime}\right|_{\partial \Delta^{n}}\).

Fix a functor \(G: \mathcal{D} \rightarrow \mathcal{C}\) which is homotopy inverse to \(F\), so that there exists a 2 -simplex

in the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{C})\), where \(\alpha\) and \(\beta\) are (mutually inverse) isomorphisms. Precomposing with the morphism \(\sigma_{0}: \partial \Delta^{n} \rightarrow \mathcal{C}\), we obtain a 2 -simplex

in the \(\infty\)-category \(\operatorname{Fun}\left(\partial \Delta^{n}, \mathcal{C}\right)\). Since \(\mathcal{C}\) is an \(\infty\)-category, Theorem 1.5.6.1 guarantees that we can lift 4.46 to a 2 -simplex

in the \(\infty\)-category \(\operatorname{Fun}\left(\Delta^{n}, \mathcal{C}\right)\). By construction, \(\gamma\) is an isomorphism relative to \(\partial \Delta^{n}\). Invoking our assumption that \(\mathcal{C}\) is minimal, we deduce that \(\sigma=\sigma^{\prime}\).

03TB Corollary 4.7.6.12. Let \(\mathcal{C}\) be a minimal \(\infty\)-category and let \(\kappa\) be an uncountable cardinal. Then \(\mathcal{C}\) is essentially \(\kappa\)-small if and only if it is \(\kappa\)-small.

Proof. Suppose that \(\mathcal{C}\) is essentially \(\kappa\)-small. Then there exists an equivalence of \(\infty\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\), where \(\mathcal{D}\) is \(\kappa\)-small. Since \(\mathcal{C}\) is minimal, the functor \(F\) is a monomorphism of simplicial sets (Lemma 4.7.6.11), so that \(\mathcal{C}\) is also \(\kappa\)-small (Remark 4.7.4.8).

Proposition 4.7.6.13 (Uniqueness). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an equivalence of \(\infty\)-categories. If 03TC \(\mathcal{C}\) and \(\mathcal{D}\) are minimal, then \(F\) is an isomorphism of simplicial sets.

Proof. Let \(G: \mathcal{D} \rightarrow \mathcal{C}\) be a homotopy inverse to \(F\). It follows from Lemma 4.7.6.11 that \(F\) and \(G\) are monomorphisms of simplicial sets. We will complete the proof by showing that the composite map \((F \circ G): \mathcal{D} \rightarrow \mathcal{D}\) is an epimorphism of simplicial sets (so that, in particular, \(F\) is an epimorphism). Let \(\sigma\) be an \(n\)-simplex of \(\mathcal{D}\); we wish to show that \(\sigma\) belongs to the image of \(F \circ G\). The proof proceeds by induction on \(n\). Set \(\sigma_{0}=\left.\sigma\right|_{\partial \Delta^{n}}\); our inductive hypothesis then guarantees that we can write \(\sigma_{0}=(F \circ G)\left(\tau_{0}\right)\) for some morphism \(\tau_{0}: \partial \Delta^{n} \rightarrow \mathcal{D}\).

Choose a 2 -simplex

in the \(\infty\)-category \(\operatorname{Fun}(\mathcal{D}, \mathcal{D})\), where \(\alpha\) and \(\beta\) are isomorphisms. Precomposing with \(\tau_{0}\) : \(\partial \Delta^{n} \rightarrow \mathcal{D}\), we obtain a 2 -simplex

03TD
in the \(\infty\)-category \(\operatorname{Fun}\left(\partial \Delta^{n}, \mathcal{D}\right)\). Using Corollary 4.4.5.9, we can lift \(\alpha\left(\tau_{0}\right)\) to an isomorphism \(\widetilde{\alpha}: \sigma \rightarrow \tau\) in the \(\infty\)-category \(\operatorname{Fun}\left(\Delta^{n}, \mathcal{D}\right)\). Since \(\mathcal{D}\) is an \(\infty\)-category, Theorem 1.5.6.1 guarantees that we can lift 4.47) to a 2 -simplex

in the \(\infty\)-category \(\operatorname{Fun}\left(\Delta^{n}, \mathcal{D}\right)\). By construction, \(\gamma\) is an isomorphism relative to \(\partial \Delta^{n}\). Our assumption that \(\mathcal{D}\) is minimal then guarantees that \(\sigma=(F \circ G)(\tau)\) belongs to the image of \(F \circ G\).

03TE Corollary 4.7.6.14. Let \(\mathcal{C}\) and \(\mathcal{D}\) be minimal \(\infty\)-categories. Then \(\mathcal{C}\) and \(\mathcal{D}\) are equivalent if and only if they are isomorphic.

We now prove the existence of minimal models.
03TF Proposition 4.7.6.15 (Existence). Let \(\mathcal{D}\) be an \(\infty\)-category. Then there exists an equivalence of \(\infty\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\), where \(\mathcal{C}\) is minimal.
\(03 T \mathrm{C}\) Corollary 4.7 .6 .16 . The construction
\(\{\) Minimal \(\infty\)-Categories \(\} /\) Isomorphism \(\rightarrow\{\infty\)-Categories \(\} /\) Equivalence is a bijection.

Proof. Injectivity is a restatement of Corollary 4.7.6.14, and surjectivity follows from Proposition 4.7.6.15.

03TH Corollary 4.7.6.17. Let \(\mathcal{C}\) be a simplicial set. Then there is a least uncountable cardinal \(\kappa\) for which \(\mathcal{C}\) is essentially \(\kappa\)-small. Moreover, \(\kappa\) is always a successor cardinal.

Proof. By virtue of Proposition 4.7.6.15, we may assume that \(\mathcal{C}\) is a minimal \(\infty\)-category. In this case, the desired result follows by combining Corollary 4.7.6.12 with Remark 4.7.4.7.

Proof of Proposition 4.7.6.15. Let \(\mathcal{D}\) be an \(\infty\)-category. If \(\sigma\) and \(\sigma^{\prime}\) are \(n\)-simplices of \(\mathcal{D}\), we write \(\sigma \sim \sigma^{\prime}\) if they are isomorphic relative to \(\partial \Delta^{n}\). Note that, if this condition is satisfied, then we must have \(\left.\sigma\right|_{\partial \Delta^{n}}=\left.\sigma^{\prime}\right|_{\partial \Delta^{n}}\). In particular, if \(\sigma\) and \(\sigma^{\prime}\) are both degenerate, we must have \(\sigma=\sigma^{\prime}\). Let \(R(n)\) denote a collection of \(n\)-simplices of \(\mathcal{D}\) which contains all degenerate \(n\)-simplices, and contains exactly one element of every \(\sim\)-class. We let \(\mathcal{C} \subseteq \mathcal{D}\) denote the simplicial subset consisting of all simplices \(\tau: \Delta^{m} \rightarrow \mathcal{D}\) having the property that, for every morphism of linearly ordered sets \(\alpha:[n] \rightarrow[m]\), the \(n\)-simplex \(\Delta^{n} \rightarrow \Delta^{m} \xrightarrow{\tau} \mathcal{D}\) belongs to \(R(n)\) (by construction, it suffices to check this in the case where \(\alpha\) is injective). To complete the proof, it will suffice to establish the following:
(1) The simplicial set \(\mathcal{C}\) is an \(\infty\)-category.
(2) The \(\infty\)-category \(\mathcal{C}\) is minimal.
(3) The inclusion map \(\mathcal{C} \hookrightarrow \mathcal{D}\) is an equivalence of \(\infty\)-categories.

We begin by proving (1). Suppose we are given integers \(0<i<n\) and a morphism of simplicial sets \(\sigma_{0}: \Lambda_{i}^{n} \rightarrow \mathcal{C}\); we wish to show that \(\sigma_{0}\) can be extended to an \(n\)-simplex \(\sigma\) of \(\mathcal{C}\). Since \(\mathcal{D}\) is an \(\infty\)-category, we can extend \(\sigma_{0}\) to an \(n\)-simplex \(\sigma^{\prime \prime}: \Delta^{n} \rightarrow \mathcal{D}\). Let \(\bar{\sigma}^{\prime \prime}=d_{i}^{n}\left(\sigma^{\prime \prime}\right)\) denote the \(i\) th face of \(\sigma^{\prime \prime}\). Then there is a unique element \(\bar{\sigma}^{\prime} \in R(n-1)\) satisfying \(\bar{\sigma}^{\prime} \sim \bar{\sigma}^{\prime \prime}\). Choose an isomorphism \(\bar{\alpha}: \bar{\sigma}^{\prime} \rightarrow \bar{\sigma}^{\prime \prime}\) in the \(\infty\)-category \(\operatorname{Fun}\left(\Delta^{n-1}, \mathcal{D}\right)\)
whose image in \(\operatorname{Fun}\left(\partial \Delta^{n-1}, \mathcal{D}\right)\) is an identity morphism. Then \(\bar{\alpha}\) can be lifted uniquely to an isomorphism \(\widetilde{\alpha}:\left.\widetilde{\sigma}^{\prime} \rightarrow \sigma^{\prime \prime}\right|_{\partial \Delta^{n}}\) relative to the horn \(\Lambda_{i}^{n}\). Applying Proposition 4.4.5.8, we can lift \(\widetilde{\alpha}\) to an isomorphism \(\alpha: \sigma^{\prime} \rightarrow \sigma^{\prime \prime}\) in the \(\infty\)-category \(\operatorname{Fun}\left(\Delta^{n}, \mathcal{D}\right)\). By construction, the restriction \(\left.\sigma^{\prime}\right|_{\partial \Delta^{n}}\) factors through \(\mathcal{C}\). Let \(\sigma\) be the unique \(n\)-simplex of \(\mathcal{D}\) which belongs to \(R(n)\) and satisfies \(\sigma \sim \sigma^{\prime}\). Then \(\sigma\) is an \(n\)-simplex of \(\mathcal{C}\) satisfying \(\left.\sigma\right|_{\Lambda_{i}^{n}}=\left.\sigma^{\prime}\right|_{\Lambda_{i}^{n}}=\left.\sigma^{\prime \prime}\right|_{\Lambda_{i}^{n}}=\sigma_{0}\). This completes the proof of (1).

We now prove (2). Let \(\sigma\) and \(\sigma^{\prime}\) be \(n\)-simplices of \(\mathcal{C}\) which are isomorphic relative to \(\partial \Delta^{n}\). Then, when regarded as \(n\)-simplices of \(\mathcal{D}\), we have \(\sigma \sim \sigma^{\prime}\). Since \(\sigma\) and \(\sigma^{\prime}\) both belong to \(R(n)\), we conclude that \(\sigma=\sigma^{\prime}\).

To prove (3), we will show that \(\mathcal{C}\) is a deformation retract of \(\mathcal{D}\); that is, there exists a functor \(H: \Delta^{1} \times \mathcal{D} \rightarrow \mathcal{D}\) satisfying the following conditions:
(i) The restriction \(\left.H\right|_{\{0\} \times \mathcal{D}}\) is the identity functor \(\operatorname{id}_{\mathcal{D}}\).
(ii) The restriction \(\left.H\right|_{\{1\} \times \mathcal{D}}\) factors through \(\mathcal{C}\).
(iii) The restriction \(\left.H\right|_{\Delta^{1} \times \mathcal{C}}\) coincides with the projection map
\[
\Delta^{1} \times \mathcal{C} \rightarrow \mathcal{C} \subseteq \mathcal{D}
\]
(iv) For each object \(D \in \mathcal{D}\), the restriction \(\left.H\right|_{\Delta^{1} \times\{D\}}\) is an isomorphism in \(\mathcal{D}\).

Note that these conditions guarantee that the functor \(\left.H\right|_{\{1\} \times \mathcal{D}}: \mathcal{D} \rightarrow \mathcal{C}\) is a homotopy inverse to the inclusion map \(\mathcal{C} \hookrightarrow \mathcal{D}\).

Let \(Q\) denote the set of pairs \(\left(S, H_{S}\right)\), where \(S \subseteq \mathcal{D}\) is a simplicial subset which contains \(\mathcal{C}\) and \(H_{S}: \Delta^{1} \times S \rightarrow \mathcal{D}\) is a morphism of simplicial sets which satisfies the analogues of conditions (i) through (iv). We regard \(Q\) as a partially ordered set, where \(\left(S, H_{S}\right) \leq\left(S^{\prime}, H_{S^{\prime}}\right)\) if \(S \subseteq S^{\prime}\) and \(H_{S}=\left.H_{S^{\prime}}\right|_{\Delta^{1} \times S}\). This partially ordered set satisfies the hypotheses of Zorn's lemma, and therefore contains a maximal element ( \(S_{\max }, H_{\max }\) ). To complete the proof, it will suffice to show that \(S_{\max }=\mathcal{D}\). Assume otherwise. Then there is some \(n\)-simplex \(\tau: \Delta^{n} \rightarrow \mathcal{D}\) which is not contained in \(S_{\text {max }}\). Choose \(n\) as small as possible, so that \(\tau_{0}=\left.\tau\right|_{\partial \Delta^{n}}\) factors through \(S_{\max }\). Then the composite map
\[
\Delta^{1} \times \partial \Delta^{n} \xrightarrow{\text { id } \times \tau_{0}} \Delta^{1} \times S_{\max } \xrightarrow{H_{\max }} \mathcal{D}
\]
can be viewed as an isomorphism \(\alpha_{0}: \tau_{0} \rightarrow \tau_{0}^{\prime}\) in the \(\infty\)-category \(\operatorname{Fun}\left(\partial \Delta^{n}, \mathcal{D}\right)\), where \(\tau_{0}^{\prime}\) belongs to \(\operatorname{Fun}\left(\partial \Delta^{n}, \mathcal{C}\right)\). Using Proposition 4.4.5.8, we can lift \(\alpha_{0}\) to an isomorphism \(\tau \rightarrow \tau^{\prime}\) in the \(\infty\)-category \(\operatorname{Fun}\left(\Delta^{n}, \mathcal{D}\right)\). Let \(\tau^{\prime \prime}\) be the unique \(n\)-simplex of \(\mathcal{D}\) which belongs to \(R(n)\) and satisfies \(\tau^{\prime} \sim \tau^{\prime \prime}\). Then there exists an isomorphism \(\beta: \tau^{\prime} \rightarrow \tau^{\prime \prime}\) in the \(\infty\)-category \(\operatorname{Fun}\left(\Delta^{n}, \mathcal{D}\right)\) whose image in \(\operatorname{Fun}\left(\partial \Delta^{n}, \mathcal{D}\right)\) is an identity morphism. Using Theorem 1.5.6.1,
we can lift the degenerate 2 -simplex

of \(\operatorname{Fun}\left(\partial \Delta^{n}, \mathcal{D}\right)\) to a 2 -simplex

in the \(\infty\)-category \(\operatorname{Fun}\left(\Delta^{n}, \mathcal{D}\right)\). Let \(S\) denote the simplicial subset of \(\mathcal{D}\) given by the union of \(S_{\max }\) with the image of \(\tau\). Then \(H_{\max }\) extends uniquely to a morphism \(H_{S}: \Delta^{1} \times S \rightarrow \mathcal{D}\) for which the composite map
\[
\Delta^{1} \times \Delta^{n} \xrightarrow{\mathrm{id} \times \tau} \Delta^{1} \times S \xrightarrow{H_{S}} \mathcal{D}
\]
coincides with \(\gamma\). By construction, the pair \(\left(S, H_{S}\right)\) is an element of \(Q\) satisfying \(\left(S, H_{S}\right)>\) \(\left(S_{\max }, H_{\max }\right)\), contradicting the maximality of \(\left(S_{\max }, H_{\max }\right)\).

\subsection*{4.7.7 Small Kan Complexes}

03TJ In the setting of Kan complexes, essential \(\kappa\)-smallness can be tested at the level of homotopy groups.

03TK Proposition 4.7.7.1. Let \(X\) be a Kan complex and let \(\kappa\) be an uncountable regular cardinal. Then \(X\) is essentially \(\kappa\)-small if and only if it satisfies the following pair of conditions:
(1) The set \(\pi_{0}(X)\) is \(\kappa\)-small.
(2) For each vertex \(x \in X\) and each integer \(n>0\), the homotopy group \(\pi_{n}(X, x)\) is \(\kappa\)-small.

Proof. By virtue of Proposition 4.7.6.15, we may assume without loss of generality that the Kan complex \(X\) is minimal. If \(X\) is essentially \(\kappa\)-small, then it is \(\kappa\)-small (Corollary 4.7.6.12), so that conditions (1) and (2) follow immediately from the definitions. Conversely, suppose that (1) and (2) are satisfied; we wish to show that \(X\) is \(\kappa\)-small. By virtue of Proposition 4.7.4.9, it will suffice to show that the collection of \(n\)-simplices of \(X\) is \(\kappa\)-small,
for each \(n \geq 0\). Our proof proceeds by induction on \(n\). Using our inductive hypothesis (together with Remark 4.7.3.4 and Proposition 4.7.3.5), we see that the set \(\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\partial \Delta^{n}, X\right)\) is \(\kappa\)-small. Since \(\kappa\) is regular, it will suffice to show that each fiber of the restriction map \(\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\Delta^{n}, X\right) \rightarrow \operatorname{Hom}_{\text {Set }_{\Delta}}\left(\partial \Delta^{n}, X\right)\) is \(\kappa\)-small.

Set \(E=\operatorname{Fun}\left(\Delta^{n}, X\right)\) and \(B=\operatorname{Fun}\left(\partial \Delta^{n}, X\right)\), so that the inclusion map \(\partial \Delta^{n} \hookrightarrow \Delta^{n}\) induces a Kan fibration \(q: E \rightarrow B\) (Corollary 3.1.3.3) For each vertex \(b \in B\), let \(E_{b}\) denote the fiber \(\{b\} \times_{B} E\); we wish to show that the set of vertices of \(E_{b}\) is \(\kappa\)-small. Since the Kan complex \(X\) is minimal, each vertex of \(E_{b}\) belongs to a different connected component. It will therefore suffice to show that the set \(\pi_{0}\left(E_{b}\right)\) is \(\kappa\)-small. If \(n=0\), this follows from condition (1). Let us therefore assume that \(n>0\), and identify \(b\) with a morphism of simplicial sets \(\partial \Delta^{n} \rightarrow X\). If this morphism is not nullhomotopic, then the Kan complex \(E_{b}\) is empty and there is nothing to prove. We may therefore assume that there is a homotopy from \(b\) to a constant map \(b^{\prime}: \partial \Delta^{n} \rightarrow\{x\} \hookrightarrow X\). In this case, Proposition 5.2.2.18 supplies a homotopy equivalence of \(E_{b}\) with \(E_{b^{\prime}}\). We are therefore reduced to proving that the set \(\pi_{0}\left(E_{b^{\prime}}\right) \simeq \pi_{n}(X, x)\) is \(\kappa\)-small, which follows from condition (2).

Corollary 4.7.7.2. Let \(\kappa\) be an uncountable regular cardinal and let \(f: X \rightarrow Y\) be a Kan fibration between Kan complexes, where \(Y\) is essentially \(\kappa\)-small. The following conditions are equivalent:
(a) The Kan complex \(X\) is essentially \(\kappa\)-small.
(b) For each vertex \(y \in Y\), the fiber \(X_{y}=\{y\} \times_{Y} X\) is essentially \(\kappa\)-small.

Proof. The implication \((a) \Rightarrow(b)\) follows from Corollary 4.7.5.16 (and does not require the regularity of \(\kappa\) ). Assume that condition (b) is satisfied; we will show that \(X\) satisfies the criteria of Proposition 4.7.7.1.
(1) Let \(y\) be a vertex of \(Y\) and let \([y]\) denote its image in \(\pi_{0}(Y)\). Since \(f\) is a Kan fibration, the tautological map \(\pi_{0}\left(X_{y}\right) \rightarrow\{[y]\} \times_{\pi_{0}(Y)} \pi_{0}(X)\) is a surjection. Assumption (b) guarantees that \(\pi_{0}\left(X_{y}\right)\) is \(\kappa\)-small, so that the fiber \(\{[y]\} \times_{\pi_{0}(Y)} \pi_{0}(X)\) is also \(\kappa\)-small. Since \(\pi_{0}(Y)\) is \(\kappa\)-small, the regularity of \(\kappa\) guarantees that \(\pi_{0}(X)\) is also \(\kappa\)-small.
(2) Fix a vertex \(x \in X\) having image \(y=f(x)\), and let \(n>0\) be a positive integer. For each integer \(n>0\), Proposition 3.2.6.2 supplies an exact sequence of groups
\[
\pi_{n}\left(X_{y}, x\right) \rightarrow \pi_{n}(X, x) \xrightarrow{\pi_{n}(f)} \pi_{n}(Y, y) .
\]

Consequently, every nonempty fiber of the group homomorphism \(\pi_{n}(f)\) carries a transitive action of the \(\kappa\)-small group \(\pi_{n}\left(X_{y}, x\right)\), and is therefore \(\kappa\)-small. Since the group \(\pi_{n}(Y, y)\) is \(\kappa\)-small, the regularity of \(\kappa\) guarantees that \(\pi_{n}(X, x)\) is \(\kappa\)-small.

03TM Exercise 4.7.7.3. Let \(\kappa\) be an uncountable regular cardinal and let \(f: X \rightarrow Y\) be Kan fibration between Kan complexes. Suppose that \(X\) is essentially \(\kappa\)-small, that each fiber \(X_{y}=\{y\} \times_{Y} X\) is essentially \(\kappa\)-small, and that the morphism \(\pi_{0}(f): \pi_{0}(X) \rightarrow \pi_{0}(Y)\) is surjective. Show that \(Y\) is also essentially \(\kappa\)-small.

\subsection*{4.7.8 Local Smallness}

03TN In mathematical practice, it is very common to encounter categories \(\mathcal{C}\) which are not small but are nonetheless locally small: that is, for every pair of objects \(X, Y \in \mathcal{C}\), the set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is small. We now consider a quantitative counterpart of this condition in the \(\infty\)-categorical setting.

03TP Definition 4.7.8.1. Let \(\kappa\) be an uncountable cardinal. We say that an \(\infty\)-category \(\mathcal{C}\) is locally \(\kappa\)-small if, for every pair of objects \(X, Y \in \mathcal{C}\), the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is essentially \(\kappa\)-small.

03TQ Example 4.7.8.2. Let \(\kappa\) be an uncountable cardinal and let \(\mathcal{C}\) be a category. Then the \(\infty\)-category \(\mathrm{N}_{\bullet}(\mathcal{C})\) is locally \(\kappa\)-small if and only if, for every pair of objects \(X, Y \in \mathcal{C}\), the set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is \(\kappa\)-small.

03TR Example 4.7.8.3. Let \(\kappa\) be an uncountable regular cardinal and let \(X\) be a Kan complex. Then \(X\) is locally \(\kappa\)-small if and only if, for every vertex \(x \in X\) and every integer \(n>0\), the homotopy group \(\pi_{n}(X, x)\) is \(\kappa\)-small.

03TS Example 4.7.8.4. Let \(\kappa\) be an uncountable cardinal and let \(\mathcal{C}\) be an \(\infty\)-category which is essentially \(\kappa\)-small. Then \(\mathcal{C}\) is locally \(\kappa\)-small: that is, for every pair of objects \(X, Y \in \mathcal{C}\), the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is essentially \(\kappa\)-small. This is a special case of Proposition 4.7.5.14 since \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) can be identified with the oriented fiber product \(\{X\} \tilde{x}_{\mathcal{C}}\{Y\}\).

03TT Remark 4.7.8.5 (Homotopy Invariance). Let \(\kappa\) be an uncountable cardinal and let \(F: \mathcal{C} \rightarrow\) \(\mathcal{D}\) be an equivalence of \(\infty\)-categories. Then \(\mathcal{C}\) is locally \(\kappa\)-small if and only if \(\mathcal{D}\) is locally \(\kappa\)-small.

03TU Variant 4.7.8.6. Let \(\mathcal{C}\) be an \(\infty\)-category. We say that \(\mathcal{C}\) is locally small if, for every pair of objects \(X, Y \in \mathcal{C}\), the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is essentially small (that is, it is homotopy equivalent to to a small Kan complex: see Variant 4.7.5.4).

03TW Proposition 4.7.8.7. Let \(\kappa\) be an uncountable regular cardinal and let \(\mathcal{C}\) be an \(\infty\)-category. The following conditions are equivalent:
(1) The \(\infty\)-category \(\mathcal{C}\) is essentially \(\kappa\)-small.
(2) The \(\infty\)-category \(\mathcal{C}\) is locally \(\kappa\)-small and the set of isomorphism classes \(\pi_{0}\left(\mathcal{C}^{\simeq}\right)\) is \(\kappa\)-small.
(3) The Kan complex \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)^{\simeq}\) is essentially \(\kappa\)-small.
(4) For every finite simplicial set \(K\), the Kan complex \(\operatorname{Fun}(K, \mathcal{C}) \simeq\) is essentially \(\kappa\)-small.
(5) For every integer \(n \geq 0\), the set \(\pi_{0}\left(\operatorname{Fun}\left(\Delta^{n}, \mathcal{C}\right)^{\simeq}\right)\) is \(\kappa\)-small. Moreover, for every map \(b: \partial \Delta^{n} \rightarrow \mathcal{C}\), the fundamental group \(\pi_{1}\left(\operatorname{Fun}\left(\partial \Delta^{n}, \mathcal{C}\right)^{\simeq}, b\right)\) is \(\kappa\)-small.

Proof. The implication (1) \(\Rightarrow(2)\) follows from Example 4.7.8.4 We next show that \((2) \Rightarrow(3)\). Assume that condition (2) is satisfied; we wish to show that the Kan complex \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)^{\simeq}\) is essentially \(\kappa\)-small. Corollary 4.4.5.4 implies that the restriction map
\[
\theta: \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)^{\simeq} \rightarrow \operatorname{Fun}\left(\partial \Delta^{1}, \mathcal{C}\right)^{\simeq} \simeq \mathcal{C}^{\simeq} \times \mathcal{C}^{\simeq}
\]
is a Kan fibration. Moreover, for each vertex \((X, Y) \in \mathcal{C}^{\simeq} \times \mathcal{C}^{\simeq}\), the fiber \(\theta^{-1}\{(X, Y)\}\) can be identified with the morphism space \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\), which is essentially \(\kappa\)-small by virtue of (2). Using Corollary 4.7.7.2 (and Remark 4.7.5.8), we are reduced to proving that the Kan complex \(\mathcal{C}^{\simeq}\) is essentially \(\kappa\)-small. Fix a vertex \(X \in \mathcal{C}^{\simeq}\). For \(n \geq 2\), Example 4.6.1.13 supplies an isomorphism \(\pi_{n}\left(\mathcal{C}^{\simeq}, X\right) \simeq \pi_{n-1}\left(\operatorname{Hom}_{\mathcal{C}}(X, X)\right.\), id \(\left.X_{X}\right)\), so that the homotopy group \(\pi_{n}\left(\mathcal{C}^{\simeq}, X\right)\) is essentially small by virtue of assumption (2). Similarly, the fundamental group \(\pi_{1}\left(\mathcal{C}^{\simeq}, X\right)\) can be identified with the subset of \(\pi_{0}\left(\operatorname{Hom}_{\mathcal{C}}(X, X)\right)\) spanned by the homotopy classes of isomorphisms, which is also \(\kappa\)-small. Since \(\pi_{0}\left(\mathcal{C}^{\simeq}\right)\) is \(\kappa\)-small by virtue of assumption (2), Proposition 4.7.7.1 implies that the Kan complex \(\mathcal{C}^{\simeq}\) is essentially \(\kappa\)-small.

We now show that (3) implies (4). Assume that the Kan complex \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)^{\simeq}\) is essentially \(\kappa\)-small and let \(K\) be a finite simplicial set; we wish to show that \(\operatorname{Fun}(K, \mathcal{C})^{\simeq}\) is also essentially \(\kappa\)-small. We proceed by induction on the dimension \(n\) of \(K\) and the number of nondegenerate \(n\)-simplices of \(K\). If \(K\) is empty, there is nothing to prove. Otherwise, there exists a pushout square of simplicial sets

Since the horizontal maps are monomorphisms, this diagram is also a categorical pushout square (Example 4.5.4.12) and therefore induces a homotopy pullback diagram of Kan
complexes

Our inductive hypothesis guarantees that \(\operatorname{Fun}\left(\partial \Delta^{n}, \mathcal{C}\right) \simeq\) and \(\operatorname{Fun}\left(K^{\prime}, \mathcal{C}\right) \simeq\) are essentially \(\kappa\)-small. It will therefore suffice to show that the Kan complex \(\operatorname{Fun}\left(\Delta^{n}, \mathcal{C}\right)^{\simeq}\) is essentially \(\kappa\)-small (Corollary 4.7.5.16). If \(n=1\), this follows from assumption (3). If \(n \geq 2\), then the inclusion map \(\Lambda_{1}^{n} \hookrightarrow \Delta^{n}\) induces a homotopy equivalence \(\operatorname{Fun}\left(\Delta^{n}, \mathcal{C}\right)^{\simeq} \rightarrow \operatorname{Fun}\left(\Lambda_{1}^{n} \mathcal{C}\right)^{\simeq}\), so that the desired result again follows from our inductive hypothesis. It will therefore suffice to treat the case \(n=0\) : that is, to show that the Kan complex \(\mathcal{C}^{\simeq}\) is essentially \(\kappa\)-small. This follows from Corollary 4.7.5.13, since \(\mathcal{C}^{\simeq}\) is homotopy equivalent to the summand \(\operatorname{Isom}(\mathcal{C})^{\simeq} \subseteq \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right) \simeq(\) see Corollary 4.4.5.10).

The implication \((4) \Rightarrow(5)\) follows from Proposition 4.7.7.1. We will complete the proof by showing that (5) implies (1). Assume that condition (5) is satisfied; we will show that \(\mathcal{C}\) is essentially \(\kappa\)-small. We now proceed as in the proof of Proposition 4.7.7.1. Using Proposition 4.7.6.15, we can reduce to the case where \(\mathcal{C}\) is minimal. In this case, we wish to show that \(\mathcal{C}\) is \(\kappa\)-small. By virtue of Proposition 4.7.4.9, it will suffice to show that the collection of \(n\)-simplices of \(\mathcal{C}\) is \(\kappa\)-small, for each \(n \geq 0\). Our proof proceeds by induction on \(n\). Using our inductive hypothesis (together with Remark 4.7.3.4 and Proposition 4.7.3.5), we see that the set \(\operatorname{Hom}_{\text {Set }_{\Delta}}\left(\partial \Delta^{n}, \mathcal{C}\right)\) is \(\kappa\)-small. Since \(\kappa\) is regular, it will suffice to show that each fiber of the restriction map \(\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\Delta^{n}, \mathcal{C}\right) \rightarrow \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\partial \Delta^{n}, \mathcal{C}\right)\) is \(\kappa\)-small.

Set \(E=\operatorname{Fun}\left(\Delta^{n}, \mathcal{C}\right)^{\simeq}\) and \(B=\operatorname{Fun}\left(\partial \Delta^{n}, \mathcal{C}\right)^{\simeq}\), so that the inclusion map \(\partial \Delta^{n} \hookrightarrow \Delta^{n}\) induces a Kan fibration \(q: E \rightarrow B\) (Corollary 4.4.5.4). Fix a vertex \(b \in B\) and set \(E_{b}=\{b\} \times_{B} E\); we wish to show that the set of vertices of \(E_{b}\) is \(\kappa\)-small. Since \(\mathcal{C}\) is minimal, each vertex of \(E_{b}\) belongs to a different connected component. It will therefore suffice to show that the set of connected components \(\pi_{0}\left(E_{b}\right)\) is \(\kappa\)-small. Assumption (5) guarantees that the set \(\pi_{0}(E)\) is \(\kappa\)-small. Moreover Corollary 3.2.6.5 shows that every nonempty fiber of the map \(\pi_{0}\left(E_{b}\right) \rightarrow \pi_{0}(E)\) is equipped with a transitive action of the fundamental group \(\pi_{1}(B, b)\), which is also \(\kappa\)-small. Since \(\kappa\) is regular, it follows that the set \(\pi_{0}\left(E_{b}\right)\) is also \(\kappa\)-small, as desired.

03UR Corollary 4.7.8.8. Let \(\kappa\) be an infinite cardinal, let \(\lambda\) be an uncountable cardinal of exponential cofinality \(\geq \kappa\) (Definition 4.7.3.16), and let \(\mathcal{C}\) be an \(\infty\)-category which is locally \(\lambda\)-small. Then, for every \(\kappa\)-small simplicial set \(K\), the \(\infty\)-category \(\operatorname{Fun}(K, \mathcal{C})\) is locally \(\lambda\)-small. Moreover, if \(\kappa\) is uncountable, then it suffices to assume that \(K\) is essentially \(\kappa\)-small.

Proof. Let \(F, F^{\prime}: K \rightarrow \mathcal{C}\) be diagrams; we wish to show that the morphism space \(\operatorname{Hom}_{\text {Fun }(K, \mathcal{C})}\left(F, F^{\prime}\right)\) is essentially \(\lambda\)-small. Let \(\mathcal{C}_{0} \subseteq \mathcal{C}\) be the full subcategory spanned by the essential images of \(F\) and \(F^{\prime}\). Proposition 4.7.8.7 guarantees that \(\mathcal{C}_{0}\) is essentially \(\lambda\)-small. It will therefore suffice to show that \(\operatorname{Fun}\left(K, \mathcal{C}_{0}\right)\) is locally \(\lambda\)-small, which follows immediately from Remark 4.7.5.10.

Corollary 4.7.8.9. Let \(\mathcal{C}\) and \(\mathcal{D}\) be \(\infty\)-categories. If \(\mathcal{C}\) is essentially small and \(\mathcal{D}\) is locally small, then the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\) is locally small.

Variant 4.7.8.10. Let \(\lambda\) be an uncountable cardinal, let \(\mathcal{C}\) be an \(\infty\)-category which is locally \(\lambda\)-small, and let \(K\) be a simplicial set. Suppose that \(K\) is \(\kappa\)-small, where \(\kappa=\operatorname{ecf}(\lambda)\) is the exponential cofinality of \(\lambda\). Then, for any diagram \(f: K \rightarrow \mathcal{C}\), the \(\infty\)-categories \(\mathcal{C}_{f /}\) and \(\mathcal{C}_{/ f}\) are locally \(\lambda\)-small. Moreover, if \(\kappa\) is uncountable, then it suffices to assume that \(K\) is essentially \(\kappa\)-small.

Proof. We will show that the slice \(\infty\)-category \(\mathcal{C}_{/ f}\) is locally \(\lambda\)-small; the analogous assertion for \(\mathcal{C}_{f /}\) follows by a similar argument. Fix a pair of objects \(X, Y \in \mathcal{C}_{/ f}\); we wish to show that the morphism space \(\operatorname{Hom}_{\mathcal{C}_{/ f}}(X, Y)\) is essentially \(\lambda\)-small. Let \(\mathcal{C}^{\prime}\) be the smallest full subcategory of \(\mathcal{C}\) which contains \(f(K)\) together with the images of \(X\) and \(Y\). Replacing \(\mathcal{C}\) by \(\mathcal{C}^{\prime}\), we can reduce to the case where \(\mathcal{C}\) is essentially \(\kappa\)-small. In this case, the \(\infty\)-category \(\mathcal{C}_{/ f}\) is essentially \(\lambda\)-small (Corollary 4.7.5.17), so the desired result follows from Example 4.7.8.4.

Example 4.7.8.11. Let \(\lambda\) be an uncountable cardinal and let \(\mathcal{C}\) be an \(\infty\)-category which is locally \(\lambda\)-small. Then, for every object \(X \in \mathcal{C}\), the \(\infty\)-categories \(\mathcal{C}_{/ X}\) and \(\mathcal{C}_{X /}\) are locally \(\lambda\)-small.

\subsection*{4.7.9 Small Fibrations}

It will sometimes be convenient to work with a relative version of Definition 4.7.5.1. an uncountable regular cardinal. We say that \(U\) is essentially \(\kappa\)-small if, for every simplex \(\sigma: \Delta^{n} \rightarrow \mathcal{C}\), the \(\infty\)-category \(\Delta^{n} \times_{\mathcal{C}} \mathcal{E}\) is essentially \(\kappa\)-small. We say that \(U\) is locally \(\kappa\)-small if, for every simplex \(\sigma: \Delta^{n} \rightarrow \mathcal{C}\), the \(\infty\)-category \(\Delta^{n} \times_{\mathcal{C}} \mathcal{E}\) is locally \(\kappa\)-small.

Variant 4.7.9.2. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an inner fibration of simplicial sets. We say that \(U\) is essentially small if, for every simplex \(\sigma: \Delta^{n} \rightarrow \mathcal{C}\), the \(\infty\)-category \(\Delta^{n} \times_{\mathcal{C}} \mathcal{E}\) is essentially small. We say that \(U\) is locally small if, for every \(n\)-simplex \(\sigma: \Delta^{n} \rightarrow \mathcal{C}\), the \(\infty\)-category \(\Delta^{n} \times_{\mathcal{C}} \mathcal{E}\) is locally small.

047D Remark 4.7.9.3. Let \(\kappa\) be an uncountable regular cardinal and suppose we are given a pullback diagram of simplicial sets

where \(U\) and \(U^{\prime}\) are inner fibrations. If \(U\) is essentially \(\kappa\)-small, then \(U^{\prime}\) is essentially \(\kappa\)-small. If \(U\) is locally \(\kappa\)-small, then \(U^{\prime}\) is locally \(\kappa\)-small.

047E Remark 4.7.9.4. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an inner fibration of simplicial sets and let \(\kappa\) be an uncountable regular cardinal. Then \(U\) is essentially \(\kappa\)-small if and only if it is locally \(\kappa\)-small and, for each vertex \(C \in \mathcal{C}\), the set of isomorphism classes \(\pi_{0}(\mathcal{E} \widetilde{\bar{C}})\) is \(\kappa\)-small. See Proposition 4.7.8.7.

047 F Proposition 4.7.9.5. Let \(\kappa\) be an uncountable regular cardinal, let \(\mathcal{C}\) be an \(\infty\)-category which is locally \(\kappa\)-small, and let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an inner fibration. The following conditions are equivalent:
(1) The inner fibration \(U\) is locally \(\kappa\)-small.
(2) For every edge \(\Delta^{1} \rightarrow \mathcal{C}\), the \(\infty\)-category \(\Delta^{1} \times_{\mathcal{C}} \mathcal{E}\) is locally \(\kappa\)-small.
(3) The \(\infty\)-category \(\mathcal{E}\) is locally \(\kappa\)-small.

Proof. The implication (1) \(\Rightarrow(2)\) is immediate from the definitions. Assume next that (2) is satisfied; we will prove (3). Let \(X\) and \(Y\) be objects of \(\mathcal{E}\), and set \(\bar{X}=U(X)\) and \(\bar{Y}=U(Y)\). We wish to show that the Kan complex \(\operatorname{Hom}_{\mathcal{E}}(X, Y)\) is essentially \(\kappa\)-small. By virtue of Proposition 4.6.1.21, the functor \(U\) induces a Kan fibration \(\theta: \operatorname{Hom}_{\mathcal{E}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{C}}(\bar{X}, \bar{Y})\). Our assumption that \(\mathcal{C}\) is locally \(\kappa\)-small guarantees that the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(\bar{X}, \bar{Y})\) is essentially \(\kappa\)-small. By virtue of Corollary 4.7.7.2, it will suffice to show that for every morphism \(\bar{e}: \bar{X} \rightarrow \bar{Y}\) in \(\mathcal{C}\), the Kan complex \(\operatorname{Hom}_{\mathcal{E}}(X, Y)_{\bar{e}}=\{\bar{e}\} \times_{\operatorname{Hom}_{\mathcal{C}}(\bar{X}, \bar{Y})} \operatorname{Hom}_{\mathcal{E}}(X, Y)\) is essentially \(\kappa\)-small. This follows immediately from assumption (2).

We now complete the proof by showing that (3) implies (1). Assume that \(\mathcal{E}\) is locally \(\kappa\)-small and choose a simplex \(\sigma: \Delta^{n} \rightarrow \mathcal{C}\); we will show that the \(\infty\)-category \(\mathcal{E}_{\sigma}=\Delta^{n} \times_{\mathcal{C}} \mathcal{E}\) is locally \(\kappa\)-small. Fix a pair of objects \(\widetilde{X}, \widetilde{Y} \in \mathcal{E}_{\sigma}\); we wish to show that the Kan complex \(\operatorname{Hom}_{\mathcal{E}_{\sigma}}(\widetilde{X}, \widetilde{Y})\) is essentially \(\kappa\)-small. Let \(X\) and \(Y\) denote the images of \(\widetilde{X}\) and \(\widetilde{Y}\) in the \(\infty\)-category \(\mathcal{E}\), and set \(\bar{X}=U(X)\) and \(\bar{Y}=U(Y)\) as above. If the Kan complex Hom \(\mathcal{E}_{\sigma}(\widetilde{X}, \tilde{Y})\) is nonempty, then it can be identified with a fiber of the \(\operatorname{Kan}\) fibration \(\theta: \operatorname{Hom}_{\mathcal{E}}(X, Y) \rightarrow\) \(\operatorname{Hom}_{\mathcal{C}}(\bar{X}, \bar{Y})\), which is essentially \(\kappa\)-small by virtue of Corollary 4.7.7.2.

Corollary 4.7.9.6. Let \(\kappa\) be an uncountable regular cardinal and let \(\mathcal{C}\) be an \(\infty\)-category which is essentially \(\kappa\)-small, and let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an inner fibration. If the \(\infty\)-category \(\mathcal{E}\) is essentially \(\kappa\)-small, then then \(U\) is essentially \(\kappa\)-small. The converse holds if \(U\) is an isofibration.

Proof. Assume first that \(\mathcal{E}\) is essentially \(\kappa\)-small. Applying Proposition 4.7.9.5, we deduce that \(U\) is locally \(\kappa\)-small. It will therefore suffice to show that, for each object \(C \in \mathcal{C}\), the \(\infty\)-category \(\mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E}\) is essentially \(\kappa\)-small (Remark 4.7.9.4. Using Corollary 4.5.2.23. we can factor \(U\) as a composition \(\mathcal{E} \xrightarrow{\iota} \mathcal{E}^{\prime} \xrightarrow{U^{\prime}} \mathcal{C}\), where \(U^{\prime}\) is an isofibration and \(\iota\) is an equivalence of \(\infty\)-categories. Then \(\mathcal{E}^{\prime}\) is essentially \(\kappa\)-small, so Corollary 4.7.5.16 guarantees that the fiber \(\mathcal{E}_{C}^{\prime}\) is essentially \(\kappa\)-small. Remark 4.5.2.24 guarantees that the map of fibers \(\mathcal{E}_{C} \rightarrow \mathcal{E}_{C}^{\prime}\) is fully faithful, so \(\mathcal{E}_{C}\) is also essentially \(\kappa\)-small (Corollary 4.7.5.13).

Now suppose that \(U\) is an isofibration which is essentially \(\kappa\)-small; we wish to show that the \(\infty\)-category \(\mathcal{E}\) is essentially \(\kappa\)-small. Proposition 4.7.9.5 guarantees that \(U\) is locally \(\kappa\)-small. It will therefore suffice to show that the set of isomorphism classes \(\pi_{0}\left(\mathcal{E}^{\sim}\right)\) is \(\kappa\)-small. In fact, we will show that the core \(\mathcal{E}^{\simeq}\) is an essentially \(\kappa\)-small Kan complex. This is a special case of Corollary 4.7.7.2, since \(U\) induces a Kan fibration \(U^{\simeq}: \mathcal{E}^{\simeq} \rightarrow \mathcal{C}^{\simeq}\) whose fibers are essentially \(\kappa\)-small (see Proposition 4.4.3.7).

Warning 4.7.9.7. If \(U: \mathcal{E} \rightarrow \mathcal{C}\) is not assumed to be an isofibration, then the converse assertion of Corollary 4.7.9.6 does not necessarily hold. For example, suppose that \(\mathcal{C}=\mathrm{N}_{\bullet}\left(\mathcal{C}_{0}\right)\) is the nerve of an essentially \(\kappa\)-small category \(\mathcal{C}_{0}\), and let \(\mathcal{E}=\operatorname{sk}_{0}(\mathcal{C})\) be the constant simplicial set associated to the collection of objects of \(\mathcal{C}_{0}\). Then the inclusion map \(\mathcal{E} \hookrightarrow \mathcal{C}\) is an essentially \(\kappa\)-small inner fibration (which is usually not an isofibration). However, the \(\infty\)-category \(\mathcal{E}\) is essentially \(\kappa\)-small if and only if the set of objects of \(\mathcal{C}_{0}\) is \(\kappa\)-small.

Corollary 4.7.9.8. Let \(\kappa\) be an uncountable regular cardinal. Then an \(\infty\)-category \(\mathcal{C}\)
047H
\(\qquad\)
  he
is locally \(\kappa\)-small (in the sense of Definition 4.7.8.1) if and only if the inner fibration \(U: \mathcal{C} \rightarrow \Delta^{0}\) is locally \(\kappa\)-small (in the sense of Definition 4.7.9.1). Similarly, \(\mathcal{C}\) is essentially \(\kappa\)-small (in the sense of Definition 4.7.5.1) if and only if \(U\) is essentially \(\kappa\)-small.
Corollary 4.7.9.9 (Transitivity of Local Smallness). Let \(V: \mathcal{E} \rightarrow \mathcal{D}\) and \(U: \mathcal{D} \rightarrow \mathcal{C}\) be 047K inner fibrations of simplicial sets, let \(\kappa\) be an uncountable regular cardinal, and suppose that \(U\) is locally \(\kappa\)-small. Then \(V\) is locally \(\kappa\)-small if and only if \(U \circ V\) is locally \(\kappa\)-small.

Proof. Suppose first that \(V\) is locally \(\kappa\)-small. Choose an \(n\)-simplex \(\sigma: \Delta^{n} \rightarrow \mathcal{C}\); we wish to show that the \(\infty\)-category \(\Delta^{n} \times_{\mathcal{C}} \mathcal{E}\) is locally \(\kappa\)-small. This follows by applying Proposition 4.7.9.5 to the inner fibration of \(\infty\)-categories \((\mathrm{id} \times V): \Delta^{n} \times_{\mathcal{C}} \mathcal{E} \rightarrow \Delta^{n} \times_{\mathcal{C}} \mathcal{D}\), which is locally \(\kappa\)-small by virtue of Remark 4.7.9.3.

Now suppose that \(U \circ V\) is locally \(\kappa\)-small, and choose an \(n\)-simplex \(\tilde{\sigma}: \Delta^{n} \rightarrow \mathcal{D}\); we wish to show that the fiber product \(\Delta^{n} \times_{\mathcal{D}} \mathcal{E}\) is locally \(\kappa\)-small. To prove this, we are free
to replace \(\mathcal{D}\) and \(\mathcal{E}\) by \(\Delta^{n} \times_{\mathcal{C}} \mathcal{D}\) and \(\Delta^{n} \times_{\mathcal{C}} \mathcal{E}\), respectively, and thereby reduce to the case where \(\mathcal{C}=\Delta^{n}\) is a locally \(\kappa\)-small \(\infty\)-category. In this case, our assumptions on \(U\) and \(U \circ V\) guarantee that the \(\infty\)-categories \(\mathcal{D}\) and \(\mathcal{E}\) are also locally \(\kappa\)-small (Proposition 4.7.9.5), so that \(V\) is automatically locally \(\kappa\)-small (by Proposition 4.7.9.5 again).

047L Variant 4.7.9.10 (Transitivity of Essential Smallness). Let \(V: \mathcal{E} \rightarrow \mathcal{D}\) and \(U: \mathcal{D} \rightarrow \mathcal{C}\) be inner fibrations of simplicial sets, let \(\kappa\) be an uncountable regular cardinal, and suppose that \(U\) is essentially \(\kappa\)-small. Then:
- If \(V\) is an essentially \(\kappa\)-small isofibration, then \(U \circ V\) is essentially \(\kappa\)-small.
- If \(U \circ V\) is essentially \(\kappa\)-small, then \(V\) is essentially \(\kappa\)-small.

Proof. We proceed as in the proof of Corollary 4.7.9.9. Assume first that \(V\) is an essentially \(\kappa\)-small isofibration, and choose an \(n\)-simplex \(\sigma: \Delta^{n} \rightarrow \mathcal{C}\); we wish to show that the \(\infty\)-category \(\Delta^{n} \times_{\mathcal{C}} \mathcal{E}\) is essentially \(\kappa\)-small. This follows by applying Corollary 4.7.9.6 to the isofibration of \(\infty\)-categories (id \(\times V\) ) : \(\Delta^{n} \times_{\mathcal{C}} \mathcal{E} \rightarrow \Delta^{n} \times_{\mathcal{C}} \mathcal{D}\), which is essentially \(\kappa\)-small by virtue of Remark 4.7.9.3.

Now suppose that \(U \circ V\) is essentially \(\kappa\)-small, and choose an \(n\)-simplex \(\widetilde{\sigma}: \Delta^{n} \rightarrow \mathcal{D}\); we wish to show that the fiber product \(\Delta^{n} \times_{\mathcal{D}} \mathcal{E}\) is essentially \(\kappa\)-small. To prove this, we are free to replace \(\mathcal{D}\) and \(\mathcal{E}\) by \(\Delta^{n} \times_{\mathcal{C}} \mathcal{D}\) and \(\Delta^{n} \times_{\mathcal{C}} \mathcal{E}\), respectively, and thereby reduce to the case where \(\mathcal{C}=\Delta^{n}\). In particular, we may assume that \(\mathcal{C}\) is an essentially \(\kappa\)-small \(\infty\)-category and that the functors \(U\) and \(U \circ V\) are isofibrations (Example4.4.1.6). Applying Corollary 4.7.9.6, we deduce that the \(\infty\)-categories \(\mathcal{D}\) and \(\mathcal{E}\) are essentially \(\kappa\)-small, so that \(V\) is also automatically essentially \(\kappa\)-small (by Corollary 4.7.9.6 again).

047M Corollary 4.7.9.11. Let \(\kappa\) be an uncountable regular cardinal and let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an inner fibration of \(\infty\)-categories. Then \(U\) is locally \(\kappa\)-small if and only if, for every edge \(\Delta^{1} \rightarrow \mathcal{C}\), the \(\infty\)-category \(\Delta^{1} \times_{\mathcal{C}} \mathcal{E}\) is locally \(\kappa\)-small.

Proof. The "only if" direction is immediate from the definitions. To prove the converse, we may assume without loss of generality that \(\mathcal{C}=\Delta^{n}\) is a standard simplex, in which case the desired result follows from Proposition 4.7.9.5.

047N Corollary 4.7.9.12. Let \(\kappa\) be an uncountable regular cardinal and let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an inner fibration of \(\infty\)-categories. Then \(U\) is essentially \(\kappa\)-small if and only if, for every edge \(\Delta^{1} \rightarrow \mathcal{C}\), the \(\infty\)-category \(\Delta^{1} \times_{\mathcal{C}} \mathcal{E}\) is essentially \(\kappa\)-small.

Proof. Combine Corollary 4.7.9.11 with Remark 4.7.9.4
03TY Warning 4.7.9.13. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an inner fibration of \(\infty\)-categories. If \(U\) is essentially \(\kappa\)-small, then the \(\infty\)-category \(\mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E}\) is essentially \(\kappa\)-small for each object \(C \in \mathcal{C}\).

Beware that the converse is false in general. For example, let \(S\) be a set and let \(\mathcal{E}\) be the category containing a pair of objects \(X\) and \(Y\), with morphisms given by
\[
\begin{aligned}
\operatorname{Hom}_{\mathcal{E}}(X, X)=\left\{\operatorname{id}_{X}\right\} & \operatorname{Hom}_{\mathcal{E}}(Y, Y)=\left\{\operatorname{id}_{Y}\right\} \\
\operatorname{Hom}_{\mathcal{E}}(X, Y)=S & \operatorname{Hom}_{\mathcal{E}}(Y, X)=\emptyset
\end{aligned}
\]

Then there is a unique isofibration \(U: \mathrm{N}_{\bullet}(\mathcal{E}) \rightarrow \Delta^{1}\) satisfying \(U(X)=0\) and \(U(Y)=1\). The fibers \(U^{-1}\{0\}\) and \(U^{-1}\{1\}\) are isomorphic to \(\Delta^{0}\) (and are therefore essentially \(\kappa\)-small for every uncountable cardinal \(\kappa\) ). However, the \(\infty\)-category \(\mathrm{N}_{\bullet}(\mathcal{E})\) is essentially \(\kappa\)-small if and only if the set \(S\) is \(\kappa\)-small.

\subsection*{4.8 Truncations in Higher Category Theory}

Recall that a simplicial set \(\mathcal{C}\) is an \(\infty\)-category if, for every pair of integers \(0<i<m\), every inner horn \(\sigma_{0}: \Lambda_{i}^{m} \rightarrow \mathcal{C}\) can be extended to an \(m\)-simplex of \(\mathcal{C}\) (Definition 1.4.0.1). In this case, \(\mathcal{C}\) is (isomorphic to the nerve of) an ordinary category if and only if the extension \(\sigma\) is always unique (Proposition 1.3.4.1). More generally, we say that \(\mathcal{C}\) is an \((n, 1)\)-category if the extension \(\sigma\) is unique whenever \(m>n\) (Definition 4.8.1.1). In \(\$ 4.8 .1\), we summarize the formal properties of this definition and give some basic examples.

Beware that the notion of \((n, 1)\)-category is not homotopy-invariant: that is, if \(\mathcal{C}\) and \(\mathcal{D}\) are equivalent \(\infty\)-categories and \(\mathcal{D}\) is an \((n, 1)\)-category, then \(\mathcal{C}\) need not be an \((n, 1)\)-category. We can therefore ask the following:
Question 4.8.0.1. Let \(\mathcal{C}\) be an \(\infty\)-category. Under what conditions does there exists an 0579 equivalence of \(\infty\)-categories \(\mathcal{C} \rightarrow \mathcal{D}\), where \(\mathcal{D}\) is an ( \(n, 1\) )-category?

We partially address Question 4.8.0.1 in \(\$ 4.8 .2\) by introducing the notion of a locally truncated \(\infty\)-category. If \(m\) is an integer, we say that an \(\infty\)-category \(\mathcal{C}\) is locally \(m\)-truncated if, for every pair of objects \(X, Y \in \mathcal{C}\), the morphism space \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is \(m\)-truncated (Definition 4.8.2.1). It is easy to see that every \((n, 1)\)-category is locally \((n-1)\)-truncated (Example 4.8.2.2). Conversely, if \(\mathcal{C}\) is a locally \((n-1)\)-truncated \(\infty\) category, then there exists an equivalence \(\mathcal{C} \rightarrow \mathcal{D}\), where \(\mathcal{D}\) is an ( \(n, 1\) )-category. We will give two proofs of this result:
- In \(\$ 4.8 .3\) we show that a locally \((n-1)\)-truncated \(\infty\)-category \(\mathcal{C}\) is an \((n, 1)\)-category if and only if it is minimal in dimensions \(\geq n\) (Proposition 4.8.3.1). In particular, if \(\mathcal{D}\) is a minimal model of \(\mathcal{C}\), then \(\mathcal{D}\) is an \((n, 1)\)-category.
- In \(\S 4.8 .4\), we associate to every \(\infty\)-category \(\mathcal{C}\) an \((n, 1)\)-category \(\mathrm{h}_{\leq n}(\mathcal{C})\), which we call the homotopy \(n\)-category of \(\mathcal{C}\) (Construction 4.8.4.9). The homotopy \(n\)-category \(\mathrm{h}_{\leq n}(\mathcal{C})\) is equipped with a comparison functor \(\mathcal{C} \rightarrow \mathrm{h}_{\leq n}(\mathcal{C})\), which is an equivalence if and only if \(\mathcal{C}\) is locally \((n-1)\)-truncated (Corollary 4.8.4.16).

Let \(\mathcal{C}\) and \(\mathcal{D}\) be ordinary categories. Recall that a functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) is an equivalence of categories if and only if it satisfies the following three conditions:
- The functor \(F\) is essentially surjective: that is, every object of \(\mathcal{D}\) is isomorphic to \(F(X)\), for some objects \(X \in \mathcal{C}\).
- The functor \(F\) is full: that is, for every pair of objects \(X, Y \in \mathcal{C}\), the function \(F_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\) is surjective.
- The functor \(F\) is faithful: that is, for every pair of objects \(X, Y \in \mathcal{C}\), the function \(F_{X, Y}\) is injective.

057A Exercise 4.8.0.2. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between categories. Show that \(F\) is faithful if and only if, for every diagram \(\sigma\) :

in the category \(\mathcal{C}\), if \(F(\sigma)\) is a commutative diagram in \(\mathcal{D}\), then \(\sigma\) is also commutative.
To emphasize the parallels between the preceding conditions, it is convenient to reformulate them using the language of simplicial sets. To simplify the discussion, let us assume that the functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) is an isofibration (Definition 4.4.1.1). In this case:
(0) The functor \(F\) is essentially surjective if and only if it is surjective on objects: that is, every lifting problem

admits a solution.
(1) The functor \(F\) is full if and only if every lifting problem

admits a solution.
(2) The functor \(F\) is faithful if and only if every lifting problem

These conditions have a counterpart in the setting of \(\infty\)-categories:
Definition 4.8.0.3 (Preliminary). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an isofibration \(\infty\)-categories and let 057B \(m \geq 0\) be an integer. We say that \(F\) is \(m\)-full if every lifting problem

admits a solution.
In \(\$ 4.8 .5\), we extend Definition 4.8.0.3 to the case where \(F\) is an arbitrary functor of \(\infty\)-categories (see Definition 4.8.5.10 for a homotopy-invariant formulation, and Proposition 4.8.5.29 for a comparison with Definition 4.8.0.3).

Example 4.8.0.4. Let \(F_{0}: \mathcal{C}_{0} \rightarrow \mathcal{D}_{0}\) be a functor of ordinary categories and let \(F: 057 \mathrm{C}\) \(\mathrm{N}_{\bullet}\left(\mathcal{C}_{0}\right) \rightarrow \mathrm{N}_{\bullet}\left(\mathcal{D}_{0}\right)\) denote the induced of \(\infty\)-categories. Then:
- The functor \(F\) is 0 -full if and only if \(F_{0}\) is essentially surjective.
- The functor \(F\) is 1-full if and only if \(F_{0}\) is full.
- The functor \(F\) is 2 -full if and only if \(F_{0}\) is faithful.
- For \(m \geq 3\), the functor \(F\) is automatically \(m\)-full (see Exercise 1.3.1.5).

Fix an integer \(n\). We will say that a functor of \(\infty\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\) is essentially \(n\)-categorical if it is \(m\)-full for every nonnegative integer \(m \geq n+2\) (Definition 4.8.6.1). In \$4.8.6 we will see that this condition has many familiar specializations:
- A functor of \(\infty\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\) is essentially ( -1 )-categorical if and only if it is fully faithful, and essentially ( -2 )-categorical if and only if it is an equivalence of \(\infty\)-categories. See Remark 4.8.5.11.
- Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n \geq-1\). Then the projection map \(\mathcal{C} \rightarrow \Delta^{0}\) is essentially \(n\)-categorical if and only if \(\mathcal{C}\) is locally \((n-1)\)-truncated: that is, if and only if \(\mathcal{C}\) is equivalent to an ( \(n, 1\) )-category. See Example 4.8.6.4.
- If \(\mathcal{C}\) and \(\mathcal{D}\) are Kan complexes, then a functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) is essentially \(n\)-categorical if and only if it is \(n\)-truncated, in the sense of Definition 3.5.9.1. See Example 4.8.6.3.

In \(\$ 4.8 .7\), we introduce a dual version of this condition. We will say that a functor of \(\infty\) categories \(F: \mathcal{C} \rightarrow \mathcal{D}\) is categorically \(n\)-connective if it is \(m\)-full for every integer \(0 \leq m \leq n\) (Definition 4.8.7.1). Roughly speaking, this condition asserts that, up to equivalence, the \(\infty\)-category \(\mathcal{D}\) can be be built from \(\mathcal{C}\) using only simplices of dimension strictly larger than \(n\) (see Corollary 4.8.7.16 for a precise formulation). In the special case where \(\mathcal{C}\) and \(\mathcal{D}\) are Kan complexes, this recovers the theory of relative connectivity developed in \$3.5.1 (Example 4.8.7.3. As with the usual notion of connectivity, it can sometimes be useful to extend the notion of categorical connectivity to morphisms of between simplicial sets which are not \(\infty\)-categories; we consider this extension in \(\S 4.8 .9\) (Definition 4.8.9.2).

Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n\) be an integer. In \(\S 4.8 .8\), we show that \(F\) admits a factorization
\[
\mathcal{C} \xrightarrow{F^{\prime}} \mathcal{D}^{\prime} \xrightarrow{G} \mathcal{D},
\]
where \(F^{\prime}\) is categorically \((n+1)\)-connective and \(G\) is essentially \(n\)-categorical (Theorem 4.8.8.3). Moreover, this factorization is unique up to equivalence (Remark 4.8.8.8). In the special case where \(\mathcal{D}=\Delta^{0}\), this can be achieved by taking \(\mathcal{D}^{\prime}\) to be the homotopy \(n\)-category \(\mathrm{h}_{\leq n}(\mathcal{C})\) constructed in \(\S 44.8 .4\) (Example 4.8.8.7). More generally, if \(F\) is an inner fibration of \(\infty\)-categories, we will show that the system of \(\infty\)-categories \(\left\{\mathrm{h}_{\leq n}\left(\mathcal{C}_{D}\right)\right\}_{D \in \mathcal{D}}\) can be realized as the fibers of an inner fibration \(G: \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D}) \rightarrow \mathcal{D}\) which realizes the desired factorization (Construction 4.8.8.10).

\subsection*{4.8.1 ( \(n, 1\) )-Categories}

057D Recall that a simplicial set \(\mathcal{C}\) is (isomorphic to) the nerve of a category if and only if, for every pair of integers \(0<i<m\), the restriction map
\[
\operatorname{Hom}_{\text {Set }_{\Delta}}\left(\Delta^{m}, \mathcal{C}\right) \rightarrow \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\Lambda_{i}^{m}, \mathcal{C}\right)
\]
is a bijection. In this section, we study a hierarchy of weaker filling conditions.
057E Definition 4.8.1.1. Let \(n\) be a positive integer. We say that a simplicial set \(\mathcal{C}\) is an \((n, 1)\)-category if it satisfies the following condition for every pair of integers \(0<i<m\) :
(*) Every morphism of simplicial sets \(\sigma_{0}: \Lambda_{i}^{m} \rightarrow \mathcal{C}\) can be extended to an \(m\)-simplex \(\sigma\) of \(\mathcal{C}\). Moreover, if \(m>n\), then \(\sigma\) is unique.

Remark 4.8.1.2. Let \(n\) be a positive integer and let \(\mathcal{C}\) be a simplicial set. If \(\mathcal{C}\) is an 057 F \((n, 1)\)-category, then it is an \(\infty\)-category. Conversely, if \(\mathcal{C}\) is an \(\infty\)-category, then it is an ( \(n, 1\) )-category if and only if, for every pair of integers \(0<i<m\) with \(m>n\), the restriction map \(\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\Delta^{m}, \mathcal{C}\right) \rightarrow \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\Lambda_{i}^{m}, \mathcal{C}\right)\) is injective.

Example 4.8.1.3. An \(\infty\)-category \(\mathcal{C}\) is a \((1,1)\)-category if and only if it is isomorphic to 057G \(\mathrm{N}_{\bullet}\left(\mathcal{C}_{0}\right)\), for some category \(\mathcal{C}_{0}\). By virtue of Proposition 4.8.1.7. this is a restatement of Proposition 1.3.4.1. Note that in this case, the category \(\mathcal{C}_{0}\) is well-defined up to unique isomorphism (Proposition 1.3.3.1).

Example 4.8.1.4. Let \(\mathcal{C}\) be a 2-category, and suppose that every 2 -morphism in \(\mathcal{C}\) is an isomorphism. Then the Duskin nerve \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{C})\) is a \((2,1)\)-category, in the sense of Definition 4.8.1.8. This follows by combining Propositions 4.8.1.7 and 2.3.3.1.

Warning 4.8.1.5. We have now given several a priori different definitions for the notion of 057 J \((2,1)\)-category:
(1) According to Definition 2.2.8.5, a (2,1)-category is a 2-category \(\mathcal{C}\) in which every 2-morphism is an isomorphism.
(2) According to Definition 4.8.1.8 (or Definition 4.8.1.1), a (2,1)-category is a simplicial set which satisfies some additional conditions.

However, these definitions are compatible with one another. If \(\mathcal{C}\) is a \((2,1)\)-category in the sense of \((1)\), then the Duskin nerve \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{C})\) is a \((2,1)\)-category in the sense of (2) (Example 4.8.1.4). We will later see that the converse is also true: every ( 2,1 )-category in the sense (2) is isomorphic to the Duskin nerve \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{C})\), where \(\mathcal{C}\) is a 2-category in which every 2-morphism is an isomorphism (in this case, Theorem 2.3.4.1 guarantees that \(\mathcal{C}\) is unique up to non-strict isomorphism). See Proposition [?].

Exercise 4.8.1.6. Let \(n\) be a positive integer and let \(\mathcal{C}\) be a differential graded category 057 K which satisfies the following condition:
- For every pair of objects \(X, Y \in \mathcal{C}\), the chain complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}\) is concentrated in degrees \(<n\) : that is, the abelian groups \(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{m}\) vanish for \(m \geq n\).

Show that the differential graded nerve \(\mathrm{N}_{\bullet}^{\mathrm{dg}}(\mathcal{C})\) is an \((n, 1)\)-category (see the proof of Theorem 2.5.3.10.

It will be useful to work with a reformulation of Definition 4.8.1.1. Recall that:
- A simplicial set \(\mathcal{C}\) is weakly \(n\)-coskeletal if the restriction map
\[
\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\Delta^{m}, \mathcal{C}\right) \rightarrow \operatorname{Hom}_{\text {Set }_{\Delta}}\left(\partial \Delta^{m}, \mathcal{C}\right)
\]
is a bijection for \(m \geq n+2\) and an injection for \(m=n+1\) (Definition 3.5.4.1).
- An \(\infty\)-category \(\mathcal{C}\) is minimal in dimension \(n\) if, whenever \(\sigma\) and \(\tau\) are \(n\)-simplices of \(\mathcal{C}\) which are isomorphic relative to \(\partial \Delta^{n}\), then \(\sigma=\tau\) (Definition 4.7.6.4).

057L Proposition 4.8.1.7. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n\) be a positive integer. Then \(\mathcal{C}\) is an ( \(n, 1\) )-category (in the sense of Definition 4.8.1.1) if and only if it is weakly \(n\)-coskeletal and minimal in dimension \(n\).

Proof. We proceed as in the proof of Proposition 3.5.5.12. Assume first that \(\mathcal{C}\) is an \((n, 1)\)-category. Then, for any integer \(m>n\), the composition of the restriction maps
\[
\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\Delta^{m}, \mathcal{C}\right) \xrightarrow{\theta_{m}} \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\partial \Delta^{m}, \mathcal{C}\right) \rightarrow \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\Lambda_{1}^{m}, \mathcal{C}\right)
\]
is a bijection. In particular, \(\theta_{m}\) is an injection. To show that \(\mathcal{C}\) is weakly \(n\)-coskeletal, it will suffice to show that \(\theta_{m}\) is surjective for \(m \geq n+2\). Fix a morphism \(\sigma_{0}: \partial \Delta^{m} \rightarrow \mathcal{C}\); we wish to show that \(\sigma_{0}\) can be extended to an \(m\)-simplex of \(\mathcal{C}\). Since \(\mathcal{C}\) is an \((n, 1)\)-category, there is a unique \(m\)-simplex \(\sigma\) of \(\mathcal{C}\) satisfying \(\left.\sigma\right|_{\Lambda_{1}^{m}}=\left.\sigma_{0}\right|_{\Lambda_{1}^{m}}\). We complete the argument by observing that \(\left.\sigma\right|_{\partial \Delta^{m}}=\sigma_{0}\), by virtue of the injectivity of the map \(\theta_{m-1}\).

We next show that if \(\mathcal{C}\) is an \((n, 1)\)-category, then it is minimal in dimension \(n\). Let \(\sigma_{0}, \sigma_{1}: \Delta^{n} \rightarrow \mathcal{C}\) be \(n\)-simplices of \(\mathcal{C}\) and let \(h: \Delta^{1} \times \Delta^{n} \rightarrow \mathcal{C}\) be a natural isomorphism from \(\sigma_{0}=\left.h\right|_{\{0\} \times \Delta^{n}}\) to \(\sigma_{1}=\left.h\right|_{\{1\} \times \Delta^{n}}\) whose restriction to \(\Delta^{1} \times \partial \Delta^{n}\) factors through \(\partial \Delta^{n}\); we wish to show that \(\sigma_{0}=\sigma_{1}\). For \(0 \leq i \leq n\), let \(\alpha_{i}:[n+1] \rightarrow[1] \times[n]\) denote the nondecreasing function given by the formula
\[
\alpha_{i}(j)= \begin{cases}(0, j) & \text { if } j \leq i \\ (1, j-1) & \text { if } j>i,\end{cases}
\]
and let \(\tau_{i}\) denote the \((n+1)\)-simplex of \(\mathcal{C}\) given by the composition
\[
\Delta^{n+1} \xrightarrow{\alpha_{i}} \Delta^{1} \times \Delta^{n} \xrightarrow{h} \mathcal{C} .
\]

Let \(\rho_{i}, \rho_{i}^{\prime}: \Delta^{n} \rightarrow \mathcal{C}\) be the \(n\)-simplices of \(X\) given by \(\rho_{i}=d_{i}^{n+1}\left(\tau_{i}\right)\) and \(\rho_{i}^{\prime}=d_{i+1}^{n+1}\left(\tau_{i}\right)\); by construction, we have
\[
\sigma_{0}=\rho_{n}^{\prime} \quad \rho_{n}=\rho_{n-1}^{\prime} \quad \cdots \quad \rho_{1}=\rho_{0}^{\prime} \quad \rho_{0}=\sigma_{1} .
\]

We will complete the proof by showing that \(\rho_{i}=\rho_{i}^{\prime}\) for \(0 \leq i \leq n\). We will treat the case \(i>0\) (the case \(i<n\) follows by a similar argument). Using our assumption that \(h\) is constant
along the boundary \(\partial \Delta^{n}\), we see that the degenerate \((n+1)\)-simplex \(s_{i}^{n}\left(\rho_{i}\right)\) coincides with \(\tau_{i}\) on the horn \(\Lambda_{i}^{n+1} \subset \Delta^{n+1}\). Since \(\mathcal{C}\) is an ( \(n, 1\) )-category, it follows that \(\tau_{i}=s_{i}^{n}\left(\rho_{i}\right)\). Applying the face operator \(d_{i+1}^{n+1}\), we obtain \(\rho_{i}=\rho_{i}^{\prime}\).

We now prove the converse. Assume that \(\mathcal{C}\) is a weakly \(n\)-coskeletal \(\infty\)-category which is minimal in dimension \(n\); we will show that it is an \((n, 1)\)-category. Fix a pair of integers \(0<i<m\) with \(m>n\) and a pair of \(m\)-simplices \(\tau_{0}, \tau_{1}: \Delta^{m} \rightarrow X\) which coincide on the horn \(\Lambda_{i}^{m} \subset \Delta^{m}\); we wish to show that \(\tau_{0}=\tau_{1}\). Since \(\mathcal{C}\) is weakly \(n\)-coskeletal, it will suffice to prove that \(\tau_{0}\) and \(\tau_{1}\) coincide on the boundary \(\partial \Delta^{m}\) : that is, to show that the \((m-1)\)-simplices \(\sigma_{0}=d_{i}^{m}\left(\tau_{0}\right)\) and \(\sigma_{1}=d_{i}^{m}\left(\tau_{1}\right)\) coincide. Note that \(\sigma_{0}\) and \(\sigma_{1}\) have the same restriction to the boundary \(\partial \Delta^{m-1}\). Consequently, if \(m \geq n+2\), the desired result follows from our assumption that \(\mathcal{C}\) is weakly \(n\)-coskeletal. We may therefore assume that \(m=n+1\). Since \(\mathcal{C}\) is minimal in dimension \(n\), it will suffice to show that there is an isomorphism from \(\sigma_{0}\) to \(\sigma_{1}\left(\right.\) in the \(\infty\)-category \(\left.\operatorname{Fun}\left(\Delta^{n}, \mathcal{C}\right)\right)\) whose image in \(\operatorname{Fun}\left(\partial \Delta^{n}, \mathcal{C}\right)\) is an identity morphism. In fact, we will prove a stronger claim: there is an isomorphism from \(\tau_{0}\) to \(\tau_{1}\) in the \(\infty\)-category \(\operatorname{Fun}\left(\Delta^{m}, \mathcal{C}\right)\) whose image in \(\operatorname{Fun}\left(\Lambda_{i}^{m}, \mathcal{C}\right)\) is an identity morphism. This follows from the observation that the restriction map \(\operatorname{Fun}\left(\Delta^{m}, \mathcal{C}\right) \rightarrow \operatorname{Fun}\left(\Lambda_{i}^{m}, \mathcal{C}\right)\) is a trivial Kan fibration; see Proposition 1.5.7.6.

Motivated by Proposition 4.8.1.7, we introduce a generalization of Definition 4.8.1.1.
Definition 4.8.1.8. Let \(n\) be an integer. We say that a simplicial set \(\mathcal{C}\) is an \((n, 1)\)-category if it is an \(\infty\)-category which is weakly \(n\)-coskeletal and (if \(n \geq 0\) ) minimal in dimension \(n\).

For \(n>0\), Definitions 4.8.1.8 and 4.8.1.1 are equivalent: this is the content of Proposition 4.8.1.7. The advantage of Definition 4.8.1.8 is that it also makes sense for \(n \leq 0\). However, for \(n<0\) it is rather trivial:

Example 4.8.1.9. A simplicial set \(\mathcal{C}\) is a \((-1,1)\)-category if and only if it is either empty 057 N or isomorphic to \(\Delta^{0}\). See Example 3.5.4.4

Example 4.8.1.10. For \(n \leq-2\), a simplicial set \(\mathcal{C}\) is an \((n, 1)\)-category if and only it is 057 P isomorphic to \(\Delta^{0}\). See Example 3.5.4.3.

Example 4.8.1.11. Let \(X\) be a Kan complex and let \(n \geq 0\) be an integer. Then \(X\) is an \(n\)-groupoid (in the sense of Definition 3.5.5.1) if and only if it is an ( \(n, 1\) )-category (in the sense of Definition 4.8.1.8. This is a reformulation of Proposition 3.5.5.12.

Remark 4.8.1.12 (Monotonicity). Let \(\mathcal{C}\) be an ( \(m, 1\) )-category for some integer \(m\). Then 057R \(\mathcal{C}\) is an ( \(n, 1\) )-category for every integer \(n \geq m\).

Remark 4.8.1.13 (Symmetry). Let \(n\) be an integer and let \(\mathcal{C}\) be an \((n, 1)\)-category. Then 057S the opposite simplicial set \(\mathcal{C}^{\text {op }}\) is also an ( \(n, 1\) )-category.

057 T Remark 4.8.1.14. Let \(n\) be an integer and let \(\left\{\mathcal{C}_{j}\right\}_{j \in J}\) be a collection of \((n, 1)\)-categories. Then the product \(\mathcal{C}=\prod_{j \in J} \mathcal{C}_{j}\) is also an ( \(n, 1\) )-category.

057 U Proposition 4.8.1.15. A simplicial set \(\mathcal{C}\) is a \((0,1)\)-category if and only if there exists an isomorphism \(\mathcal{C} \simeq \mathrm{N}_{\bullet}(Q)\), for some partially ordered set \((Q, \leq)\).

Proof. By virtue of Remark 4.8.1.12, we may assume without loss of generality that \(\mathcal{C}\) is a \((1,1)\)-category: that is, it is isomorphic to \(\mathrm{N}_{\bullet}\left(\mathcal{C}_{0}\right)\), for some category \(\mathcal{C}_{0}\) (see Example 4.8.1.3). In this case, \(\mathcal{C}\) is a ( 0,1 )-category if and only if it satisfies the following additional conditions:
(0) The \(\infty\)-category \(\mathcal{C}\) is minimal in dimension 0 : that is, if \(X\) and \(Y\) are isomorphic objects of \(\mathcal{C}_{0}\), then \(X=Y\).
(1) The restriction map \(\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\Delta^{1}, \mathcal{C}\right) \rightarrow \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\partial \Delta^{1}, \mathcal{C}\right)\) is injective: that is, for every pair of objects \(X, Y \in \mathcal{C}_{0}\), there is at most one morphism from \(X\) to \(Y\).
(2) The restriction map \(\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\Delta^{2}, \mathcal{C}\right) \rightarrow \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\partial \Delta^{2}, \mathcal{C}\right)\) is bijective: that is, every diagram

in the category \(\mathcal{C}_{0}\) is automatically commutative.
Note that conditions (1) and (2) are equivalent to one another: they both assert that \(\mathcal{C}_{0}\) can be recovered from the set of objects \(Q=\operatorname{Ob}(\mathcal{C})\), endowed with the reflexive and transitive relation \(\leq_{Q}\) defined by
\[
\left(X \leq_{Q} Y\right) \Leftrightarrow \operatorname{Hom}_{\mathcal{C}_{0}}(X, Y) \neq \emptyset
\]

In this case, condition (0) is satisfied if and only if the relation \(\leq_{Q}\) is also antisymmetric: that is, the relation \(\leq_{Q}\) is a partial ordering of \(Q\).

057 V Remark 4.8.1.16. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(\mathcal{C}_{0} \subseteq \mathcal{C}\) be a simplicial subset which is also an \(\infty\)-category. If \(\mathcal{C}\) is an \((n, 1)\)-category for some integer \(n \geq-1\), then \(\mathcal{C}_{0}\) is also an ( \(n, 1\) )-category. For \(n \geq 1\), this follows from Remark 4.8.1.2. The case \(n=0\) follows from Proposition 4.8.1.15 (since any subcategory of a partially ordered set is also a partially ordered set), and the case \(n=-1\) is trivial (see Example 4.8.1.9).

057W Example 4.8.1.17. Let \(n \geq 0\) and let \(\mathcal{C}\) be an \((n, 1)\)-category. Then the core \(\mathcal{C}^{\simeq}\) is an \(n\)-groupoid. This follows by combining Remark 4.8.1.16 with Example 4.8.1.11.

Remark 4.8.1.18. Let \(\left\{\mathcal{C}_{j}\right\}_{j \in \mathcal{J}}\) be a diagram of simplicial sets having limit \(\mathcal{C}=\lim _{\check{\leftarrow}}{ }_{j \in \mathcal{J}} \mathcal{C}_{j}\)
057X and let \(n\) be an integer. If each \(\mathcal{C}_{j}\) is an \((n, 1)\)-category and \(\mathcal{C}\) is an \(\infty\)-category, then \(\mathcal{C}\) is also an ( \(n, 1\) )-category. For \(n \leq-2\), this is trivial (Example 4.8.1.10). The case \(n \geq-1\) follows from Remarks 4.8.1.14 and 4.8.1.16, since \(\mathcal{C}\) can be identified with a simplicial subset of the product \(\prod_{j \in J} \mathcal{C}_{j}\).

Proposition 4.8.1.19. Let \(n\) be a positive integer and let \(\mathcal{C}\) be an ( \(n, 1\) )-category. Then, for 057 Y every pair of objects \(X, Y \in \mathcal{C}\), the pinched morphism spaces \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) and \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) are \((n-1)\)-groupoids.

Proof. We will show that the right-pinched morphism space \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) is an \((n-1)\) groupoid; the analogous statement for the left-pinched morphism space \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) follows by a similar argument. If \(n=1\), then \(\mathcal{C}\) can be identified with the nerve of an ordinary category \(\mathcal{C}_{0}\) (Example 4.8.1.3) and the desired result follows from Example 4.6.5.12. We may therefore assume that \(n>1\). Since \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) is a Kan complex, it will suffice to show that it is an \((n-1,1)\)-category (Example 4.8.1.11). Let \(m \geq n\) and let \(\sigma_{0}\) and \(\sigma_{1}\) be \(m\)-simplices of \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) which satisfy \(\left.\sigma_{0}\right|_{\Lambda_{i}^{m}}=\left.\sigma_{1}\right|_{\Lambda_{i}^{m}}\) for some \(0<i<m\); we wish to show that \(\sigma_{0}=\sigma_{1}\). Let us identify \(\sigma_{0}\) and \(\sigma_{1}\) with morphisms \(\tau_{0}, \tau_{1}: \Delta^{m+1} \rightarrow \mathcal{C}\) which carry the simplicial subset \(\Delta^{m} \subset \Delta^{m+1}\) to the object \(X\) and the final vertex of \(\Delta^{m+1}\) to the object \(Y\). Our assumptions then guarantee that \(\tau_{0}\) and \(\tau_{1}\) have the same restriction to \(\Lambda_{i}^{m+1}\). Since \(\mathcal{C}\) is an ( \(n, 1\) )-category, it follows that \(\tau_{0}=\tau_{1}\).

Corollary 4.8.1.20. Let \(n\) be an integer and let \(\mathcal{C}\) be an (n,1)-category. Then, for every pair of objects \(X, Y \in \mathcal{C}\), the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is \((n-1)\)-truncated.

Proof. For \(n \leq-1\), there is nothing to prove (see Examples 4.8.1.10 and 4.8.1.9). The case \(n=0\) follows from Proposition 4.8.1.15. We may therefore assume \(n>0\). By virtue of Proposition 4.6.5.10, it will suffice to show that the pinched morphism space \(K=\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) is \((n-1)\)-truncated. This follows from Example 3.5.7.2, since \(K\) is an ( \(n-1\) )-groupoid (Proposition 4.8.1.19).

Warning 4.8.1.21. Let \(n \geq 1\) be an integer and let \(\mathcal{C}\) be an \((n, 1)\)-category. For every pair 0580 of objects \(X, Y \in \mathcal{C}\), Corollary 4.8.1.20 guarantees that the morphism space \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is ( \(n-1\) )-truncated, and is therefore homotopy equivalent to an \((n-1\) )-groupoid (for example, it is homotopy equivalent to the pinched morphism spaces \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) and \(\left.\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\right)\). Beware that, for \(n \geq 2\), the \(\operatorname{Kan}\) complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) itself is generally not an \((n-1)\) groupoid. For example, this usually fails in the case where \(\mathcal{C}=\mathrm{N}_{\bullet}^{\mathrm{D}}\left(\mathcal{C}_{0}\right)\) arises as the Duskin nerve of a 2 -category \(\mathcal{C}_{0}\) : see Remark 8.1.8.8. However, the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is always weakly \((n-1)\)-coskeletal: see Corollary 4.8.3.5.

0581 Proposition 4.8.1.22 (Exponentation for ( \(n, 1\) )-Categories). Let \(n\) be an integer and let \(\mathcal{C}\) be an \((n, 1)\)-category. Then, for any simplicial set \(K\), the simplicial set \(\operatorname{Fun}(K, \mathcal{C})\) is also an \((n, 1)\)-category.

Proof. It follows from Theorem 1.5 .3 .7 that \(\operatorname{Fun}(K, \mathcal{C})\) is an \(\infty\)-category. Since \(\mathcal{C}\) is weakly \(n\)-coskeletal, the \(\infty\)-category \(\operatorname{Fun}(K, \mathcal{C})\) is also weakly \(n\)-coskeletal (Corollary 3.5.4.13). To complete the proof, it will suffice to show that if \(n \geq 0\), then \(\operatorname{Fun}(K, \mathcal{C})\) is minimal in dimension \(n\) (Proposition 4.8.1.7). Suppose we are given a pair of \(n\)-simplices \(\sigma_{0}, \sigma_{1}: \Delta^{n} \rightarrow\) \(\operatorname{Fun}(K, \mathcal{C})\) and an isomorphism \(\sigma_{0} \xrightarrow{\sim} \sigma_{1}\) whose restriction to \(\partial \Delta^{n}\) is an identity morphism; we wish to show that \(\sigma_{0}=\sigma_{1}\). Let us identify \(\sigma_{0}\) and \(\sigma_{1}\) with diagrams \(f_{0}, f_{1}: \Delta^{n} \times K \rightarrow \mathcal{C}\). Since \(\mathcal{C}\) is weakly \(n\)-coskeletal, it will suffice to show that \(f_{0}\) and \(f_{1}\) coincide on \(m\)-simplices \(\tau=\left(\tau^{\prime}, \tau^{\prime \prime}\right)\) of \(\Delta^{n} \times K\) for \(m \leq n\). If \(\tau^{\prime}\) factors through the boundary \(\partial \Delta^{n}\), this follows immediately from the equality \(\left.\sigma_{0}\right|_{\partial \Delta^{n}}=\left.\sigma_{1}\right|_{\partial \Delta^{n}}\). We may therefore assume without loss of generality that \(m=n\) and that \(\tau^{\prime}: \Delta^{m} \rightarrow \Delta^{n}\) is the identity map. In this case, our assumption guarantees that there is an isomorphism of \(f_{0}(\tau)\) with \(f_{1}(\tau)\) whose image in \(\operatorname{Fun}\left(\partial \Delta^{n}, \mathcal{C}\right)\) is an identity morphism. The equality \(f_{0}(\tau)=f_{1}(\tau)\) now follows from the fact that \(\mathcal{C}\) is minimal in dimension \(n\) (Proposition 4.8.1.7).

0582 Corollary 4.8.1.23. Let \(n\) be an integer and let \(F_{0}: \mathcal{C}_{0} \rightarrow \mathcal{C}\) and \(F_{1}: \mathcal{C}_{1} \rightarrow \mathcal{C}\) be functors of \((n, 1)\)-categories. Then the oriented fiber product \(\mathcal{C}_{0} \tilde{x}_{\mathcal{C}} \mathcal{C}_{1}\) and the homotopy fiber product \(\mathcal{C}_{0} \times{ }_{\mathcal{C}}^{\mathrm{h}} \mathcal{C}_{1}\) are also \((n, 1)\)-categories.

Proof. By definition, the oriented fiber product \(\mathcal{C}_{0} \tilde{x}_{\mathcal{C}} \mathcal{C}_{1}\) can be realized as an iterated fiber product
\[
\mathcal{C}_{0} \times_{\operatorname{Fun}(\{0\}, \mathcal{C})} \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right) \times \operatorname{Fun}(\{1\}, \mathcal{C}) \mathcal{C}_{1},
\]
which is an \((n, 1)\)-category by virtue of Propositions 4.8.1.22 and Remark 4.8.1.18. The homotopy fiber product \(\mathcal{C}_{0} \times{ }_{\mathcal{C}}^{\mathrm{h}} \mathcal{C}_{1}\) is a full subcategory of \(\mathcal{C}_{0} \tilde{x}_{\mathcal{C}} \mathcal{C}_{1}\), which coincides with \(\mathcal{C}_{0} \tilde{x}_{\mathcal{C}} \mathcal{C}_{1}\) for \(n \leq-1\). Applying Remark 4.8.1.16, we see that it is also an \((n, 1)\)-category.

\subsection*{4.8.2 Locally Truncated \(\infty\)-Categories}

0583 We now formulate a homotopy-invariant counterpart of Definition 4.8.1.8.
0584 Definition 4.8.2.1. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n\) be an integer. We say that \(\mathcal{C}\) is locally \(n\)-truncated if, for every pair of objects \(X, Y \in \mathcal{C}\), the \(\operatorname{Kan}\) complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is \(n\)-truncated (see Definition 3.5.7.1).

0585 Example 4.8.2.2. Let \(n\) be an integer. Then every \((n, 1)\)-category is locally \((n-1)\)-truncated (Corollary 4.8.1.20). In particular:
- If \(Q\) is a partially ordered set, then the nerve \(\mathrm{N}_{\bullet}(Q)\) is locally \((-1)\)-truncated \(\infty\) category (Proposition 4.8.1.15).
- If \(\mathcal{C}\) is an ordinary category, then the nerve \(\mathrm{N}_{\bullet}(\mathcal{C})\) is a locally 0 -truncated \(\infty\)-category (Example 4.8.1.3).
- If \(\mathcal{C}\) is a 2 -category in which every 2 -morphism is an isomorphism, then the Duskin nerve \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{C})\) is a locally 1 -truncated \(\infty\)-category (Example 4.8.1.4).

Remark 4.8.2.3. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a fully faithful functor of \(\infty\)-categories. If \(\mathcal{D}\) is 0586 locally \(n\)-truncated, then \(\mathcal{C}\) is locally \(n\)-truncated. The converse holds if \(F\) is an equivalence of \(\infty\)-categories. In particular, if \(\infty\)-categories \(\mathcal{C}\) and \(\mathcal{D}\) are equivalent, then \(\mathcal{C}\) is locally \(n\)-truncated if and only if \(\mathcal{D}\) is locally \(n\)-truncated.

Let \(\mathcal{C}\) be an \(\infty\)-category. Combining Example 4.8 .2 .2 with Remark 4.8.2.3, we see for \(\mathcal{C}\) to be equivalent to an ( \(n, 1\) )-category, it is necessary for \(\mathcal{C}\) to be locally ( \(n-1\) )-truncated. In \(\$ 4.8 .3\), we will prove that this condition is also sufficient, provided that \(n \geq-1\) (Corollary 4.8.3.3.

Example 4.8.2.4. Let \(n \geq-1\) be an integer and let \(X\) be a Kan complex. Then \(X\) is 0587 \(n\)-truncated (in the sense of Definition 3.5.7.1) if and only if it is locally ( \(n-1\) )-truncated when regarded as an \(\infty\)-category (in the sense of Definition 4.8.2.1). This is reformulation of Example 3.5.9.18. See Corollary 4.8.3.11 for a more general statement.

Remark 4.8.2.5. Let \(\mathcal{C}\) be an \(\infty\)-category containing a pair of objects \(X, Y \in \mathcal{C}\). For every 0588 integer \(n\), the following conditions are equivalent:
- The morphism space \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is \(n\)-truncated.
- The left-pinched morphism space \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) is \(n\)-truncated.
- The right-pinched morphism space \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) is \(n\)-truncated.

This follows from Corollary 3.5.7.12, since the pinch inclusion maps
\[
\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y) \hookrightarrow \operatorname{Hom}_{\mathcal{C}}(X, Y) \hookleftarrow \operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)
\]
are homotopy equivalences (Proposition 4.6.5.10).
Proposition 4.8.2.6. Let \(\mathcal{C}\) be a locally Kan simplicial category. For every integer n, the 0589 following conditions are equivalent:
- The homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) is locally \(n\)-truncated.
- For every pair of objects \(X, Y \in \mathcal{C}\), the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) • is n-truncated.

Proof. For every pair of objects \(X, Y \in \mathcal{C}\), Theorem 4.6.8.5 supplies a homotopy equivalence from \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) • to the pinched morphism space \(\operatorname{Hom}_{\mathrm{N}_{\bullet}(\mathcal{C})}^{\mathrm{L}}(X, Y)\). The desired result now follows from Remark 4.8.2.5.

058 A Variant 4.8.2.7. Let \(\mathcal{C}\) be a differential graded category. For every integer \(n \geq-1\), the following conditions are equivalent:
- The differential graded nerve \(\mathrm{N}_{\bullet}^{\mathrm{dg}}(\mathcal{C})\) is locally \(n\)-truncated.
- For every pair of objects \(X, Y \in \mathcal{C}\), the chain complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}\) is homologically \(n\)-truncated: that is, the homology groups \(\mathrm{H}_{m}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}\right)\) vanish for \(m>n\).

Proof. For every pair of objects \(X, Y \in \mathcal{C}\), Example 4.6.5.15 supplies an isomorphism from of the Eilenberg-MacLane space \(\mathrm{K}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{*}\right)\) with the pinched morphism space \(\operatorname{Hom}_{\mathrm{N}^{\mathrm{dg}}(\mathcal{C})}^{\mathrm{L}}(X, Y)\). The result now follows by combining Remark 4.8 .2 .5 with the criterion of Example 3.5.7.10.

Example 4.8.2.2 admits a slight generalization:
058B Proposition 4.8.2.8. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n\) be an integer. If \(\mathcal{C}\) is an \(n\)-coskeletal simplicial set (Definition 3.5.3.1), then it is locally \((n-2)\)-truncated.

Proof. For every pair of objects \(X, Y \in \mathcal{C}\), our assumption that \(\mathcal{C}\) is \(n\)-coskeletal guarantees that the pinched morphism space \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) is \((n-1)\)-coskeletal (Remark 4.6.5.4). In particular, it is \((n-2)\)-truncated (Example 3.5.7.2). The desired result now follows from Remark 4.8.2.5

Our next goal is to show that every \(\infty\)-category \(\mathcal{C}\) admits an optimal approximation by a locally \(n\)-truncated \(\infty\)-category.

058C Definition 4.8.2.9. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n\) be an integer. We say that \(F\) exhibits \(\mathcal{D}\) as a local n-truncation of \(\mathcal{C}\) if the following conditions are satisfied:
(1) The functor \(F\) is essentially surjective (Definition 4.6.2.11).
(2) For every pair of objects \(X, Y \in \mathcal{C}\), the induced map of Kan complexes
\[
F_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))
\]
exhibits \(\operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\) as an \(n\)-truncation of \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\), in the sense of Definition 3.5.7.19

058D Remark 4.8.2.10. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n\) be an integer. Suppose that \(F\) exhibits \(\mathcal{D}\) as a local \(n\)-truncation of \(\mathcal{C}\). Then \(\mathcal{D}\) is locally \(n\)-truncated: that is, for every pair of objects \(\bar{X}, \bar{Y} \in \mathcal{D}\), the morphism space \(\operatorname{Hom}_{\mathcal{D}}(\bar{X}, \bar{Y})\) is \(n\)-truncated. To prove this, we can use the essential surjectivity of \(F\) to reduce to the case where \(\bar{X}=F(X)\) and \(\bar{Y}=F(Y)\) for some objects \(X, Y \in \mathcal{C}\). In this case, the assertion follows from the observation that \(\operatorname{Hom}_{\mathcal{D}}(\bar{X}, \bar{Y})\) is an \(n\)-truncation of \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\).

Conversely, if \(\mathcal{D}\) is locally \(n\)-truncated, then \(F\) exhibits \(\mathcal{D}\) as a local \(n\)-truncation of \(\mathcal{C}\) if and only if it is essentially surjective and satisfies the following weaker version of condition (2):
(2') For every pair of objects \(X, Y \in \mathcal{C}\), the map of Kan complexes
\[
F_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))
\]
is \((n+1)\)-connective.
Example 4.8.2.11. Let \(\mathcal{C}\) be an \(\infty\)-category and let hC be its homotopy category. Then 058 E the tautological map \(\mathcal{C} \rightarrow \mathrm{N}_{\bullet}(\mathrm{hC})\) exhibits \(\mathrm{N}_{\bullet}(\mathrm{hC})\) as a local 0 -truncation of \(\mathcal{C}\).

Remark 4.8.2.12. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories, where \(F 058 \mathrm{~F}\) exhibits \(\mathcal{D}\) as a local \(n\)-truncation of \(\mathcal{C}\). Then \((G \circ F): \mathcal{C} \rightarrow \mathcal{E}\) exhibits \(\mathcal{E}\) as an \(n\)-truncation of \(\mathcal{C}\) if and only if \(G\) is an equivalence of \(\infty\)-categories.

Proposition 4.8.2.13. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(n \geq 0\) be an integer, and let \(\operatorname{cosk}_{n}(\mathcal{C}) 058 \mathrm{G}\) denote the \(n\)-coskeleton of \(\mathcal{C}\) (Notation 3.5.3.18). Then:
(1) The simplicial set \(\operatorname{cosk}_{n}(\mathcal{C})\) is an \(\infty\)-category.
(2) The tautological map \(\mathcal{C} \rightarrow \operatorname{cosk}_{n}(\mathcal{C})\) exhibits \(\operatorname{cosk}_{n}(\mathcal{C})\) as a local \((n-2)\)-truncation of \(\mathcal{C}\).

Proof. We first prove (1). We proceed as in the proof of Proposition 3.5.3.23. Fix integers \(0<i<m\) and a morphism of simplicial sets \(\sigma_{0}: \Lambda_{i}^{m} \rightarrow \operatorname{cosk}_{n}(\mathcal{C})\); we wish to show that \(\sigma_{0}\) can be extended to an \(m\)-simplex of \(\operatorname{cosk}_{n}(\mathcal{C})\). Using Remark 3.5.3.21, we can identify \(\sigma_{0}\) with a morphism of simplicial sets \(f_{0}: \operatorname{sk}_{n}\left(\Lambda_{i}^{m}\right) \rightarrow \mathcal{C}\); we wish to show that \(f_{0}\) can be extended to the \(n\)-skeleton of \(\Delta^{m}\). If \(n<m-1\), then \(\operatorname{sk}_{n}\left(\Lambda_{i}^{m}\right)=\operatorname{sk}_{n}\left(\Delta^{m}\right)\) and there is nothing to prove. We may therefore assume that \(n \geq m-1\), so that \(\operatorname{sk}_{n}\left(\Lambda_{i}^{m}\right)=\Lambda_{i}^{m}\). In this case, our assumption that \(\mathcal{C}\) is an \(\infty\)-category guarantees that \(f_{0}\) can be extended to an \(n\)-simplex of \(\mathcal{C}\).

We now prove (2). By construction, the tautological map \(F: \mathcal{C} \rightarrow \operatorname{cosk}_{n}(\mathcal{C})\) is bijective on objects, and therefore essentially surjective. By virtue of Proposition 4.6.5.10, it will suffice to show that for every pair of objects \(X, Y \in \mathcal{C}\), the induced map of pinched morphism spaces
\[
\theta: \operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y) \rightarrow \operatorname{Hom}_{\operatorname{cosk}_{n}(\mathcal{C})}^{\mathrm{L}}(X, Y)
\]
exhibits \(\operatorname{Hom}_{\operatorname{cosk}_{n}(\mathcal{C})}^{\mathrm{L}}(X, Y)\) as an \((n-2)\)-truncation of \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\). This is a special case of Example 3.5.7.23. since \(\theta\) exhibits \(\operatorname{Hom}_{\operatorname{cosk}_{n}(\mathcal{C})}^{\mathrm{L}}(X, Y)\) as an \((n-1)\)-coskeleton of \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) (Remark 4.6.5.4).

058H Proposition 4.8.2.14. Let \(n\) be an integer and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories which exhibits \(\mathcal{D}\) as a local n-truncation of \(\mathcal{C}\). Then \(\mathcal{C}\) is locally \(n\)-truncated if and only if \(F\) is an equivalence of \(\infty\)-categories.

Proof. By assumption, \(F\) is essentially surjective. It follows from Theorem 4.6.2.20 that \(F\) is an equivalence of \(\infty\)-categories if and only if, for every pair of objects \(X, Y \in \mathcal{C}\), the induced map of Kan complexes
\[
F_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))
\]
is a homotopy equivalence. Since \(F_{X, Y}\) exhibits \(\operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\) as an \(n\)-truncation of \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\), this is equivalent to the requirement that \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is \(n\)-truncated.

058J Corollary 4.8.2.15. Let \(\mathcal{C}\) be an \(\infty\)-category and let hC denote its homotopy category. The following conditions are equivalent:
(1) The \(\infty\)-category \(\mathcal{C}\) is locally 0 -truncated.
(2) The comparison map \(\mathcal{C} \rightarrow \mathrm{N}_{\bullet}(\mathrm{hC})\) is an equivalence of \(\infty\)-categories.
(3) The comparison map \(\mathcal{C} \rightarrow \mathrm{N}_{\bullet}(\mathrm{hC})\) is a trivial Kan fibration.
(4) The \(\infty\)-category \(\mathcal{C}\) is equivalent to (the nerve of) an ordinary category.

Proof. The implication \((1) \Rightarrow(2)\) follows from Example 4.8.2.11 and Proposition 4.8.2.14 Since the comparison map \(\mathcal{C} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is an isofibration (Corollary 4.4.1.9), the equivalence \((2) \Leftrightarrow(3)\) follows from Proposition 4.5.5.20. The implication \((2) \Rightarrow(4)\) is clear, and the implication \((4) \Rightarrow(1)\) follows from Example 4.8.2.2.

058K Exercise 4.8.2.16. Show that an \(\infty\)-category \(\mathcal{C}\) is locally \((-1)\)-truncated if and only if there is an equivalence of \(\infty\)-categories \(u: \mathcal{C} \rightarrow \mathrm{N}_{\bullet}(Q)\), for some partially ordered set \(Q\). In this case, the morphism \(u\) is automatically a trivial Kan fibration (see Example 4.4.1.6 and Proposition 4.5.5.20.

058L Corollary 4.8.2.17. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n \geq 0\) be an integer. The following conditions are equivalent:
(1) The \(\infty\)-category \(\mathcal{C}\) is locally \((n-2)\)-truncated.
(2) The tautological map \(\mathcal{C} \rightarrow \operatorname{cosk}_{n}(\mathcal{C})\) is an equivalence of \(\infty\)-categories.
(3) There exists an \(n\)-coskeletal \(\infty\)-category \(\mathcal{D}\) which is equivalent to \(\mathcal{C}\).

Proof. The implication (1) \(\Rightarrow(2)\) follows from Propositions 4.8.2.13 and 4.8.2.14 The implication \((2) \Rightarrow(3)\) is clear (since \(\operatorname{cosk}_{n}(\mathcal{C})\) is an \(\infty\)-category), and the implication \((3) \Rightarrow(1)\) follows from Proposition 4.8.2.8 (together with Remark 4.8.2.3).

Local \(n\)-truncations can be characterized by a universal mapping property:
Proposition 4.8.2.18. Let \(n\) be an integer and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, 058M where \(\mathcal{D}\) is locally \(n\)-truncated. The following conditions are equivalent:
(1) The functor \(F\) exhibits \(\mathcal{D}\) as a local n-truncation of \(\mathcal{C}\), in the sense of Definition 4.8.2.9.
(2) For every locally \(n\)-truncated \(\infty\)-category \(\mathcal{E}\), precomposition with \(F\) induces an equivalence of \(\infty\)-categories \(\operatorname{Fun}(\mathcal{D}, \mathcal{C}) \rightarrow \operatorname{Fun}(\mathcal{C}, \mathcal{E})\).
(3) For every locally n-truncated \(\infty\)-category \(\mathcal{E}\), precomposition with \(F\) induces a bijection
\[
\pi_{0}\left(\operatorname{Fun}(\mathcal{D}, \mathcal{E})^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}(\mathcal{C}, \mathcal{E})^{\simeq}\right)
\]

Proof. Without loss of generality we may assume that \(n \geq-2\). We first show that (1) implies (2). By virtue of Corollary 4.8.2.17, we can assume without loss of generality that \(\mathcal{D}\) and \(\mathcal{E}\) are \((n+2)\)-coskeletal. In this case, \(F\) factors (uniquely) as a composition \(\mathcal{C} \xrightarrow{F^{\prime}} \operatorname{cosk}_{n+2}(\mathcal{C}) \xrightarrow{F^{\prime \prime}} \mathcal{D}\), where \(F^{\prime}\) exhibits \(\operatorname{cosk}_{n+2}(\mathcal{C})\) as a local \(n\)-truncation of \(\mathcal{C}\) (Proposition 4.8.2.13). Applying Remark 4.8.2.12, we see that \(F^{\prime \prime}\) is an equivalence of \(\infty\)-categories. We may therefore replace \(\mathcal{D}\) by \(\operatorname{cosk}_{n+2}(\mathcal{C})\) and thereby reduce to the case where \(F\) exhibits \(\mathcal{D}\) as an \((n+2)\)-coskeleton of \(\mathcal{C}\). In this case, Proposition 3.5.3.17 guarantees that the precomposition functor
\[
\operatorname{Fun}(\mathcal{D}, \mathcal{E}) \xrightarrow{\circ F} \operatorname{Fun}(\mathcal{C}, \mathcal{E})
\]
is an isomorphism of simplicial sets (and therefore an equivalence of \(\infty\)-categories).
The implication \((2) \Rightarrow(3)\) follows immediately from the definitions. We will complete the proof by showing that (3) implies (1). As before, we may assume that \(\mathcal{D}=\operatorname{cosk}_{n+2}(\mathcal{D})\) is \((n+2)\)-coskeletal from Proposition 4.5.1.22, so that \(F\) factors (uniquely) as a composition \(\mathcal{C} \xrightarrow{F^{\prime}} \operatorname{cosk}_{n+2}(\mathcal{C}) \xrightarrow{F^{\prime \prime}} \mathcal{D}\); we wish to show that the homotopy class \(\left[F^{\prime \prime}\right]\) is an isomorphism in the homotopy category hQCat. Since \(\operatorname{cosk}_{n+2}(\mathcal{C})\) and \(\mathcal{D}\) are locally \(n\)-truncated, it will suffice to show that for every locally \(n\)-truncated \(\infty\)-category \(\mathcal{E}\), the horizontal map in the diagram

is a bijection. This is clear, since the vertical maps are bijections.

Let hQCat denote the homotopy category of \(\infty\)-categories (Construction 4.5.1.1). For every integer \(n \geq-1\), we let hQCat \({ }^{\leq n}\) denote the full subcategory of hQCat spanned by the those \(\infty\)-categories \(\mathcal{C}\) which are locally \((n-1)\)-truncated. We then have the following:
058 N Corollary 4.8.2.19. Let \(n \geq-1\) be an integer. Then the inclusion functor \(\mathrm{hQCat}^{\leq n} \hookrightarrow\) hQCat admits a left adjoint, given on objects by the construction \(\mathcal{C} \mapsto \operatorname{cosk}_{n+1}(\mathcal{C})\).

\subsection*{4.8.3 Minimality Conditions}
\(058 \mathrm{P} \quad\) Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n\) be an integer. We then have the following implications (see Proposition 4.8.2.8):

Beware that, in general, none of these implications is reversible. However, the failure of reversibility can be measured using the minimality conditions introduced in §4.7.6.

058 Q Proposition 4.8.3.1. Let \(n\) be an integer and let \(\mathcal{C}\) be an \(\infty\)-category. Assume that, if \(n \leq-2\), then \(\mathcal{C}\) is nonempty. Then:
(1) The \(\infty\)-category \(\mathcal{C}\) is \((n+1)\)-coskeletal if and only if it is locally \((n-1)\)-truncated and minimal in dimensions \(\geq n+2\) (see Definition 4.7.6.4).
(2) The \(\infty\)-category \(\mathcal{C}\) is weakly \(n\)-coskeletal if and only if it is locally \((n-1)\)-truncated and minimal in dimensions \(\geq n+1\).
(3) The \(\infty\)-category \(\mathcal{C}\) is an \((n, 1)\)-category if and only if it is locally \((n-1)\)-truncated and minimal in dimensions \(\geq n\).

We will give the proof of Proposition 4.8.3.1 at the end of this section. First, let us collect some consequences.

Corollary 4.8.3.2. Let \(\mathcal{C}\) be a minimal \(\infty\)-category and let \(n \geq-1\) be an integer. Then \(\mathcal{C} 058 \mathrm{R}\) is an \((n, 1)\)-category if and only if it is locally \((n-1)\)-truncated.

Corollary 4.8.3.3. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n \geq-1\) be an integer. Then \(\mathcal{C}\) is locally 058 S ( \(n-1\) )-truncated if and only if it is equivalent to an ( \(n, 1\) )-category.

Proof. Combine Proposition 4.7.6.15 with Corollary 4.8.3.2
Corollary 4.8.3.4. Let \(n\) be an integer and let \(\mathcal{C}\) be an \(\infty\)-category which is weakly \((n-1)-058 \mathrm{~T}\) coskeletal. Then \(\mathcal{C}\) is an ( \(n, 1\) )-category.

Corollary 4.8.3.5. Let \(n\) be an integer and let \(\mathcal{C}\) be an ( \(n, 1\) )-category. Then, for every 058 U pair of objects \(X, Y \in \mathcal{C}\), the morphism space \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is weakly \((n-1)\)-coskeletal.

Proof. For \(n<0\), the result is trivial (see Example 4.8.1.9). We will therefore assume that \(n \geq 0\). It follows from Corollary 4.8.1.23 that the morphism space \(\operatorname{Hom}_{\mathcal{C}}(X, Y)=\) \(\{X\} \tilde{x}_{\mathcal{C}}\{Y\}\) is also ( \(n, 1\) )-category; in particular, it is minimal in dimensions \(\geq n\). Since \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is \((n-1)\)-truncated (Corollary 4.8.1.20), it is locally \((n-2)\)-truncated (Example 4.8.2.4). Applying Proposition 4.8.3.1, we conclude that \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) is weakly \((n-1)\) coskeletal.

Our proof of Proposition 4.8.3.1 will make use of some auxiliary results of independent interest. Recall that, if \(\mathcal{C}\) is a simplicial set, then the weak \(n\)-coskeleton \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) is the simplicial subset of \(\operatorname{cosk}_{n}(\mathcal{C})\) given by the image of the tautological map \(\operatorname{cosk}_{n+1}(\mathcal{C}) \rightarrow\) \(\operatorname{cosk}_{n}(\mathcal{C})\) (see Notation 3.5.4.19).

Proposition 4.8.3.6. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(n\) be an integer, and let \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) denote 058 V the weak \(n\)-coskeleton of \(\mathcal{C}\). Then:
(1) The simplicial set \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) is an \(\infty\)-category.
(2) The tautological map \(F: \mathcal{C} \rightarrow \operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) is an inner fibration of \(\infty\)-categories.
(3) If \(n \geq-1\), the functor \(F\) exhibits exhibits \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) as a local \((n-1)\)-truncation of \(\mathcal{C}\).
(4) If \(n \neq 0\), then \(F\) is an isofibration of \(\infty\)-categories.

Proof. For \(n<0\), the weak coskeleton \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) is either empty (if \(n=-1\) and \(\mathcal{C}\) is empty) or isomorphic to \(\Delta^{0}\); in either case, assertions (1) through (4) are clear. We may therefore assume that \(n \geq 0\). The map \(F\) factors as a composition
\[
\mathcal{C} \xrightarrow{F^{\prime}} \operatorname{cosk}_{n+1}(\mathcal{C}) \xrightarrow{F^{\prime \prime}} \operatorname{cosk}_{n}^{\circ}(\mathcal{C}),
\]
where \(F^{\prime \prime}\) is a trivial Kan fibration (Proposition 3.5.4.22). Since \(\operatorname{cosk}_{n+1}(\mathcal{C})\) is an \(\infty\)-category (Proposition 4.8.2.13), assertion (1) follows from Proposition 1.5.5.11.

To prove (2), we proceed as in Proposition 3.5.4.26. Suppose we are given a pair of integers \(0<i<m\); we wish to show that every lifting problem

admits a solution. We consider two cases:
- If \(m \leq n+1\), then we can choose an \(m\)-simplex \(\sigma\) of \(\mathcal{C}\) satisfying \(F(\sigma)=\bar{\sigma}\). Since \(F\) is bijective on simplices of dimension \(\leq n\), the commutativity of the diagram 4.48) guarantees that \(\left.\sigma\right|_{\Lambda_{i}^{m}}=\sigma_{0}\).
- If \(m \geq n+2\), then our assumption that \(\mathcal{C}\) is an \(\infty\)-category guarantees that \(\sigma_{0}\) can be extended to an \(m\)-simplex \(\sigma\) of \(X\). The commutativity of the diagram (4.48) then guarantees that \(F(\sigma)\) and \(\bar{\sigma}\) have the same restriction to the horn \(\Lambda_{i}^{m} \subset \Delta^{m}\). In particular, they have the same restriction to the \(n\)-skeleton of \(\Delta^{m}\), so \(F(\sigma)=\bar{\sigma}\).

Since \(F^{\prime \prime}\) is an equivalence of \(\infty\)-categories, assertion (3) follows by combining Proposition 4.8 .2 .13 with Remark 4.8.2.12. It remains to prove (4). Let \(Y\) be an object of \(\mathcal{C}\) and suppose we are given an isomorphism morphism \(\bar{u}: \bar{X} \rightarrow Y\) in the \(\infty\)-category \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C})\). If \(n \geq 1\), then \(F\) is bijective on vertices and edges; it follows that we can write \(\bar{u}=F(u)\) for a unique morphism \(u: X \rightarrow Y\) in \(\mathcal{C}\). To complete the proof, it will suffice to show that \(u\) is an isomorphism. Equivalently, we wish to show that the homotopy class \([u]\) is an isomorphism in the homotopy category hC . This is clear: the nerve \(\mathrm{N}_{\bullet}(\mathrm{hC})\) is weakly 1coskeletal (Example 3.5.4.6), so the tautological map \(\mathcal{C} \rightarrow \mathrm{N}_{\bullet}(\mathrm{hC})\) factors (uniquely) through \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) (Proposition 3.5.4.18).

058X Warning 4.8.3.7. . The functor \(F: \mathcal{C} \rightarrow \operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) is generally not an isofibration in the case \(n=0\).

058 Y Warning 4.8.3.8. In the situation of Proposition 4.8.3.6 the \(\operatorname{map} \mathcal{C} \rightarrow \operatorname{cosk}_{n+1}(\mathcal{C})\) is generally not an inner fibration.

0582 Corollary 4.8.3.9. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n \geq-2\) be an integer. Then \(\mathcal{C}\) is locally \(n\)-truncated if and only if the tautological map \(F: \mathcal{C} \rightarrow \operatorname{cosk}_{n+1}^{\circ}(\mathcal{C})\) is a trivial Kan fibration.

Proof. It follows from Proposition 4.8.3.6 that \(F\) exhibits \(\operatorname{cosk}_{n+1}^{\circ}(\mathcal{C})\) as a local \(n\)-truncation of \(\mathcal{C}\). Applying Proposition 4.8.2.14, we see that \(\mathcal{C}\) is locally \(n\)-truncated if and only if \(F\) is an equivalence of \(\infty\)-categories. We wish to show that if this condition is satisfied, then \(F\)
is a trivial Kan fibration. By virtue of Proposition 4.5.5.20, it will suffice to show that \(F\) is an isofibration. For \(n \neq-1\), this is automatic (Proposition 4.8.3.6). We will therefore assume that \(n=-1\). Using Proposition 4.8.3.6, we see that \(F\) is an inner fibration. Fix a morphism \(\bar{u}: \bar{X} \rightarrow \bar{Y}\) in the \(\infty\)-category \(\operatorname{cosk}_{0}^{\circ}(\mathcal{C})\). Then there are unique objects \(X, Y \in \mathcal{C}\) satisfying \(\bar{X}=F(X)\) and \(\bar{Y}=F(Y)\). Choose a morphism \(u: X \rightarrow Y\) satisfying \(F(u)=\bar{u}\). To complete the proof, it will suffice to show that if \(\bar{u}\) is an isomorphism in \(\operatorname{cosk}_{0}^{\circ}(\mathcal{C})\), then \(u\) is an isomorphism in \(\mathcal{C}\). Let \(\bar{v}: \bar{Y} \rightarrow \bar{X}\) be a homotopy inverse to \(\bar{u}\). Then we can write \(\bar{v}=F(v)\) for some morphism \(v: Y \rightarrow X\) of \(\mathcal{C}\). Since the mapping space \(\operatorname{Hom}_{\mathcal{C}}(X, X)\) is either empty or contractible, the composition \(v \circ u\) is automatically homotopic to \(\mathrm{id}_{X}\) : that is \(v\) is a left homotopy inverse to \(u\). A similar argument shows that \(v\) is right homotopy inverse to \(u\), so that \(u\) is an isomorphism as desired.

Corollary 4.8.3.10. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n \geq 0\) be an integer. The following 0590 conditions are equivalent:
(1) For every morphism \(f: X \rightarrow Y\) of \(\mathcal{C}\), the set \(\pi_{n}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y), f\right)\) consists of a single element.
(2) Every diagram \(\partial \Delta^{n+2} \rightarrow \mathcal{C}\) can be extended to an \((n+2)\)-simplex of \(\mathcal{C}\).

Proof. By virtue of Proposition 4.8.2.13, we can replace \(\mathcal{C}\) by \(\operatorname{cosk}_{n+2}(\mathcal{C})\) and thereby reduce to the case where the \(\infty\)-category \(\mathcal{C}\) is \((n+2)\)-coskeletal. In this case, the \(\infty\)-category \(\mathcal{C}\) is locally \(n\)-truncated (Proposition 4.8.2.8), and satisfies condition (1) if and only if it is locally ( \(n-1\) )-truncated. Applying Corollary 4.8.3.9, we see that (1) is equivalent to the following:
(1') The tautological map \(\mathcal{C} \rightarrow \operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) is a trivial Kan fibration.
The equivalence of ( \(1^{\prime}\) ) and (2) now follows from Corollary 3.5.4.24.
Corollary 4.8.3.11. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n \geq-2\) be an integer. Then \(\mathcal{C}\) is 0591 locally \(n\)-truncated if and only if the restriction map
\[
\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\Delta^{m}, \mathcal{C}\right) \rightarrow \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\partial \Delta^{m}, \mathcal{C}\right)
\]
is surjective for every integer \(m \geq n+3\).
Proposition 4.8.3.12. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(m>0\) be an integer. Then the 0592 restriction map
\[
\theta_{m}: \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\Delta^{m}, \mathcal{C}\right) \rightarrow \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\partial \Delta^{m}, \mathcal{C}\right)
\]
is injective if and only if the following conditions are satisfied:
(1) The \(\infty\)-category \(\mathcal{C}\) is minimal in dimension \(m\).
(2) The restriction map \(\theta_{m+1}\) is surjective.

0593 Remark 4.8.3.13. In the case \(m=0\), the formulation of Proposition 4.8.3.12 requires a slight modification. The restriction map \(\theta_{0}\) is injective if and only if \(\mathcal{C}\) satisfies the following pair of conditions:
(1) The \(\infty\)-category \(\mathcal{C}\) is minimal in dimension 0 : that is, if \(X\) and \(Y\) are isomorphic objects of \(\mathcal{C}\), then \(X=Y\).
(2') For every pair of objects \(X, Y \in \mathcal{C}\), there exists an isomorphism from \(X\) to \(Y\).
Note that condition \(\left(2^{\prime}\right)\) is stronger than condition (2) of Proposition 4.8.3.12, which demands only that there exists a morphism from \(X\) to \(Y\).

Proof of Proposition 4.8.3.12. Let \(\mathcal{C}\) be an integer and let \(m>0\) be an integer. It follows immediately from the definitions that, if the restriction map
\[
\theta_{m}: \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\Delta^{m}, \mathcal{C}\right) \rightarrow \operatorname{Hom}_{\text {Set }_{\Delta}}\left(\partial \Delta^{m}, \mathcal{C}\right)
\]
is injective, then \(\mathcal{C}\) is minimal in dimension \(m\). We claim that, if this condition is satisfied, then \(\theta_{m+1}\) is surjective: that is, every morphism \(\tau_{0}: \partial \Delta^{m+1} \rightarrow \mathcal{C}\) can be extended to an \((m+1)\)-simplex of \(\mathcal{C}\). Fix an integer \(0<i<m+1\). Our assumption that \(\mathcal{C}\) is an \(\infty\)-category guarantees that we can choose an \((m+1)\)-simplex \(\tau\) of \(\mathcal{C}\) satisfying \(\left.\tau\right|_{\Lambda_{i}^{m+1}}=\left.\tau_{0}\right|_{\Lambda_{i}^{m+1}}\). In particular, \(\tau\) and \(\tau_{0}\) have the same restriction to the \((m-1)\)-skeleton of \(\Delta^{m+1}\). Invoking the injectivity of \(\theta_{m}\), we conclude that \(\left.\tau\right|_{\partial \Delta^{m+1}}=\tau_{0}\).

We now prove the converse. Assume that \(\mathcal{C}\) is minimal in dimension \(m\) and that \(\theta_{m+1}\) is surjective; we wish to show that \(\theta_{m}\) is injective. Let \(\sigma_{0}\) and \(\sigma_{1}\) be \(m\)-simplices of \(\mathcal{C}\) which have the same restriction to \(\partial \Delta^{m}\); we wish to show that \(\sigma_{0}=\sigma_{1}\). Let
\[
X(0) \subset X(1) \subset \cdots \subset X(m) \subset X(m+1)=\Delta^{1} \times \Delta^{m}
\]
be the filtration of Lemma 3.1.2.12, so that \(X(0)=\left(\Delta^{1} \times \partial \Delta^{m}\right) \cup\left(\{1\} \times \Delta^{m}\right)\) and the inclusion map \(X(i) \hookrightarrow X(i+1)\) is inner anodyne for \(0 \leq i<m\). There is a unique morphism of simplicial sets \(h_{0}: X(0) \rightarrow \mathcal{C}\) such that \(\left.h_{0}\right|_{\{1\} \times \Delta^{m}}\) coincides with \(\sigma_{1}\), and \(\left.h_{0}\right|_{\Delta^{1} \times \partial \Delta^{m}}\) factors through the projection map \(\Delta^{1} \times \partial \Delta^{m} \rightarrow \partial \Delta^{m}\). Since \(\mathcal{C}\) is an \(\infty\)-category, we can extend \(h_{0}\) to a diagram \(h_{m}: X(m) \rightarrow \mathcal{C}\). Invoking the surjectivity of \(\theta_{m+1}\), we see that \(h_{m}\) can be extended to a morphism \(h: \Delta^{1} \times \Delta^{m} \rightarrow \mathcal{C}\) satisfying \(\left.h\right|_{\{0\} \times \Delta^{m}}=\sigma_{0}\). By construction, \(h\) is an isomorphism from \(\sigma_{0}\) to \(\sigma_{1}\) in the \(\infty\)-category \(\operatorname{Fun}\left(\Delta^{m}, \mathcal{C}\right)\) whose image in \(\operatorname{Fun}\left(\partial \Delta^{m}, \mathcal{C}\right)\) is an identity morphism. Since \(\mathcal{C}\) is minimal in dimension \(m\), it follows that \(\sigma_{0}=\sigma_{1}\).

Proof of Proposition 4.8.3.1. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n\) be an integer. For every integer \(m \geq 0\), we let \(\theta_{m}: \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\Delta^{m}, \mathcal{C}\right) \rightarrow \operatorname{Hom}_{\text {Set }_{\Delta}}\left(\partial \Delta^{m}, \mathcal{C}\right)\) denote the restriction
map. By virtue of Corollary 4.8.3.11, the map \(\theta_{m}\) is surjective for \(m \geq n+2\) if and only if \(\mathcal{C}\) is locally \((n-1)\)-truncated (and nonempty if \(n \leq-2\) ). Assume that these equivalent conditions are satisfied. Then:
(1) The \(\infty\)-category \(\mathcal{C}\) is \((n+1)\)-coskeletal if and only if \(\theta_{m}\) is injective for \(m \geq n+2\). By virtue of Proposition 4.8.3.12 (and Remark 4.8.3.13), this is equivalent to the requirement that \(\mathcal{C}\) is minimal in dimensions \(\geq n+2\).
(2) The \(\infty\)-category \(\mathcal{C}\) is weakly \(n\)-coskeletal if and only if \(\theta_{m}\) is injective for \(m \geq n+1\). By virtue of Proposition 4.8.3.12 (and Remark 4.8.3.13), this is equivalent to the requirement that \(\mathcal{C}\) is minimal in dimensions \(\geq n+1\).
(3) The \(\infty\)-category \(\mathcal{C}\) is an ( \(n, 1\) )-category if and only if \(\mathcal{C}\) is minimal in dimensions \(\geq n\). This follows immediately from (2) (see Definition 4.8.1.8).

We conclude this section by recording another consequence of Proposition 4.8.3.12.
Corollary 4.8.3.14. Let \(X\) be a Kan complex and let \(n\) be a nonnegative integer. The 0594 following conditions are equivalent:
(a) The Kan complex \(X\) is \(n\)-reduced: that is, it has a single \(m\)-simplex for each \(0 \leq m \leq n\) (Definition 3.5.2.8).
(b) The Kan complex \(X\) is \((n+1)\)-connective and minimal in dimensions \(\leq n\).

Proof. Without loss of generality, we may assume that \(X\) is nonempty (otherwise, neither (a) nor (b) is satisfied). In this case, \(X\) is \(n\)-reduced if and only if the restriction map \(\theta_{m}: \operatorname{Hom}_{\text {Set }_{\Delta}}\left(\Delta^{m}, \mathcal{C}\right) \rightarrow \operatorname{Hom}_{\text {Set }_{\Delta}}\left(\partial \Delta^{m}, \mathcal{C}\right)\) is injective for each \(m \leq n\). Corollary 4.8.3.14 now follows by combining Proposition 4.8.3.12 (and Remark 4.8.3.13) with the criterion of Proposition 3.5.1.12.

Corollary 4.8.3.15. Let \(X\) be a minimal Kan complex and let \(n \geq 0\) be an integer. Then 0595 \(X\) is \(n\)-reduced if and only if it is \((n+1)\)-connective.

\subsection*{4.8.4 Higher Homotopy Categories}

Let \(\mathcal{C}\) be an \(\infty\)-category. In \(\S 1.4 .5\) we constructed the homotopy category \(\mathrm{h} \mathcal{C}\), and showed 0596 that it is characterized (up to isomorphism) by the following universal property: for any
category \(\mathcal{D}\), there is a bijection

This motivates the following:
0597 Definition 4.8.4.1. Let \(F: \mathcal{C} \rightarrow \mathcal{C}^{\prime}\) be a functor of \(\infty\)-categories and let \(n\) be an integer. We say that \(F\) exhibits \(\mathcal{C}^{\prime}\) as a homotopy n-category of \(\mathcal{C}\) if the following conditions are satisfied:
(1) The \(\infty\)-category \(\mathcal{C}^{\prime}\) is an ( \(n, 1\) )-category (Definition 4.8.1.8).
(2) For every \((n, 1)\)-category \(\mathcal{D}\), precomposition with \(F\) induces a bijection

0598 Notation 4.8.4.2. Let \(n\) be a nonnegative integer. We will see in a moment that for every \(\infty\)-category \(\mathcal{C}\), there exists a functor \(F: \mathcal{C} \rightarrow \mathcal{C}^{\prime}\) which exhibits \(\mathcal{C}^{\prime}\) as a homotopy \(n\)-category of \(\mathcal{C}\) (Corollary 4.8.4.16). It follows immediately from the definition that the simplicial set \(\mathcal{C}^{\prime}\) is unique up to (canonical) isomorphism and depends functorially on \(\mathcal{C}\). To emphasize this dependence, we will often denote \(\mathcal{C}^{\prime}\) by \(\mathrm{h}_{\leq n}(\mathcal{C})\) and refer to it as the homotopy \(n\)-category of \(\mathcal{C}\). For a more explicit description of \(\mathrm{h}_{\leq n}(\mathcal{C})\) (at least for \(n>0\) ), see Construction 4.8.4.9 (and Proposition 4.8.4.15).

0599 Example 4.8.4.3. Let \(\mathcal{C}\) be an \(\infty\)-category and let hC denote its homotopy category (Definition 1.4.5.3). Then the comparison map \(F: \mathcal{C} \rightarrow \mathrm{N}_{\bullet}(\mathrm{hC})\) of Construction 1.4.5.6 exhibits \(\mathrm{N}_{\bullet}(\mathrm{h} \mathcal{C})\) as a homotopy 1-category of \(\mathcal{C}\), in the sense of Definition 4.8.4.1. This is a reformulation of Proposition 1.4.5.7 (see Example 4.8.1.3). Stated more informally, there is a canonical isomorphism of simplicial sets \(\mathrm{h}_{\leq 1}(\mathcal{C}) \simeq \mathrm{N}_{\bullet}(\mathrm{hC})\). We will sometimes abuse notation by identifying the homotopy 1 -category \(\mathrm{h}_{\leq 1}(\mathcal{C})\) with the ordinary category hC .

059A Exercise 4.8.4.4. Let \(\mathcal{C}\) be an \(\infty\)-category, and let \(Q=\pi_{0}\left(\mathcal{C}^{\simeq}\right)\) denote the collection of isomorphism classes of objects of \(\mathcal{C}\). For each object \(X \in \mathcal{C}\), let \([X] \in Q\) denote its isomorphism class. Show that:
- There is a partial ordering \(\leq_{Q}\) on the set \(Q\), where \([X] \leq_{Q}[Y]\) if and only if there exists a morphism from \(X\) to \(Y\) in the \(\infty\)-category \(\mathcal{C}\).
- There is a unique functor \(F: \mathcal{C} \rightarrow \mathrm{N}_{\bullet}(Q)\) which carries each object \(X \in \mathcal{C}\) to the isomorphism class \([X] \in Q\).
- The functor \(F\) exhibits \(\mathrm{N}_{\bullet}(Q)\) as a homotopy 0 -category of \(\mathcal{C}\), in the sense of Definition 4.8.4.1.

Example 4.8.4.5. Let \(\mathcal{C}\) be an \(\infty\)-category. Then:
059B
- For every integer \(n \leq-2\), the unique functor \(F: \mathcal{C} \rightarrow \Delta^{0}\) exhibits \(\Delta^{0}\) as a homotopy n-category of \(\mathcal{C}\).
- If \(\mathcal{C}\) is nonempty, then \(F\) also exhibits \(\Delta^{0}\) as a homotopy ( -1 )-category of \(\mathcal{C}\).
- If \(\mathcal{C}\) is empty, then the identity map id : \(\mathcal{C} \rightarrow \emptyset\) exhibits the empty simplicial set as a homotopy (-1)-category of \(\mathcal{C}\).

Example 4.8.4.6. Let \(X\) be a Kan complex, let \(n\) be a nonnegative integer, and let \(\pi_{\leq n}(X)\) denote the fundamental \(n\)-groupoid of \(X\) (Notation 3.5.6.6). Then the tautological map \(u: X \rightarrow \pi_{\leq n}(X)\) exhibits \(\pi_{\leq n}(X)\) as a homotopy \(n\)-category of \(X\), in the sense of Definition 4.8.4.1. Since \(\pi_{\leq n}(X)\) is an ( \(n, 1\) )-category (Example 4.8.1.11), it will suffice that for every \((n, 1)\)-category \(\mathcal{D}\), precomposition with \(u\) induces a bijection \(\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\pi_{\leq n}(X), \mathcal{D}\right) \rightarrow\) \(\operatorname{Hom}_{\text {Set }_{\Delta}}(X, \mathcal{D})\). By virtue of Proposition 4.4.3.17, we can replace \(\mathcal{D}\) by its core \(\mathcal{D}^{\simeq}\), and thereby reduce to the case where \(\mathcal{D}\) is an \(n\)-groupoid (Example 4.8.1.17). In this case, the desired result follows from the universal property of Proposition 3.5.6.5

In the situation of Notation 4.8.4.2, the homotopy \(n\)-category \(\mathrm{h}_{\leq n}(\mathcal{C})\) automatically satisfies a stronger universal property:

Proposition 4.8.4.7. Let \(F: \mathcal{C} \rightarrow \mathcal{C}^{\prime}\) be a functor of \(\infty\)-categories and let \(n\) be an integer. 059D The following conditions are equivalent:
(1) For every ( \(n, 1\) )-category \(\mathcal{D}\), precomposition with \(F\) induces a bijection of sets
\[
\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\mathcal{C}^{\prime}, \mathcal{D}\right) \rightarrow \operatorname{Hom}_{\operatorname{Set}_{\Delta}}(\mathcal{C}, \mathcal{D}) .
\]
(2) For every \((n, 1)\)-category \(\mathcal{D}\), precomposition with \(F\) induces an isomorphism of \(\infty\) categories
\[
\operatorname{Fun}\left(\mathcal{C}^{\prime}, \mathcal{D}\right) \rightarrow \operatorname{Fun}(\mathcal{C}, \mathcal{D})
\]

Proof. Assume that (1) is satisfied; we will prove (2) (the reverse implication follows immediately from the definitions). Let \(\mathcal{D}\) be an \((n, 1)\)-category; we wish to show that precomposition with \(F\) induces an isomorphism of simplicial sets from \(\operatorname{Fun}\left(\mathcal{C}^{\prime}, \mathcal{D}\right)\) to \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\). Equivalently, we wish to show that for every simplicial set \(K\), the induced map
\[
\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(K, \operatorname{Fun}\left(\mathcal{C}^{\prime}, \mathcal{D}\right)\right) \rightarrow \operatorname{Hom}_{\operatorname{Set}_{\Delta}}(K, \operatorname{Fun}(\mathcal{C}, \mathcal{D})) .
\]

This follows by applying condition (1) to the simplicial set \(\operatorname{Fun}(K, \mathcal{D})\), which is an \((n, 1)\) category by virtue of Proposition 4.8.1.22.

059E Corollary 4.8.4.8. Let \(n \geq-1\) be an integer and let \(F: \mathcal{C} \rightarrow \mathcal{C}^{\prime}\) be a functor of \(\infty\)-categories which exhibits \(\mathcal{C}^{\prime}\) as a homotopy \(n\)-category of \(\mathcal{C}\) (Definition 4.8.4.1). Then \(F\) exhibits \(\mathcal{C}^{\prime}\) as a local \((n-1)\)-truncation of \(\mathcal{C}\) (Definition 4.8.2.9).

Proof. Since \(\mathcal{C}^{\prime}\) is an ( \(n, 1\) )-category, it is locally \((n-1)\)-truncated (Example 4.8.2.2). It will therefore suffice to show that, for every locally \((n-1)\)-truncated \(\infty\)-category \(\mathcal{D}\), precomposition with \(F\) induces an equivalence of \(\infty\)-categories \(\theta: \operatorname{Fun}\left(\mathcal{C}^{\prime}, \mathcal{D}\right) \rightarrow \operatorname{Fun}(\mathcal{C}, \mathcal{D})\) (Proposition 4.8.2.18). By virtue of Corollary 4.8.3.3, we may assume that \(\mathcal{D}\) is an \((n, 1)\) category. In this case, Proposition 4.8.4.7 guarantees that \(\theta\) is an isomorphism of simplicial sets.

Our next goal is to show that every \(\infty\)-category \(\mathcal{C}\) admits a homotopy \(n\)-category, for every integer \(n\). For \(n \leq 0\), this follows from Exercise 4.8.4.4 and Example 4.8.4.5. To handle the case \(n>0\), we will use a generalization of Construction 3.5.6.10.

059F Construction 4.8.4.9. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(n\) be a positive integer, and let \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) denote the weak \(n\)-coskeleton of \(\mathcal{C}\) (Notation 3.5.4.19). For every integer \(m \geq 0\), we will identify \(m\)-simplices of \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) with diagrams \(\sigma: \operatorname{sk}_{n}\left(\Delta^{m}\right) \rightarrow \mathcal{C}\) which can be extended to the \((n+1)\)-skeleton of \(\Delta^{m}(\operatorname{Remark} 3.5 .4 .21)\). Given two such morphisms \(\sigma, \sigma^{\prime}: \operatorname{sk}_{n}\left(\Delta^{m}\right) \rightarrow \mathcal{C}\), we write \(\sigma \sim_{m} \sigma^{\prime}\) if \(\sigma\) and \(\sigma^{\prime}\) are isomorphic relative to \(\mathrm{sk}_{n-1}\left(\Delta^{m}\right)\) (Definition 4.7.6.1). The construction
\[
\left([m] \in \Delta^{\mathrm{op}}\right) \mapsto \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\Delta^{m}, \operatorname{cosk}_{n}^{\circ}(\mathcal{C})\right) / \sim_{m}
\]
determines a simplicial set, which we will denote by \(\mathrm{h}_{\leq n}(\mathcal{C})\). By construction, it is equipped with an epimorphism of simplicial sets \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C}) \rightarrow \mathrm{h}_{\leq n}(\mathcal{C})\), which determines a comparison \(\operatorname{map} \mathcal{C} \rightarrow \mathrm{h}_{\leq n}(\mathcal{C})\).

059G Remark 4.8.4.10. In the situation of Construction 4.8.4.9, the relation \(\sigma \sim_{m} \sigma^{\prime}\) implies that \(\sigma=\sigma^{\prime}\) whenever \(m<n\). It follows that the tautological map \(\mathcal{C} \rightarrow \mathrm{h}_{\leq n}(\mathcal{C})\) is bijective on simplices of dimension \(<n\), and surjective on simplices of dimension \(n\).

Proposition 4.8.4.11. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(n\) be a positive integer, and let \(\mathrm{h}_{\leq n}(\mathcal{C})\) be 059 H the simplicial set of Construction 4.8.4.9. Then, for every simplicial set \(A\), the comparison map
\[
\theta: \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(A, \operatorname{cosk}_{n}^{\circ}(\mathcal{C})\right) \rightarrow \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(A, \mathrm{~h}_{\leq n}(\mathcal{C})\right)
\]
is surjective. Moreover, if \(f_{0}, f_{1}: A \rightarrow \operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) are morphisms of simplicial sets which correspond to diagrams \(u_{0}, u_{1}: \operatorname{sk}_{n}(A) \rightarrow \mathcal{C}\), then \(\theta\left(f_{0}\right)=\theta\left(f_{1}\right)\) if and only if \(u_{0}\) and \(u_{1}\) are isomorphic relative to \(\mathrm{sk}_{n-1}(A)\).

Proof. We proceed as in the proof of Proposition 3.5.6.12. Fix a morphism of simplicial sets \(g: A \rightarrow \mathrm{~h}_{\leq n}(\mathcal{C})\). Using Remark 4.8.4.10 (and Proposition 1.1.4.12, we see that \(\left.g\right|_{\operatorname{sk}_{n}(A)}\) can be lifted to a morphism of simplicial sets \(u: \operatorname{sk}_{n}(A) \rightarrow \mathcal{C}\). We will show that \(u\) can be extended to the \((n+1)\)-skeleton of \(A\) (and is therefore classified by a morphism \(f: A \rightarrow \operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) satisfying \(\theta(f)=g\); see Remark 3.5.4.21. By virtue of Proposition 1.1.4.12, this is equivalent to the assertion that for every ( \(n+1\) )-simplex \(\sigma\) of \(A\) having restriction \(\sigma_{0}=\left.\sigma\right|_{\partial \Delta^{n+1}}\), the composition \(\left(g \circ \sigma_{0}\right): \partial \Delta^{n+1} \rightarrow \mathcal{C}\) can be extended to an \((n+1)\)-simplex of \(\mathcal{C}\). Choose a lift of \(g(\sigma)\) to an \((n+1)\)-simplex of \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C})\), which we can identify with a diagram \(\tau_{0}: \partial \Delta^{n+1} \rightarrow \mathcal{C}\) which admits an extension \(\tau: \Delta^{n+1} \rightarrow \mathcal{C}\). By construction, \(g \circ \sigma_{0}\) and \(\tau_{0}\) coincide after composing with the comparison map \(\mathcal{C} \rightarrow \mathrm{h}_{\leq n}(\mathcal{C})\). Using Proposition 1.1.4.12 again, we see that \(g \circ \sigma_{0}\) and \(\tau_{0}\) are isomorphic relative to \(\mathrm{sk}_{n-1}\left(\Delta^{n+1}\right)\). The desired result now follows from Corollary 4.4.5.3. This completes the proof that \(\theta\) is surjective.

Now suppose that we are given a pair of morphisms \(f_{0}, f_{1}: A \rightarrow \operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) satisfying \(\theta\left(f_{0}\right)=\theta\left(f_{1}\right)\). We wish to show that the associated maps \(u_{0}, u_{1}: \mathrm{sk}_{n}(A) \rightarrow \mathcal{C}\) are isomorphic relative to \(\mathrm{sk}_{n-1}(A)\) (the converse is immediate from the definitions). Using Remark 4.8.4.10 we deduce that \(u_{0}\) and \(u_{1}\) coincide on \(\mathrm{sk}_{n-1}(A)\). By virtue of Proposition 1.1.4.12, we are reduced to showing that for every nondegenerate \(n\)-simplex \(\sigma\) of \(A\), the compositions \(u_{0} \circ \sigma\) and \(u_{1} \circ \sigma\) are isomorphic relative to \(\partial \Delta^{n}\). This follows from our assumption that the maps \(\theta\left(f_{0}\right), \theta\left(f_{1}\right): A \rightarrow \mathrm{~h}_{\leq n}(\mathcal{C})\) coincide on the simplex \(\sigma\).

Remark 4.8.4.12. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(n\) be a positive integer, and let \(A\) be a simplicial set. Stated more informally, Proposition 4.8.4.11 asserts that \(\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(A, \mathrm{~h}_{\leq n}(\mathcal{C})\right)\) can be viewed as a subquotient of the set \(\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\operatorname{sk}_{n}(A), \mathcal{C}\right)\) :
- A diagram \(u: \operatorname{sk}_{n}(A) \rightarrow \mathcal{C}\) determines a morphism from \(A\) to \(\mathrm{h}_{\leq n}(\mathcal{C})\) if and only if \(u\) can be extended to the \((n+1)\)-skeleton of \(A\).
- Two diagrams \(u_{0}, u_{1}: \operatorname{sk}_{n}(A) \rightarrow \mathcal{C}\) determine the same morphism \(A\) to \(\mathrm{h}_{\leq n}(\mathcal{C})\) if and only if they are isomorphic relative to the ( \(n-1\) )-skeleton of \(A\).

Compare with Remark 3.5.6.13
Corollary 4.8.4.13. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n\) be a positive integer. Then the 059 K comparison map \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C}) \rightarrow \mathrm{h}_{\leq n}(\mathcal{C})\) of Construction 4.8.4.9 is a trivial Kan fibration.

Proof. Fix an integer \(m \geq 0\); we wish to show that every lifting problem

admits a solution.
Let \(\sigma\) be any \(m\)-simplex of \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) satisfying \(q(\sigma)=\bar{\sigma}\). By virtue of Remark 4.8.4.10, the commutativity of the diagram (4.49) guarantees that \(\sigma_{0}\) and \(\sigma\) coincide on the \((n-1)\)-skeleton of \(\partial \Delta^{m}\). Consequently, if \(m \leq n\), then \(\sigma\) is a solution to the the lifting problem (4.49). We will therefore assume that \(m>n\). In this case, the boundary \(\partial \Delta^{m}\) contains the \(n\)-skeleton of \(\Delta^{m}\). It will therefore suffice to show that \(\sigma_{0}\) can be extended to an \(m\)-simplex \(\sigma^{\prime}\) of \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) : the commutativity of the diagram (4.49) guarantees that any such extension satisfies the identity \(q\left(\sigma^{\prime}\right)=\bar{\sigma}\) (Proposition 4.8.4.11). If \(m \geq n+2\), then the existence of \(\sigma^{\prime}\) is automatic (since \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) is \((n+1)\)-coskeletal). It will therefore suffice to treat the case \(m=n+1\). In this case, we can identify \(\sigma_{0}\) with a diagram \(\tau_{0}: \partial \Delta^{n+1} \rightarrow \mathcal{C}\), and we wish to show that \(\tau_{0}\) can be extended to an \((n+1)\)-simplex of \(\mathcal{C}\). Note that \(\left.\sigma\right|_{\partial \Delta^{n+1}}\) determines another diagram \(\tau_{1}: \partial \Delta^{n+1} \rightarrow \mathcal{C}\). Moreover, the commutativity of the diagram (4.49) guarantees that \(\tau_{0}\) and \(\tau_{1}\) are isomorphic relative to \(\mathrm{sk}_{n-1}\left(\Delta^{n+1}\right)\) (Proposition 4.8.4.11). Using Corollary 4.4.5.3, we are reduced to showing that \(\tau_{1}\) can be extended to an \((n+1)\)-simplex of \(\mathcal{C}\), which follows from the existence of \(\sigma\).

059M Corollary 4.8.4.14. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n\) be a positive integer. Then the simplicial set \(\mathrm{h}_{\leq n}(\mathcal{C})\) of Construction 4.8.4.9 is an \((n, 1)\)-category.

Proof. By virtue of Proposition 4.8.3.6, the weak \(n\)-coskeleton \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) is an \(\infty\)-category. Combining Corollary 4.8.4.13 with Proposition 1.5.5.11, we conclude that \(\mathrm{h}_{\leq n}(\mathcal{C})\) is also an \(\infty\)-category. To complete the proof, it will suffice to show that if \(\sigma\) and \(\tau\) are \(m\)-simplices of \(\mathrm{h}_{\leq n}(\mathcal{C})\) for some \(m>n\) which satisfy \(\left.\sigma\right|_{\Lambda_{i}^{m}}=\left.\tau\right|_{\Lambda_{i}^{m}}\) for some \(0<i<m\), then \(\sigma=\tau\). Choose maps \(\widetilde{\sigma}, \widetilde{\tau}: \operatorname{sk}_{n}\left(\Delta^{m}\right) \rightarrow \mathcal{C}\) representing \(\sigma\) and \(\tau\). Using Proposition 4.8.4.11, we can choose an isomorphism \(\alpha\) from \(\left.\widetilde{\sigma}\right|_{\operatorname{sk}_{n}\left(\Lambda_{i}^{m}\right)}\) to \(\left.\widetilde{\tau}\right|_{\mathrm{sk}_{n}\left(\Lambda_{i}^{m}\right)}\) whose image in Fun \(\left(\mathrm{sk}_{n-1}\left(\Lambda_{i}^{m}\right), \mathcal{C}\right)\) is an identity morphism. If \(m \geq n+2\), then \(\alpha\) is also an isomorphism from \(\left.\widetilde{\sigma}\right|_{\operatorname{sk}_{n}\left(\Delta^{m}\right)}\) to \(\left.\widetilde{\tau}\right|_{\mathrm{sk}_{n}\left(\Delta^{m}\right)}\), so that \(\sigma=\tau\) as desired. In the case \(m=n+1\), the morphisms \(\tilde{\sigma}\) and \(\tilde{\tau}\) can be extended to diagrams \(\bar{\sigma}, \bar{\tau}: \Delta^{n+1} \rightarrow \mathcal{C}\). Using Proposition 1.5.7.6, we can extend \(\alpha\) to an isomorphism of \(\bar{\sigma}\) with \(\bar{\tau}\). Restricting to the \(n\)-skeleton of \(\Delta^{m}\), we again conclude that \(\sigma=\tau\).

059N Proposition 4.8.4.15. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n\) be a positive integer. Then
the comparison map \(\mathcal{C} \rightarrow \mathrm{h}_{\leq n}(\mathcal{C})\) of Construction 4.8.4.9 exhibits \(\mathrm{h}_{\leq n}(\mathcal{C})\) as a homotopy \(n\)-category of \(\mathcal{C}\).

Proof. By virtue of Corollary 4.8.4.14 it will suffice to show that for every ( \(n, 1\) )-category \(\mathcal{D}\), the composite map
\[
\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\mathrm{h}_{\leq n}(\mathcal{C}), \mathcal{D}\right) \xrightarrow{\theta} \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\operatorname{cosk}_{n}^{\circ}(\mathcal{C}), \mathcal{D}\right) \xrightarrow{\theta^{\prime}} \operatorname{Hom}_{\operatorname{Set}_{\Delta}}(\mathcal{C}, \mathcal{D})
\]
is a bijection. Since \(\mathcal{D}\) is weakly \(n\)-coskeletal, the map \(\theta^{\prime}\) is a bijection. By construction, \(\mathrm{h}_{\leq n}(\mathcal{C})\) is a quotient of the weak coskeleton \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C})\), so \(\theta\) is an injection. We will complete the proof by showing that \(\theta\) is also a surjection: that is, every diagram \(F: \operatorname{cosk}_{n}^{\circ}(\mathcal{C}) \rightarrow \mathcal{D}\) factors through \(\mathrm{h}_{\leq n}(\mathcal{C})\). Let \(\sigma\) and \(\sigma^{\prime}\) be \(m\)-simplices of \(\operatorname{cosk}_{n}^{\circ}(\mathcal{C})\) satisfying \(\sigma \sim_{m} \sigma^{\prime}\) (see Construction 4.8.4.9; we wish to show that \(F(\sigma)=F\left(\sigma^{\prime}\right)\). This follows from the observation that \(\mathcal{D}\) is minimal in dimension \(n\) (Proposition 4.8.1.7).

Corollary 4.8.4.16. Let \(\mathcal{C}\) be an \(\infty\)-category. For every integer \(n\), there exists a functor 059 P \(F: \mathcal{C} \rightarrow \mathrm{h}_{\leq n}(\mathcal{C})\) which exhibits \(\mathrm{h}_{\leq n}(\mathcal{C})\) as a homotopy \(n\)-category of \(\mathcal{C}\). Moreover:
(1) The functor \(F\) is bijective on \(m\)-simplices for \(m<n\).
(2) The functor \(F\) factors (uniquely) as a composition \(\mathcal{C} \xrightarrow{F^{\prime}} \operatorname{cosk}_{n}^{\circ}(\mathcal{C}) \xrightarrow{F^{\prime \prime}} \mathrm{h}_{\leq n}(\mathcal{C})\), where \(F^{\prime}\) is the inner fibration of Proposition 4.8.3.6.
(3) The functor \(F^{\prime \prime}\) is a trivial Kan fibration.
(4) If \(n \geq-1\), the functor \(F\) exhibits \(\mathrm{h}_{\leq n}(\mathcal{C})\) as a local \((n-1)\)-truncation of \(\mathcal{C}\). In particular, \(\mathcal{C}\) is locally \((n-1)\)-truncated if and only if \(F\) is an equivalence of \(\infty\)-categories.
(5) The functor \(F\) is an isofibration.

Proof. The existence of \(F\) follows from Example 4.8.4.5 (in the case \(n<0\) ), Exercise 4.8.4.4 (in the case \(n=0\) ), and Proposition 4.8.4.15 (in the case \(n>0\) ). Assertion (1) is vacuous for \(n \leq 0\), and follows from Construction 4.8.4.9 for \(n>0\). Since \(\mathrm{h}_{\leq n}(\mathcal{C})\) is an ( \(n, 1\) )-category, it is weakly \(n\)-coskeletal, so that assertion (2) follows from Proposition 3.5.4.18.

We next prove (3). For \(n<0\), the morphism \(F^{\prime \prime}\) is an isomorphism (see Example 4.8.4.5) and there is nothing to prove. For \(n>0\), the desired result follows from Corollary 4.8.4.13. We may therefore assume that \(n=0\). We wish to show that every lifting problem

admits a solution. For \(m \geq 2\), this is automatic ( \(\operatorname{since}^{\operatorname{cosk}}{ }_{n}^{\circ}(\mathcal{C})\) and \(\mathcal{C}^{\prime}\) are both 1-coskeletal). The cases \(m=0\) and \(m=1\) follow immediately from the construction of \(\mathrm{h}_{\leq n}(\mathcal{C})\) given in Exercise 4.8.4.4.

Assertion (4) follows by combining (3) with Proposition 4.8.3.6. We now prove (5). For \(n \neq 0\), the morphism \(F^{\prime}\) is an isofibration (Proposition 4.8.3.6), so the desired result follows from (3). In the case \(n=0, \mathrm{~h}_{\leq n}(\mathcal{C})\) is isomorphic to the nerve of a partially ordered set, so the result is automatic (Example 4.4.1.6).

059Q Corollary 4.8.4.17. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(n\) be an integer, and let \(A \subseteq B\) be simplicial sets. If \(B\) has dimension \(\leq n+1\), then every lifting problem

has a solution. If \(B\) has dimension \(\leq n-1\), then the solution is unique.
059R Remark 4.8.4.18. Let \(n\) be an integer. Then, for every collection of \(\infty\)-categories \(\left\{\mathcal{C}_{i}\right\}_{i \in I}\), the canonical map
\[
\mathrm{h}_{\leq n}\left(\prod_{i \in I} \mathcal{C}_{i}\right) \rightarrow \prod_{i \in I} \mathrm{~h}_{\leq n}\left(\mathcal{C}_{i}\right)
\]
is an isomorphism. This follows by inspecting the explicit descriptions supplied by Construction 4.8.4.9 (for the case \(n>0\) ), Exercise 4.8.4.4 (for the case \(n=0\) ) and Example 4.8.4.5 (for the case \(n<0\) ).

059 S Remark 4.8.4.19. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(\mathcal{C}_{0} \subseteq \mathcal{C}\) be a full subcategory. Then, for every integer \(n \geq-1\), the homotopy category \(\mathrm{h}_{\leq n}\left(\mathcal{C}_{0}\right)\) can be identified with the full subcategory of \(\mathrm{h}_{\leq n}(\mathcal{C})\) spanned by the images of objects which belong \(\mathcal{C}_{0}\).

059 T Proposition 4.8.4.20. Let \(n\) be an integer and suppose we are given a pullback diagram of \(\infty\)-categories

If \(\mathcal{C}\) is an ( \(n, 1\) )-category, then the diagram

is also a pullback square.
Proof. If \(n \leq 0\), then we can identify \(\mathcal{C}_{01}\) with the full subcategory of \(\mathcal{C}_{0} \times \mathcal{C}_{1}\) spanned by those objects \(\left(C_{0}, C_{1}\right)\) satisfying \(F_{0}\left(C_{0}\right)=F_{1}\left(C_{1}\right)\). In this case, the desired result follows by combining Remarks 4.8.4.18 and 4.8.4.19. We may therefore assume without loss of generality that \(n>0\). Fix a simplicial set \(A\); we wish to show that the tautological map
\(\theta: \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(A, \mathrm{~h}_{\leq n}\left(\mathcal{C}_{01}\right)\right) \rightarrow \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(A, \mathrm{~h}_{\leq n}\left(\mathcal{C}_{0}\right)\right) \times_{\operatorname{Hom}_{\text {Set }_{\Delta}}\left(A, \mathrm{~h}_{\leq n}(\mathcal{C})\right)} \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(A, \mathrm{~h}_{\leq n}\left(\mathcal{C}_{1}\right)\right)\).
is a monomorphism. We first show that \(\theta\) is injective. Suppose we are given a pair of maps \(u, u^{\prime}: A \rightarrow \mathrm{~h}_{\leq n}\left(\mathcal{C}_{01}\right)\) satisfying \(\theta(u)=\theta\left(u^{\prime}\right)\); we wish to show that \(u=u^{\prime}\). Using Remark 4.8.4.12, we can choose representatives of \(u\) and \(u^{\prime}\) by morphisms \(\widetilde{u}, \widetilde{u}^{\prime}: \operatorname{sk}_{n}(A) \rightarrow \mathcal{C}_{01}\). Our assumption that \(\theta(u)=\theta\left(u^{\prime}\right)\) guarantees that there are natural isomorphisms
\[
\alpha_{0}: G_{0} \circ \widetilde{u} \rightarrow G_{0} \circ \widetilde{u}^{\prime} \quad \alpha_{1}: G_{1} \circ \widetilde{u} \rightarrow G_{1} \circ \widetilde{u}^{\prime}
\]
which are the identity when restricted to \(\mathrm{sk}_{n-1}(A)\). It follows from the proof of Proposition 4.8.1.7 shows that \(\alpha_{0}\) and \(\alpha_{1}\) have the same image in \(\operatorname{Fun}\left(\operatorname{sk}_{n}(A), \mathcal{C}\right)\). We can therefore identify the pair \(\left(\alpha_{0}, \alpha_{1}\right)\) with an isomorphism from \(\widetilde{u}\) to \(\widetilde{u}^{\prime}\) (which is the identity when restricted to \(\left.\operatorname{sk}_{n-1}(A)\right)\), which proves that \(u=u^{\prime}\).

We now prove that \(\theta\) is surjective. Choose an element \(\left(u_{0}, u_{1}\right)\) of the fiber product \(\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(A, \mathrm{~h}_{\leq n}\left(\mathcal{C}_{0}\right)\right) \times_{\operatorname{Hom}_{\text {Set }_{\Delta}}\left(A, \mathrm{~h}_{\leq n}(\mathcal{C})\right)} \operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(A, \mathrm{~h}_{\leq n}\left(\mathcal{C}_{1}\right)\right)\). Using Remark 4.8.4.12, we can choose representatives of \(u_{0}\) and \(u_{1}\) by morphisms \(\widetilde{u}_{0}: \operatorname{sk}_{n+1}(A) \rightarrow \mathcal{C}_{0}\) and \(\widetilde{u}_{1}\) : \(\operatorname{sk}_{n+1}(A) \rightarrow \mathcal{C}_{1}\). Since \(\mathcal{C}\) is an ( \(n, 1\) )-category, the tautological map \(\mathcal{C} \rightarrow \mathrm{h}_{\leq n}(\mathcal{C})\) is an isomorphism. It follows that \(F_{0} \circ \widetilde{u}_{0}\) coincides with \(F_{1} \circ \widetilde{u}_{1}\), so that the pair ( \(\left.\widetilde{u}_{0}, \widetilde{u}_{1}\right)\) determines a morphism \(\widetilde{u}: \operatorname{sk}_{n+1}(A) \rightarrow \mathcal{C}\). This represents a morphism \(u: A \rightarrow \mathrm{~h}_{\leq n}(\mathcal{C})\) satisfying \(\theta(u)=\left(u_{0}, u_{1}\right)\).

\subsection*{4.8.5 Full and Faithful Functors}

Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Recall that \(F\) is fully faithful if, for every 059U pair of objects \(X, Y \in \mathcal{C}\), the map of morphism spaces
\[
F_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))
\]
is a homotopy equivalence (Definition 4.6.2.1). It is sometimes convenient to break this into two separate conditions:

059 V Definition 4.8.5.1 (Full Functors). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. We say that \(F\) is full if, for every pair of objects \(X, Y \in \mathcal{C}\), the induced map
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))
\]
is surjective on connected components.
059W Definition 4.8.5.2 (Faithful Functors). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. We say that \(F\) is faithful if, for every pair of objects \(X, Y \in \mathcal{C}\), the induced map
\[
F_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))
\]
is a homotopy equivalence from \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) to a summand of \(\operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\).
059X Remark 4.8.5.3. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Then \(F\) is fully faithful (in the sense of Definition 4.6.2.1) if and only if it is both full and faithful (in the sense of Definitions 4.8.5.1 and 4.8.5.2).

059 Y Example 4.8.5.4. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between categories. Then the functor of \(\infty\)-categories \(\mathrm{N}_{\bullet}(F): \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{D})\) is full (in the sense of Definition 4.8.5.1) if and only if the functor \(F\) is full (in the usual category-theoretic sense). Similarly, \(\mathrm{N}_{\bullet}(F)\) is faithful (in the sense of Definition 4.8.5.2) if and only if \(F\) is faithful. Consequently, we can view Definitions 4.8.5.1 and Definition 4.8.5.2 as generalizations of their classical counterparts.
\(059 Z\) Remark 4.8.5.5. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Then \(F\) is full (in the sense of Definition 4.8.5.1 if and only if the induced functor of homotopy categories \(\mathrm{h} F: \mathrm{hC} \rightarrow \mathrm{h} \mathcal{D}\) is full (in the usual category-theoretic sense).

05A0 Remark 4.8.5.6. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories. If \(G \circ F\) is full and \(F\) is essentially surjective, then \(G\) is also full.

05A1 Exercise 4.8.5.7. Let \(f: X \rightarrow Y\) be a morphism of Kan complexes. Show that \(f\) is full (in the sense of Definition 4.8.5.1 if and only if it satisfies the following pair of conditions:
(a) The map of connected components \(\pi_{0}(f): \pi_{0}(X) \rightarrow \pi_{0}(Y)\) is injective.
(b) For every vertex \(x \in X\) having image \(y=f(x)\), the map of fundamental groups \(\pi_{1}(f): \pi_{1}(X, x) \rightarrow \pi_{1}(Y, y)\) is surjective.

The counterpart of Remark 4.8.5.5 for faithful functors is slightly more involved.

Proposition 4.8.5.8. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Then \(F\) is faithful if 05A2 and only if it satisfies the following pair of conditions:
(1) The induced functor of homotopy categories \(\mathrm{h} F: \mathrm{hC} \rightarrow \mathrm{h} \mathrm{\mathcal{D}}\) is faithful.
(2) The diagram of \(\infty\)-categories

is a categorical pullback square.
Remark 4.8.5.9. In the situation of Proposition 4.8.5.8 the comparison map \(\mathcal{D} \rightarrow \mathrm{N}_{\mathbf{\bullet}}(\mathrm{h} \mathcal{D})\) 05A4 is automatically an isofibration (Corollary 4.4.1.9). By virtue of Proposition 4.5.2.26, condition (2) is equivalent to the following:
\(\left(2^{\prime}\right)\) The functor \(F\) induces an equivalence of \(\infty\)-categories \(F^{\prime}: \mathcal{C} \rightarrow \mathrm{N}_{\bullet}(\mathrm{hC}) \times_{\mathrm{N}_{\bullet}(\mathrm{hD})} \mathcal{D}\).
Note that the functor \(F^{\prime}\) is bijective on objects, and therefore essentially surjective. Using Theorem 4.6.2.20 we can reformulate ( \(2^{\prime}\) ) as follows:
\(\left(2^{\prime \prime}\right)\) For every pair of objects \(X, Y \in \mathcal{C}\), the functor \(F\) induces a homotopy equivalence
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \pi_{0}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)\right) \times_{\pi_{0}\left(\operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\right)} \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y)) .
\]

Proof of Proposition 4.8.5.8. By definition, a functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) is faithful if and only if, for every pair of objects \(X, Y \in \mathcal{C}\), the induced map \(F_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\) induces a homotopy equivalence from \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) to a summand of \(\operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\). This is equivalent to the following pair of assertions:
\(\left(1_{X, Y}\right)\) The map of sets \(\pi_{0}\left(F_{X, Y}\right): \pi_{0}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)\right) \rightarrow \pi_{0}\left(\operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\right)\) is injective. ( \(2_{X, Y}\) ) The map of Kan complexes
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \pi_{0}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)\right) \times_{\pi_{0}\left(\operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\right.} \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))
\] is a homotopy equivalence.

The desired result now follows by allowing the objects \(X\) and \(Y\) to vary (and applying Remark 4.8.5.9.

Note the asymmetry between Remark 4.8.5.5 and Proposition 4.8.5.8: in the highercategorical setting, fullness is a relatively weak condition which can be tested at the level of homotopy categories, but faithfulness is not. It will therefore be useful to further analyze Definition 4.8.5.2.

05A5 Definition 4.8.5.10. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Then:
- We say that \(F\) is 0 -full if it is essentially surjective: that is, every object of \(\mathcal{D}\) is isomorphic to \(F(X)\), for some object \(X \in \mathcal{C}\) (Definition 4.6.2.11).
- We say that \(F\) is 1-full if it is full: that is, for objects \(X, Y \in \mathcal{C}\) having images \(\bar{X}=F(X)\) and \(\bar{Y}=F(Y)\) in \(\mathcal{D}\), the map
\[
\pi_{0}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)\right) \rightarrow \pi_{0}\left(\operatorname{Hom}_{\mathcal{D}}(\bar{X}, \bar{Y})\right)
\]
is surjective (Definition 4.8.5.1).
- For \(n \geq 2\), we say that \(F\) is \(n\)-full if, for every morphism \(u: X \rightarrow Y\) in the \(\infty\)-category \(\mathcal{C}\) having image \(\bar{u}: \bar{X} \rightarrow \bar{Y}\) in \(\mathcal{D}\), the induced map
\[
\pi_{m}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y), u\right) \rightarrow \pi_{m}\left(\operatorname{Hom}_{\mathcal{D}}(\bar{X}, \bar{Y}), \bar{u}\right)
\]
is injective for \(m=n-2\) and surjective for \(m=n-1\).
05A6 Remark 4.8.5.11. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Then:
- The functor \(F\) is faithful if and only if it is \(n\)-full for each \(n \geq 2\) (see Example 3.5.9.3).
- The functor \(F\) is fully faithful if and only if it is \(n\)-full for each \(n \geq 1\) (see Remark 4.8.5.3).
- The functor \(F\) is an equivalence of \(\infty\)-categories if and only if it is \(n\)-full for each \(n \geq 0\) (see Theorem 4.6.2.20).

05A7 Example 4.8.5.12. Let \(n \geq-2\) be an integer and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\) categories which exhibits \(\mathcal{D}\) as a local \(n\)-truncation of \(\mathcal{D}\) (see Definition 4.8.2.9). Then \(F\) is \(m\)-full for \(m \leq n+2\). In particular, for any \(\infty\)-category \(\mathcal{C}\), the canonical maps
\[
\mathcal{C} \rightarrow \operatorname{cosk}_{n+2}(\mathcal{C}) \quad \mathcal{C} \rightarrow \operatorname{cosk}_{n+1}^{\circ}(\mathcal{C}) \quad \mathcal{C} \rightarrow \mathrm{h}_{\leq n+1}(\mathcal{C})
\]
are \(m\)-full for \(m \leq n+2\).
05A8 Remark 4.8.5.13. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n \geq-2\) be an integer. Then \(\mathcal{C}\) is locally \(n\)-truncated if and only if the projection map \(\mathcal{C} \rightarrow \Delta^{0}\) is \(m\)-full for all \(m \geq n+3\).

Remark 4.8.5.14 (Symmetry). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n \geq 0\) 05A9 be an integer. Then \(F\) is \(n\)-full if and only the opposite functor \(F^{\mathrm{op}}: \mathcal{C}^{\mathrm{op}} \rightarrow \mathcal{D}^{\mathrm{op}}\) is \(n\)-full.

Remark 4.8.5.15 (Composition). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\) - 05AA categories and let \(n \geq 0\) be an integer. If \(F\) and \(G\) are \(n\)-full, then the composite functor \(G \circ F\) is \(n\)-full.

Remark 4.8.5.16 (Change of Target). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories, where \(G\) is fully faithful. For \(n \geq 1\), the functor \(F\) is \(n\)-full if and only if the composite functor \(G \circ F\) is \(n\)-full. If \(G\) is an equivalence of \(\infty\)-categories, then this is also true when \(n=0\).

Remark 4.8.5.17 (Isomorphism Invariance). Let \(F_{0}, F_{1}: \mathcal{C} \rightarrow \mathcal{D}\) be functors of \(\infty\)-categories which are isomorphic (as objects of the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\) ). Then \(F_{0}\) is \(n\)-full if and only if \(F_{1}\) is \(n\)-full. To see this, let \(\operatorname{Isom}(\mathcal{D})\) denote the full subcategory of \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{D}\right)\) spanned by the isomorphisms (Example 4.4.1.14, so that the evaluation functors \(\mathrm{ev}_{0}, \mathrm{ev}_{1}: \operatorname{Isom}(\mathcal{D}) \rightarrow \mathcal{D}\) are equivalences of \(\infty\)-categories (Corollary 4.4.5.10). The assumption that \(F_{0}\) and \(F_{1}\) are isomorphic guarantees that there exists a functor \(F: \mathcal{C} \rightarrow \operatorname{Isom}(\mathcal{D})\) satisfying \(F_{0}=\operatorname{ev}_{0} \circ F\) and \(F_{1}=\mathrm{ev}_{1} \circ F\). Using Remark 4.8.5.16, we see that \(F_{0}\) is \(n\)-full if and only if \(F\) is \(n\)-full. Similarly, \(F_{1}\) is \(n\)-full if and only if \(F\) is \(n\)-full.

Remark 4.8.5.18 (Change of Source). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories and let \(n \geq 0\) be an integer. If \(F\) is an equivalence of \(\infty\)-categories, then \(G\) is \(n\)-full if and only if \(G \circ F\) is \(n\)-full. The "only if" direction follows immediately from Remark 4.8.5.15 For the converse, suppose that \(G \circ F\) is \(n\)-full, and let \(F^{-1}: \mathcal{D} \rightarrow \mathcal{C}\) be a homotopy inverse to \(F\). Then \(F^{-1}\) is an equivalence of \(\infty\)-categories; in particular, it is \(n\)-full (Remark 4.8.5.11. Applying Remark 4.8.5.15, we conclude that the composition \(G \circ F \circ F^{-1}\) is also \(n\)-full. This composition is isomorphic to \(G\), so \(G\) is \(n\)-full as well (Remark 4.8.5.17).

Remark 4.8.5.19. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(u: X \rightarrow Y\) be a
05AB

05AC

05AD morphism of \(\mathcal{C}\) having image \(\bar{u}: \bar{X} \rightarrow \bar{Y}\) in \(\mathcal{D}\). For each integer \(n\), the requirement that the map
\[
\pi_{n}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y), u\right) \rightarrow \pi_{n}\left(\operatorname{Hom}_{\mathcal{D}}(\bar{X}, \bar{Y}), \bar{u}\right)
\]
is injective or surjective depends only on the isomorphism class of \(u\) (as an object of the \(\infty\)-category \(\left.\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)\right)\).

In the setting of Kan complexes, Definition 4.8.5.10 can be simplified:
Proposition 4.8.5.20. Let \(f: X \rightarrow Y\) be a morphism of Kan complexes. Then:
(a) The morphism \(f\) is 0 -full (in the sense of Definition 4.8.5.10) if and only if the induced map \(\pi_{0}(f): \pi_{0}(X) \rightarrow \pi_{0}(Y)\) is surjective.
(b) For \(n \geq 1\), the morphism \(f\) is \(n\)-full if and only if, for every vertex \(x \in X\) having image \(y=f(x)\), the induced map \(\pi_{m}(f): \pi_{m}(X, x) \rightarrow \pi_{m}(Y, y)\) is injective for \(m=n-1\) and surjective for \(m=n\).

Proof. Assertion (a) is immediate from the definitions. We will prove (b). The case \(n=1\) follows from Exercise 4.8.5.7. Let us therefore assume that \(n \geq 2\). By definition, \(f\) is \(n\)-full if and only if, for every edge \(u: x \rightarrow x^{\prime}\) of \(X\) having image \(v: y \rightarrow y^{\prime}\) in \(Y\), the induced map
\[
\pi_{m-1}\left(\operatorname{Hom}_{X}\left(x, x^{\prime}\right), u\right) \rightarrow \pi_{m-1}\left(\operatorname{Hom}_{Y}\left(y, y^{\prime}\right), v\right)
\]
is injective for \(m=n-1\) and surjective for \(m=n\). By virtue of Remark 4.8.5.19, it suffices to check this in the special case where \(u=\mathrm{id}_{x}\) is a degenerate edge of \(X\). Assertion (b) now follows from isomorphisms
\[
\pi_{m-1}\left(\operatorname{Hom}_{X}(x, x), \mathrm{id}_{x}\right) \simeq \pi_{m}(X, x) \quad \pi_{m-1}\left(\operatorname{Hom}_{Y}(y, y), \operatorname{id}_{y}\right) \simeq \pi_{m}(Y, y)
\]
of Example 4.6.1.13.
05AG Remark 4.8.5.21. In the situation of Proposition 4.8.5.20. suppose that \(f\) is a Kan fibration. Then assertions (a) and (b) can be reformulated as follows:
\(\left(a^{\prime}\right)\) The Kan fibration \(f\) is 0 -full if and only if, for each vertex \(y \in Y\), the fiber \(X_{y}=\{y\} \times_{Y} X\) is nonempty.
( \(b^{\prime}\) ) For \(n \geq 1\), the Kan fibration \(f\) is \(n\)-full if and only if, for every vertex \(x \in X\) having image \(y=f(x)\), the set \(\pi_{n-1}\left(X_{y}, x\right)\) consists of a single element.

See Corollary 3.2.6.8 (and Variant 3.2.6.9 for the case \(n=1\) ).
05AH Corollary 4.8.5.22. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n \geq 1\). Then \(F\) is \(n\)-full if and only if, for every pair of objects \(X, Y \in \mathcal{C}\), the induced map of morphism spaces
\[
F_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))
\]
is \((n-1)\)-full.
05AJ Remark 4.8.5.23. Stated more informally, Corollary 4.8.5.22 asserts that a functor \(F\) : \(\mathcal{C} \rightarrow \mathcal{D}\) is \(n\)-full if it is surjective up to homotopy on \(n\)-morphisms (having fixed source and target). For an alternative formulation of this heuristic, see Proposition 4.8.5.29 below.

05AK Corollary 4.8.5.24. Let \(f: X \rightarrow Y\) be a morphism of Kan complexes and let \(n\) be an integer. Then:
- The morphism \(f\) is \(n\)-connective (in the sense of Definition 3.5.1.13) if and only if it is \(m\)-full for every nonnegative integer \(m \leq n\).
- The morphism \(f\) is \(n\)-truncated (in the sense of Definition 3.5.9.1) if and only if it is \(m\)-full for every nonnegative integer \(m \geq n+2\).

Corollary 4.8.5.25. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories and let \(n \geq 2\) 05AL be an integer. Then \(F\) is \(n\)-full if and only if, for every morphism \(u: X \rightarrow Y\) of \(\mathcal{C}\) having image \(\bar{u}: \bar{X} \rightarrow \bar{Y}\) in \(\mathcal{D}\), the set \(\pi_{n-2}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{\bar{u}}, u\right)\) consists of a single element. Here \(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{\bar{u}}\) denotes the fiber \(\{\bar{u}\} \times_{\operatorname{Hom}_{\mathcal{D}}(\bar{X}, \bar{Y})} \operatorname{Hom}_{\mathcal{C}}(X, Y)\).
Proof. By virtue of Corollary 4.8.5.22, the functor \(F\) is \(n\)-full if and only if, for every pair of objects \(X, Y \in \mathcal{C}\), the map of Kan complexes
\[
F_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))
\]
is \((n-1)\)-full. Since \(F\) is an inner fibration, \(F_{X, Y}\) is a Kan fibration (Proposition 4.6.1.21). The desired result now follows from Remark 4.8.5.21.

Variant 4.8.5.26. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories. Then \(F\) is full if
05AM and only if, for every pair of objects \(X, Y \in \mathcal{C}\), the induced map
\[
F_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))
\]
is surjective on vertices.
Proposition 4.8.5.27. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories and let \(n \geq 1\) 05AN be an integer. The following conditions are equivalent:
(1) The functor \(F\) is \(n\)-full.
(2) For every pullback diagram of \(\infty\)-categories

the functor \(F^{\prime}\) is \(n\)-full.
(3) For every pullback diagram of \(\infty\)-categories

the functor \(F^{\prime}\) is \(n\)-full.

Proof. For \(n \geq 2\), this follows from the criterion of Corollary 4.8.5.25. For \(n=1\), it follows from the criterion of Variant 4.8.5.26.

05AP Corollary 4.8.5.28. Let \(n \geq 0\) be an integer, and suppose we are given a categorical pullback diagram of \(\infty\)-categories
05AQ

If \(F\) is \(n\)-full, then \(F^{\prime}\) is \(n\)-full. The converse holds if \(G\) is full and essentially surjective.
Proof. The case \(n=0\) follows from Remark 4.6.2.18. We will therefore assume that \(n \geq 1\). Using Corollary 4.5.2.23, we can reduce to the case where \(F\) and \(G\) are isofibrations. In this case, our assumption that 4.51 is a categorical pullback square guarantees that the induced \(\operatorname{map} \mathcal{C}^{\prime} \rightarrow \mathcal{D}^{\prime} \times_{\mathcal{D}} \mathcal{C}\) is an equivalence of \(\infty\)-categories (Proposition 4.5.2.26). Using Remark 4.8.5.18 \(\mathcal{C}^{\prime}\) by the fiber product \(\mathcal{D}^{\prime} \times_{\mathcal{D}} \mathcal{C}\) and thereby reduce to the case where the diagram (4.51) is a pullback square. Note that, if the functor \(G\) is full and essentially surjective, then every morphism of \(\mathcal{D}\) can be lifted to a morphism of \(\mathcal{D}^{\prime}\). The desired result now follows from the criterion of Proposition 4.8.5.27.

05AR Proposition 4.8.5.29. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories and let \(n \geq 1\) be an integer. Then \(F\) is \(n\)-full if and only if every lifting problem

admits a solution. If \(F\) is an isofibration, then this is also true in the case \(n=0\).
Proof. The case \(n=0\) reduces to the observation that an isofibration is essentially surjective if and only if it is surjective on objects. The case \(n=1\) is a reformulation of Variant 4.8.5.26 We may therefore assume without loss of generality that \(n \geq 2\). Using Proposition 4.8.5.27, we can reduce to the case where \(\mathcal{D}=\Delta^{m}\) is a standard simplex. In this case, the functor \(F\) is \(n\)-full if and only if, for every morphism \(u: X \rightarrow Y\) of \(\mathcal{C}\), the set \(\pi_{n-2}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y), u\right)\) consists of a single element (Corollary 4.8.5.25). The desired result now follows from Corollary 4.8.3.10.

For later use, we record a few variants of Remark 4.8.5.15.

Proposition 4.8.5.30. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories and let 05AS \(n \geq 1\). If \(G \circ F\) is \(n\)-full and \(G\) is \((n+1)\)-full, then \(F\) is \(n\)-full.

Proof. We first treat the case \(n=1\). Fix a pair of objects \(X, Y \in \mathcal{C}\) having images \(\bar{X}\) and \(\bar{Y}\) in \(\mathcal{D}\). We wish to show that every morphism \(\bar{u}: \bar{X} \rightarrow \bar{Y}\) is homotopic to \(F(v)\), for some morphism \(v: X \rightarrow Y\) in \(\mathcal{C}\). Our assumption that \((G \circ F)\) is 1-full guarantees that we can choose \(v\) such that \((G \circ F)(v)\) is homotopic to \(G(\bar{u})\). Since \(G\) is 2-full, the map \(\pi_{0}\left(\operatorname{Hom}_{\mathcal{D}}(\bar{X}, \bar{Y})\right) \rightarrow \pi_{0}\left(\operatorname{Hom}_{\mathcal{E}}(G(\bar{X}), G(\bar{Y}))\right.\) is injective, so that \(F(v)\) is homotopic to \(\bar{u}\) as desired.

We now treat the case \(n \geq 2\). Without loss of generality, we may assume that \(F\) and \(G\) are inner fibrations. Using Proposition 4.8.5.27, we can further reduce to the case where \(\mathcal{E}\) is a standard simplex. Fix a morphism \(u: X \rightarrow Y\) of \(\mathcal{C}\) having image \(\bar{u}: \bar{X} \rightarrow \bar{Y}\) in \(\mathcal{D}\). We wish to show that the map
\[
\theta_{m}: \pi_{m}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y), u\right) \rightarrow \pi_{m}\left(\operatorname{Hom}_{\mathcal{D}}(\bar{X}, \bar{Y}), \bar{u}\right)
\]
is injective for \(m=n-2\) and surjective for \(m=n-1\). This is clear: our assumption that \(G \circ F\) is \(n\)-full guarantees that the set \(\pi_{n-2}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y), u\right)\) consists of a single element (so \(\theta_{n-2}\) is automatically injective), and our assumption that \(G\) is ( \(n+1\) )-full guarantees that the set \(\pi_{n-1}\left(\operatorname{Hom}_{\mathcal{D}}(\bar{X}, \bar{Y}), \bar{u}\right)\) consists of a single element (so that \(\theta_{n-1}\) is automatically surjective).

Exercise 4.8.5.31. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories where \(G\) is full and conservative. Show that if \(G \circ F\) is essentially surjective, then \(F\) is also essentially surjective. Beware that the hypothesis that \(G\) is conservative cannot be omitted.

Proposition 4.8.5.32. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories and let 05AU \(n \geq 2\). Assume that \(G \circ F\) is \(n\)-full and that \(F\) is essentially surjective, full, and \((n-1)\)-full. Then \(G\) is \(n\)-full.

Remark 4.8.5.33. For \(n=0\) and \(n=1\), we have stronger versions of Proposition 4.8.5.32. 05AV
- If \(G \circ F\) is 0 -full, then \(G\) is 0 -full (this is a restatement of Remark 4.6.2.17).
- If \(G \circ F\) is 1 -full and \(F\) is 0 -full, then \(G\) is 1 -full (this is a restatement of Remark 4.8.5.6).

Proof of Proposition 4.8.5.32. Without loss of generality, we may assume that \(F\) and \(G\) are inner fibrations. Using Proposition 4.8.5.27, we can reduce to the case where \(\mathcal{E}\) is a standard simplex. In this case, we must show that for every morphism \(\bar{u}: \bar{X} \rightarrow \bar{Y}\) of \(\mathcal{D}\), the set \(\pi_{n-2}\left(\operatorname{Hom}_{\mathcal{D}}(\bar{X}, \bar{Y}), \bar{u}\right)\) consists of a single element. Since \(F\) is full and essentially surjective, we can assume without loss of generality that \(\bar{u}=F(u)\) for some morphism \(u: X \rightarrow Y\) in
the \(\infty\)-category \(\mathcal{C}\). In this case, our assumption that \(F\) is \((n-1)\)-full guarantees that the map
\[
\pi_{n-2}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y), u\right) \rightarrow \pi_{n-2}\left(\operatorname{Hom}_{\mathcal{D}}(\bar{X}, \bar{Y}), \bar{u}\right)
\]
is surjective. It will therefore suffice to show that the set \(\pi_{n-2}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y), u\right)\) consists of a single element, which follows from our assumption that \(G \circ F\) is \(n\)-full.

\subsection*{4.8.6 Essentially Categorical Functors}

05AW Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n\) be an integer. Combining Corollary 4.8.3.3 with Remark 4.8.5.13, we see that the following conditions are equivalent:
- The \(\infty\)-category \(\mathcal{C}\) is equivalent to an ( \(n, 1\) )-category.
- The projection map \(\mathcal{C} \rightarrow \Delta^{0}\) is \(m\)-full for \(m \geq n+2\).

This motivates the following:
05AX Definition 4.8.6.1. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n\) be an integer. We say that \(F\) is essentially \(n\)-categorical if it is \(m\)-full for \(m \geq n+2\).

05AY Example 4.8.6.2. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Then:
- The functor \(F\) is essentially 0 -categorical if and only if it is faithful.
- The functor \(F\) is essentially \((-1)\)-categorical if and only if it is fully faithful.
- The functor \(F\) is essentially (-2)-categorical if and only if it is an equivalence of \(\infty\)-categories. In this case, \(F\) is also essentially \(n\)-categorical for any \(n \leq-2\).

This is a restatement of Remark 4.8.5.11.
05AZ Example 4.8.6.3. Let \(f: X \rightarrow Y\) be a morphism of Kan complexes and let \(n\) be an integer. Then \(f\) is essentially \(n\)-categorical (in the sense of Definition 4.8.6.1) if and only if it is \(n\)-truncated (in the sense of Definition 3.5.9.1. See Corollary 4.8.5.24.

05B0 Example 4.8.6.4. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n\) be an integer. The following conditions are equivalent:
(1) The projection map \(\mathcal{C} \rightarrow \Delta^{0}\) is essentially \(n\)-categorical.
(2) The \(\infty\)-category \(\mathcal{C}\) is locally ( \(n-1\) )-truncated. Moreover, if \(n \leq-2\), then \(\mathcal{C}\) is nonempty.
(3) The \(\infty\)-category \(\mathcal{C}\) is equivalent to an ( \(n, 1\) )-category.
(4) For \(m \geq n+2\), every morphism \(\partial \Delta^{m} \rightarrow \mathcal{C}\) can be extended to an \(m\)-simplex of \(\mathcal{E}\).

The equivalence \((1) \Leftrightarrow(2)\) follows from Remark 4.8.5.13, the equivalence \((2) \Leftrightarrow(3)\) from Corollary 4.8.3.3, and the equivalence \((2) \Leftrightarrow(4)\) from Corollary 4.8.3.11.

Remark 4.8.6.5 (Symmetry). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n\) be an integer. Then \(F\) is essentially \(n\)-categorical if and only if the opposite functor \(F^{\mathrm{op}}: \mathcal{C}^{\mathrm{op}} \rightarrow \mathcal{D}^{\mathrm{op}}\) is essentially \(n\)-categorical. See Remark 4.8.5.14.
Remark 4.8.6.6 (Monotonicity). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(m \leq n\) be integers. If \(F\) is essentially \(m\)-categorical, then it is essentially \(n\)-categorical.

Remark 4.8.6.7 (Transitivity). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories and let \(n\) be an integer. Then:
(a) If \(F\) and \(G\) are essentially \(n\)-categorical, then the composite functor \(G \circ F\) is essentially \(n\)-categorical.
(b) If \(G \circ F\) is essentially \(n\)-categorical and \(G\) is essentially \((n+1)\)-categorical, then \(F\) is essentially \(n\)-categorical.
(c) If \(G \circ F\) is essentially \(n\)-categorical and \(F\) is essentially \((n-1)\)-categorical, full, and essentially surjective, then \(G\) is essentially \(n\)-categorical.

Assertion ( \(a\) ) follows from Remark 4.8.5.15, assertion (b) from Proposition 4.8.5.30 (together with Exercise 4.8.5.31 in the case \(n \leq-2\) ), and assertion \((c)\) follows from Proposition 4.8.5.32 (together with Remark 4.5.1.18 in the case \(n \leq-2\) ).

Remark 4.8.6.8. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories and let \(n\) be an integer. Suppose that \(G\) is essentially \(n\)-categorical. Then \(F\) is essentially \(n\)-categorical if and only if \(G \circ F\) is essentially \(n\)-categorical. This follows by combining Remarks 4.8.6.6 and 4.8.6.7.

Example 4.8.6.9. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n \geq-1\) be an integer. Suppose that \(\mathcal{D}\) is locally \((n-1)\)-truncated. Then \(F\) is essentially \(n\)-categorical if and only if \(\mathcal{C}\) is also locally \((n-1)\)-truncated. This follows by applying Remark 4.8.6.8 in the special case \(\mathcal{E}=\Delta^{0}\) (see Example 4.8.6.4).

Remark 4.8.6.10 (Homotopy Invariance). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of
```

05B4

``` \(\infty\)-categories and let \(n\) be an integer. If \(F\) is an equivalence of \(\infty\)-categories, then \(G \circ F\) is essentially \(n\)-categorical if and only if \(G\) is essentially \(n\)-categorical. If \(G\) is an equivalence of \(\infty\)-categories, then \(G \circ F\) is essentially \(n\)-categorical if and only if \(F\) is essentially \(n\)-categorical. Both assertions are special cases of Remark 4.8.6.7.

Remark 4.8.6.11 (Isomorphism Invariance). Let \(F_{0}, F_{1}: \mathcal{C} \rightarrow \mathcal{D}\) be functors of \(\infty\)-categories which are isomorphic (when regarded as objects of the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\) ). Then \(F_{0}\) is essentially \(n\)-categorical if and only if \(F_{1}\) is essentially \(n\)-categorical. See Remark 4.8.5.17.

05B8 Remark 4.8.6.12. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n \geq-1\). Then \(F\) is essentially \(n\)-categorical if and only if, for every pair of objects \(X, Y \in \mathcal{C}\), the map of Kan complexes
\[
F_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))
\]
is \((n-1)\)-truncated. This follows by combining Example 4.8.6.3 with Corollary 4.8.5.22.
05B9 Remark 4.8.6.13. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories. For \(n \geq 0, F\) is essentially \(n\)-categorical if and only if the diagonal map \(\delta: \mathcal{C} \rightarrow \mathcal{C} \times_{\mathcal{D}} \mathcal{C}\) is essentially \((n-1)\)-categorical. This follows by combining Remark 4.8.6.12 with Corollary 3.5.9.17 since \(F\) induces a \(\operatorname{Kan}\) fibration \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\) for every pair of objects \(X, Y \in \mathcal{C}\) (Proposition 4.6.1.21).

05BA Warning 4.8.6.14. Remark 4.8.6.13 is generally false in the case \(n=-1\), even if we assume that \(F\) is an isofibration. For example, let \(\mathcal{D}\) be an \(\infty\)-category and let \(\mathcal{C} \subseteq \mathcal{D}\) be a subcategory. Then the inclusion map \(F: \mathcal{C} \rightarrow \mathcal{D}\) is an inner fibration (which is even an isofibration, if \(\mathcal{C}\) is a replete subcategory of \(\mathcal{D}\) ). The diagonal \(\delta: \mathcal{C} \rightarrow \mathcal{C} \times \mathcal{D} \mathcal{C}\) is an isomorphism of simplicial sets, and therefore an equivalence of \(\infty\)-categories. However, \(F\) need not be fully faithful.

05BB Variant 4.8.6.15. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. For \(n \geq 0\), the functor \(F\) is essentially \(n\)-categorical if and only if the composite map
\[
\mathcal{C} \hookrightarrow \mathcal{C} \times{ }_{\mathcal{D}} \mathcal{C} \hookrightarrow \mathcal{C} \times{ }_{\mathcal{D}}^{\mathrm{h}} \mathcal{C}
\]
is essentially \((n-1)\)-categorical. To prove this, we can use Corollaries 4.5.2.23 and 4.5.2.20 to reduce to the situation where \(F\) is an isofibration. In this case, the desired result is a reformulation of Remark 4.8.6.13 (see Corollary 4.5.2.28).

05BC Remark 4.8.6.16. Let \(n\) be an integer and suppose we are given a categorical pullback diagram of \(\infty\)-categories

If \(F\) is essentially \(n\)-categorical, then \(F^{\prime}\) is essentially \(n\)-categorical. The converse holds if \(G\) is full and essentially surjective. See Corollary 4.8.5.28.

05BD Proposition 4.8.6.17. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories and let \(n \geq 0\) be an integer. The following conditions are equivalent:
(1) The functor \(F\) is essentially \(n\)-categorical.
(2) For every pullback diagram of \(\infty\)-categories

the functor \(F^{\prime}\) is essentially \(n\)-categorical.
(3) For every pullback diagram of \(\infty\)-categories

where \(\mathcal{D}^{\prime}\) is locally \((n-1)\)-truncated, the \(\infty\)-category \(\mathcal{C}^{\prime}\) is also locally \((n-1)\)-truncated.
(4) For every pullback diagram of \(\infty\)-categories

the \(\infty\)-category \(\mathcal{C}^{\prime}\) is locally \((n-1)\)-truncated.
Proof. Combine Proposition 4.8.5.27 with the criterion of Example 4.8.6.9.
Warning 4.8.6.18. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories and let \(n \geq-1\) be 05BE an integer. If \(F\) is essentially \(n\)-categorical, then each fiber \(\mathcal{C}_{D}=\{D\} \times_{\mathcal{D}} \mathcal{C}\) of \(F\) is a locally ( \(n-1\) )-truncated \(\infty\)-category. Beware that the converse is false in general, even if \(F\) is an isofibration. However, it holds under additional assumptions: see Variant 5.1.5.17.

Proposition 4.8.6.19. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories and let \(n \geq-105 \mathrm{BF}\) be an integer. The following conditions are equivalent:
(1) The functor \(F\) is essentially \(n\)-categorical.
(2) For every integer \(m \geq n+2\), every lifting problem

admits a solution.
(3) For every simplicial set \(B\) and every simplicial subset \(A \subseteq B\) which contains the ( \(n+1\) )skeleton of \(B\), every lifting problem

admits a solution.
Proof. The equivalence (1) \(\Leftrightarrow(2)\) follows from Proposition 4.8.5.29. The implication \((3) \Rightarrow(2)\) is immediate, and the reverse implication follows from Proposition 1.1.4.12.

05BG Corollary 4.8.6.20. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, let \(B\) be a simplicial set, and let \(A \subseteq B\) be a simplicial subset. If \(F\) is essentially \(n\)-categorical, then the induced functor \(F^{\prime}: \operatorname{Fun}(B, \mathcal{C}) \rightarrow \operatorname{Fun}(A, \mathcal{C}) \times \operatorname{Fun}(A, \mathcal{D}) \operatorname{Fun}(B, \mathcal{D})\) is also essentially \(n\)-categorical.

Proof. If \(n \leq-2\), then \(F\) is an equivalence of \(\infty\)-categories; it then follows from Corollary 4.5.2.30 that \(F^{\prime}\) is also an equivalence of \(\infty\)-categories. We may therefore assume that \(n \geq-1\). Using Proposition 3.1.7.1, we can reduce to the case where \(F\) is an inner fibration, so that \(F^{\prime}\) is also an inner fibration (Proposition 4.1.4.1). By virtue of Proposition 4.8.6.19. it will suffice to show that for every simplicial set \(B^{\prime}\) and every simplicial subset \(A^{\prime} \subseteq B^{\prime}\) which contains the ( \(n+1\) )-skeleton of \(B\), every lifting problem

05BH

Unwinding the definitions, we can rewrite (4.52) as a lifting problem

The existence of a solution now follows from Proposition 4.8.6.19, since \(F\) is essentially \(n\)-categorical and \(\left(A \times B^{\prime}\right) \coprod_{\left(A \times A^{\prime}\right)}\left(B \times A^{\prime}\right)\) contains the \((n+1)\)-skeleton of \(B \times B^{\prime}\).

Corollary 4.8.6.21. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, let \(B\) be a simplicial 05BJ set, and let \(n\) be an integer. If \(F\) is essentially \(n\)-categorical, then the induced functor \(\operatorname{Fun}(B, \mathcal{C}) \rightarrow \operatorname{Fun}(B, \mathcal{D})\) is also essentially \(n\)-categorical.

Proof. Apply Corollary 4.8.6.20 in the special case \(A=\emptyset\).
Corollary 4.8.6.22. Let \(n \geq-1\) be an integer and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an essentially \(n\) - 05BK categorical inner fibration of \(\infty\)-categories. Then, for every diagram \(B \rightarrow \mathcal{D}\), the \(\infty\)-category Fun \(_{/ \mathcal{D}}(B, \mathcal{C})\) is locally \((n-1)\)-truncated.

Proof. It follows from Corollary 4.1.4.2 that \(F\) induces an inner fibration \(F^{\prime}: \operatorname{Fun}(B, \mathcal{C}) \rightarrow\) Fun \((B, \mathcal{D})\), and from Corollary 4.8.6.21 that \(F^{\prime}\) is essentially \(n\)-categorical. In particular, every fiber of \(F\) is locally \((n-1)\)-truncated.

We now study a special class of essentially \(n\)-categorical functors.
Definition 4.8.6.23. Let \(n\) be a positive integer. We say that a morphism of simplicial 05BL sets \(F: \mathcal{C} \rightarrow \mathcal{D}\) is an \(n\)-categorical inner fibration if it satisfies the following condition:
(*) For every pair of integers \(0<i<m\), every lifting problem

admits a solution. Moreover, if \(m>n\), then the solution is unique.
It will sometimes be useful to extend Definition 4.8.6.23 to allow \(n\) to be an arbitrary integer.

05BM Variant 4.8.6.24. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets.
- We say that \(U\) is a 0 -categorical inner fibration if, for every morphism \(\Delta^{m} \rightarrow \mathcal{D}\), the fiber product \(\Delta^{m} \times_{\mathcal{D}} \mathcal{C}\) is isomorphic to the nerve of a partially ordered set.
- We say that \(F\) is a \((-1)\)-categorical inner fibration if it induces an isomorphism from \(\mathcal{C}\) to a full simplicial subset of \(\mathcal{D}\) (Definition 4.1.2.15).
- For \(n \leq-2\), we say that \(F\) is an \(n\)-categorical inner fibration if it is an isomorphsm of simplicial sets.

05BN Example 4.8.6.25. Let \(\mathcal{C}\) be a simplicial set and let \(F: \mathcal{C} \rightarrow \Delta^{0}\) be the projection map. Then \(F\) is an \(n\)-categorical inner fibration if and only if \(\mathcal{C}\) is an \((n, 1)\)-category.

05BP Example 4.8.6.26. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets. Then \(F\) is a \(1-\) categorical inner fibration (Definition 4.8.6.23) if and only if it is an inner covering map (Definition 4.1.5.1).

05BQ Remark 4.8.6.27. Let \(m \leq n\) be integers. If \(F: \mathcal{C} \rightarrow \mathcal{D}\) is an \(m\)-categorical inner fibration, then it is also an \(n\)-categorical inner fibration (see Remark 4.8.1.12). In particular, \(F\) is an inner fibration.

05BR Remark 4.8.6.28. Suppose we are given a pullback diagram of simplicial sets

If \(F\) is an \(n\)-categorical inner fibration, then \(F^{\prime}\) is also an \(n\)-categorical inner fibration.
05BS Remark 4.8.6.29. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets. It follows from Example 4.8.6.25 and Remark 4.8.6.28 that if \(F\) is an \(n\)-categorical inner fibration, then the fiber \(\mathcal{C}_{D}=\{D\} \times_{\mathcal{D}} \mathcal{C}\) is an ( \(n, 1\) )-category for each vertex \(D \in \mathcal{D}\). Beware that the converse is generally false.

05BT Remark 4.8.6.30 (Symmetry). Let \(n\) be an integer and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an \(n\)-categorical inner fibration of simplicial sets. Then the opposite map \(F^{\mathrm{op}}: \mathcal{C}^{\mathrm{op}} \rightarrow \mathcal{D}^{\mathrm{op}}\) is also an \(n\)-categorical inner fibration.

05BU Proposition 4.8.6.31. Let \(n\) be an integer, let \(\mathcal{D}\) be an ( \(n, 1\) )-category, and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories. Then \(F\) is \(n\)-categorical if and only if \(\mathcal{C}\) is an ( \(n, 1\) )-category.

Proof. For \(n \neq 0\), the desired result follows from immediately from the definitions. Let us therefore assume that \(n=0\), so that \(\mathcal{D}\) is isomorphic to the nerve of a partially ordered set. If \(\mathcal{C}\) is also isomorphic to the nerve of a partially ordered set, then any fiber product \(\Delta^{m} \times_{\mathcal{D}} \mathcal{C}\) has the same property (since the formation of nerves commutes with fiber products). Conversely, suppose that \(F\) is a 0 -categorical inner fibration. In this case, we claim that \(\mathcal{C}\) satisfies the criteria of \({ }^{* * *}\) snip \({ }^{* * *}\)
(a) The simplicial set \(\mathcal{C}\) is a \((1,1)\)-category: this follows by applying Proposition 4.8.6.31 in the case \(n=1\).
(b) Let \(u, u^{\prime}: X \rightarrow Y\) be morphisms in \(\mathcal{C}\) having the same source and target; we wish to show that \(f=f^{\prime}\). Our assumption that \(\mathcal{D}\) is a \((0,1)\)-category guarantees that \(F(u)=F\left(u^{\prime}\right)\). The desired result now follows from the observation that the fiber product \(\Delta^{1} \times_{\mathcal{D}} \mathcal{C}\) is a ( 0,1 )-category.
(c) Let \(X\) and \(Y\) be isomorphic objects of \(\mathcal{C}\); we wish to show that \(X=Y\). Fix morphisms \(u: X \rightarrow Y\) and \(v: Y \rightarrow X\). Since \(\mathcal{D}\) is a \((1,0)\)-category, we have \(F(u)=\mathrm{id}_{D}=F(v)\) for some object \(D \in \mathcal{D}\). In this case, we can regard \(u\) and \(v\) as morphisms of the \(\infty\)-category \(\mathcal{C}_{D}=\{D\} \times_{\mathcal{D}} \mathcal{C}\). Our assumption that \(F\) is a 0 -categorical inner fibration guarantees that \(\mathcal{C}_{D}\) is a \((0,1)\)-category, so that \(X=Y\).

Remark 4.8.6.32. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets and let \(n\) be an integer. 05BV Then \(F\) is an \(n\)-categorical inner fibration if and only if, for every pullback diagram of simplicial sets

the projection map \(F^{\prime}\) is an \(n\)-categorical inner fibration. For \(n \geq 0\), this is equivalent to the requirement that \(\mathcal{C}^{\prime}\) is an \((n, 1)\)-category (Proposition 4.8.6.31).

Corollary 4.8.6.33 (Transitivity). Let \(n\) be an integer and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) 05BW be inner fibrations of simplicial sets, where \(G\) is \(n\)-categorical. Then \(F\) is \(n\)-categorical if and only if \(G \circ F\) is \(n\)-categorical.

Proof. For \(n<0\), this follows immediately from the definitions. We may therefore assume that \(n \geq 0\). Using Remark 4.8.6.32, we can reduce to the case where \(\mathcal{E}=\Delta^{m}\) is a standard simplex. In this case, our assumption on \(G\) guarantees that \(\mathcal{D}\) is an \((n, 1)\)-category. We
wish to show that \(\mathcal{C}\) is an \((n, 1)\)-category if and only if the inner fibration \(F\) is \(n\)-categorical, which follows from Proposition 4.8.6.31

05BX Proposition 4.8.6.34. Let \(n\) be an integer and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an n-categorical inner fibration of \(\infty\)-categories. Then \(F\) is essentially \(n\)-categorical.

For a partial converse, see Corollary 4.8.8.23
Proof of Proposition 4.8.6.34. If \(n=-2\), then \(F\) is an isomorphism of simplicial sets and therefore an equivalence of \(\infty\)-categories (Example 4.5.1.11). If \(n=-1\), then \(F\) is an isomorphism from \(\mathcal{C}\) onto a full subcategory of \(\mathcal{D}\), and therefore fully faithful (Example 4.6.2.2. We may therefore assume without loss of generality that \(n \geq 0\). By virtue of Proposition 4.8.6.17, we may assume without loss of generality that \(\mathcal{D}\) is a standard simplex; in this case, we wish to show that \(\mathcal{C}\) is locally \((n-1)\)-truncated. This follows from Example 4.8 .2 .2 since \(\mathcal{C}\) is an ( \(n, 1\) )-category (Proposition 4.8.6.31).

\subsection*{4.8.7 Categorically Connective Functors}

05BY Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n\) be an integer. Recall that \(F\) is essentially \((n-1)\)-categorical if it is \(m\)-full for every nonnegative integer \(m>n\). In this section, we study a dual version of this condition.

05BZ Definition 4.8.7.1. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n\) be an integer. We say that \(F\) is categorically \(n\)-connective if it is \(m\)-full for every nonnegative integer \(m \leq n\) (see Definition 4.8.5.10).
05C0 Example 4.8.7.2. For small values of \(n\), we can make Definition 4.8.7.1 more concrete:
- A functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) is categorically 1 -connective if and only if it is full and essentially surjective.
- A functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) is categorically 0 -connective if and only if it is essentially surjective.
- For \(n<0\), every functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) is categorically \(n\)-connective.

05C1 Example 4.8.7.3. Let \(f: X \rightarrow Y\) be a morphism of Kan complexes and let \(n\) be an integer. Then \(f\) is categorically \(n\)-connective (in the sense of Definition 4.8.7.1) if and only if it is \(n\)-connective (in the sense of Definition 3.5.1.13). See Corollary 4.8.5.24.

05C2 Warning 4.8.7.4. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n\) be an integer. If \(F\) is categorically \(n\)-connective, then it is an \(n\)-connective morphism of simplicial sets (Corollary 4.8.7.17). Beware that the converse is false in general. For example, the projection map \(\Delta^{1} \rightarrow \Delta^{0}\) is a homotopy equivalence (and therefore \(n\)-connective for every integer \(n\) ) which is not categorically 2 -connective.

Remark 4.8.7.5. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n\) be an integer. 05C3 Then \(F\) is categorically \(n\)-connective if and only if it satisfies the following pair of conditions:
- The functor \(F\) is locally \((n-1)\)-connective. That is, for every pair of objects \(X, Y \in \mathcal{C}\), the map of Kan complexes
\[
F_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))
\]
is \((n-1)\)-connective.
- If \(n \geq 0\), then \(F\) is essentially surjective.

See Corollary 4.8.5.22.
Remark 4.8.7.6 (Symmetry). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n\) 05C4 be an integer. Then \(F\) is categorically \(n\)-connective if and only if the opposite functor \(F^{\mathrm{op}}: \mathcal{C}^{\mathrm{op}} \rightarrow \mathcal{D}^{\mathrm{op}}\) is categorically \(n\)-connective.

Remark 4.8.7.7 (Monotonicity). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let 05C5 \(m \leq n\) be integers. If \(F\) is categorically \(n\)-connective, then it is categorically \(m\)-connective.
Remark 4.8.7.8. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Then \(F\) is an equivalence of 05C6 \(\infty\)-categories if and only if it is categorically \(n\)-connective for every integer \(n\). See Remark 4.8.5.11.

Remark 4.8.7.9. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. It follows from Remark 4.8.7.5 that if \(F\) is categorically \((n+1)\)-connective, then the induced map of homotopy \(n\)-categories \(\mathrm{h}_{\leq n}(\mathcal{C}) \rightarrow \mathrm{h}_{\leq n}(\mathcal{D})\) is an equivalence. In particular, if \(F\) is categorically 2connective, then it induces an equivalence of homotopy categories \(\mathrm{hC} \rightarrow \mathrm{hD}\).

Remark 4.8.7.10. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Then:
\(\qquad\) 
- If \(F\) is categorically 1 -connective and \(\mathcal{C}\) is a Kan complex, then \(\mathcal{D}\) is also a Kan complex.
- If \(F\) is categorically 2 -connective, then \(\mathcal{C}\) is a Kan complex if and only if \(\mathcal{D}\) is a Kan complex.
Remark 4.8.7.11. Let \(n\) be an integer, and suppose we are given a categorical pullback 05C9 diagram of \(\infty\)-categories

If \(F\) is categorically \(n\)-connective, then \(F^{\prime}\) is categorically \(n\)-connective. The converse holds if \(G\) is full and essentially surjective. See Corollary 4.8.5.28,

05CA Proposition 4.8.7.12 (Transitivity). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories and let \(n\) be an integer. Then:
(1) If \(F\) and \(G\) are categorically \(n\)-connective, then the composite functor \(G \circ F\) is categorically \(n\)-connective.
(2) If \(G \circ F\) is categorically \(n\)-connective, \(G\) is categorically \((n+1)\)-connective, and \(n \geq 1\), then \(F\) is categorically \(n\)-connective.
(3) If \(G \circ F\) is categorically \(n\)-connective and \(F\) is categorically \((n-1)\)-connective, then \(G\) is categorically n-connective.

Proof. Assertions (1) and (3) follow by combining Remark 4.8.5.15 with Proposition 4.8.5.32 (supplemented by Remark 4.8.5.33), respectively. It will therefore suffice to prove (2). Assume that \(n \geq 1\), that \(G \circ F\) is categorically \(n\)-connective, and that \(G\) is categorically \((n+1)\)-connective; we wish to prove that \(F\) is categorically \(n\)-connective: that is, that \(F\) is \(m\)-full for \(m \leq n\). If \(m>0\), this follows from Proposition 4.8.5.30. It will therefore suffice to treat the case \(m=0\) : that is, to show that \(F\) is essentially surjective. This follows from the essential surjectivity of \(G \circ F\), since \(G\) induces an equivalence of homotopy categories (Remark 4.8.7.9).

05CB Proposition 4.8.7.13. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n \geq 0\) be an integer. Suppose that \(F\) is bijective on simplices of dimension \(<n\) and surjective on simplices of dimension \(n\). Then \(F\) is categorically \(n\)-connective.

Proof. Note that \(F\) is automatically essentially surjective (since it is surjective on objects). By virtue of Remark 4.8.7.5, it will suffice to show that for every pair of objects \(X, Y \in \mathcal{C}\), the map of Kan complexes
\[
F_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))
\]
is \((n-1)\)-connective. This follows from Corollary 3.5.2.2, since \(F_{X, Y}\) is bijective on simplices of dimension \(<n-1\) and surjective on simplices of dimension \(n\).

In the case where \(F\) is an isofibration, Definition 4.8.7.1 can be reformulated as a lifting property.

05CC Proposition 4.8.7.14. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an isofibration of \(\infty\)-categories and let \(n\) be an integer. The following conditions are equivalent:
(1) The functor \(F\) is categorically \(n\)-connective.
(2) For every integer \(0 \leq m \leq n\), every lifting problem

admits a solution.
(3) For every simplicial set \(B\) of dimension \(\leq n\) and every simplicial subset \(A \subseteq B\), every lifting problem

admits a solution.
Proof. The equivalence (1) \(\Leftrightarrow(2)\) follows from Proposition 4.8.5.29. The implication \((3) \Rightarrow(2)\) is immediate, and the reverse implication follows from Proposition 1.1.4.12.

We now prove a partial converse to Proposition 4.8.7.13
Proposition 4.8.7.15. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an isofibration of \(\infty\)-categories and let \(n\) be an 05CD integer. The following conditions are equivalent:
(1) The functor \(F\) is categorically \(n\)-connective.
(2) The functor \(F\) factors as a composition
\[
\mathcal{C} \xrightarrow{F^{\prime}} \mathcal{D}^{\prime} \xrightarrow{U} \mathcal{D},
\]
where \(F^{\prime}\) is a monomorphism which is bijective on m-simplices for \(m \leq n\), and \(U\) is a trivial Kan fibration.
(3) The functor \(U\) factors as a composition
\[
\mathcal{C} \xrightarrow{F^{\prime}} \mathcal{D}^{\prime} \xrightarrow{U} \mathcal{D},
\]
where \(F^{\prime}\) is bijective on m-simplices for \(m<n\), surjective on \(n\)-simplices, and \(U\) is categorically \(n\)-connective.

Proof. We proceed as in the proof of Corollary 3.5.2.4. The implication \((2) \Rightarrow(3)\) is clear, and the implication \((3) \Rightarrow(1)\) follows from Propositions 4.8.7.12 and 4.8.7.13. We will complete the proof by showing that (1) implies (2). Assume that \(F\) is categorically \(n\)-connective. Using a variant of Exercise 3.1.7.11, we can choose a factorization of \(F\) as a composition \(\mathcal{C} \xrightarrow{F^{\prime}} \mathcal{D}^{\prime} \xrightarrow{U} \mathcal{D}\) with the following properties;
(a) For every integer \(m>n\), every lifting problem

admits a solution.
(b) The morphism \(F^{\prime}\) can be realized as a transfinite pushout of inclusion maps \(\partial \Delta^{m} \hookrightarrow \Delta^{m}\) for \(m>n\).

It follows immediately from \((b)\) that \(F\) is a monomorphism which is bijective on simplices of dimension \(\leq n\). We will complete the proof by showing that \(U\) is a trivial Kan fibration: that is, every lifting problem

admits a solution. For \(m>n\), this follows from (b). For \(m \leq n\), we can identify 4.53 with a lifting problem

which admits a solution by virtue of our assumption that \(F\) is a categorically \(n\)-connective isofibration (Proposition 4.8.7.14).

05CF Corollary 4.8.7.16. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n\) be an integer. Then \(F\) is categorically \(n\)-connective if and only if it factors as a composition
\[
\mathcal{C} \xrightarrow{E} \mathcal{C}^{\prime} \xrightarrow{F^{\prime}} \mathcal{D}^{\prime} \xrightarrow{G} \mathcal{D}
\]
where \(E\) and \(G\) are equivalences of \(\infty\)-categories and \(F^{\prime}\) is bijective on simplices of dimension \(\leq n\). Moreover, we can arrange that \(E\) and \(F^{\prime}\) are monomorphisms and that \(G\) is a trivial Kan fibration.

Proof. Combine Proposition 4.8.7.15 with Corollary 4.5.2.23.
Corollary 4.8.7.17. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. If \(F\) is categorically 05CG \(n\)-connective, then it is \(n\)-connective.

Proof. Using Corollary 4.8.7.16 (and Remark 4.5.3.4), we can reduce to the case where \(F\) is bijective on simplices of dimension \(\leq n\). In this case, the desired result follows from Corollary 3.5.2.2.

Corollary 4.8.7.18. Let \(n\) be an integer and let \(F: \mathcal{A} \rightarrow \mathcal{B}\) and \(G: \mathcal{C} \rightarrow \mathcal{D}\) be functors 05CH of \(\infty\)-categories. Suppose that \(F\) is categorically \(n\)-connective and that \(G\) is essentially ( \(n-1\) )-categorical. Then the diagram of \(\infty\)-categories

is a categorical pullback square.
For a partial converse, see Proposition 4.8.9.1.
Remark 4.8.7.19. In the situation of Corollary 4.8.7.18. suppose that one of the following 05CK additional conditions is satisfied:
(a) The functor \(F\) is a monomorphism of simplicial sets.
(b) The functor \(G\) is an isofibration.

Condition (a) guarantees that the horizontal maps in the diagram (4.54) are isofibrations (Corollary 4.4.5.3) and condition (b) guarantees that the vertical maps are isofibrations (Corollary 4.4.5.6). In either case, the conclusion of Corollary 4.8.7.18 is equivalent to the requirement that the functor
\[
V: \operatorname{Fun}(\mathcal{B}, \mathcal{C}) \rightarrow \operatorname{Fun}(\mathcal{A}, \mathcal{C}) \times_{\operatorname{Fun}(\mathcal{A}, \mathcal{D})} \operatorname{Fun}(\mathcal{B}, \mathcal{D})
\]
is an equivalence of \(\infty\)-categories (Proposition 4.5.2.26). If conditions (a) and (b) are both satisfied, then \(G\) is an isofibration of \(\infty\)-categories (Proposition 4.4.5.1). In this case, the conclusion of Corollary 4.8.7.18 is equivalent to the requirement that \(G\) is a trivial Kan fibration (Proposition 4.5.5.20).

Proof of Corollary 4.8.7.18. Using Corollary 4.8.7.16 we can reduce to the case where \(F\) is a monomorphism which is bijective on simplices of dimension \(\leq n\). The desired result now follows from Corollary 4.8.6.20 (and Remark 4.8.7.19).

05CL Proposition 4.8.7.20. Let \(m\) and \(n\) be nonnegative integers and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a categorically \((m+n)\)-connective functor of \(\infty\)-categories. Let \(B\) be a simplicial set of dimension \(\leq m\), and let \(A \subseteq B\) be a simplicial subset. Then the induced functor
\[
G: \operatorname{Fun}(B, \mathcal{C}) \rightarrow \operatorname{Fun}(A, \mathcal{C}) \times_{\operatorname{Fun}(A, \mathcal{D})} \operatorname{Fun}(B, \mathcal{D})
\]
is categorically n-connective.
Proof. We proceed as in the proof of Proposition 3.5.2.11. Using Corollary 4.5.2.23 (and Corollary 4.5.2.30), we can reduce to the case where \(F\) is an isofibration. In this case, \(G\) is also an isofibration (Proposition 4.4.5.1). By virtue of Proposition 4.8.7.14, it will suffice to show that if \(B^{\prime}\) is a simplicial set of dimension \(\leq n\) and \(A^{\prime} \subseteq B^{\prime}\) is a simplicial subset, then every lifting problem

admits a solution. Unwinding the definitions, we can rewrite (4.55) as a lifting problem

Since the simplicial set \(B \times B^{\prime}\) has dimension \(\leq m+n\) (Proposition 1.1.3.6), the existence of a solution follows from our assumption that \(F\) is categorically \((m+n)\)-connective (Proposition 4.8.7.14).

05CN Corollary 4.8.7.21. Let \(m\) and \(n\) be nonnegative integers, let \(B\) be a simplicial set of dimension \(\leq m\), and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be functor of \(\infty\)-categories which is categorically \((m+n)\) connective. Then the induced map \(\operatorname{Fun}(B, \mathcal{C}) \rightarrow \operatorname{Fun}(B, \mathcal{D})\) is categorically n-connective.

Proof. Applying Proposition 4.8.7.20 in the special case \(A=\emptyset\).

\subsection*{4.8.8 Relative Higher Homotopy Categories}

Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between categories. Recall that the essential image of \(F\) is 05CP the full subcategory \(\mathcal{D}^{\prime} \subseteq \mathcal{D}\) spanned by those objects which are isomorphic to \(F(X)\), for some object \(X \in \mathcal{C}\). The functor \(F\) then factors as a composition
\[
\mathcal{C} \rightarrow \mathcal{D}_{0} \hookrightarrow \mathcal{D},
\]
where the functor on the left is essentially surjective and the functor on the right is fully faithful. It is sometimes useful to consider a different factorization.
Proposition 4.8.8.1. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between categories. Then \(F\) factors as a 05CQ composition
\[
\mathcal{C} \xrightarrow{F^{\prime}} \mathcal{D}^{\prime} \xrightarrow{G} \mathcal{D}
\]
where \(G\) is faithful and \(F^{\prime}\) is both full and essentially surjective.
Proof. We construct the category \(\mathcal{D}^{\prime}\) as follows:
- The objects of \(\mathcal{D}^{\prime}\) are the objects of \(\mathcal{C}\). To avoid confusion, for each object \(X \in \mathcal{C}\), we write \(\bar{X}\) for the corresponding object of \(\mathcal{D}^{\prime}\).
- For every pair of objects \(X, Y \in \mathcal{C}\), we take \(\operatorname{Hom}_{\mathcal{D}^{\prime}}(\bar{X}, \bar{Y})\) to be image of the map \(F_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y))\). To avoid confusion, if \(u: F(X) \rightarrow F(Y)\) is a morphism of \(\mathcal{D}\) which belongs to the image of \(F_{X, Y}\), we write \(\bar{u}: \bar{X} \rightarrow \bar{Y}\) for the corresponding morphism of \(\mathcal{D}^{\prime}\).
- For every pair of objects \(X, Y, Z \in \mathcal{C}\), the composition law
\[
\circ: \operatorname{Hom}_{\mathcal{D}^{\prime}}(\bar{Y}, \bar{Z}) \times \operatorname{Hom}_{\mathcal{D}^{\prime}}(\bar{X}, \bar{Y}) \rightarrow \operatorname{Hom}_{\mathcal{D}^{\prime}}(\bar{X}, \bar{Z})
\]
is the restriction of the composition law \(\operatorname{Hom}_{\mathcal{D}}(F(Y), F(Z)) \times \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y)) \rightarrow\) \(\operatorname{Hom}_{\mathcal{D}}(F(X), F(Z))\) for the category \(\mathcal{D}\) : that is, it satisfies the formula \(\bar{v} \circ \bar{u}=\bar{v} \circ u\).

Let \(F^{\prime}: \mathcal{C} \rightarrow \mathcal{D}^{\prime}\) be the functor which carries each object \(X \in \mathcal{C}\) to the object \(\bar{X} \in \mathcal{D}^{\prime}\), and each morphism \(u: X \rightarrow Y\) of \(\mathcal{C}\) to the morphism \(\overline{F(u)}: \bar{X} \rightarrow \bar{Y}\) of \(\mathcal{D}^{\prime}\). Let \(G: \mathcal{D}^{\prime} \rightarrow \mathcal{D}\) be the functor which carries each object \(\bar{X} \in \mathcal{D}^{\prime}\) to the object \(F(X) \in \mathcal{D}\), and each morphism \(\bar{u}: \bar{X} \rightarrow \bar{Y}\) of \(\mathcal{D}^{\prime}\) to the morphism \(u: F(X) \rightarrow F(Y)\) of \(\mathcal{D}\). Then the functor \(G\) is faithful, the functor \(F^{\prime}\) is full and essentially surjective, and the composition \(G \circ F^{\prime}\) is equal to \(F\).

Exercise 4.8.8.2 (Uniqueness). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between categories. The proof 05CR of Proposition 4.8.8.1 constructs a factorization
\[
\mathcal{C} \xrightarrow{F^{\prime}} \mathcal{D}^{\prime} \xrightarrow{G} \mathcal{D}
\]
where \(G\) is faithful and \(F^{\prime}\) is both full and bijective on objects. Show that these properties characterize the category \(\mathcal{D}^{\prime}\) up to (unique) isomorphism.

Our goal in this section is to prove the following \(\infty\)-categorical generalization of Proposition 4.8.8.1

05CS Theorem 4.8.8.3. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n\) be an integer. Then \(F\) admits a factorization \(\mathcal{C} \xrightarrow{F^{\prime}} \mathcal{D}^{\prime} \xrightarrow{G} \mathcal{D}\) with the following properties:
- The functor \(G\) is essentially \(n\)-categorical: that is, it is \(m\)-full for \(m \geq n+2\).
- The functor \(F^{\prime}\) is categorically \((n+1)\)-connective: that is, it is \(m\)-full for \(m \leq n+1\).

05 CT Example 4.8.8.4. For \(n \leq-2\), Theorem 4.8.8.3 asserts that every functor of \(\infty\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\) admits a factorization \(\mathcal{C} \xrightarrow{F^{\prime}} \mathcal{D}^{\prime} \xrightarrow{G} \mathcal{D}\), where the functor \(G\) is an equivalence of \(\infty\)-categories. This is trivial: we can take \(\mathcal{D}^{\prime}=\mathcal{D}\) and \(G\) to be the identity functor.
05CU Example 4.8.8.5. When \(n=-1\), Theorem 4.8.8.3 asserts that every functor of \(\infty\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\) admits a factorization \(\mathcal{C} \xrightarrow{F^{\prime}} \mathcal{D}^{\prime} \xrightarrow{G} \mathcal{D}\), where the functor \(G\) is fully faithful and the functor \(F^{\prime}\) is essentially surjective. For example, we can take \(\mathcal{D}^{\prime} \subseteq \mathcal{D}\) to be the essential image of the functor \(F\), and \(G: \mathcal{D}^{\prime} \hookrightarrow \mathcal{D}\) to be the inclusion map. See Remark 4.6.2.12.
05 CV Example 4.8.8.6. When \(n=0\), Theorem 4.8 .8 .3 asserts that every functor of \(\infty\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\) admits a factorization \(\mathcal{C} \xrightarrow{F^{\prime}} \mathcal{D}^{\prime} \xrightarrow{G} \mathcal{D}\), where the functor \(G\) is faithful and the functor \(F^{\prime}\) is both full and essentially surjective. When \(\mathcal{C}\) and \(\mathcal{D}\) are (nerves of) ordinary categories, this follows from Proposition 4.8.8.1. To handle the general case, we can use (the proof of) Proposition 4.8.8.1 to factor the functor \(\mathrm{h} F\) as a composition \(\mathrm{hC} \xrightarrow{F_{0}^{\prime}} \mathcal{D}_{0}^{\prime} \xrightarrow{G_{0}} \mathrm{~h} \mathrm{\mathcal{D}}\) where \(G_{0}\) is a faithful functor and \(F_{0}^{\prime}\) is a full functor which is essentially surjective (or even bijective on objects). To prove Theorem 4.8.8.3, we can take \(\mathcal{D}^{\prime}\) to be the fiber product \(\mathrm{N}_{\bullet}\left(\mathcal{D}_{0}^{\prime}\right) \times_{\mathrm{N} \bullet}(\mathrm{hD}) \mathcal{D}\), and \(G: \mathcal{D}^{\prime} \rightarrow \mathcal{D}\) to be the functor given by projection onto the second factor (which is faithful by virtue of Proposition 4.8.5.8).
05 CW Example 4.8.8.7. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(n\) be an integer. Then the projection \(\operatorname{map} \mathcal{C} \rightarrow \Delta^{0}\) factors as a composition
\[
\mathcal{C} \xrightarrow{F^{\prime}} \mathrm{h}_{\leq n}(\mathcal{C}) \xrightarrow{G} \Delta^{0},
\]
where \(\mathrm{h}_{\leq n}(\mathcal{C})\) is the homotopy \(n\)-category constructed in \(\S 44.8 .4\). This factorization satisfies the requirements of Theorem 4.8.8.3. the functor \(G\) is essentially \(n\)-categorical because \(\mathrm{h}_{\leq n}(\mathcal{C})\) is an \((n, 1)\)-category (Example 4.8.6.4), and the functor \(F^{\prime}\) is categorically \((n+1)\)-connective by Example 4.8.5.12.
05CX Remark 4.8.8.8 (Uniqueness). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Then, for every integer \(n\), the factorization of Theorem 4.8.8.3 is well-defined up to equivalence. More precisely, if the functor \(F\) admits two factorizations
\[
\mathcal{C} \xrightarrow{F_{0}^{\prime}} \mathcal{D}_{0}^{\prime} \xrightarrow{G_{0}} \mathcal{D} \quad \mathcal{C} \xrightarrow{F_{1}^{\prime}} \mathcal{D}_{1}^{\prime} \xrightarrow{G_{1}} \mathcal{D}
\]
where the functors \(F_{0}^{\prime}\) and \(F_{1}^{\prime}\) are essentially \(n\)-categorical, and the functors \(G_{0}\) are \(G_{1}\) are categorically \((n+1)\)-connective, then we can find a commutative diagram

where the vertical maps are equivalences of \(\infty\)-categories. To prove this, we can use Corollary 4.5 .2 .23 to reduce to the case where \(F_{0}^{\prime}\) is a monomorphism of simplicial sets and \(G_{1}\) is an isofibration. In this case, Corollary 4.8.7.18 (and Remark 4.8.7.19) guarantee that the functors \(F_{0}^{\prime}\) and \(G_{1}\) induce a trivial Kan fibration
\[
\operatorname{Fun}\left(\mathcal{D}_{0}^{\prime}, \mathcal{D}_{1}^{\prime}\right) \rightarrow \operatorname{Fun}\left(\mathcal{C}, \mathcal{D}_{1}^{\prime}\right) \times_{\operatorname{Fun}(\mathcal{C}, \mathcal{D})} \operatorname{Fun}\left(\mathcal{D}_{0}^{\prime}, \mathcal{D}\right)
\]

In particular, this map is surjective on vertices, so the lifting problem

has a solution. A choice of solution determines a commutative diagram

It follows from Proposition 4.8.7.12 that the functor \(H\) is categorically \((n+1)\)-connective, and from Remark 4.8.6.7 that \(H\) is essentially \(n\)-categorical. Applying Remark 4.8.5.11, we conclude that \(H\) is an equivalence of \(\infty\)-categories.

05CY Corollary 4.8.8.9. Let \(f: X \rightarrow Z\) be a morphism of Kan complexes and let \(n\) be an integer. Then \(f\) factors as a composition \(X \xrightarrow{f^{\prime}} Y \xrightarrow{f^{\prime \prime}} Z\), where \(f^{\prime \prime}\) is \(n\)-truncated and \(f^{\prime}\) is \((n+1)\)-connective.

Proof. Using Theorem 4.8.8.3, we can factor \(f\) as a composition \(f^{\prime \prime} \circ f^{\prime}\), where \(f^{\prime \prime}: \mathcal{C} \rightarrow Z\) is an essentially \(n\)-categorical functor of \(\infty\)-categories and \(f^{\prime}: X \rightarrow \mathcal{C}\) is categorically ( \(n+1\) )-connective. If \(n \leq-1\), then \(f^{\prime \prime}\) induces an equivalence from \(\mathcal{C}\) to a summand of \(Z\), so that \(\mathcal{C}\) is a Kan complex. If \(n \geq 0\), Remark 4.8.7.10 guarantees that \(\mathcal{C}\) is a Kan complex. Setting \(Y=\mathcal{C}\), we observe that \(f^{\prime \prime}\) is \(n\)-truncated (Example 4.8.6.3) and \(f^{\prime}\) is ( \(n+1\) )-connective (Example 4.8.7.3).

We will prove Theorem 4.8.8.3 in general by reducing to the special case studied in Example 4.8.8.7. For this, we will need a relative version of the construction \(\mathcal{C} \mapsto \mathrm{h}_{\leq n}(\mathcal{C})\) introduced in \(\$ 4.8 .4\)

05CZ Construction 4.8.8.10 (Relative Homotopy \(n\)-Categories). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of simplicial sets and let \(n \geq 0\) be an integer. For every \(m\)-simplex \(\sigma\) of \(\mathcal{D}\), let \(\mathcal{C}_{\sigma}\) denote the fiber product \(\Delta^{m} \times_{\mathcal{D}} \mathcal{C}\). We let \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})_{m}\) denote the collection of pairs \((\sigma, \tau)\), where \(\sigma\) is an \(m\)-simplex of \(\mathcal{D}\) and \(\tau\) is a section of the projection map
\[
\mathrm{h}_{\leq n}\left(\mathcal{C}_{\sigma}\right) \rightarrow \mathrm{h}_{\leq n}\left(\Delta^{m}\right) \simeq \Delta^{m} .
\]

If \(f:\left[m^{\prime}\right] \rightarrow[m]\) is a nondecreasing function, we let \(f^{*}: \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})_{m} \rightarrow \mathrm{~h}_{\leq n}(\mathcal{C} / \mathcal{D})_{m^{\prime}}\) denote the map given by \(f^{*}(\sigma, \tau)=\left(\sigma^{\prime}, \tau^{\prime}\right)\), where \(\sigma^{\prime}\) is the composite map \(\Delta^{m^{\prime}} \xrightarrow{\bar{f}} \Delta^{m} \xrightarrow{\sigma} \mathcal{D}\) and \(\tau^{\prime}\) is given by the composition
\[
\begin{aligned}
\Delta^{m^{\prime}} & \simeq \Delta^{m^{\prime}} \times \times_{\Delta^{m}} \Delta^{m} \\
& \xrightarrow{(\mathrm{id}, \tau)} \\
& \Delta^{m^{\prime}} \times{ }_{\Delta^{m}} \mathrm{~h}_{\leq n}\left(\mathcal{C}_{\sigma}\right) \\
& \simeq \mathrm{h}_{\leq n}\left(\Delta^{m^{\prime}} \times \Delta^{m} \mathcal{C}_{\sigma}\right) \\
& \simeq \mathrm{h}_{\leq n}\left(\mathcal{C}_{\sigma^{\prime}}\right),
\end{aligned}
\]
where the second isomorphism is provided by Proposition 4.8.4.20. By means of this construction, we can view the assignment \([m] \mapsto \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})_{m}\) as a simplicial set, which we will denote by \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\). Note that the construction \((\sigma, \tau) \mapsto \sigma\) determines a comparison map of simplicial sets \(G: \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D}) \rightarrow \mathcal{D}\).

It will be useful to extend this construction to the case where \(n<0\). If \(n=-1\), we define \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\) to be the full simplicial subset of \(\mathcal{D}\) whose vertices belong to the image of \(F\), and we take \(G: \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D}) \hookrightarrow \mathcal{D}\) to be the inclusion map. If \(n \leq-2\), we define \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\) to be the simplicial set \(\mathcal{D}\), and \(G\) to be the identity morphism \(\operatorname{id}_{\mathcal{D}}\).

Example 4.8.8.11. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories and let \(n\) be an 05D0 integer. Then there is a comparison map from the simplicial set \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\) to the homotopy \(n\)-category \(\mathrm{h}_{\leq n}(\mathcal{C})\). For \(n \geq 0\), this map carries an \(m\)-simplex \((\sigma, \tau)\) of \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\) to the \(m\)-simplex of \(\mathrm{h}_{\leq n}(\mathcal{C})\) given by the composite map
\[
\Delta^{m} \xrightarrow{\tau} \mathrm{~h}_{\leq n}\left(\mathcal{C}_{\sigma}\right) \rightarrow \mathrm{h}_{\leq n}(\mathcal{C}) .
\]

If \(\mathcal{D}\) is an ( \(n, 1\) )-category, then this comparison map is an isomorphism (Proposition 4.8.4.20).
Example 4.8.8.12. Let \(\mathcal{C}\) be an \(\infty\)-category, so that the projection map \(F: \mathcal{C} \rightarrow \Delta^{0}\) is an
05D1 inner fibration. Since \(\Delta^{0}\) is an ( \(n, 1\) )-category, Example 4.8.8.11 supplies an isomorphism of simplicial sets \(\mathrm{h}_{\leq n}\left(\mathcal{C} / \Delta^{0}\right) \simeq \mathrm{h}_{\leq n}(\mathcal{C})\).

Remark 4.8.8.13 (Base Change). Suppose we are given a pullback diagram of simplicial 05D2 sets

where the vertical maps are inner fibrations. Then, for every integer \(n\), the simplicial set \(\mathrm{h}_{\leq n}\left(\mathcal{C}^{\prime} / \mathcal{D}^{\prime}\right)\) can be identified with the fiber product \(\mathcal{D}^{\prime} \times_{\mathcal{D}} \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\). In particular, for every vertex \(D \in \mathcal{D}\), we have a canonical isomorphism
\[
\{D\} \times_{\mathcal{D}} \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D}) \simeq \mathrm{h}_{\leq n}\left(\{D\} \times_{\mathcal{D}} \mathcal{C}\right) .
\]

Proposition 4.8.8.14. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of simplicial sets and let \(n\) be 05D3 an integer. Then the comparison map \(G: \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D}) \rightarrow \mathcal{D}\) of Construction 4.8.8.10 is an \(n\)-categorical inner fibration (see Definition 4.8.6.23).

Proof. For \(n<0\), this is immediate from the construction. We may therefore assume without loss of generality that \(n \geq 0\). Using Remarks 4.8.6.32 and 4.8.8.13, we can reduce to the case where \(\mathcal{D}=\Delta^{m}\) is a standard simplex. In particular, \(\mathcal{D}\) is an ( \(n, 1\) )-category. In this case, Example 4.8.8.11 guarantees that the simplicial set \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D}) \simeq \mathrm{h}_{\leq n}(\mathcal{D})\) is an \((n, 1)\)-category. The desired result now follows from Proposition 4.8.6.31.

Remark 4.8.8.15. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of simplicial sets and let \(n\) be an 05D4 integer. Then the comparison map \(G: \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D}) \rightarrow \mathcal{D}\) of Construction 4.8.8.10 fits into a
commutative diagram

For \(n \geq 0\), the morphism \(F^{\prime}\) carries each \(m\)-simplex of \(\mathcal{C}\) to the \(m\)-simplex \((F(\sigma), \tau)\) of \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\), where \(\tau\) is the composite map
\[
\Delta^{m} \xrightarrow{(\mathrm{id}, \sigma)} \Delta^{m} \times_{\mathcal{D}} \mathcal{C}=\mathcal{C}_{\sigma} \rightarrow \mathrm{h}_{\leq n}\left(\mathcal{C}_{\sigma}\right) .
\]

The simplicial set \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\) of Construction 4.8 .8 .10 can be characterized by a universal mapping property:
05D5 Proposition 4.8.8.16. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of simplicial sets and let \(n\) be an integer. Then, for every \(n\)-categorical inner fibration \(\mathcal{D}^{\prime} \rightarrow \mathcal{D}\), the comparison map of Remark 4.8.8.15 induces an isomorphism of simplicial sets
\[
\theta: \operatorname{Fun}_{\mathcal{D}}\left(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D}), \mathcal{D}^{\prime}\right) \rightarrow \operatorname{Fun}_{\mathcal{D}}\left(\mathcal{C}, \mathcal{D}^{\prime}\right) .
\]

Proof. We may assume without loss of generality that \(n \geq 0\) (otherwise, the result follows immediately from the construction). For every morphism of simplicial sets \(K \rightarrow \mathcal{D}\), Remark 4.8.8.15 determines a comparison map
\[
\theta_{K}: \operatorname{Fun}_{/ \mathcal{D}}\left(K \times_{\mathcal{D}} \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D}), \mathcal{D}^{\prime}\right) \rightarrow \operatorname{Fun}_{/ \mathcal{D}}\left(K \times_{\mathcal{D}} \mathcal{C}, \mathcal{D}^{\prime}\right)
\]

We will prove that each \(\theta_{K}\) is an isomorphism of simplicial sets; Proposition 4.8.8.16 then follows by taking \(K=\mathcal{D}\). Note that the construction \(K \mapsto \theta_{K}\) carries colimits (in the category of simplicial sets with a morphism to \(\mathcal{D}\) ) to limits (in the arrow category \(\left.\operatorname{Fun}\left([1], \operatorname{Set}_{\Delta}\right)\right)\). By virtue of Remark 1.1.3.13, we can assume without loss of generality that \(K\) is a standard simplex. Replacing \(F\) by the projection map \(K \times_{\mathcal{D}} \mathcal{C} \rightarrow K\) and \(\mathcal{D}^{\prime}\) by the fiber product \(K \times{ }_{\mathcal{C}} \mathcal{D}^{\prime}\), we are reduced to proving Proposition 4.8.8.16 in the special case where \(\mathcal{D}\) is a standard simplex: in particular, it is an ( \(n, 1\) )-category. In this case, \(\mathcal{D}^{\prime}\) is also an ( \(n, 1\) )-category (Proposition 4.8.6.31), and we can identify \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\) with the homotopy \(n\)-category of \(\mathcal{C}\) (Example 4.8.8.11). Applying Proposition 4.8.4.7. we see that the horizontal maps in the commutative diagram

are isomorphisms. The desired result now follows by passing to fibers of the vertical maps.
Remark 4.8.8.17. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of simplicial sets, let \(n\) be an integer, and let \(A \subseteq B\) be simplicial sets. If \(B\) has dimension \(\leq n+1\), then every lifting problem

has a solution. Moreover, if \(B\) has dimension \(\leq n-1\), then the solution is unique. To prove this, we can assume without loss of generality that \(B=\Delta^{m}\) is a standard simplex for some \(m \leq n+1\), and that \(A=\partial \Delta^{m}\) is its boundary (see Proposition 1.1.4.12). The case \(n \leq-2\) is vacuous, and the case \(n=-1\) is immediate from the definition. We may therefore assume that \(n \geq 0\). Replacing \(F\) by the projection map \(\Delta^{m} \times_{\mathcal{D}} \mathcal{C} \rightarrow \Delta^{m}\), we can reduce to the case where \(\mathcal{D}\) is a standard simplex, so that \(U^{\prime}\) identifies \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\) with the homotopy \(n\)-category \(\mathrm{h}_{\leq n}(\mathcal{C})\) (Example 4.8.8.11). In this case, the desired result follows from Corollary 4.8.4.17

Proposition 4.8.8.18. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of simplicial sets and let \(n\) be an integer. Then the comparison map \(F^{\prime}: \mathcal{C} \rightarrow \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\) of Remark 4.8.8.15 is an inner fibration.

Proof. Without loss of generality, we may assume that \(n \geq 0\). Using Remarks 4.1.1.13 and 4.8.8.13, we can reduce to the case where \(\mathcal{D}=\Delta^{m}\) is a standard simplex. In this case, \(F^{\prime}\) identifies with the tautological map \(\mathcal{C} \rightarrow \mathrm{h}_{\leq n}(\mathcal{C})\) (Example 4.8.8.11), so the desired result follows from Corollary 4.8.4.16.

Corollary 4.8.8.19. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories and let \(n\) be 05D8 an integer. Then the simplicial set \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\) is an \(\infty\)-category. Moreover, the functor \(F^{\prime}: \mathcal{C} \rightarrow \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\) of Remark 4.8.8.15 is categorically \((n+1)\)-connective.

Proof. Since \(\mathcal{D}\) is an \(\infty\)-category and the comparison map \(G: \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D}) \rightarrow \mathcal{D}\) is an inner fibration (Proposition 4.8.8.14), the simplicial set \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\) is also an \(\infty\)-category (Remark 4.1.1.9. Fix an integer \(m \leq n+1\); we wish to show that the functor \(F^{\prime}\) is \(m\)-full. For \(n=-2\), there is nothing to prove. If \(n=-1\), then \(U^{\prime}\) is surjective on objects (by construction) and therefore essentially surjective. We may therefore assume without loss of generality that \(n \geq 0\). Since \(U^{\prime}\) is an inner fibration (Proposition 4.8.8.18), it will suffice to show that for every morphism \(\Delta^{1} \rightarrow \mathrm{~h}_{\leq n}(\mathcal{E} / \mathcal{C})\), the projection map \(\Delta^{1} \times_{\mathrm{h}_{\leq n}(\mathcal{E} / \mathcal{C})} \mathcal{E} \rightarrow \Delta^{1}\) is \(m\)-full (Proposition 4.8.5.27. Using Remark 4.8.8.13, we can replace \(F\) by the projection
map \(\Delta^{1} \times{ }_{\mathcal{D}} \mathcal{C} \rightarrow \Delta^{1}\), and thereby reduce to the situation where \(\mathcal{D}=\Delta^{1}\) is an \((n, 1)\)-category. In this case, the functor \(F^{\prime}\) exhibits \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\) as a homotopy \(n\)-category of \(\mathcal{C}\) (Example 4.8.8.11, so the desired result follows from Example 4.8.5.12

Proof of Theorem 4.8.8.3. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(n\) be an integer. We wish to show that \(F\) factors as a composition \(G \circ F^{\prime}\), where \(G\) is essentially \(n\)-categorical and \(F^{\prime}\) is categorically \((n+1)\)-connective. Using Proposition 4.1.3.2, we can reduce to the case where \(F\) is an inner fibration. In this case, the factorization
\[
\mathcal{C} \xrightarrow{F^{\prime}} \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D}) \xrightarrow{G} \mathcal{C}
\]
of Remark 4.8.8.15 has the desired properties: Proposition 4.8.8.14 guarantees that \(G\) is an \(n\) categorical inner fibration (and is therefore essentially \(n\)-categorical, by virtue of Proposition 4.8.6.34), and Corollary 4.8.8.19 guarantees that \(F^{\prime}\) is categorically \((n+1)\)-connective.

05D9 Warning 4.8.8.20. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories. In the case \(n=0\), our proof of Theorem 4.8.8.3 shows that \(F\) factors as a composition
\[
\mathcal{E} \xrightarrow{F^{\prime}} \mathrm{h}_{\leq 0}(\mathcal{C} / \mathcal{D}) \xrightarrow{G} \mathcal{D},
\]
where \(F^{\prime}\) is fully faithful and essentially surjective, and \(G\) is a 0 -categorical inner fibration (in particular, \(G\) is faithful). Beware that generally does not coincide with the factorization constructed in Example 4.8.8.6. If \(u: X \rightarrow Y\) is an isomorphism in the \(\infty\)-category \(\mathcal{C}\) having the property that \(F(u)\) is an identity morphism in \(\mathcal{D}\), then the functor \(F^{\prime}\) carries \(X\) and \(Y\) to the same object of \(\mathrm{h}_{\leq 0}(\mathcal{C} / \mathcal{D})\). Consequently, the functor \(F^{\prime}\) is generally not bijective on objects.

A related phenomenon occurs in the case \(n=-1\). By construction, \(\mathrm{h}_{\leq-1}(\mathcal{C} / \mathcal{D})\) is the full subcategory of \(\mathcal{D}\) spanned by objects of the form \(F(X)\), where \(X\) is an object of \(\mathcal{C}\). If the inner fibration \(U\) is not an isofibration, this subcategory might be smaller than the essential image of \(F\).

We close this section with a few additional observations about Construction 4.8.8.10.
05DA Proposition 4.8.8.21. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of simplicial sets, let \(n\) be an integer, and let \(G: \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D}) \rightarrow \mathcal{D}\) be the comparison map of Construction 4.8.8.10. Then:
(1) If \(F\) is a left fibration, then \(G\) is a left fibration.
(2) If \(F\) is a right fibration, then \(G\) is a right fibration.
(3) If \(F\) is a Kan fibration, then \(G\) is a Kan fibration.
(4) If \(F\) is an isofibration of \(\infty\)-categories, then \(G\) is an isofibration of \(\infty\)-categories.

Proof. We first prove (1). Assume that \(F\) is a left fibration, and suppose we are given integers \(0 \leq i<n\); we wish to show that every lifting problem

admits a solution. If \(m \leq n+2\), then \(\sigma_{0}\) can be lifted to a morphism \(\Lambda_{i}^{m} \rightarrow \mathcal{C}\) (Remark 4.8.8.17), so the desired result follows from our assumption that \(F\) is a left fibration. We may therefore assume that \(m \geq n+3\). If \(n=-2\), then \(G\) is an isomorphism and there is nothing to prove. If \(n=-1\), then \(G\) identifies \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\) with a full simplicial subset of \(\mathcal{D}\), and the desired result follows from the observation that \(\Lambda_{i}^{m}\) contains every vertex of \(\Delta^{m}\). We may therefore assume that \(n \geq 0\). Replacing \(F\) by the projection map \(\Delta^{m} \times_{\mathcal{D}} \mathcal{C} \rightarrow \Delta^{m}\), we can reduce to the case where \(\mathcal{D}=\Delta^{m}\) is a standard simplex. In this case, \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\) is an ( \(n, 1\) )-category (Example 4.8.8.11). In particular, it is an \((n+1)\)-coskeletal simplicial set, so the lifting problem (4.56) has a unique solution (since \(\Lambda_{i}^{m}\) contains the \((n+1)\)-skeleton of \(\Delta^{m}\) ).

Assertion (2) follows by applying (1) to the opposite inner fibration \(U^{\mathrm{op}}: \mathcal{C}^{\mathrm{op}} \rightarrow \mathcal{D}^{\mathrm{op}}\). Assertion (3) follows by combining (1) and (2) with Example 4.2.1.5. It remains to prove (4). Fix an object \(Y \in \mathrm{~h}_{\leq n}(\mathcal{C} / \mathcal{D})\) and an isomorphism \(\bar{e}: \bar{X} \rightarrow V(Y)\) in the \(\infty\)-category \(\mathcal{D}\); we wish to show that \(\bar{e}\) can be lifted to an isomorphism \(e: X \rightarrow Y\) of \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\). If \(n \leq-2\), then \(G\) is an isomorphism and the result is obvious. Otherwise, the comparison map \(F^{\prime}: \mathcal{C} \rightarrow \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\) is surjective on vertices, so we can choose an object \(\tilde{Y} \in \mathcal{C}\) satisfying \(F^{\prime}(\tilde{Y})=Y\). If \(F\) is an isofibration, then there exists an isomorphism \(\widetilde{e}: \widetilde{X} \rightarrow \tilde{Y}\) of \(\mathcal{C}\) satisfying \(F(\widetilde{e})=\bar{e}\). It follows that \(e=F^{\prime}(\widetilde{e})\) is an isomorphism in \(\mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\) satisfying \(G(e)=\bar{e}\).

Proposition 4.8.8.22. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories and let \(n\) be 05DC an integer. The following conditions are equivalent:
(1) The functor \(F\) is essentially \(n\)-categorical.
(2) The comparison map \(F^{\prime}: \mathcal{C} \rightarrow \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D})\) of Remark 4.8.8.15 is an equivalence of \(\infty\)-categories.

Proof. It follows from Proposition 4.8.8.14 (and Proposition 4.8.6.34) that the comparison \(\operatorname{map} G: \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D}) \rightarrow \mathcal{D}\) is essentially \(n\)-categorical. By virtue of Remark 4.8.6.8, we can replace (1) by the following condition:
(1 ) The functor \(F^{\prime}\) is essentially \(n\)-categorical: that is, it is \(m\)-full for \(m \geq n+2\).
Since \(F^{\prime}\) is also \(m\)-full for \(m \leq n+1\) (Corollary 4.8.8.19), the equivalence \(\left(1^{\prime}\right) \Leftrightarrow(2)\) follows from Remark 4.8.5.11.

05DD Corollary 4.8.8.23. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. For every integer \(n\), the following conditions are equivalent:
(1) The functor \(F\) is essentially \(n\)-categorical.
(2) The functor \(F\) factors as a composition \(\mathcal{C} \xrightarrow{F^{\prime}} \mathcal{D}^{\prime} \xrightarrow{G} \mathcal{D}\), where \(F^{\prime}\) is an equivalence of \(\infty\)-categories and \(G\) is an n-categorical isofibration.

Proof. The implication \((2) \Rightarrow(1)\) follows from Proposition 4.8.6.34 (together with Remark 4.8.5.18). To prove the converse, we may assume without loss of generality that \(F\) is an isofibration (Corollary 4.5.2.23). In this case, the factorization \(\mathcal{C} \xrightarrow{F^{\prime}} \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D}) \xrightarrow{G} \mathcal{D}\) of Remark 4.8.8.15 has the desired properties: Proposition 4.8.8.22 guarantees that \(F^{\prime}\) is an equivalence of \(\infty\)-categories, Proposition 4.8.8.21 guarantees that \(G\) is an isofibration, and Proposition 4.8.8.14 guarantees that \(G\) is \(n\)-categorical.

05DE Proposition 4.8.8.24. Let \(n\) be an integer, and suppose we are given a commutative diagram of \(\infty\)-categories

where the vertical maps are inner fibrations. If \(F\) is categorically \((n+1)\)-connective, then it induces an equivalence of \(\infty\)-categories \(F^{\prime}: \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{E}) \rightarrow \mathrm{h}_{\leq n}(\mathcal{D} / \mathcal{E})\).

Proof. We have a commutative diagram of \(\infty\)-categories

Here \(F\) is categorically \((n+1)\)-connective by assumption, and the vertical maps are categorically \((n+1)\)-connective by virtue of Corollary 4.8.8.19. Applying Proposition 4.8.7.12, we
see that the functor \(F^{\prime}\) is also categorically \((n+1)\)-connective. We also have a commutative diagram

where the vertical maps are essentially \(n\)-categorical (Proposition 4.8.8.14). Using Remark 4.8.6.8, we see that \(F^{\prime}\) is also essentially \(n\)-categorical. Using Remark 4.8.5.11, we see that \(F^{\prime}\) is an equivalence of \(\infty\)-categories.

Corollary 4.8.8.25. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories and let \(n\) be an 05DF integer. The following conditions are equivalent:
(1) The comparison map \(G: \mathrm{h}_{\leq n}(\mathcal{C} / \mathcal{D}) \rightarrow \mathcal{D}\) is an equivalence of \(\infty\)-categories.
(2) The functor \(F\) is categorically \((n+1)\)-connective.

Proof. The implication (1) \(\Rightarrow(2)\) follows from Proposition 4.8.8.14 and Remark 4.8.5.16. The reverse implication follows by applying Proposition 4.8 .8 .24 in the special case \(\mathcal{E}=\mathcal{D}\).

\subsection*{4.8.9 Categorically Connective Morphisms of Simplicial Sets}

Using Theorem 4.8.8.3, we can give an alternative characterization of categorical connec- 05DG tivity.

Proposition 4.8.9.1. Let \(F: \mathcal{A} \rightarrow \mathcal{B}\) be a functor of \(\infty\)-categories and let \(n\) be an integer. 05DH The following conditions are equivalent:
(1) The functor \(F\) is categorically n-connective (Definition 4.8.7.1).
(2) For every essentially ( \(n-1\) )-categorical functor of \(\infty\)-categories \(U: \mathcal{C} \rightarrow \mathcal{D}\), the diagram

is a categorical pullback square.
(3) For every ( \(n-1\) )-categorical isofibration \(U: \mathcal{C} \rightarrow \mathcal{B}\), precomposition with \(F\) induces an equivalence of \(\infty\)-categories
\[
\theta_{\mathcal{C}}: \operatorname{Fun}_{\mathcal{B}}(\mathcal{B}, \mathcal{C}) \rightarrow \operatorname{Fun}_{/ \mathcal{B}}(\mathcal{A}, \mathcal{C}) .
\]

Proof. The implication (1) \(\Rightarrow(2)\) is a restatement of Corollary 4.8.7.18, and the implication \((2) \Rightarrow(3)\) follows from Corollary 4.5.2.32. To show that (3) implies (1), we may assume without loss of generality that \(F\) is an isofibration. Then the comparison map \(G: \mathrm{h}_{\leq n-1}(() \mathcal{A} / \mathcal{B}) \rightarrow \mathcal{B}(n-1)\)-categorical isofibration (Propositions 4.8.8.14 and 4.8.8.21). If \(U: \mathcal{C} \rightarrow \mathcal{B}\) is another \((n-1)\)-categorical isofibration, then we can use Proposition 4.8.8.16 to identify \(\theta_{\mathcal{C}}\) with the map with the functor Fun \(/ \mathcal{B}\left(\mathcal{B}, \mathcal{B}^{\prime}\right) \rightarrow \operatorname{Fun}_{/ \mathcal{B}}\left(\mathrm{h}_{\leq n-1}(\mathcal{A} / \mathcal{B}), \mathcal{C}\right)\) given by precomposition with \(G\). If condition (3) is satisfied, then \(G\) is an equivalence of \(\infty\)-categories, so that \(F\) is categorically \(n\)-connective by virtue of Corollary 4.8.8.25.

Motivated by Proposition 4.8.9.1, we introduce a generalization of Definition 4.8.7.1.
05DJ Definition 4.8.9.2. Let \(f: A \rightarrow B\) be a morphism of simplicial sets and let \(n\) be an integer. We say that \(f\) is categorically \(n\)-connective if, for every essentially ( \(n-1\) )-categorical functor of \(\infty\)-categories \(U: \mathcal{C} \rightarrow \mathcal{D}\), the diagram

is a categorical pullback square.
05DK Remark 4.8.9.3. In the situation of Definition 4.8.9.2, we can assume without loss of generality that the functor \(U: \mathcal{C} \rightarrow \mathcal{D}\) is an isofibration (see Corollary 4.5.2.23). Replacing \(\mathcal{C}\) by the simplicial set \(\mathrm{h}_{\leq n-1}(\mathcal{C} / \mathcal{D})\), we can further arrange that the isofibration \(U\) is ( \(n-1\) )-categorical (Proposition 4.8.8.22).

05DL Remark 4.8.9.4. Let \(n\) be an integer. The notion of categorical \(n\)-connectivity is completely determined by the following two properties:
(1) If \(F: \mathcal{A} \rightarrow \mathcal{B}\) is a functor of \(\infty\)-categories, then it is categorically \(n\)-connective in the sense of Definition 4.8.9.2 if and only if it is categorically \(n\)-connective in the sense of Definition 4.8.7.1. that is, \(F\) is \(m\)-full for every nonnegative integer \(m \leq n\) (see Proposition 4.8.9.1).
(2) Suppose we are given a commutative diagram of simplicial sets

where the horizontal maps are categorical equivalences. Then \(f\) is categorically \(n\) connective if and only if \(f^{\prime}\) is categorically \(n\)-connective. See Proposition 4.5.2.19

If \(f: A \rightarrow B\) is any morphism of simplicial sets, then we can use Proposition 4.1.3.2 to choose a commutative diagram

where the horizontal maps are categorical equivalences and \(F\) is a functor of \(\infty\)-categories. Combining (1) and (2), we see that \(f\) is categorically \(n\)-connective if and only if the functor \(F\) is \(m\)-full for \(m \leq n\).

Remark 4.8.9.5. Let \(f: A \rightarrow B\) be a morphism of simplicial sets. If \(f\) is categorically \(n\)-connective, then it is \(n\)-connective. This follows from Remark 4.8.9.4 and Corollary 4.8.7.17. Beware that the converse is false in general (Warning 4.8.7.4).

Remark 4.8.9.6 (Transitivity). Let \(f: A \rightarrow B\) and \(g: B \rightarrow C\) be morphisms of simplicial 05DN sets and let \(n\) be an integer.
(1) Suppose that \(f\) and \(g\) are categorically \(n\)-connective. Then \(g \circ f\) is categorically \(n\) connective.
(2) Suppose that \(g \circ f\) is categorically \(n\)-connective, \(g\) is categorically \((n+1)\)-connective, and \(n \geq 1\). Then \(f\) is categorically \(n\)-connective.
(3) Suppose that \(g \circ f\) is categorically \(n\)-connective and that \(f\) is categorically ( \(n-1\) )connective. Then \(g\) is categorically \(n\)-connective.

To prove these assertions, we can use Remark 4.8.9.4 to reduce to the case where \(A, B\), and \(C\) are \(\infty\)-categories, in which case the result follows from Proposition 4.8.7.12
Proposition 4.8.9.7. Suppose we are given a categorical pushout square of simplicial sets

where \(f\) is categorically \(n\)-connective. Then \(f^{\prime}\) is also categorically \(n\)-connective.
Proof. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be an essentialy ( \(n-1\) )-categorical functor of \(\infty\)-categories, and consider the cubical diagram

Our assumption that \(f\) is categorically \(n\)-connective guarantees that the right face is a categorical pullback square, and our assumption on (4.57) guarantees that the front and back faces are categorical pullback squares. Applying Proposition 4.5.2.18, we conclude that the left face is also a categorical pullback square.

05DR Proposition 4.8.9.8. Let \(f: A \hookrightarrow B\) be a monomorphism of simplicial sets and let \(n\) be an integer. The following conditions are equivalent:
(1) The morphism \(f\) is categorically n-connective.
(2) For every essentially (n-1)-categorical functor of \(\infty\)-categories \(U: \mathcal{C} \rightarrow \mathcal{D}\), the restriction map
\[
V: \operatorname{Fun}(B, \mathcal{C}) \rightarrow \operatorname{Fun}(A, \mathcal{C}) \times_{\operatorname{Fun}(A, \mathcal{D})} \operatorname{Fun}(B, \mathcal{D})
\]
is an equivalence of \(\infty\)-categories.
(3) For every essentially ( \(n-1\) )-categorical isofibration of \(\infty\)-categories \(U: \mathcal{C} \rightarrow \mathcal{D}\), the functor \(V\) is a trivial Kan fibration.
(3) Every lifting problem

admits a solution, provided that \(U\) is an essentially ( \(n-1\) )-categorical isofibration of \(\infty\)-categories.

Proof. The equivalences \((1) \Leftrightarrow(2) \Leftrightarrow(3)\) follow from Remarks 4.8.7.19 and 4.8.9.3, and the implication \((3) \Rightarrow(4)\). is immediate. We will complete the proof by showing that (4) implies (3). Assume that condition (4) is satisfied, and let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be an essentially ( \(n-1\) )-categorical isofibration of \(\infty\)-categories. We wish to show that, for every simplicial set \(B^{\prime}\) and every simplicial subset \(A^{\prime} \subseteq B^{\prime}\), every lifting problem

05DS
admits a solution. Unwinding the definitions, we can rewrite 4.58) as a lifting problem

The existence of a solution follows from (4), since \(V^{\prime}\) is also an essentially ( \(n-1\) )-categorical isofibration of \(\infty\)-categories (Corollary 4.8.6.20 and Proposition 4.4.5.1).

Example 4.8.9.9. Let \(B\) be a simplicial set and let \(A \subseteq B\) be a simplicial subset which 05DT contains the \(n\)-skeleton of \(B\). Then the inclusion map \(A \hookrightarrow B\) is categorically \(n\)-connective. In particular, for every simplicial set \(B\), the inclusion map \(\mathrm{sk}_{n}(B) \hookrightarrow B\) is categorically \(n\)-connective.

Proposition 4.8.9.10. Let \(n \geq 0\) be an integer and let \(f: A \rightarrow B\) be a morphism of 05DU simplicial sets which is bijective on simplices of dimension \(<n\) and surjective on \(n\)-simplices. Then \(f\) is categorically \(n\)-connective.

Proof. Using Proposition 1.1.4.12, we can choose a simplicial subset \(A^{\prime} \subseteq \operatorname{sk}_{n}(A)\) which contains the ( \(n-1\) )-skeleton of \(A\), such that \(f\) restricts to an isomorphism of \(A^{\prime}\) with the \(n\)-skeleton of \(B\). It follows from Example 4.8.9.9 \(\left.f\right|_{A^{\prime}}\) is categorically \(n\)-connective, and that the inclusion map \(A^{\prime} \hookrightarrow A\) is categorically \((n-1)\)-connective. Applying Remark 4.8.9.6, we deduce that \(f\) is categorically \(n\)-connective.

\section*{Chapter 5}

\section*{Fibrations of \(\infty\)-Categories}

Let Ab denote the category of abelian groups. For every commutative ring \(A\), we let \(\operatorname{Mod}_{A}(\mathrm{Ab})\) denote the category of \(A\)-modules. Every homomorphism of commutative rings \(u: A \rightarrow B\) determines a functor
\[
T_{u}: \operatorname{Mod}_{A}(\mathrm{Ab}) \rightarrow \operatorname{Mod}_{B}(\mathrm{Ab}) \quad T_{u}(M)=B \otimes_{A} M,
\]
which we will refer to as extension of scalars along \(u\). One can summarize the situation informally by saying that there is a functor from commutative rings to (large) categories, which carries each commutative ring \(A\) to the category \(\operatorname{Mod}_{A}(\mathrm{Ab})\) and each ring homomorphism \(u: A \rightarrow B\) to the functor \(T_{u}\). However, we encounter the following subtleties:
(1) Let \(u: A \rightarrow B\) and \(v: B \rightarrow C\) be homomorphisms of commutative rings. Then the diagram of categories

might not be strictly commutative. If \(M\) is an \(A\)-module, one cannot reasonably expect \(C \otimes_{A} M\) to be identical to the iterated tensor product \(C \otimes_{B}\left(B \otimes_{A} M\right)\). Instead, there is a canonical isomorphism
\[
\mu_{v, u}(M): C \otimes_{B}\left(B \otimes_{A} M\right) \simeq C \otimes_{A} M,
\]
which depends functorially on \(M\), so that the collection \(\left\{\mu_{v, u}(M)\right\}_{M \in \operatorname{Mod}_{A}(\mathrm{Ab})}\) can be viewed as an isomorphism of functors \(\mu_{v, u}: T_{v} \circ T_{u} \simeq T_{v u}\).
(2) Let \(A\) be a commutative ring, and let \(\operatorname{id}_{A}: A \rightarrow A\) be the identity map. Then the extension of scalars functor \(T_{\mathrm{id}_{A}}: \operatorname{Mod}_{A}(\mathrm{Ab}) \rightarrow \operatorname{Mod}_{A}(\mathrm{Ab})\) might not be equal to the identity functor \(\operatorname{id}_{\operatorname{Mod}_{A}(\mathrm{Ab})}\). However, there is a natural isomorphism \(\epsilon_{A}: \operatorname{id}_{\operatorname{Mod}_{A}(\mathrm{Ab})} \simeq\) \(T_{\mathrm{id}_{A}}\), which carries each \(A\)-module \(M\) to the \(A\)-module isomorphism
\[
M \simeq A \otimes M \quad x \mapsto 1 \otimes x .
\]

Let Cat denote the ordinary category whose objects are categories (which, for the moment, we do not require to be small) and whose morphisms are functors. Because of the technical issues outlined above, the construction \(A \mapsto \operatorname{Mod}_{A}(\mathrm{Ab})\) cannot be viewed as a functor from the category of commutative rings to the category Cat. However, this can be remedied using the language of 2-categories. Recall that Cat can be realized as the underlying category of a (strict) 2-category Cat (Example 2.2.0.4). The construction \(A \mapsto \operatorname{Mod}_{A}(\mathrm{Ab})\) can be promoted to a functor of 2-categories
\[
\text { Mod. : }\{\text { Commutative rings }\} \rightarrow \text { Cat },
\]
whose composition and identity constraints are given by the natural isomorphisms \(\mu_{v, u}\) : \(T_{v} \circ T_{u} \simeq T_{v u}\) and \(\epsilon_{A}: \operatorname{id}_{\operatorname{Mod}_{A}(\mathrm{Ab})} \simeq T_{\mathrm{id}_{A}}\) described in (1) and (2) (see Definition 2.2.4.5).

It is often more convenient to encode the functoriality of the construction \(A \mapsto \operatorname{Mod}_{A}(\mathrm{Ab})\) in a different way. Let \(\mathcal{C}\) be an ordinary category. To every functor of 2 -categories \(\mathscr{F}: \mathcal{C} \rightarrow\) Cat, one can associate a new category \(\int_{\mathcal{C}} \mathscr{F}\), called the category of elements of \(\mathscr{F}\) (Definition 5.6.1.1). By definition, objects of the category \(\int_{\mathcal{C}} \mathscr{F}\) are given by pairs \((C, X)\), where \(C\) is an object of the category \(\mathcal{C}\) and \(X\) is an object of the category \(\mathscr{F}(C)\). The construction \((C, X) \mapsto C\) determines a forgetful functor \(U: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\), whose fiber over an object \(C \in \mathcal{C}\) can be identified with the category \(\mathscr{F}(C)\). Moreover, the functor \(\mathscr{F}\) can be recovered (up to isomorphism) from the category \(\int_{\mathcal{C}} \mathscr{F}\) together with the functor \(U\).

Passage from the data of the functor \(\mathscr{F}\) to its category of elements \(\int_{\mathcal{C}} \mathscr{F}\) has several advantages. It can be somewhat cumbersome to specify a functor of 2-categories \(\mathscr{F}: \mathcal{C} \rightarrow \mathbf{C a t}\) explicitly: one must give not only the values of \(\mathscr{F}\) on objects and morphisms of \(\mathcal{C}\), but also the composition and identity constraints of the functor \(\mathscr{F}\) (see Definition 2.2.4.5). The same information is encoded implicitly in the composition law for morphisms in the category of elements \(\int_{\mathcal{C}} \mathscr{F}\), in a way that is often easier to access in practice. For example, suppose that \(\mathcal{C}\) is the category of commutative rings and that \(\mathscr{F}\) is the functor \(A \mapsto \operatorname{Mod}_{A}(\mathrm{Ab})\) described above. By definition, the functor \(\mathscr{F}\) carries each ring homomorphism \(u: A \rightarrow B\) to the extension of scalars functor
\[
T_{u}: \operatorname{Mod}_{A}(\mathrm{Ab}) \rightarrow \operatorname{Mod}_{B}(\mathrm{Ab}) \quad T_{u}(M)=B \otimes_{A} M
\]

Note that the construction of this functor requires certain choices, since the tensor product \(B \otimes_{A} M\) is well-defined only up to (canonical) isomorphism. However, the category \(\operatorname{Mod}(\mathrm{Ab})=\int_{\mathcal{C}} \mathscr{F}\) has a more direct description which does not depend on these choices:
- The objects of \(\operatorname{Mod}(\mathrm{Ab})\) are pairs \((A, M)\), where \(A\) is a commutative ring and \(M\) is an \(A\)-module.
- A morphism from \((A, M)\) to \((B, N)\) in the category \(\operatorname{Mod}(\mathrm{Ab})\) is a pair \((u, f)\), where \(u\) : \(A \rightarrow B\) is a homomorphism of commutative rings and \(f: M \rightarrow N\) is a homomorphism of \(A\)-modules.

To characterize those categories which can be obtained as a category of elements \(\int_{\mathcal{C}} \mathscr{F}\), it will be convenient to introduce some terminology.

Definition 5.0.0.1. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a functor between categories and let \(f: X \rightarrow Y\) be a 01RF morphism in the category \(\mathcal{E}\).
- We say that \(f\) is \(U\)-cartesian if, for every object \(W \in \mathcal{E}\), the diagram of sets

is a pullback square.
- We say that \(f\) is \(U\)-cocartesian if, for every object \(Z \in \mathcal{E}\), the diagram of sets

is a pullback square.
Example 5.0.0.2. Let \(\operatorname{Mod}(\mathrm{Ab})\) be the category defined above and let \(\mathrm{CAlg}(\mathrm{Ab})\) denote 01 RK the category of commutative rings, so that the construction \((A, M) \mapsto A\) determines a forgetful functor \(U: \operatorname{Mod}(\mathrm{Ab}) \rightarrow \mathrm{CAlg}(\mathrm{Ab})\). Then:
- A morphism \((u, f):(A, M) \rightarrow(B, N)\) in the category \(\operatorname{Mod}(\mathrm{Ab})\) is \(U\)-cartesian if and only if the underlying \(A\)-module homomorphism \(f: M \rightarrow N\) is an isomorphism (so that the \(A\)-module \(M\) is obtained from the \(B\)-module \(N\) by restriction of scalars along the ring homomorphism \(u\) ).
- A morphism \((u, f):(A, M) \rightarrow(B, N)\) in the category \(\operatorname{Mod}(\mathrm{Ab})\) is \(U\)-cocartesian if and only if the underlying \(A\)-module homomorphism \(f: M \rightarrow N\) induces a \(B\)-module isomorphism \(B \otimes_{A} M \simeq N\) (so that the \(B\)-module \(N\) is obtained from the \(A\)-module \(M\) by extension of scalars along the ring homomorphism \(u\) ).

01 RN Definition 5.0.0.3. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a functor between categories. We say that \(U\) is a cartesian fibration if it satisfies the following condition:
- For every object \(Y\) of the category \(\mathcal{E}\) and every morphism \(\bar{f}: \bar{X} \rightarrow U(Y)\) in the category \(\mathcal{C}\), there exists a pair \((X, f)\) where \(X\) is an object of \(\mathcal{E}\) satisfying \(U(X)=\bar{X}\) and \(f: X \rightarrow Y\) is a \(U\)-cartesian morphism of \(\mathcal{E}\) satisfying \(U(f)=\bar{f}\).

We say that \(U\) is a cocartesian fibration if it satisfies the following dual condition:
- For every object \(X\) of the category \(\mathcal{E}\) and every morphism \(\bar{f}: U(X) \rightarrow \bar{Y}\) in the category \(\mathcal{C}\), there exists a pair \((Y, f)\) where \(Y\) is an object of \(\mathcal{E}\) satisfying \(U(Y)=\bar{Y}\) and \(f: X \rightarrow Y\) is a \(U\)-cocartesian morphism of \(\mathcal{E}\) satisfying \(U(f)=\bar{f}\).

01 Q6 Warning 5.0.0.4. The terminology of Definition 5.0.0.3 is not standard. Many authors use the term fibration or Grothendieck fibration for what we refer to as a cartesian fibration of categories, and use the term opfibration or Grothendieck opfibration for what we refer to as a cocartesian fibration of categories. Our motivation is to be consistent with the terminology we will use for the analogous definitions in the \(\infty\)-categorical setting (see \(\$ 5.1\) ), where it is important to distinguish between several different notions of fibration.

01RQ Example 5.0.0.5. Let \(\operatorname{Mod}(\mathrm{Ab})\) be the category described in Example 5.0.0.2 Then the forgetful functor \(U: \operatorname{Mod}(\mathrm{Ab}) \rightarrow \mathrm{CAlg}(\mathrm{Ab})\) is both a cartesian fibration and a cocartesian fibration.

023F Exercise 5.0.0.6. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a functor between categories. Show that the following conditions are equivalent:
- The functor \(U\) is a fibration in groupoids (Definition 4.2.2.1).
- The functor \(U\) is a cartesian fibration and every morphism of \(\mathcal{E}\) is \(U\)-cartesian.
- The functor \(U\) is a cartesian fibration and, for every object \(C \in \mathcal{C}\), the fiber \(\mathcal{E}_{C}=\) \(\{C\} \times_{\mathcal{C}} \mathcal{E}\) is a groupoid.

For a more general statement, see Proposition 5.1.4.14.
Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a functor between categories. A classical theorem of Grothendieck ([27]) asserts that \(U\) is a cocartesian fibration if \(\mathcal{E}\) can be realized as the category of elements of Cat-valued functor on \(\mathcal{C}\) : that is, if and only if there exists a functor of 2-categories
\(\mathscr{F}: \mathcal{C} \rightarrow \mathbf{C a t}\) and an isomorphism of categories \(\mathcal{E} \simeq \int_{\mathcal{C}} \mathscr{F}\) which carries \(U\) to the forgetful functor \(\int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) (Corollary 5.6.5.19). Moreover, the functor \(\mathscr{F}\) is uniquely determined up to isomorphism. Fixing the category \(\mathcal{C}\), the category of elements construction supplies a dictionary
\[
\begin{equation*}
\{\text { Functors } \mathscr{F}: \mathcal{C} \rightarrow \mathbf{C a t}\} \simeq\{\text { Cocartesian fibrations } U: \mathcal{E} \rightarrow \mathcal{C}\}, \tag{5.1}
\end{equation*}
\]
which is the starting point for the theory of fibered categories.
The goal of chapter is to introduce an \(\infty\)-categorical generalization of the correspondence (5.1). We begin in \(\S 5.1\) by developing an \(\infty\)-categorical counterpart of the theory of (co)cartesian fibrations. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a morphism of simplicial sets. We say that an edge \(e\) of \(\mathcal{E}\) is \(U\)-cocartesian if every lifting problem

admits a solution, provided that \(n \geq 2\) and the restriction \(\left.\sigma_{0}\right|_{\Delta^{1}}\) is equal to \(e\) (Definition 5.1.1.1. We will be primarily interested in the situation where \(U\) is an inner fibration of \(\infty\)-categories; in this case, we show that an edge \(e \in \mathcal{E}\) is \(U\)-cocartesian if and only if it satisfies a homotopy-theoretic counterpart of Definition 5.0.0.1 (Proposition 5.1.2.1). We say that a morphism of simplicial sets \(U: \mathcal{E} \rightarrow \mathcal{C}\) is a cocartesian fibration if it is an inner fibration having the property that, for every vertex \(X \in \mathcal{E}\) and every edge \(\bar{e}: U(X) \rightarrow \bar{Y}\), there exists a \(U\)-cocartesian edge \(e: X \rightarrow Y\) satisfying \(U(e)=\bar{e}\) (Definition 5.1.4.1). This can be regarded as a generalization of Definition 5.0.0.3 a functor of ordinary categories \(U: \mathcal{E} \rightarrow \mathcal{C}\) is a cocartesian fibration if and only if the induced map \(\mathrm{N}_{\bullet}(U): \mathrm{N}_{\bullet}(\mathcal{E}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is a cocartesian fibration of simplicial sets (Example 5.1.4.2). It also generalizes the notion of left fibration introduced in \(\S 4.2\), a morphism of simplicial sets \(U: \mathcal{E} \rightarrow \mathcal{C}\) is a left fibration if and only if it is a cocartesian fibration and every edge of \(\mathcal{E}\) is \(U\)-cocartesian (Proposition 5.1.4.14.

The remainder of this section is devoted to the problem of classifying cocartesian fibrations \(U: \mathcal{E} \rightarrow \mathcal{C}\), where \(\mathcal{C}\) is a fixed \(\infty\)-category. For each object \(C \in \mathcal{C}\), let \(\mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E}\) denote the corresponding fiber of \(U\). We can then ask the following:

Question 5.0.0.7. What additional data is needed to reconstruct the \(\infty\)-category \(\mathcal{E}\) from 0350 the collection of \(\infty\)-categories \(\left\{\mathcal{E}_{C}\right\}_{C \in \mathcal{C}}\) ?

In \(\$ 5.2\), we give a partial answer to Question 5.0.0.7. Let \(f: C \rightarrow D\) be a morphism in the \(\infty\)-category \(\mathcal{C}\). For each object \(X \in \mathcal{E}_{C}\), our assumption that \(U\) is a cocartesian fibration guarantees that we can lift \(f\) to a \(U\)-cocartesian morphism \(\tilde{f}: X \rightarrow Y\) of \(\mathcal{E}\). We will see
that the construction \(X \mapsto Y\) can be upgraded to a functor of \(\infty\)-categories \(f_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\), which we will refer to as the functor of covariant transport along \(f\) (Definition 5.2.2.4). The construction of the functor \(f\) ! requires some auxiliary choices, but its isomorphism class [ \(f_{!}\)] is uniquely determined (Proposition 5.2.2.8). Moreover, the construction \(f \mapsto f_{!}\)is compatible with composition (Proposition 5.2.5.1), and therefore determines a functor of ordinary categories
\[
\operatorname{hTr}_{\mathcal{E} / \mathcal{C}}: \mathrm{hC} \rightarrow \mathrm{hQCat} \quad C \mapsto \mathcal{E}_{C} ;
\]
here hQCat denotes the homotopy category of \(\infty\)-categories (Construction 4.5.1.1). We will refer to \(\mathrm{h} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) as the homotopy transport representation of the cocartesian fibration \(U\) (Construction 5.2.5.2).

In some cases, the homotopy transport representation \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) provides an answer to Question 5.0.0.7.
- If \(U: \mathcal{E} \rightarrow \mathcal{C}\) is a left covering map of simplicial sets, then we can regard \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) as a functor from the homotopy category hC to the category of sets. In this case, we can reconstruct \(\mathcal{E}\) (up to isomorphism) as the fiber product
\[
\mathcal{C} \times_{\mathrm{N}_{\bullet}(\text { Set })} \mathrm{N}_{\bullet}\left(\text { Set }_{*}\right),
\]
where \(\operatorname{Set}_{*}\) denotes the category of pointed sets (Proposition 5.2.7.2). It follows that the the construction \(\mathcal{E} \mapsto \mathrm{hTr}_{\mathcal{E} / \mathcal{C}}\) defines an equivalence of categories
\[
\{\text { Left covering maps } U: \mathcal{E} \rightarrow \mathcal{C}\} \simeq \operatorname{Fun}(\mathrm{hC}, \text { Set }),
\]
which we regard as a generalization of the classical theory of covering spaces (Corollary 5.2.7.3).
- Suppose that \(\mathcal{C}=\Delta^{1}\) is the standard 1-simplex. In this case, the homotopy transport representation \(\mathrm{h} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) records the data of the \(\infty\)-categories \(\mathcal{E}_{0}\) and \(\mathcal{E}_{1}\), together with (the isomorphism class of) the covariant transport functor \(F: \mathcal{E}_{0} \rightarrow \mathcal{E}_{1}\) associated to the nondegenerate edge of \(\mathcal{C}\). From this data, one can reconstruct the \(\infty\)-category \(\mathcal{E}\) up to equivalence. More precisely, we show that \(\mathcal{E}\) is categorically equivalent to the mapping cylinder \(\left(\Delta^{1} \times \mathcal{E}_{0}\right) \coprod_{\left(\{1\} \times \mathcal{E}_{0}\right)} \mathcal{E}_{1}\); see Corollary 5.2.4.2.

In general, the homotopy transport representation of a cocartesian fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\) does not contain enough information to reconstruct the \(\infty\)-category \(\mathcal{E}\), even up to equivalence. The essence of the problem is that the functor \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) encodes only the isomorphism classes of the covariant transport functors associated to the morphisms of \(\mathcal{C}\). To address Question 5.0.0.7. it is necessary to consider a refinement of \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) which witnesses the functoriality of the construction \(C \mapsto \mathcal{E}_{C}\) before passing to the homotopy category hQCat. In \(\$ 5.3\), we
specialize to the situation where \(\mathcal{C}=\mathrm{N}_{\bullet}\left(\mathcal{C}_{0}\right)\) is (the nerve of) an ordinary category \(\mathcal{C}_{0}\). In this case, we associate to each cocartesian fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\) a functor of ordinary categories \(\operatorname{sTr}_{\mathcal{E} / \mathcal{C}_{0}}: \mathcal{C}_{0} \rightarrow\) QCat, which we refer to as the strict transport representation of \(\mathcal{C}\) (Construction 5.3.1.5). The strict transport representation is a refinement of the homotopy transport representation: more precisely, there is a canonical isomorphism of \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) with the composite functor
\[
\mathrm{hC} \simeq \mathcal{C}_{0} \xrightarrow{\mathrm{sTr}_{\mathcal{E}} / \mathcal{C}_{0}} \mathrm{QCat} \rightarrow \mathrm{hQCat}
\]
(Corollary 5.3.1.8). Moreover, we show that this refinement provides an answer to Question 5.0.0.7 according to Theorem 5.3.5.6 the construction \(\mathcal{E} \mapsto s \operatorname{si}_{\mathcal{E} / \mathcal{C}_{0}}\) induces a bijection

Moreover, the inverse bijection admits an explicit description: it carries (the equivalence class of) a functor \(\mathscr{F}: \mathcal{C}_{0} \rightarrow\) QCat to (the equivalence class of) a cocartesian fibration \(\mathrm{N}_{\bullet}^{\mathscr{F}}\left(\mathcal{C}_{0}\right) \rightarrow \mathrm{N}_{\bullet}\left(\mathcal{C}_{0}\right)\). Here \(\mathrm{N}_{\bullet}^{\mathscr{F}}\left(\mathcal{C}_{0}\right)\) is an \(\infty\)-category which we refer to as the \(\mathscr{F}\)-weighted nerve of \(\mathcal{C}_{0}\) (Definition 5.3.3.1).

Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of \(\infty\)-categories. In general, it is not reasonable to expect that the homotopy transport representation \(\mathrm{h}_{\operatorname{Tr}_{\mathcal{E}} \mathcal{C}}: \mathrm{hC} \rightarrow \mathrm{hQCat}\) can be promoted to a strictly commutative diagram in the category of simplicial sets. In other words, \(h \operatorname{Tr}_{\mathcal{E}} / \mathcal{C}\) generally cannot be lifted to a morphism from \(\mathcal{C}\) to the nerve \(\mathrm{N}_{\bullet}\) (QCat). To address Question 5.0 .0 .7 in complete generality, we will instead contemplate homotopy coherent refinements of \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\), given by morphisms from \(\mathcal{C}\) to the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\text {hc }}\) (QCat). Here we regard QCat as a locally Kan simplicial category, with morphism spaces given by \(\operatorname{Hom}_{\mathrm{QCat}}\left(\mathcal{D}, \mathcal{D}^{\prime}\right)=\operatorname{Fun}\left(\mathcal{D}, \mathcal{D}^{\prime}\right)^{\simeq}\). The homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathrm{QCat})\) is then an \(\infty\) category which we will denote by \(\mathcal{Q C}\) and refer to as the \(\infty\)-category of small \(\infty\)-categories (Construction 5.5.4.1). In \(\S 5.5\), we study several variants of this construction. In particular, we introduce an \(\infty\)-category \(\mathcal{Q C}_{\text {Obj }}\) whose objects are pairs \((\mathcal{D}, X)\), where \(\mathcal{D}\) is a small \(\infty\) category and \(X\) is an object of \(\mathcal{D}\), and whose morphisms are pairs \((F, u):(\mathcal{D}, X) \rightarrow\left(\mathcal{D}^{\prime}, X^{\prime}\right)\) where \(F: \mathcal{D} \rightarrow \mathcal{D}^{\prime}\) is a functor of \(\infty\)-categories and \(u: F(X) \rightarrow X^{\prime}\) is a morphism in \(\mathcal{D}^{\prime}\) (Definition 5.5.6.10).

The construction \((\mathcal{D}, X) \mapsto \mathcal{D}\) determines a forgetful functor \(V: \mathcal{Q C}_{\text {Obj }} \rightarrow \mathcal{Q C}\), which is a cocartesian fibration of \(\infty\)-categories (Proposition 5.5.6.11). In 5.0.0.7, we address Question 5.0 .0 .7 in general by showing that \(V\) is a universal cocartesian fibration. For any functor of \(\infty\)-categories \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\), we let \(\int_{\mathcal{C}} \mathscr{F}\) denote the fiber product \(\mathcal{C} \times{ }_{\mathcal{Q C}} \mathcal{Q C}{ }_{\text {Obj }}\). We will refer
to \(\int_{\mathcal{C}} \mathscr{F}\) as the \(\infty\)-category of elements of \(\mathscr{F}\) (Definition 5.6.2.4; by construction, its objects are pairs \((C, X)\) where \(C\) is an object of \(\mathcal{C}\) and \(X\) is an object of the \(\infty\)-category \(\mathscr{F}(C)\). Note that projection onto the first factor determines a forgetful functor \(U: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\), which is a cocartesian fibration of \(\infty\)-categories (since it is a pullback of the cocartesian fibration \(V)\). Our main result is that the construction \(\mathscr{F} \mapsto \int_{\mathcal{C}} \mathscr{F}\) induces a bijection from the set of isomorphism classes in \(\operatorname{Fun}(\mathcal{C}, \mathcal{Q C})\) to the set of equivalence classes of \(\infty\)-categories equipped with a cocartesian fibration to \(\mathcal{C}\) (Theorem 5.6.0.2. In particular, every cocartesian fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\) fits into a categorical pullback square

where the functor \(\operatorname{Tr}_{\mathcal{E} / \mathcal{C}}: \mathcal{C} \rightarrow \mathcal{Q C}\) is uniquely determined up to isomorphism. The functor \(\operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) is an \(\infty\)-categorical refinement of the homotopy transport representation \(\mathrm{h} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) (Remark 5.6.5.15), which we will refer to as the covariant transport representation of \(U\) (Definition 5.6.5.1).

0158 Remark 5.0.0.8. The classical theory of fibered categories was introduced by Grothendieck in [27] (Exposé 6).

\subsection*{5.1 Cartesian Fibrations}

01 T 1 The goal in this section is to extend the theory of (co)cartesian fibrations to the setting of \(\infty\)-categories. The first step is to introduce an \(\infty\)-categorical analogue of Definition 5.0.0.1. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a functor between categories, and let \(f: X \rightarrow Y\) be a morphism in \(\mathcal{E}\). By definition, \(f\) is \(U\)-cartesian if and only if, for every morphism \(h: W \rightarrow Y\) in \(\mathcal{E}\), every commutative diagram

in the category \(\mathcal{C}\) can be lifted uniquely to a commutative diagram

in the category \(\mathcal{E}\). Equivalently, the morphism \(f\) is \(U\)-cartesian if and only if every lifting problem

01 T 2
has a unique solution, assuming that \(\sigma_{0}\) carries the "final edge" \(\mathrm{N}_{\bullet}(\{1<2\}) \subseteq \Lambda_{2}^{2}\) to the morphism \(f\).

In the \(\infty\)-categorical setting, it is unreasonable to ask for the lifting problem (5.2) to admit a unique solution. Instead, we should require that the collection of possible choices for \(\sigma\) are, in some sense, parametrized by a contractible space. In \(\$ 5.1 .1\), we formalize this idea by considering analogues of (5.2) for higher-dimensional simplices. If \(U: \mathcal{E} \rightarrow \mathcal{C}\) is an arbitrary morphism of simplicial sets, we will say that an edge \(f\) of \(\mathcal{E}\) is \(U\)-cartesian if every lifting problem

admits a solution, provided that \(n \geq 2\) and \(\sigma_{0}\) carries the "final edge" \(\mathrm{N}_{\bullet}(\{n-1<n\}) \subseteq \Lambda_{n}^{n}\) to \(f\) (Definition 5.1.1.1). In the special case where \(\mathcal{E}\) and \(\mathcal{C}\) are the nerves of ordinary categories, this reduces to the classical definition of cartesian morphism (Corollary 5.1.2.2).

The definition of \(U\)-cartesian edge makes sense for any morphism of simplicial sets \(U: \mathcal{E} \rightarrow \mathcal{C}\). However, it has poor formal properties in general. We will be primarily interested in the case where \(\mathcal{E}\) and \(\mathcal{C}\) are \(\infty\)-categories and \(U\) is an inner fibration. Assume that these conditions are satisfied and let \(f: X \rightarrow Y\) be a morphism of \(\mathcal{E}\), having image \(\bar{f}: \bar{X} \rightarrow \bar{Y}\) in \(\mathcal{D}\). For every object \(W \in \mathcal{E}\) having image \(\bar{X}=U(X) \in \mathcal{C}\), composition with
the homotopy class \([f]\) determines a commutative diagram

in the homotopy category hKan, which (after suitable modifications on the left hand side) can be lifted to a commutative diagram in the category of simplicial sets. In \(\$ 5.1 .2\) we show that \(f\) is \(U\)-cartesian if and only if, for every object \(W \in \mathcal{E}\), the resulting lift is a homotopy pullback diagram of Kan complexes (Proposition 5.1.2.1). This has a number of pleasant consequences: for example, it implies that the collection of \(U\)-cartesian morphisms is closed under composition (for a stronger statement, see Corollary 5.1.2.4).

Suppose we are given a pullback diagram of simplicial sets

and let \(f\) be an edge of \(\mathcal{E}^{\prime}\). It follows immediately from the definitions that if \(F(f)\) is \(U\)-cartesian, then \(f\) is \(U^{\prime}\)-cartesian (Remark 5.1.1.11). The converse holds when \(U\) is a cartesian fibration (Remark 5.1.4.6), but is false in general. In \$5.1.3, we address this point by introducing the more general notion of a locally \(U\)-cartesian edge of a simplicial set \(\mathcal{E}\) equipped with a \(\operatorname{map} U: \mathcal{E} \rightarrow \mathcal{C}\) (Definition 5.1.3.1).

Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an inner fibration of simplicial sets. In \(\$ 5.1 .4\) we study the situation where \(\mathcal{E}\) has "sufficiently many" \(U\)-cartesian edges in the following sense: for every vertex \(Y \in \mathcal{E}\), every edge \(\bar{f}: \bar{X} \rightarrow U(Y)\) of \(\mathcal{C}\) can be lifted to a \(U\)-cartesian edge \(f: X \rightarrow Y\) of \(\mathcal{C}\). If this condition is satisfied, we say that \(U\) is a cartesian fibration of simplicial sets. This definition has the following features:
- A functor of ordinary categories \(U: \mathcal{E} \rightarrow \mathcal{C}\) is a cartesian fibration (in the sense of Definition 5.0.0.3) if and only if the induced functor of \(\infty\)-categories \(\mathrm{N}_{\bullet}(U): \mathrm{N}_{\bullet}(\mathcal{E}) \rightarrow\) \(\mathrm{N}_{\bullet}(\mathcal{C})\) is a cartesian fibration (Example 5.1.4.2).
- Every right fibration of simplicial sets \(U: \mathcal{E} \rightarrow \mathcal{C}\) is a cartesian fibration. Conversely, a cartesian fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\) is a right fibration if and only if every fiber of \(U\) is a Kan complex (Proposition 5.1.4.14).
- The collection of cartesian fibrations is closed under the formation of pullbacks (Remark 5.1.4.6) and composition (Proposition 5.1.4.13).
- Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cartesian fibration of simplicial sets and let \(f: K \rightarrow \mathcal{E}\) be any morphism of simplicial sets. Then the induced maps \(\mathcal{E}_{/ f} \rightarrow \mathcal{C}_{/(U \circ f)}\) and \(\mathcal{E}_{f /} \rightarrow \mathcal{C}_{(U \circ f) /}\) are cartesian fibrations (Propositions 5.1.4.17 and 5.1.4.19).

Suppose we are given a commutative diagram of \(\infty\)-categories

where \(U\) and \(V\) are isofibrations. Recall that, if \(F\) is an equivalence of \(\infty\)-categories, then the induced map of fibers \(F_{E}: \mathcal{C}_{E} \rightarrow \mathcal{D}_{E}\) is also an equivalence of \(\infty\)-categories for every object \(E \in \mathcal{E}\) (Corollary 4.5.2.32). The converse is false in general (Warning 4.5.2.33). Nevertheless, in \(\S 5.1 .6\) we show that the converse is true if we assume that \(U\) is a cartesian fibration and that \(F\) carries \(U\)-cartesian morphisms of \(\mathcal{C}\) to \(V\)-cartesian morphisms of \(\mathcal{D}\) (Theorem 5.1.6.1). In 55.1.7, we prove a counterpart of this result in the case where \(\mathcal{E}\) is not assumed to be an \(\infty\)-category (Proposition 5.1.7.14): in this case, \(\mathcal{C}\) and \(\mathcal{D}\) need not be \(\infty\)-categories, but it is still possible to show that \(F\) is an equivalence of inner fibrations over \(\mathcal{E}\) (see Definition 5.1.7.1.

Remark 5.1.0.1. The entirety of the preceding discussion can be dualized. If \(U: \mathcal{E} \rightarrow \mathcal{C}\) is a morphism of simplicial sets, we will say that an edge \(f\) of \(\mathcal{E}\) is \(U\)-cocartesian if it is \(U^{\text {op }}\)-cartesian when viewed as an edge of the opposite simplicial set \(\mathcal{E}^{\text {op }}\). We say that \(U\) is a cocartesian fibration if the opposite functor \(U^{\mathrm{op}}: \mathcal{E}^{\mathrm{op}} \rightarrow \mathcal{C}^{\mathrm{op}}\) is a cartesian fibration. For the sake of brevity, we will sometimes state our results only for cartesian fibrations (in which case there is always a counterpart for cocartesian fibrations, which can be obtained by passing to opposite simplicial sets).

\subsection*{5.1.1 Cartesian Edges of Simplicial Sets}

Our first goal is to adapt Definition 5.0.0.1 to the setting of \(\infty\)-categories.

01 T5 Definition 5.1.1.1. Let \(q: X \rightarrow S\) be a morphism of simplicial sets, and let \(e\) be an edge of \(X\). We say that \(e\) is \(q\)-cartesian if every lifting problem

admits a solution, provided that \(n \geq 2\) and the composite map
\[
\Delta^{1} \simeq \mathrm{~N}_{\bullet}(\{n-1<n\}) \hookrightarrow \Lambda_{n}^{n} \xrightarrow{\sigma_{0}} X
\]
corresponds to the edge \(e\).
We say that \(e\) is \(q\)-cocartesian if every lifting problem

admits a solution, provided that \(n \geq 2\) and the composite map
\[
\Delta^{1} \simeq \mathrm{~N}_{\bullet}(\{0<1\}) \hookrightarrow \Lambda_{0}^{n} \xrightarrow{\sigma_{0}} X
\]
corresponds to the edge \(e\).
01T6 Remark 5.1.1.2. Let \(q: X \rightarrow S\) be a morphism of simplicial sets and let \(q^{\mathrm{op}}: X^{\mathrm{op}} \rightarrow S^{\mathrm{op}}\) be the opposite morphism. Then an edge \(e\) of \(X\) is \(q\)-cartesian if and only if it is \(q^{\text {op }}\)-cocartesian (where we identify \(e\) with an edge of the opposite simplicial set \(X^{\text {op }}\) ).

01 T7 Example 5.1.1.3. Let \(q: X \rightarrow S\) be a right fibration of simplicial sets. Then every edge of \(X\) is \(q\)-cartesian. Similarly, if \(q: X \rightarrow S\) is a left fibration of simplicial sets, then every edge of \(X\) is \(q\)-cocartesian.

01 T8 Example 5.1.1.4. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(q: \mathcal{C} \rightarrow \Delta^{0}\) be the projection map, and let \(e: X \rightarrow Y\) be a morphism in \(\mathcal{C}\). The following conditions are equivalent:
- The morphism \(e\) is an isomorphism.
- The morphism \(e\) is \(q\)-cartesian.
- The morphism \(e\) is \(q\)-cocartesian.

This is a restatement of Theorem 4.4.2.6.
Example 5.1.1.5. Let \(q: X \rightarrow S\) be a morphism of simplicial sets which restricts to an 01T9 isomorphism from \(X\) to a full simplicial subset of \(S\) (see Definition 4.1.2.15). Then every edge of \(X\) is both \(q\)-cartesian and \(q\)-cocartesian.

Remark 5.1.1.6. Let \(p: X \rightarrow Y\) and \(q: Y \rightarrow Z\) be morphisms of simplicial sets, and let \(e 01 \mathrm{TA}\) be an edge of the simplicial set \(X\). If \(e\) is \(p\)-cartesian and \(p(e)\) is a \(q\)-cartesian edge of \(Y\), then \(e\) is \((q \circ p)\)-cartesian. For a partial converse, see Corollary 5.1.2.6.

Remark 5.1.1.7. Let \(q: X \rightarrow S\) be a morphism of simplicial sets, let \(X^{\prime} \subseteq X\) be a full 02R4 simplicial subset, and let \(q^{\prime}=\left.q\right|_{X^{\prime}}\). If \(e\) is an edge of \(X^{\prime}\) which is \(q\)-cartesian when viewed as an edge of \(X\), then it it is \(q^{\prime}\)-cartesian. This follows by combining Remark 5.1.1.6 with Example 5.1.1.5.

Proposition 5.1.1.8. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories and let \(e: X \rightarrow Y 01 \mathrm{~TB}\) be a morphism in \(\mathcal{C}\). The following conditions are equivalent:
(1) The morphism \(e\) is an isomorphism in \(\mathcal{C}\).
(2) The morphism \(e\) is \(q\)-cartesian and \(q(e)\) is an isomorphism in \(\mathcal{D}\).
(3) The morphism \(e\) is \(q\)-cocartesian and \(q(e)\) is an isomorphism in \(\mathcal{D}\).

Proof. We will prove the equivalence (1) \(\Leftrightarrow(2)\); the proof of the equivalence (1) \(\Leftrightarrow(3)\) is similar. The implication \((1) \Rightarrow(2)\) follows from Proposition 4.4.2.13 and Remark 1.5.1.6. To prove the converse, let \(p: \mathcal{D} \rightarrow \Delta^{0}\) denote the projection map. If \(q(e)\) is an isomorphism in \(\mathcal{C}\), then it is \(p\)-cartesian (Example 5.1.1.4). If, in addition, the morphism \(e\) is \(q\)-cartesian, then it is also \((p \circ q)\)-cartesian (Remark 5.1.1.6) and is therefore an isomorphism in the \(\infty\)-category \(\mathcal{C}\) (Example 5.1.1.4).

Corollary 5.1.1.9. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories. For every object 01 TC \(X \in \mathcal{C}\), the identity morphism \(\operatorname{id}_{X}: X \rightarrow X\) is \(q\)-cartesian and \(q\)-cocartesian.

Corollary 5.1.1.10. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories, where \(\mathcal{D}\) is a Kan 023 H complex, and let \(e: X \rightarrow Y\) be a morphism of \(\mathcal{C}\). The following conditions are equivalent:
(1) The morphism \(e\) is an isomorphism in \(\mathcal{C}\).
(2) The morphism e is \(q\)-cartesian.
(3) The morphism \(e\) is \(q\)-cocartesian.

Proof. Combine Propositions 5.1.1.8 and 1.4.6.10.

01 TD Remark 5.1.1.11. Suppose we are given a pullback diagram of simplicial sets

Let \(e^{\prime}\) be an edge of the simplicial set \(X^{\prime}\), having image \(e=f\left(e^{\prime}\right)\) in \(X\). If \(e\) is \(q\)-cartesian, then \(e^{\prime}\) is \(q^{\prime}\)-cartesian. Similarly, if \(e\) is \(q\)-cocartesian, then \(e^{\prime}\) is \(q^{\prime}\)-cocartesian.

01TE Remark 5.1.1.12. Let \(q: X \rightarrow S\) be a morphism of simplicial sets and let \(e\) be an edge of the simplicial set \(X\). The following conditions are equivalent:
- The edge \(e\) is \(q\)-cartesian.
- For every pullback diagram of simplicial sets

and every edge \(e^{\prime}\) of \(X^{\prime}\) satisfying \(f\left(e^{\prime}\right)=e\), the edge \(e^{\prime}\) is \(q^{\prime}\)-cartesian.
- For every pullback diagram of simplicial sets

and every edge \(e^{\prime}\) of \(X^{\prime}\) satisfying \(f\left(e^{\prime}\right)=e\), the edge \(e^{\prime}\) is \(q^{\prime}\)-cartesian.
01 TF Proposition 5.1.1.13. Let \(q: X \rightarrow S\) be a morphism simplicial sets and let \(e: x \rightarrow y\) be an edge of \(X\). Then:
- The edge \(e\) is \(q\)-cartesian if and only if the natural map
\[
X_{/ e} \rightarrow X_{/ y} \times_{S_{/ q(y)}} S_{/ q(e)}
\]
is a trivial Kan fibration of simplicial sets.
- The edge \(e\) is \(q\)-cocartesian if and only if the natural map
\[
X_{e /} \rightarrow X_{x /} \times_{S_{q(x) /}} S_{q(e) /}
\]
is a trivial Kan fibration of simplicial sets.
Proof. We will prove the first assertion; the proof of the second is similar. By definition, the natural map \(X_{/ e} \rightarrow X_{/ y} \times S_{/ q(y)} S_{/ q(e)}\) is a trivial Kan fibration if and only if, for every integer \(n \geq 0\), every lifting problem

admits a solution. By virtue of Lemma 4.3.6.15, this is equivalent to the datum of a lifting problem

where \(\sigma_{0}\) carries the final edge \(\mathrm{N}_{\bullet}(\{n+1<n+2\}) \subseteq \Lambda_{n+2}^{n+2}\) to \(e\).
Corollary 5.1.1.14. Let \(q: X \rightarrow S\) and \(f: K \rightarrow X\) be morphisms of simplicial sets, and let 01 TG \(q^{\prime}: X_{f /} \rightarrow S_{(q \circ f) /}\) be the morphism induced by \(q\). Let \(\bar{e}: \bar{x} \rightarrow \bar{y}\) be an edge of the simplicial set \(X_{f /}\), and let \(e: x \rightarrow y\) be its image in \(X\). If e is \(q\)-cartesian, then \(\bar{e}\) is \(q^{\prime}\)-cartesian.

Proof. Since \(e\) is \(q\)-cartesian, the restriction map
\[
\theta: X_{/ e} \rightarrow X_{/ y} \times_{S_{/ q(y)}} S_{/ q(e)}
\]
is a trivial Kan fibration (Proposition 5.1.1.13). We wish to show that the restriction map
\[
\bar{\theta}:\left(X_{f /}\right)_{/ \bar{e}} \rightarrow\left(X_{f /}\right)_{/ \bar{y}} \times \times_{\left(S_{(q \circ f) /) / / q^{\prime}(\bar{y})}\right.}\left(S_{(q \circ f) /}\right)_{/ q^{\prime}(\bar{e})} .
\]
is also a trivial Kan fibration. We can identify \(\bar{e}\) with a morphism of simplicial sets \(\bar{f}: K \rightarrow X_{/ e}\), and \(\bar{\theta}\) with the induced map
\[
\left(X_{/ e}\right)_{\bar{f} /} \rightarrow\left(X_{/ y} \times_{S_{/ q(y)}} S_{/ q(e)}\right)_{(\theta \circ \bar{f}) /} .
\]

The desired result now follows from Corollary 4.3.7.17.

01 TH Corollary 5.1.1.15. Let \(q: X \rightarrow S\) be a morphism of simplicial sets and let \(e: x \rightarrow y\) be an edge of \(X\). The following conditions are equivalent:
(1) The edge e is \(q\)-cartesian.
(2) Let \(f: B \rightarrow X\) be a morphism of simplicial sets, let \(A\) be a simplicial subset of \(B\), and let \(Y\) denote the fiber product \(X_{\left.f\right|_{A} /} \times_{S_{\left(\left.q \circ f\right|_{A}\right) /}} S_{(q \circ f) /}\), so that the restriction map \(X_{f /} \rightarrow X\) factors as a composition \(X_{f /} \xrightarrow{\theta} Y \xrightarrow{\rho} X\). Then every lifting problem

admits a solution, provided that \(\rho\left(e^{\prime}\right)=e\).

Proof. For a fixed simplicial set \(B\) with a simplicial subset \(A \subseteq B\), condition (2) is equivalent to the requirement that every lifting problem

admits a solution. This condition is satisfied for every inclusion of simplicial sets \(A \subseteq B\) if and only if the map \(X_{/ e} \rightarrow X_{/ y} \times_{S_{/ q(y)}} S_{/ q(e)}\) is a trivial Kan fibration: that is, if and only if \(e\) is \(q\)-cartesian (Proposition 5.1.1.13).

01TJ Remark 5.1.1.16. In the situation of Corollary 5.1.1.15, it is sufficient to verify condition (2) in the special case where \(B=\Delta^{n}\) is a standard simplex and \(A=\partial \Delta^{n}\) is its boundary.

\subsection*{5.1.2 Cartesian Morphisms of \(\infty\)-Categories}

01TK Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between ordinary categories and let \(g: Y \rightarrow Z\) be a morphism in \(\mathcal{C}\) having image \(\bar{g}: \bar{Y} \rightarrow \bar{Z}\) in \(\mathcal{D}\). Recall that \(g\) is \(q\)-cartesian if, for every object \(X \in \mathcal{C}\)
having image \(\bar{X}=q(X)\) in \(\mathcal{D}\), the diagram of sets

is a pullback square (Definition 5.0.0.1). Our goal in this section is to give an analogous characterization of cartesian morphisms in the setting of \(\infty\)-categories.

We now encounter a slight complication: if \(X, Y\), and \(Z\) are objects of an \(\infty\)-category \(\mathcal{C}\) and \(g: Y \rightarrow Z\) is a morphism, then the composition map \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \xrightarrow{g \circ} \operatorname{Hom}_{\mathcal{C}}(X, Z)\) is only well-defined up to homotopy. We can circumvent this difficulty using the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(X, Y, Z)\) of Notation 4.6.9.1. By virtue of Corollary 4.6.9.5, the restriction map \(\operatorname{Hom}_{\mathcal{C}}(X, Y, Z) \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Y) \times \operatorname{Hom}_{\mathcal{C}}(Y, Z)\) is a trivial Kan fibration of simplicial sets, and therefore induces a homotopy equivalence \(\operatorname{Hom}_{\mathcal{C}}(X, Y, Z) \times_{\operatorname{Hom}_{\mathcal{C}}(Y, Z)}\{g\} \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Y)\). Moreover, the "long edge" of \(\Delta^{2}\) determines a map of Kan complexes
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y, Z) \times_{\operatorname{Hom}_{\mathcal{C}}(Y, Z)}\{g\} \hookrightarrow \operatorname{Hom}_{\mathcal{C}}(X, Y, Z) \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Z),
\]
which we can regard as a surrogate for the composition map \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \xrightarrow{g \circ} \operatorname{Hom}_{\mathcal{C}}(X, Z)\). This construction depends functorially on \(\mathcal{C}\) in the following sense: if \(q: \mathcal{C} \rightarrow \mathcal{D}\) is a functor of \(\infty\)-categories carrying \(X\) to \(\bar{X} \in \mathcal{D}\) and \(g\) to \(\bar{g}: \bar{Y} \rightarrow \bar{Z}\), then it induces a commutative diagram of Kan complexes

where the vertical maps are determined by \(q\) and the horizontal maps are given by restriction. We can now state our main result, which we will prove at the end of this section:

Proposition 5.1.2.1. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories and let \(g: Y \rightarrow Z 01 \mathrm{TL}\) be a morphism in \(\mathcal{C}\) having image \(\bar{g}: \bar{Y} \rightarrow \bar{Z}\) in \(\mathcal{D}\). Then \(g\) is \(q\)-cartesian if and only if, for
every object \(X \in \mathcal{C}\) having image \(\bar{X}=q(X)\) in \(\mathcal{D}\), the diagram of Kan complexes

is a homotopy pullback square.
01 TN Corollary 5.1.2.2. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between categories, and let \(\mathrm{N}_{\bullet}(q): \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow\) \(\mathrm{N}_{\bullet}(\mathcal{D})\) be the induced morphism of simplicial sets. Let \(g: Y \rightarrow Z\) be a morphism in the category \(\mathcal{C}\). Then \(g\) is \(q\)-cartesian (in the sense of Definition 5.0.0.1) if and only if it is \(\mathrm{N}_{\bullet}(q)\)-cartesian (when regarded as an edge of the simplicial set \(\mathrm{N}_{\bullet}(\mathcal{C})\) ).

Proof. Combine Proposition 5.1.2.1 with Example 4.6.9.6
01TQ Corollary 5.1.2.3. Let \(Q\) be a partially ordered set, let \(q: \mathcal{C} \rightarrow \mathrm{N}_{\bullet}(Q)\) be an inner fibration of \(\infty\)-categories, and let \(g: Y \rightarrow Z\) be a morphism in \(\mathcal{C}\). Then \(g\) is \(q\)-cartesian if and only if, for every object \(X \in \mathcal{C}\) satisfying \(q(X) \leq q(Y)\), the map
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \xrightarrow{[g] \circ} \operatorname{Hom}_{\mathcal{C}}(X, Z)
\]
of Notation 4.6.9.15 is an isomorphism in the homotopy category hKan.
Proof. By virtue of Proposition 5.1.2.1. the morphism \(g\) is \(q\)-cartesian if and only if, for each object \(X \in \mathcal{C}\), the diagram of Kan complexes

is a homotopy pullback square. If \(q(X) \not \leq q(Y)\), then the Kan complexes on the left side of the diagram (5.4) are empty, so this condition is vacuous. If \(q(X) \leq q(Y)\), then the Kan complexes on the lower half of the diagram are isomorphic to \(\Delta^{0}\), so that 5.4 is a homotopy pullback square if and only if \(\theta_{X}\) is a homotopy equivalence (Corollary 3.4.1.5). We conclude
by observing that, in the homotopy category hKan, we have a commutative diagram

where the horizontal map is an isomorphism (Corollary 4.6.9.5).

Corollary 5.1.2.4. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories and let \(\sigma: \Delta^{2} \rightarrow \mathcal{C} 01 \mathrm{TS}\) be a 2-simplex of \(\mathcal{C}\), which we will depict as a diagram

- Suppose that \(g\) is \(q\)-cartesian. Then \(f\) is \(q\)-cartesian if and only if \(h\) is \(q\)-cartesian.
- Suppose that \(f\) is \(q\)-cocartesian. Then \(g\) is \(q\)-cocartesian if and only if \(h\) is \(q\)-cocartesian.

Proof. We will prove the first assertion; the second follows by a similar argument. For every simplex \(\tau\) of the \(\infty\)-category \(\mathcal{C}\), let \(\bar{\tau}\) denote its image \(q(\tau)\) in the \(\infty\)-category \(\mathcal{D}\). By virtue of Proposition 5.1.2.1, it will suffice to show that for every object \(W \in \mathcal{C}\), the following conditions are equivalent:
(a) The commutative diagram of Kan complexes

is a homotopy pullback square.
(b) The commutative diagram of Kan complexes

is a homotopy pullback square.

By virtue of Corollaries 4.6.9.5 and 3.4.1.12, these conditions can be reformulated as follows:
( \(a^{\prime}\) ) The commutative diagram of Kan complexes

is a homotopy pullback square.
\(\left(b^{\prime}\right)\) The commutative diagram of Kan complexes

is a homotopy pullback square.

The equivalence of \(\left(a^{\prime}\right)\) and \(\left(b^{\prime}\right)\) follows by applying Proposition 3.4.1.11 to the commutative
diagram of Kan complexes

noting that the lower half of the diagram is a homotopy pullback square by virtue of our assumption that \(g\) is \(q\)-cartesian (Proposition 5.1.2.1).

Corollary 5.1.2.5. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories, and let \(f: X \rightarrow Y 01 \mathrm{TT}\) and \(f^{\prime}: X^{\prime} \rightarrow Y^{\prime}\) be morphisms of \(\mathcal{C}\) which are isomorphic as objects of the \(\infty\)-category \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)\). Then \(f\) is \(q\)-cartesian if and only if \(f^{\prime}\) is \(q\)-cartesian. Similarly, \(f\) is \(q\)-cocartesian if and only if \(f^{\prime}\) is \(q\)-cocartesian.

Proof. Our assumption that \(f\) is isomorphic to \(f^{\prime}\) in \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)\) guarantees that there exists a commutative diagram

where \(e\) and \(e^{\prime}\) are isomorphisms (and therefore \(q\)-cartesian by virtue of Proposition 5.1.1.8). The desired result now follows from Corollary 5.1.2.4.

Using Proposition 5.1.2.1, we deduce the following stronger version of Remark 5.1.1.6
Corollary 5.1.2.6 (Transitivity). Let \(p: \mathcal{C} \rightarrow \mathcal{D}\) and \(q: \mathcal{D} \rightarrow \mathcal{E}\) be inner fibrations of 01TU simplicial sets, and let \(e: Y \rightarrow Z\) be an edge of the simplicial set \(\mathcal{C}\).
- Assume that \(p(e)\) is a \(q\)-cartesian edge of \(\mathcal{D}\). Then e is \(p\)-cartesian if and only if it is ( \(q \circ p\) )-cartesian.
- Assume that \(p(e)\) is a \(q\)-cocartesian edge of \(\mathcal{D}\). Then e is \(p\)-cocartesian if and only if it is \((q \circ p)\)-cocartesian.

Proof. We will prove the first assertion; the second follows by a similar argument. Using Remark 5.1.1.12, we can reduce to the case where \(\mathcal{E}\) is an \(\infty\)-category (or even a simplex), so that \(\mathcal{C}\) and \(\mathcal{D}\) are also \(\infty\)-categories (Remark 4.1.1.9). Fix an object \(X \in \mathcal{C}\), and set \(r=q \circ p\). We have a commutative diagram of Kan complexes

If \(p(e)\) is a \(q\)-cartesian morphism of \(\mathcal{D}\), then the bottom square is a homotopy pullback (Proposition 5.1.2.1. Invoking Proposition 3.4.1.11, we deduce that the upper square is a homotopy pullback if and only if the outer rectangle is a homotopy pullback. Allowing \(X\) to vary and invoking Proposition 5.1.2.1, we conclude that \(e\) is \(p\)-cartesian if and only if is \(r\)-cartesian.

Proof of Proposition 5.1.2.1. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories, and let \(g: Y \rightarrow Z\) be a morphism in the \(\infty\)-category \(\mathcal{C}\) having image \(\bar{g}: \bar{Y} \rightarrow \bar{Z}\) in the \(\infty\)-category \(\mathcal{D}\). By virtue of Proposition 5.1.1.13, the morphism \(g\) is \(q\)-cartesian if and only if the restriction map
\[
\theta: \mathcal{C}_{/ g} \rightarrow \mathcal{C}_{/ Z} \times_{\mathcal{D}_{/ \bar{Z}}} \mathcal{D}_{/ \bar{g}}
\]
is a trivial Kan fibration of simplicial sets. Since \(q\) is an inner fibration, the morphism \(\theta\) is a right fibration (Proposition 4.3.6.8). For each object \(X \in \mathcal{C}, \theta\) restricts to a right fibration of simplicial sets
\[
\theta_{X}:\{X\} \times_{\mathcal{C}} \mathcal{C}_{/ g} \rightarrow\{X\} \times_{\mathcal{C}} \mathcal{C}_{/ Z} \times_{\mathcal{D}_{/ \bar{Z}}} \mathcal{D}_{/ \bar{g}} .
\]

Note that if \(\theta\) is a trivial Kan fibration, then so is \(\theta_{X}\). Conversely, if each \(\theta_{X}\) is a trivial Kan fibration, then every fiber of \(\theta\) is a contractible Kan complex, so that \(\theta\) is a trivial Kan fibration by virtue of Proposition 4.4.2.14. To complete the proof, it will suffice to show that \(\theta_{X}\) is a trivial Kan fibration if and only if the diagram (5.3) appearing in the statement of Proposition 5.1.2.1 is a homotopy pullback square.

For the remainder of the proof, let us regard the object \(X \in \mathcal{C}\) as fixed, and set \(\bar{X}=q(X)\).

We then have a commutative diagram of simplicial sets

Corollary 4.3.6.11 guarantees that the restriction maps
\[
\mathcal{C}_{/ g} \rightarrow \mathcal{C}_{/ Z} \rightarrow \mathcal{C} \quad \mathcal{D}_{/ \bar{g}} \rightarrow \mathcal{D}_{/ \bar{Z}} \rightarrow \mathcal{D}
\]
are right fibrations, so that each of the simplicial sets appearing in the diagram (5.5) is a Kan complex. The morphism \(\rho\) is a pullback of the restriction map \(\mathcal{C}_{/ Z} \rightarrow \mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{/ \bar{Z}}\), and is therefore a right fibration by virtue of Proposition 4.3.6.8. Applying Corollary 4.4.3.8, we deduce that \(\rho\) is a Kan fibration. The projection map
\[
\{X\} \times_{\mathcal{C}} \mathcal{C}_{/ Z} \times_{\mathcal{D}_{/ \bar{Z}}} \mathcal{D}_{/ \bar{g}} \rightarrow\{\bar{X}\} \times_{\mathcal{D}} \mathcal{D}_{/ \bar{g}}
\]
is a pullback of \(\rho\), and therefore also a Kan fibration. In particular, the target of the right fibration \(\theta_{X}\) is a Kan complex, so that \(\theta_{X}\) is a Kan fibration (Corollary 4.4.3.8). It follows that \(\theta_{X}\) is a trivial Kan fibration if and only if is a homotopy equivalence (Proposition 3.3.7.6: that is, if and only if the diagram (5.5) is a homotopy pullback square.

Let \(\sigma\) be an \(n\)-simplex of the simplicial set \(\{X\} \times_{\mathcal{C}} \mathcal{C}_{/ g}\). Then we can identify \(\sigma\) with a morphism of simplicial sets \(u_{\sigma}: \Delta^{n} \star \Delta^{1} \rightarrow \mathcal{C}\) such that \(\left.u_{\sigma}\right|_{\Delta^{n}}\) is the constant map taking the value \(X\) and \(\left.u_{\sigma}\right|_{\Delta^{1}}=g\). Let \(\pi: \Delta^{n} \times \Delta^{2} \rightarrow \Delta^{n} \star \Delta^{1} \simeq \Delta^{n+2}\) be the map given on vertices by the formula
\[
\pi(i, j)= \begin{cases}i & \text { if } j=0 \\ n+1 & \text { if } j=1 \\ n+2 & \text { if } j=2\end{cases}
\]

The composition \(u_{\sigma} \circ \pi: \Delta^{n} \times \Delta^{2} \rightarrow \mathcal{C}\) can then be regarded as an \(n\)-simplex \(\sigma^{\prime}\) of the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y, Z) \times_{\operatorname{Hom}_{\mathcal{C}}(Y, Z)}\{g\}\). The construction \(\sigma \mapsto \sigma^{\prime}\) depends functorially on \([n] \in \boldsymbol{\Delta}\), and therefore determines a morphism of Kan complexes
\[
\iota_{X, g}^{\mathrm{R}}:\{X\} \times_{\mathcal{C}} \mathcal{C}_{/ g} \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Y, Z) \times_{\operatorname{Hom}_{\mathcal{C}}(Y, Z)}\{g\} .
\]

Note that the morphism \(\iota_{X, g}\) fits into a commutative diagram

where the left vertical map is a pullback of the restriction morphism \(\mathcal{C}_{/ g} \rightarrow \mathcal{C}_{/ Y}\) (and therefore a trivial Kan fibration by virtue of Corollary 4.3.6.13), the right vertical map is a pullback of the restriction morphism \(\operatorname{Hom}_{\mathcal{C}}(X, Y, Z) \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Y) \times \operatorname{Hom}_{\mathcal{C}}(Y, Z)\) (and therefore a trivial Kan fibration by virtue of Corollary 4.6.9.5), and \(\iota_{X, Y}^{\mathrm{R}}: \operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y) \hookrightarrow \operatorname{Hom}_{\mathcal{C}}(X, Y)\) is the right-pinch inclusion map of Construction 4.6.5.7 (which is a homotopy equivalence of Kan complexes by virtue of Proposition 4.6.5.10). It follows that \(\iota_{X, g}^{\mathrm{R}}\) is also a homotopy equivalence of Kan complexes. Applying the same construction to the \(\infty\)-category \(\mathcal{D}\), we obtain a homotopy equivalence
\[
\iota_{\bar{X}, \bar{g}}:\{\bar{X}\} \times_{\mathcal{D}} \mathcal{D}_{/ \bar{g}} \rightarrow \operatorname{Hom}_{\mathcal{D}}(\bar{X}, \bar{Y}, \bar{Z}) \times_{\operatorname{Hom}_{\mathcal{D}}(\bar{Y}, \bar{Z})}\{\bar{g}\} .
\]

We have a commutative diagram of Kan complexes

where the right-pinch inclusion maps \(\iota_{X, Z}^{\mathrm{R}}\) and \(\iota_{\bar{X}, \bar{Z}}^{\mathrm{R}}\) are homotopy equivalences (Proposition 4.6.5.10. Applying Corollary 3.4.1.12, we conclude that the front face (5.3) is a homotopy pullback square if and only if the back face (5.5) is a homotopy pullback square: that is, if and only if \(\theta_{X}\) is a trivial Kan fibration.

\subsection*{5.1.3 Locally Cartesian Edges}

It will often be convenient to consider a variant of Definition 5.1.1.1,
Definition 5.1.3.1. Let \(q: X \rightarrow S\) be a morphism of simplicial sets and let \(e\) be an edge of 01 TX \(X\) having image \(\bar{e}=q(e)\) in \(S\). Form a pullback diagram of simplicial sets

so that \(e\) lifts uniquely to an edge \(\tilde{e}\) of \(X_{e}\) having nondegenerate image in \(\Delta^{1}\). We say that \(e\) is locally \(q\)-cartesian if \(\widetilde{e}\) is a \(q^{\prime}\)-cartesian edge of the simplicial set \(X_{e}\). We say that \(e\) is locally \(q\)-cocartesian if \(\widetilde{e}\) is a \(q^{\prime}\)-cocartesian edge of the simplicial set \(X_{e}\).

Remark 5.1.3.2. Let \(q: X \rightarrow S\) be a morphism of simplicial sets and \(q^{\mathrm{op}}: X^{\mathrm{op}} \rightarrow S^{\mathrm{op}}\) be 01TY the opposite morphism. Then an edge \(e\) of \(X\) is locally \(q\)-cartesian if and only if it is locally \(q^{\mathrm{op}}\)-cocartesian.

Remark 5.1.3.3. Let \(q: X \rightarrow S\) be a morphism of simplicial sets. Then every \(q\)-cartesian edge of \(X\) is locally \(q\)-cartesian, and every \(q\)-cocartesian edge of \(X\) is locally \(q\)-cocartesian (see Remark 5.1.1.11).

Remark 5.1.3.4. Let \(q: X \rightarrow S\) be a morphism of simplicial sets and let \(e: x \rightarrow y\) be an edge of \(X\). Suppose that \(S\) is isomorphic to a left cone \(K^{\triangleleft}\) and that \(q\) carries the vertex \(x \in X\) to the cone point of \(K^{\triangleleft}\). Then \(e\) is \(q\)-cartesian if and only if it is locally \(q\)-cartesian. Similarly, if \(S\) is isomorphic to a right cone \(L^{\triangleright}\) and \(q\) carries the vertex \(y \in X\) to the cone point of \(L^{\triangleright}\), then \(e\) is \(q\)-cocartesian if and only if it is locally \(q\)-cocartesian.

Remark 5.1.3.5. Suppose we are given a pullback diagram of simplicial sets

Let \(e^{\prime}\) be an edge of the simplicial set \(X^{\prime}\), having image \(e=f\left(e^{\prime}\right)\) in \(X\). Then \(e\) is locally \(q\)-cartesian if and only if \(e^{\prime}\) is locally \(q^{\prime}\)-cartesian. Similarly, \(e\) is locally \(q\)-cocartesian if and only if \(e^{\prime}\) is locally \(q^{\prime}\)-cocartesian.

01U3 Example 5.1.3.6. Let \(q: X \rightarrow S\) be a morphism of simplicial sets and let \(e\) be an edge of \(X\) such that \(q(e)=\mathrm{id}_{s}\) is a degenerate edge of \(S\). Suppose that the fiber \(X_{s}=\{s\} \times_{S} X\) is an \(\infty\)-category (this condition is satisfied, for example, if \(q\) is an inner fibration). The following conditions are equivalent:
- The edge \(e\) is locally \(q\)-cartesian.
- The edge \(e\) is locally \(q\)-cocartesian.
- The edge \(e\) is an isomorphism in the \(\infty\)-category \(X_{s}\).

To prove this, we can use Remark 5.1.3.5 to reduce to the situation where \(S=\{s\}\) consists of a single vertex. In this case, the edge \(e\) is locally \(q\)-cartesian if and only if it is \(q\)-cartesian, and locally \(q\)-cocartesian if and only if it is \(q\)-cocartesian (Remark 5.1.3.4). The desired result now follows from Example 5.1.1.4.

01U4 Proposition 5.1.3.7. Let \(q: X \rightarrow S\) be an inner fibration of simplicial sets and let \(\sigma: \Delta^{2} \rightarrow X\) be a 2-simplex of \(X\), which we will depict as a diagram

- Suppose that \(g\) is \(q\)-cartesian. Then \(f\) is locally \(q\)-cartesian if and only if \(h\) is locally \(q\)-cartesian.
- Suppose that \(f\) is \(q\)-cocartesian. Then \(g\) is locally \(q\)-cocartesian if and only if \(h\) is locally \(q\)-cocartesian.

Proof. We will prove the first assertion; the proof of the second is similar. Using Remarks 5.1.1.11 and 5.1.3.5 we can replace \(q\) by the projection map \(\Delta^{2} \times{ }_{S} X \rightarrow \Delta^{2}\), and thereby reduce to the case where \(S=\Delta^{2}\) and \(q(\sigma)\) is the identity morphism id \(\Delta^{2}\). In this case, both \(X\) and \(S\) are \(\infty\)-categories and the morphisms \(f\) and \(h\) are locally \(q\)-cartesian if and only if they are \(q\)-cartesian (Remark 5.1.3.4). The desired result now follows from Corollary 5.1.2.4

01 U5 Remark 5.1.3.8 (Uniqueness of Locally Cartesian Lifts). Let \(q: X \rightarrow S\) be an inner fibration of simplicial sets and let \(g: y \rightarrow z\) be a locally \(q\)-cartesian edge of \(X\). Suppose that \(h: x \rightarrow z\) is another edge of \(X\) satisfying \(q(h)=q(g)\). Set \(s=q(x)=q(y)\), and let
\(X_{s}=\{s\} \times_{S} X\) denote the fiber of \(q\) over the vertex \(s\). Our assumption that \(g\) is locally \(q\)-cartesian then guarantees that we can choose a 2 -simplex \(\sigma\) of \(X\) satisfying
\[
d_{0}^{2}(\sigma)=g \quad d_{1}^{2}(\sigma)=h \quad q(\sigma)=s_{0}^{1}(q(g)),
\]
which we display informally as a diagram

here \(f=d_{2}^{2}(\sigma)\) is a morphism in the \(\infty\)-category \(X_{s}\). In this case, the following conditions are equivalent:
(1) The morphism \(f\) is an isomorphism in the \(\infty\)-category \(X_{s}\).
(2) The morphism \(h\) is locally \(q\)-cartesian.

To see this, we can replace \(q\) by the projection map \(\Delta^{1} \times{ }_{S} X \rightarrow \Delta^{1}\), and thereby reduce to the case where \(g\) and \(h\) are both lifts of the unique nondegenerate edge of \(S=\Delta^{1}\). In this case, the morphism \(g\) is \(q\)-cartesian, and (1) is equivalent to the assertion that \(f\) is locally \(q\)-cartesian (Example 5.1.3.6). The equivalence of (1) and (2) is now a special case of Proposition 5.1.3.7.

Corollary 5.1.3.9. Let \(q: X \rightarrow S\) be an inner fibration of simplicial sets, let \(z\) be a vertex 01U6 of \(X\), and let \(e: s \rightarrow q(z)\) be an edge of \(S\). Suppose that there exists a \(q\)-cartesian edge \(g: y \rightarrow z\) of \(X\) satisfying \(q(g)=e\). Then any locally \(q\)-cartesian edge \(h: x \rightarrow z\) satisfying \(q(h)=e\) is \(q\)-cartesian.

Proof. By virtue of Remark 5.1.1.12, we may assume without loss of generality that \(S\) is an \(\infty\)-category (or even a simplex). Applying Remark 5.1.3.8, we deduce that there is a 2-simplex of \(X\) as depicted in the diagram

where \(f\) is an isomorphism in the \(\infty\)-category \(X\). Then \(f\) is also \(q\)-cartesian (Proposition 5.1.1.8, so Corollary 5.1.2.4 guarantees that \(h\) is \(q\)-cartesian.

We now record an analogue of Proposition 5.1.2.1 for detecting locally cartesian edges.
01 U7 Notation 5.1.3.10. Let \(q: X \rightarrow S\) be an inner fibration of simplicial sets, let \(y\) and \(z\) be vertices of \(X\) having images \(s=q(y)\) and \(t=q(z)\), and let \(\bar{e}: s \rightarrow t\) be an edge of \(S\). Recall that the relative morphism space \(\operatorname{Hom}_{X}(y, z)_{\bar{e}}\) is defined to be the fiber product \(\operatorname{Hom}_{X}(y, z) \times_{\operatorname{Hom}_{S}(s, t)}\{\bar{e}\}\) (Construction 4.6.1.15).

Let \(x\) be another vertex of \(X\) satisfying \(q(x)=s\), and let \(\sigma\) denote the image of \(\bar{e}\) under the degeneracy operator \(\operatorname{Hom}_{S}(s, t) \rightarrow \operatorname{Hom}_{S}(s, s, t)\) (see Notation 4.6.9.1). It follows from Proposition 4.6.9.4 (and Example 4.6.1.17) that restriction along the inclusion \(\Lambda_{1}^{2} \hookrightarrow \Delta^{2}\) induces a trivial Kan fibration of simplicial sets
\[
\theta: \operatorname{Hom}_{X}(x, y, z) \times_{\operatorname{Hom}_{S}(s, s, t)}\{\sigma\} \rightarrow \operatorname{Hom}_{X}(y, z)_{\bar{e}} \times \operatorname{Hom}_{X_{s}}(x, y),
\]
where \(X_{\bar{y}}\) denotes the \(\infty\)-category given by the fiber \(\{\bar{y}\} \times_{S} X\). In particular, the homotopy class \([\theta]\) is an isomorphism in the homotopy category hKan. Combining the inverse isomorphism \([\theta]^{-1}\) with the restriction map \(\operatorname{Hom}_{X}(x, y, z) \times_{\operatorname{Hom}_{S}(s, s, t)}\{\sigma\} \rightarrow \operatorname{Hom}_{X}(x, z)_{\bar{e}}\), we obtain a composition law
\[
\circ: \operatorname{Hom}_{X}(y, z)_{\bar{e}} \times \operatorname{Hom}_{X_{s}}(x, y) \rightarrow \operatorname{Hom}_{X}(x, z)_{\bar{e}} .
\]

If \(e: y \rightarrow z\) is an edge of \(X\) satisfying \(q(e)=\bar{e}\), then the restriction of this composition law to \(\{e\} \times \operatorname{Hom}_{X_{s}}(x, y)\) determines a morphism of Kan complexes \(\operatorname{Hom}_{X_{s}}(x, y) \xrightarrow{[e] \circ} \operatorname{Hom}_{X}(x, z)_{\bar{e}}\), which is well-defined up to homotopy.

01 U8 Proposition 5.1.3.11. Let \(q: X \rightarrow S\) be an inner fibration of simplicial sets, and let \(e: y \rightarrow z\) be an edge of the simplicial set \(X\) having image \(\bar{e}: s \rightarrow t\) in \(S\). Then \(e\) is locally \(q\)-cartesian if and only if, for every object \(x\) of the \(\infty\)-category \(X_{s}\), the composition map
\[
\operatorname{Hom}_{X_{s}}(x, y) \xrightarrow{[e] 0} \operatorname{Hom}_{X}(x, z)_{\bar{e}}
\]
of Notation 5.1.3.10 is an isomorphism in the homotopy category hKan.
Proof. Without loss of generality, we can replace \(q: X \rightarrow S\) by the projection map \(X \times_{S} \Delta^{1} \rightarrow \Delta^{1}\) and thereby reduce to the case where \(S=\Delta^{1}\) and \(\bar{e}\) is the unique nondegenerate edge of \(\Delta^{1}\). In this case, the edge \(e\) is locally \(q\)-cartesian if and only if it is \(q\)-cartesian, and the desired result is a special case of Corollary 5.1.2.3.

\subsection*{5.1.4 Cartesian Fibrations}

01U9 We now introduce an \(\infty\)-categorical counterpart of Definition 5.0.0.3
01UA Definition 5.1.4.1. Let \(q: X \rightarrow S\) be a morphism of simplicial sets. We say that \(q\) is a cartesian fibration if the following conditions are satisfied:
(1) The morphism \(q\) is an inner fibration.
(2) For every edge \(\bar{e}: s \rightarrow t\) of the simplicial set \(S\) and every vertex \(z \in X\) satisfying \(q(z)=t\), there exists a \(q\)-cartesian edge \(e: y \rightarrow z\) of \(X\) satisfying \(q(e)=\bar{e}\).

We say that \(q\) is a cocartesian fibration if it satisfies condition (1) together with the following dual version of (2):
(2') For every edge \(\bar{e}: s \rightarrow t\) of the simplicial set \(S\) and every vertex \(y \in X\) satisfying \(q(y)=s\), there exists a \(q\)-cocartesian edge \(e: y \rightarrow z\) of \(X\) satisfying \(q(e)=\bar{e}\).

Example 5.1.4.2. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between ordinary categories. Then \(q\) is a 01UB cartesian fibration (in the sense of Definition 5.0.0.3) if and only if the induced morphism of simplicial sets \(\mathrm{N}_{\bullet}(q): \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{D})\) is a cartesian fibration (in the sense of Definition 5.1.4.1. Similarly, \(q\) is a cocartesian fibration if and only if \(\mathrm{N}_{\bullet}(q)\) is a cocartesian fibration of simplicial sets. See Corollary 5.1.2.2.

Example 5.1.4.3. Let \(X\) be a simplicial set and let \(q: X \rightarrow \Delta^{0}\) denote the projection map. 01UC The following conditions are equivalent:
- The simplicial set \(X\) is an \(\infty\)-category.
- The morphism \(q\) is a cartesian fibration.
- The morphism \(q\) is a cocartesian fibration.

Remark 5.1.4.4. Let \(q: X \rightarrow S\) be a morphism of simplicial sets. Then \(q\) is a cartesian 01UD fibration if and only if the opposite morphism \(q^{\mathrm{op}}: X^{\mathrm{op}} \rightarrow S^{\mathrm{op}}\) is a cocartesian fibration.
Remark 5.1.4.5. Let \(q: X \rightarrow S\) be an inner fibration of simplicial sets and let \(e\) be an edge 01UE of \(X\). If \(q\) is a cartesian fibration, then \(e\) is \(q\)-cartesian if and only if it is locally \(q\)-cartesian (see Corollary 5.1.3.9. Similarly, if \(q\) is a cocartesian fibration, then \(e\) is \(q\)-cocartesian if and only if it is locally \(q\)-cocartesian.

Remark 5.1.4.6. Suppose we are given a pullback diagram of simplicial sets

If \(q\) is a cartesian fibration, then \(q^{\prime}\) is also a cartesian fibration. Moreover, an edge \(e^{\prime}\) of \(X^{\prime}\) is \(q^{\prime}\)-cartesian if and only if \(e=f\left(e^{\prime}\right)\) is a \(q\)-cartesian edge of \(X\) (this follows from Remarks
5.1.4.5 and 5.1.3.5. Similarly, if \(q\) is a cocartesian fibration, then \(q^{\prime}\) is also a cocartesian fibration (and an edge \(e^{\prime}\) of \(X^{\prime}\) is \(q^{\prime}\)-cocartesian if and only if \(e=f\left(e^{\prime}\right)\) is a \(q\)-cocartesian edge of \(X\) ).

023J Proposition 5.1.4.7. Let \(q: X \rightarrow S\) be a morphism of simplicial sets. Then \(q\) is a cartesian fibration if and only if, for every simplex \(\sigma: \Delta^{n} \rightarrow S\), the projection map \(q_{\sigma}: \Delta^{n} \times_{S} X \rightarrow \Delta^{n}\) is a cartesian fibration.

Proof. If \(q\) is a cartesian fibration, then Remark 5.1.4.6 guarantees that every pullback of \(q\) is a cartesian fibration. Conversely, suppose that for every \(n\)-simplex \(\sigma: \Delta^{n} \rightarrow S\), the projection map \(q_{\sigma}: \Delta^{n} \times_{S} X \rightarrow \Delta^{n}\) is a cartesian fibration. Applying this assumption in the case \(n=1\), we conclude that for every vertex \(y \in X\) and every edge \(\bar{e}: \bar{x} \rightarrow q(y)\) of \(S\), there exists a locally \(q\)-cartesian edge \(e: x \rightarrow y\) satisfying \(q(e)=\bar{e}\). Moreover, Remark 4.1.1.13 guarantees that \(q\) is an inner fibration. It will therefore suffice to show that every locally \(q\)-cartesian edge \(e\) of \(X\) is \(q\)-cartesian. By virtue of Remark 5.1.1.12, it suffices to verify the analogous assertion for each of the projection maps \(q_{\sigma}: \Delta^{n} \times{ }_{S} X \rightarrow \Delta^{n}\), which follows from Remark 5.1.4.5 (since \(q_{\sigma}\) is assumed to be a cartesian fibration).

01UG Proposition 5.1.4.8. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be a cartesian fibration of \(\infty\)-categories. Then \(q\) is an isofibration.

Proof. Suppose we are given an object \(Y \in \mathcal{C}\) and an isomorphism \(\bar{e}: \bar{X} \rightarrow q(Y)\) in the \(\infty\)-category \(\mathcal{D}\). We wish to show that there exists an isomorphism \(e: X \rightarrow Y\) in the \(\infty\)-category \(\mathcal{C}\) satisfying \(q(e)=\bar{e}\). Our assumption that \(q\) is a cartesian fibration guarantees that we can write \(\bar{e}=q(e)\), where \(e: X \rightarrow Y\) is a \(q\)-cartesian morphism of \(\mathcal{C}\). Since \(\bar{e}=q(e)\) is an isomorphism, Proposition 5.1.1.8 guarantees that \(e\) is an isomorphism.

01UH Remark 5.1.4.9. In the statement of Proposition 5.1.4.8, the hypothesis that \(\mathcal{C}\) and \(\mathcal{D}\) are \(\infty\)-categories is superfluous: we will later show that every cartesian fibration of simplicial sets is an isofibration (Corollary 5.6.7.5).

023K Corollary 5.1.4.10. Let \(q: X \rightarrow S\) be a morphism of simplicial sets, where \(S\) is a Kan complex. The following conditions are equivalent:
(1) The morphism \(q\) is an isofibration.
(2) The morphism \(q\) is a cartesian fibration.
(3) The morphism \(q\) is a cocartesian fibration.

Proof. We will prove the equivalence (1) \(\Leftrightarrow(2)\); the equivalence (1) \(\Leftrightarrow(3)\) follows by a similar argument. The implication \((2) \Rightarrow(1)\) is a special case of Proposition 5.1.4.8. For the converse, suppose that \(q\) is an isofibration. Then \(q\) is an inner fibration. To complete
the proof, we must show that for every vertex \(y \in X\) and every edge \(\bar{e}: \bar{x} \rightarrow q(y)\) of \(S\), we can write \(\bar{e}=q(e)\) for some \(q\)-cartesian edge \(e\) of \(X\). Since \(S\) is a Kan complex, \(\bar{e}\) is an isomorphism (Proposition 1.4.6.10). Our assumption that \(q\) is an isofibration then guarantees that we can write \(\bar{e}=q(e)\) for some isomorphism \(e: x \rightarrow y\) of \(X\). The edge \(e\) is automatically \(q\)-cartesian by virtue of Corollary 5.1.1.10.

Proposition 5.1.4.11. Let \(q: X \rightarrow S\) be a cartesian fibration of simplicial sets and let e be 01UJ an edge of \(X\) such that \(q(e)=\mathrm{id}_{s}\) is a degenerate edge of \(S\). Then \(e\) is \(q\)-cartesian if and only if it is an isomorphism in the \(\infty\)-category \(X_{s}=\{s\} \times_{S} X\).

Proof. Combine Example 5.1.3.6 with Remark 5.1.4.5.
Proposition 5.1.4.12. Let \(q: X \rightarrow S\) be a cartesian fibration of simplicial sets and let 01UK \(\sigma: \Delta^{2} \rightarrow X\) be a 2-simplex of \(X\), which we will depict as a diagram

Suppose that \(g\) is \(q\)-cartesian. Then \(f\) is \(q\)-cartesian if and only if \(h\) is \(q\)-cartesian.
Proof. Combine Proposition 5.1.3.7 with Remark 5.1.4.5.
Proposition 5.1.4.13. Let \(p: X \rightarrow Y\) and \(q: Y \rightarrow Z\) be cartesian fibrations of simplicial 01UL sets. Then:
- The composite morphism \((q \circ p): X \rightarrow Z\) is a cartesian fibration of simplicial sets.
- An edge e of \(X\) is \((q \circ p)\)-cartesian if and only if \(e\) is \(p\)-cartesian and \(p(e)\) is \(q\)-cartesian.

Proof. It follows from Remark 4.1.1.8 that \(q \circ p\) is an inner fibration. Let us say that an edge \(e\) of \(X\) is special if \(e\) is \(p\)-cartesian and \(p(e)\) is \(q\)-cartesian. Remark 5.1.1.6 guarantees that every special edge of \(X\) is \((q \circ p)\)-cartesian. Consequently, to prove the first assertion, it will suffice to verify the following:
(*) For every edge \(\bar{e}: z^{\prime} \rightarrow z\) of \(Z\) and every vertex \(x \in X\) satisfying \(z=(q \circ p)(x)\), there exists a special edge \(e: x^{\prime} \rightarrow x\) of \(X\) satisfying \(\bar{e}=(q \circ p)(e)\).

To prove \((*)\), set \(y=p(x)\). Using our assumption that \(q\) is a cartesian fibration, we can choose a \(q\)-cartesian edge \(\widetilde{e}: y^{\prime} \rightarrow y\) of the simplicial set \(Y\) satisfying \(q(\widetilde{e})=\bar{e}\). Using our assumption that \(p\) is a cartesian fibration, we can choose a \(p\)-cartesian edge \(e: x^{\prime} \rightarrow x\) of \(X\) satisfying \(p(e)=\widetilde{e}\). Then \(e\) is a special edge of \(X\) satisfying \((q \circ p)(e)=q(\widetilde{e})=\bar{e}\).

To complete the proof, it will suffice to show that every ( \(q \circ p\) )-cartesian edge \(f: x^{\prime \prime} \rightarrow x\) of \(X\) is special. Let \(\bar{f}: z^{\prime \prime} \rightarrow z\) be the image of \(f\) under \((q \circ p): X \rightarrow Z\). Using \((*)\), we can choose a special edge \(e: x^{\prime} \rightarrow x\) satisfying \((q \circ p)(e)=\bar{f}\). Since \(e\) is \((q \circ p)\)-cartesian, we can choose a 2-simplex \(\sigma\) of \(X\) satisfying
\[
d_{0}^{2}(\sigma)=e \quad d_{1}^{2}(\sigma)=f \quad(q \circ p)(\sigma)=s_{0}^{1}(\bar{e}) .
\]

Set \(g=d_{2}^{2}(\sigma)\), so that we can view \(\sigma\) informally as a diagram

Set \(y^{\prime}=p\left(x^{\prime}\right) \in Y\) and \(z^{\prime}=q\left(y^{\prime}\right) \in Z\). Since \(f\) is \((q \circ p)\)-cartesian, the edge \(g\) is an isomorphism in the \(\infty\)-category \(X_{z^{\prime}}\) (Remark 5.1.3.8). Then \(g\) is \(p^{\prime}\)-cartesian, where \(p^{\prime}: X_{z^{\prime}} \rightarrow Y_{z^{\prime}}\) is the projection map (Proposition 5.1.1.8). Applying Remark 5.1.3.5, we conclude that \(g\) is locally \(p\)-cartesian. Since \(p\) is a cartesian fibration, it follows that \(g\) is \(p\)-cartesian (Remark 5.1.4.5). Invoking Proposition 5.1.4.12, we deduce that \(f\) is also \(p\)-cartesian. Since \(p(g)\) is an isomorphism in the \(\infty\)-category \(Y_{z^{\prime}}\), it is \(q\)-cartesian (Proposition 5.1.4.11. Applying Proposition 5.1.4.12, we conclude that \(p(f)\) is also \(q\)-cartesian.

Recall that an \(\infty\)-category \(\mathcal{C}\) is a Kan complex if and only if every morphism in \(\mathcal{C}\) is an isomorphism (Proposition 4.4.2.1). We now establish a relative version of this assertion:

01UM Proposition 5.1.4.14. Let \(q: X \rightarrow S\) be a morphism of simplicial sets. The following conditions are equivalent:
(1) The morphism \(q\) is a right fibration.
(2) The morphism \(q\) is a cartesian fibration and every edge of \(X\) is \(q\)-cartesian.
(3) The morphism \(q\) is a cartesian fibration and, for every vertex \(s \in S\), the fiber \(X_{s}=\) \(\{s\} \times{ }_{S} X\) is a Kan complex.

Proof. The equivalence (1) \(\Leftrightarrow(2)\) is immediate from the definitions. The implication \((2) \Rightarrow(3)\) follows from Propositions 5.1.4.11 and 4.4.2.1. We will complete the proof by showing that (3) implies (2). Assume that \(q\) is a cartesian fibration and that each fiber of \(q\) is a Kan complex. Let \(h: x \rightarrow z\) be an edge of \(X\); we wish to show that \(h\) is \(q\)-cartesian. Since \(q\) is a cartesian fibration, we can choose a \(q\)-cartesian edge \(g: y \rightarrow z\) of \(X\) satisfying
\(q(g)=q(h)\). The assumption that \(g\) is \(q\)-cartesian then guarantees the existence of a 2-simplex \(\sigma\) of \(X\) satisfying
\[
d_{0}^{2}(\sigma)=g \quad d_{1}^{2}(\sigma)=h \quad q(\sigma)=s_{0}^{1}(q(h)),
\]
as depicted in the diagram

Set \(s=q(x)\), so that \(f\) is a morphism in the \(\infty\)-category \(X_{s}=\{s\} \times_{S} X\). Since \(X_{s}\) is a Kan complex, \(f\) is an isomorphism (Proposition 1.4.6.10). Applying Remark 5.1.3.8 and Corollary 5.1.3.9, we deduce that \(h\) is \(q\)-cartesian.

Recall that every \(\infty\)-category \(\mathcal{C}\) has an underlying Kan complex \(\mathcal{C}^{\simeq}\), obtained by discarding the noninvertible morphisms of \(\mathcal{C}\) (Construction 4.4.3.1). Using Proposition 5.1.4.14, we can establish a relative version of this result.
Corollary 5.1.4.15. Let \(q: X \rightarrow S\) be a cartesian fibration of simplicial sets, and let 01UN \(X^{\prime} \subseteq X\) be the simplicial subset spanned by those simplices \(\sigma: \Delta^{n} \rightarrow X\) which carry each edge of \(\Delta^{n}\) to a \(q\)-cartesian edge of \(X\). Then the morphism \(\left.q\right|_{X^{\prime}}: X^{\prime} \rightarrow S\) is a right fibration of simplicial sets.
Proof. Choose integers \(0<i \leq n\); we wish to show that every lifting problem

admits a solution. In the special case \(i=n=1\), this follows immediately from our assumption that \(q\) is a cartesian fibration. Assume therefore that \(n \geq 2\). We first show that \(\sigma_{0}\) can be extended to an \(n\)-simplex \(\sigma: \Delta^{n} \rightarrow X\) satisfying \(q \circ \sigma=\bar{\sigma}\). For \(i<n\), this follows from the assumption that \(q\) is an inner fibration. For \(i=n\), it follows from the assumption that the edge
\[
\Delta^{1} \simeq \mathrm{~N}_{\bullet}(\{n-1<n\}) \hookrightarrow \Lambda_{i}^{n} \xrightarrow{\sigma_{0}} X^{\prime} \hookrightarrow X
\]
is \(q\)-cartesian. We now complete the proof by showing that \(\sigma\) factors through the simplicial subset \(X^{\prime}\); that is, it carries each edge of \(\Delta^{n}\) to a \(q\)-cartesian edge of \(X\). For \(n \geq 3\), this
is immediate (since every edge of \(\Delta^{n}\) is contained in \(\Lambda_{i}^{n}\) ). The case \(n=2\) follows from Proposition 5.1.4.12.

02R5 Proposition 5.1.4.16. Let \(q: X \rightarrow S\) be a cartesian fibration of simplicial sets, and let \(X^{\prime} \subseteq X\) be a full simplicial subset with the following property:
(*) For every vertex \(y \in X^{\prime}\) and every edge \(\bar{e}: \bar{x} \rightarrow q(y)\) in \(S\), there exists a vertex \(x \in X^{\prime}\) and a \(q\)-cartesian edge \(e: x \rightarrow y\) of \(X\) satisfying \(q(e)=\bar{e}\).

Then \(q^{\prime}=\left.q\right|_{X^{\prime}}\) is a cartesian fibration from \(X^{\prime}\) to \(S\). Moreover, an edge e of \(X^{\prime}\) is \(q^{\prime}\)-cartesian if and only if it is \(q\)-cartesian.

Proof. Since the inclusion map \(X^{\prime} \hookrightarrow X\) is an inner fibration (see Definition 4.1.2.15), the restriction \(\left.q\right|_{X^{\prime}}\) is also an inner fibration. Remark 5.1.1.7 guarantees that every edge of \(X^{\prime}\) which is \(q\)-cartesian is also \(q^{\prime}\)-cartesian, so that \((*)\) immediately guarantees that \(q^{\prime}\) is a cartesian fibration. To complete the proof, we must show that if \(e: x \rightarrow z\) is a \(q^{\prime}\)-cartesian edge of \(X^{\prime}\), then \(e\) is \(q\)-cartesian when viewed as an edge of \(X\). Applying ( \(*\) ), we can choose a \(q\)-cartesian edge \(e^{\prime}: y \rightarrow z\) satisfying \(q\left(e^{\prime}\right)=q(e)\), where \(y\) belongs to \(X^{\prime}\). Then \(e^{\prime}\) is also \(q^{\prime}\)-cartesian, so Remark 5.1.3.8 guarantees that there exists a 2 -simplex

of \(X^{\prime}\), where \(u\) is an isomorphism in the \(\infty\)-category \(\{q(x)\} \times{ }_{S} X^{\prime}\). It follows that \(u\) is also an isomorphism in the \(\infty\)-category \(\{q(x)\} \times_{S} X\), and is therefore \(q\)-cartesian (Proposition 5.1.4.11. Applying Proposition 5.1.4.12, we see that the edge \(e\) is also \(q\)-cartesian.

We now study the behavior of cartesian fibrations with respect to the slice and coslice constructions of \(\$ 4.3\).

01UP Proposition 5.1.4.17. Let \(q: X \rightarrow S\) be a cartesian fibration of simplicial sets and let \(f: K \rightarrow X\) be any morphism of simplicial sets. Then:
(1) The induced map \(q^{\prime}: X_{/ f} \rightarrow S_{/(q \circ f)}\) is a cartesian fibration of simplicial sets.
(2) An edge e of \(X_{/ f}\) is \(q^{\prime}\)-cartesian if and only if its image in \(X\) is \(q\)-cartesian.

Proof. The morphism \(q^{\prime}\) factors as a composition
\[
X_{/ f} \xrightarrow{u} X \times_{S} S_{/(q \circ f)} \xrightarrow{v} S_{/(q \circ f)} .
\]

Since \(q\) is an inner fibration, the morphism \(u\) is a right fibration (Proposition 4.3.6.8). In particular, \(u\) is a cartesian fibration and every edge of \(X_{/ f}\) is \(u\)-cartesian (Proposition 5.1.4.14). The morphism \(v\) is a pullback of \(q\), and is therefore a cartesian fibration (Remark 5.1.4.6). Moreover, an edge of \(X \times{ }_{S} S_{/(q \circ f)}\) is \(v\)-cartesian if and only if its image in \(X\) is \(q\)-cartesian. Assertions (1) and (2) now follow from Proposition 5.1.4.13.

Lemma 5.1.4.18. Let \(q: X \rightarrow S\) be an inner fibration of simplicial sets, let \(f: B \rightarrow X\) be 01UQ a morphism of simplicial sets, let \(A\) be a simplicial subset of \(B\), and let
\[
q^{\prime}: X_{f /} \rightarrow X_{\left.f\right|_{A} /} \times_{S_{\left(\left.q \circ f\right|_{A}\right) /}} S_{(q \circ f) /}
\]
be the induced map. Let \(\bar{e}\) be an edge of the simplicial set \(X_{f /}\), and let \(e\) be its image in \(X\). If \(e\) is \(q\)-cartesian, then \(\bar{e}\) is \(q^{\prime}\)-cartesian.

Proof. Let \(q^{\prime \prime}: X_{\left.f\right|_{A} /} \times S_{\left(\left.q \circ f\right|_{A}\right) /} S_{(q \circ f) /} \rightarrow S_{(q \circ f) /}\) be the projection map onto the second factor. Then \(q^{\prime \prime}\) is a pullback of the map \(u: X_{\left.f\right|_{A} /} \rightarrow S_{\left(\left.q \circ f\right|_{A}\right) /}\), and is therefore an inner fibration (Corollary 4.3.6.10). By virtue of Corollary 5.1.1.14, the edge \(\bar{e}\) is \(\left(q^{\prime \prime} \circ q^{\prime}\right)\)-cartesian and the image of \(\bar{e}\) in \(X_{f_{A}}\) is \(u\)-cartesian. It follows from Remark 5.1.1.11 that \(q^{\prime}(\bar{e})\) is \(q^{\prime \prime}\)-cartesian, so that \(\bar{e}\) is \(q^{\prime}\)-cartesian by virtue of Corollary 5.1.2.6.

Proposition 5.1.4.19. Let \(q: X \rightarrow S\) be a cartesian fibration of simplicial sets and let 01UR \(f: K \rightarrow X\) be any morphism of simplicial sets. Then:
(1) The induced map \(q^{\prime}: X_{f /} \rightarrow S_{(q \circ f) /}\) is a cartesian fibration of simplicial sets.
(2) An edge \(e\) of \(X_{f /}\) is \(q^{\prime}\)-cartesian if and only if its image in \(X\) is q-cartesian.

Proof. The morphism \(q^{\prime}\) factors as a composition
\[
X_{f /} \xrightarrow{u} X \times{ }_{S} S_{(q \circ f) /} \xrightarrow{v} S_{(q \circ f) /}
\]
where \(v\) is a pullback of \(q\) and is therefore a cartesian fibration by virtue of Remark 5.1.4.6. The morphism \(u\) is a left fibration (Proposition 4.3.6.8), and therefore an inner fibration. It follows that \(q^{\prime}\) is an inner fibration (Remark 4.1.1.8).

Let us say that an edge \(e\) of \(X_{f /}\) is special if its image in \(X\) is \(q\)-cartesian. If this condition is satisfied, then \(u(e)\) is \(v\)-cartesian (Remark 5.1.4.6) and \(e\) is \(u\)-cartesian (Lemma 5.1.4.18, so that \(e\) is \(q^{\prime}\)-cartesian by virtue of Remark 5.1.1.6. This proves the "if" direction of assertion (2).

To prove (1), it will suffice to show that for every vertex \(y\) of the simplicial set \(X_{f /}\) and every edge \(\bar{e}: \bar{x} \rightarrow q^{\prime}(y)\) of the simplicial set \(S_{(q \circ f) /}\), there exists a special edge \(e: x \rightarrow y\) of \(X_{f /}\) satisfying \(q^{\prime}(e)=\bar{e}\). Since \(v\) is a cartesian fibration, we can choose a \(v\)-cartesian edge \(\widetilde{e}: \widetilde{x} \rightarrow u(y)\) of the simplicial set \(X \times{ }_{S} S_{(q \circ f) / \cdot}\). In this case, the image \(\widetilde{e}\) in \(X\) is
\(q\)-cartesian (Remark 5.1.4.6). Corollary 5.1.1.15 then guarantees that there exists an edge \(e: x \rightarrow y\) of \(X_{f /}\) satisfying \(u(e)=\widetilde{e}\). The edge \(e\) is automatically special and satisfies \(q^{\prime}(e)=(v \circ u)(e)=v(\widetilde{e})=\bar{e}\), as desired.

To complete the proof of (2), it will suffice to show that every \(q^{\prime}\)-cartesian edge \(e: x \rightarrow z\) of \(X_{f /}\) is special. It follows from the preceding argument that there exists a special edge \(e^{\prime}: y \rightarrow z\) satisfying \(q^{\prime}\left(e^{\prime}\right)=q^{\prime}(e)\), which is also \(q^{\prime}\)-cartesian. Applying Remark 5.1.3.8, we can choose a 2-simplex \(\sigma\) of \(X_{f /}\) as indicated in the diagram

where \(e^{\prime \prime}\) is an isomorphism in the \(\infty\)-category \(\left\{q^{\prime}(x)\right\} \times_{S_{(q \circ f) /}} X_{f /}\). Using Proposition 5.1.4.11, we deduce that the image of \(e^{\prime \prime}\) in \(X\) is \(q\)-cartesian. Applying Proposition 5.1.4.12, we conclude the image of \(e\) in \(X\) is also \(q\)-cartesian, as desired.

02VV Proposition 5.1.4.20. Suppose we are given a commutative diagram of simplicial sets

satisfying the following conditions:
- The morphisms \(U_{0}\) and \(U_{1}\) are cartesian fibrations.
- The morphism \(F_{0}\) carries \(U_{0}\)-cartesian edges of \(X_{0}\) to \(U\)-cartesian edges of \(X\).
- The morphism \(F_{1}\) carries \(U_{1}\)-cartesian edges of \(X_{1}\) to \(U\)-cartesian edges of \(X\).
- The morphism \(F_{1}\) is an isofibration.

Then the induced map \(U_{01}: X_{0} \times_{X} X_{1} \rightarrow S\) is also a cartesian fibration. Moreover, an edge \(e=\left(e_{0}, e_{1}\right)\) of \(X_{0} \times_{X} X_{1}\) is \(U_{01}\)-cartesian if and only if \(e_{0}\) is \(U_{0}\)-cartesian and \(e_{1}\) is \(U_{1}\)-cartesian.

Proof. Let \(\pi: X_{0} \times_{X} X_{1} \rightarrow X_{0}\) and \(\pi^{\prime}: X_{0} \times_{X} X_{1} \rightarrow X_{1}\) be the projection maps. Since \(F_{1}\) is an isofibration, \(\pi\) is also an isofibration. In particular, \(\pi\) is an inner fibration, so the
composition \(U_{01}=U_{0} \circ \pi\) is also an inner fibration. Let us say that an edge \(e=\left(e_{0}, e_{1}\right)\) of \(X_{0} \times{ }_{X} X_{1}\) is special if \(e_{0}\) is \(U_{0}\)-cartesian and \(e_{1}\) is \(U_{1}\)-cartesian. The second assumption guarantees that \(e\) is \(\pi\)-cartesian (Remark 5.1.1.11) and the first guarantees that \(\pi(e)\) is \(U_{0}\)-cartesian. Applying Corollary 5.1.2.4 we deduce that every special edge of \(X_{0} \times{ }_{X} X_{1}\) is \(U_{01}\)-cartesian.

To prove that \(U_{01}\) is a cartesian fibration, it will suffice to show that for every vertex \(x=\left(x_{0}, x_{1}\right)\) of \(X_{0} \times_{X} X_{1}\) and every edge \(\bar{e}: s \rightarrow U_{01}(x)\) in \(S\), there exists a special edge \(e: y \rightarrow x\) of \(X_{0} \times{ }_{X} X_{1}\) satisfying \(U_{01}(e)=\bar{e}\). Since \(U_{0}\) is a cartesian fibration, we can choose a \(U_{0}\)-cartesian edge \(e_{0}: y_{0} \rightarrow x_{0}\) of \(X_{0}\) satisfying \(U_{0}\left(e_{0}\right)=\bar{e}\). Similarly, we can choose a \(U_{1}\)-cartesian edge \(e_{1}: y_{1} \rightarrow x_{1}\) of \(X_{1}\) satisfying \(U_{1}\left(e_{1}\right)=\bar{e}\). We now observe that \(F_{0}\left(e_{0}\right)\) and \(F_{1}\left(e_{1}\right)\) are \(U\)-cartesian edges of \(X\) having the same target and the same image in the simplicial set \(S\). Applying Remark 5.1.3.8, we can choose a 2 -simplex \(\sigma\) of \(X\) as indicated in the diagram

where \(v\) is an isomorphism in the \(\infty\)-category \(X_{s}=\{s\} \times_{S} X\). Our assumption that \(F_{1}\) is an isofibration guarantees that we can lift \(v\) to an isomorphism \(\widetilde{v}: y_{1}^{\prime} \rightarrow y_{1}\) in the \(\infty\)-category \(\{s\} \times_{S} X_{1}\). Since \(F_{1}\) is an inner fibration, we can lift \(\sigma\) to a 2 -simplex \(\widetilde{\sigma}\) of \(X_{1}\) with boundary indicated in the diagram

It follows from Propositions 5.1.4.11 and 5.1.4.12 that \(e_{1}^{\prime}\) is a \(U_{1}\)-cartesian edge of \(X_{1}\), so that \(e=\left(e_{0}, e_{1}^{\prime}\right)\) is a special edge of \(X_{0} \times_{X} X_{1}\) with target \(x=\left(x_{0}, x_{1}\right)\) which satisfies \(U_{01}(e)=\bar{e}\).

To complete the proof of Proposition 5.1.4.20, it will suffice to show that if \(f: z \rightarrow x\) is a \(U_{01}\)-cartesian edge of the fiber product \(X_{0} \times_{X} X_{1}\), then \(f\) is special. Set \(s=U_{01}(z)\). Applying the above argument, we can choose a special edge \(e: y \rightarrow x\) satisfying \(U_{01}(e)=U_{01}(f)\). Using Remark 5.1.3.8, we can choose a 2 -simplex \(\tau\) of \(X_{0} \times{ }_{X} X_{1}\) with boundary indicated
in the diagram

where \(v\) is an isomorphism in the \(\infty\)-category \(\{s\} \times_{S}\left(X_{0} \times{ }_{X} X_{1}\right)\). Applying Propositions 5.1 .4 .11 and 5.1.4.12 to the 2 -simplices \(\pi(\tau)\) and \(\pi^{\prime}(\tau)\), we conclude that the edges \(\pi(f)\) and \(\pi^{\prime}(f)\) are \(U_{0}\)-cartesian and \(U_{1}\)-cartesian, as desired.

As an application of Proposition 5.1.4.20, we record a generalization of Proposition 5.1.4.19 which will be useful later.

03LL Corollary 5.1.4.21. Suppose we are given a commutative diagram of simplicial sets

where \(q\) and \(q^{\prime}\) are cartesian fibrations and the morphism \(u\) carries \(q^{\prime}\)-cartesian edges of \(X^{\prime}\) to \(q\)-cartesian edges of \(X\). Let \(f: K \rightarrow X\) be a morphism of simplicial sets. Then \(q^{\prime}\) induces a cartesian fibration \(\widetilde{q}^{\prime}: X^{\prime} \times_{X} X_{f /} \rightarrow S_{(q \circ f) / /}\). Moreover, an edge of \(X^{\prime} \times_{X} X_{f /}\) is \(\tilde{q}^{\prime}\)-cartesian if and only if its image in \(X^{\prime}\) is \(q^{\prime}\)-cartesian.

Proof. Let \(\tilde{u}: X^{\prime} \times_{S} S_{(q \circ f) /} \rightarrow X \times_{S} S_{(q \circ f) /}\) denote the pullback of \(u\), let \(\tilde{q}: X \times_{S} S_{(q \circ f) /} \rightarrow\) \(S_{(q \circ f) /}\) be given by projection onto the second factor, and let \(v: X_{f /} \rightarrow X \times{ }_{S} S_{(q \circ f) /}\) be the left fibration of Proposition 4.3.6.8. Note that \(\tilde{q}\) is a pullback of \(q\), and therefore a cartesian fibration (Remark 5.1.4.6). Moreover, an edge of \(X \times_{S} S_{(q \circ f) /}\) is \(\widetilde{q}\)-cartesian if and only if its image in \(X\) is \(q\)-cartesian. Similarly, the composite map \(\widetilde{q} \circ \widetilde{u}\) is a pullback of \(q^{\prime}\). It follows that \(\widetilde{q} \circ \widetilde{u}\) is a cartesian fibration, and that an edge of \(X^{\prime} \times_{S} S_{(q \circ f) /}\) is \((\widetilde{q} \circ \widetilde{u})\)-cartesian if and only if its image in \(X^{\prime}\) is \(q^{\prime}\)-cartesian. Applying Proposition 5.1.4.19, we deduce that the composition \(\widetilde{q} \circ v\) is a cartesian fibration, and that an edge of \(X_{f /}\) is \((\widetilde{q} \circ v)\)-cartesian if and only if its image in \(X\) is \(q\)-cartesian. The desired result now follows by applying Proposition
5.1.4.20 to the diagram

\subsection*{5.1.5 Locally Cartesian Fibrations}

It will sometimes be convenient to consider a generalization of Definition 5.1.4.1
Definition 5.1.5.1. Let \(q: X \rightarrow S\) be a morphism of simplicial sets. We say that \(q\) is a 01UX locally cartesian fibration if the following conditions are satisfied:
(1) The morphism \(q\) is an inner fibration.
(2) For every edge \(\bar{e}: s \rightarrow t\) of the simplicial set \(S\) and every vertex \(z \in X\) satisfying \(q(z)=t\), there exists a locally \(q\)-cartesian edge \(e: y \rightarrow z\) of \(X\) satisfying \(q(e)=\bar{e}\).

We say that \(q\) is a locally cocartesian fibration if it satisfies condition (1) together with the following dual version of (2):
(2') For every edge \(e: s \rightarrow t\) of the simplicial set \(S\) and every vertex \(y \in X\) satisfying \(q(y)=s\), there exists a locally \(q\)-cocartesian edge \(e: y \rightarrow z\) of \(X\) satisfying \(q(e)=\bar{e}\).

Example 5.1.5.2. Let \(q: X \rightarrow S\) be a morphism of simplicial sets. If \(q\) is a cartesian \(01 U Y\) fibration, then it is a locally cartesian fibration. If \(q\) is a cocartesian fibration, then it is a locally cocartesian fibration.

Exercise 5.1.5.3. Let \(Q\) be a partially ordered set, let Chain \([Q]\) denote the collection of all finite nonempty linearly ordered subsets of \(Q\) (Notation 3.3.2.1), and let Max : Chain \([Q] \rightarrow Q\) be the map which carries each element \(S \in\) Chain \([Q]\) to the largest element of \(S\).
- Show that the induced map of nerves \(\mathrm{N}_{\bullet}(\operatorname{Max}): \mathrm{N}_{\bullet}(\operatorname{Chain}[Q]) \rightarrow \mathrm{N}_{\bullet}(Q)\) is a locally cocartesian fibration.
- Show that, if \(Q=[n]\) for \(n \geq 2\), the functor \(\mathrm{N}_{\bullet}(\operatorname{Max}): \mathrm{N}_{\bullet}(\) Chain \([Q]) \rightarrow \mathrm{N}_{\bullet}(Q)\) is not a cocartesian fibration.

01V0 Remark 5.1.5.4. Let \(q: X \rightarrow S\) be a morphism of simplicial sets. Then \(q\) is a locally cartesian fibration if and only if the opposite morphism \(q^{\mathrm{op}}: X^{\mathrm{op}} \rightarrow S^{\mathrm{op}}\) is a locally cocartesian fibration.
01 V 1 Remark 5.1.5.5. Suppose we are given a pullback diagram of simplicial sets

If \(q\) is a locally cartesian fibration, then \(q^{\prime}\) is also a locally cartesian fibration (see Remark 5.1.1.11. If \(q\) is a locally cocartesian fibration, then \(q^{\prime}\) is also a locally cocartesian fibration.

01 V 2 Remark 5.1.5.6. Let \(q: X \rightarrow S\) be an inner fibration of simplicial sets. The following conditions are equivalent:
- The morphism \(q\) is a locally cartesian fibration.
- For every pullback diagram

the morphism \(q^{\prime}\) is a locally cartesian fibration.
- For every pullback diagram

the morphism \(q^{\prime}\) is a cartesian fibration.
\(01 \mathrm{V3}\) Remark 5.1.5.7. Let \(p: X \rightarrow Y\) and \(q: Y \rightarrow Z\) be morphisms of simplicial sets. If \(p\) is a cartesian fibration and \(q\) is a locally cartesian fibration, then the composition \(q \circ p\) is a locally cartesian fibration. Moreover, an edge \(e\) of \(X\) is locally \((q \circ p)\)-cartesian if and only if it is \(p\)-cartesian and \(p(e)\) is locally \(q\)-cartesian of \(Y\). To prove this, we can assume without loss of generality that \(S=\Delta^{1}\). In this case, \(q\) is a cartesian fibration (Remark 5.1.5.6), so the desired result follows from Proposition 5.1.4.13.

Warning 5.1.5.8. The collection of locally (co)cartesian fibrations is not closed under 01V4 composition.

Proposition 5.1.5.9. Let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be a locally cartesian fibration of simplicial sets and 01V5 let \(g: Y \rightarrow Z\) be an edge of \(\mathcal{C}\). The following conditions are equivalent:
(1) The edge \(g\) is \(q\)-cartesian.
(2) For every 2-simplex \(\sigma\)

of \(\mathcal{C}\), the edge \(f\) is locally \(q\)-cartesian if and only if the edge \(h\) is locally \(q\)-cartesian.
(3) For every 2-simplex \(\sigma\)

of \(\mathcal{C}\), if \(f\) is locally \(q\)-cartesian, then \(h\) is locally \(q\)-cartesian.
Proof. The implication \((1) \Rightarrow(2)\) follows from Corollary 5.1.2.6 (and does not require the assumption that \(q\) is a locally cartesian fibration), and the implication \((2) \Rightarrow(3)\) is immediate. We will complete the proof by showing that \((3) \Rightarrow(1)\). Using Remarks 5.1.1.12 and 5.1.3.5 we can reduce to the case where \(\mathcal{D}=\Delta^{n}\) is a simplex. By virtue of Corollary 5.1.2.3, it will suffice to show that for each object \(X \in \mathcal{C}\) satisfying \(q(X) \leq q(Y)\), the composition map
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \xrightarrow{[g] \circ} \operatorname{Hom}_{\mathcal{C}}(X, Z)
\]
of Notation 4.6.9.15 is an isomorphism in the homotopy category hKan. Since \(q\) is a locally cartesian fibration, we can choose a locally \(q\)-cartesian morphism \(f: X \rightarrow Y\) satisfying \(q(W)=q(X)\). Using the fact that \(\mathcal{C}\) is an \(\infty\)-category, we can choose a 2-simplex \(\sigma\) of \(\mathcal{C}\) satisfying \(d_{0}^{2}(\sigma)=g\) and \(d_{2}^{2}(\sigma)=f\). Set \(h=d_{1}^{2}(\sigma)\), so that we have a commutative diagram

in the \(\infty\)-category \(\mathcal{C}\). If assumption (3) is satisfied, then \(h\) is also a locally \(q\)-cartesian morphism of \(\mathcal{C}\). Invoking Proposition 4.6.9.12, we conclude that the diagram

commutes (in the homotopy category hKan). Since \(f\) and \(h\) are locally \(q\)-cartesian, the horizontal and left diagonal map in this diagram are isomorphisms (in the homotopy category hKan), so the right diagonal map is an isomorphism as well.

01V6 Corollary 5.1.5.10. Let \(q: X \rightarrow S\) be a locally cartesian fibration of simplicial sets. The following conditions are equivalent:
(1) The morphism \(q\) is a cartesian fibration.
(2) Every locally \(q\)-cartesian edge of \(X\) is \(q\)-cartesian.
(3) For every 2-simplex \(\sigma\) :

of the simplicial set \(X\), if \(f\) and \(g\) are locally \(q\)-cartesian, then \(h\) is locally \(q\)-cartesian.
Proof. The implication \((1) \Rightarrow(2)\) follows from Remark 5.1.4.5, the implication \((2) \Rightarrow(1)\) is immediate, and the equivalence \((2) \Leftrightarrow(3)\) follows from Proposition 5.1.5.9.

01V7 Corollary 5.1.5.11. Let \(p: X \rightarrow S\) be an inner fibration of simplicial sets. Then \(p\) is a cartesian fibration if and only if every pullback \(X \times_{S} \Delta^{n} \rightarrow \Delta^{n}\) is a cartesian fibration for \(n \leq 2\).

046 V Corollary 5.1.5.12. Let \(q: X \rightarrow S\) be a locally cartesian fibration of simplicial sets. The following conditions are equivalent:
(1) The morphism \(q\) is a right fibration.
(2) For every vertex \(s \in S\), the fiber \(X_{s}=\{s\} \times_{S} X\) is a Kan complex.
(3) Every edge of \(X\) is locally \(q\)-cartesian.
(4) Every edge of \(X\) is \(q\)-cartesian.

Proof. The implication (1) \(\Rightarrow(2)\) follows from Corollary 4.4.2.3. To show that \((2) \Rightarrow(3)\), we may assume without loss of generality that \(S=\Delta^{1}\). In this case, \(q\) is a cartesian fibration (Remark 5.1.5.6), so the desired result follows from Proposition 5.1.4.14. The implication \((3) \Rightarrow(4)\) follows from Corollary 5.1.5.10. If condition (4) is satisfied, then \(q\) is a cartesian fibration (Corollary 5.1.5.10), so that (1) follows from Proposition 5.1.4.14.

Proposition 5.1.5.13. Let \(q: X \rightarrow S\) be a locally cartesian fibration of simplicial sets and 01V8 let \(f: K \rightarrow X\) be any morphism of simplicial sets. Then:
(1) The induced map \(q^{\prime}: X_{/ f} \rightarrow S_{/(q \circ f)}\) is a locally cartesian fibration of simplicial sets.
(2) An edge e of \(X_{/ f}\) is locally \(q^{\prime}\)-cartesian if and only if its image in \(X\) is locally \(q\)-cartesian.

Proof. As in the proof of Proposition 5.1.4.17, we factor \(q^{\prime}\) as a composition
\[
X_{/ f} \xrightarrow{u} X \times_{S} S_{/(q \circ f)} \xrightarrow{v} S_{/(q \circ f)},
\]
where \(u\) is a cartesian fibration and every edge of \(X_{/ f}\) is \(u\)-cartesian (Proposition 5.1.4.14). The morphism \(v\) is a pullback of \(q\), and is therefore a locally cartesian fibration (Remark 5.1.5.5. Moreover, an edge of \(X \times_{S} S_{/(q \circ f)}\) is locally \(v\)-cartesian if and only if its image in \(X\) is locally \(q\)-cartesian (Remark 5.1.3.5). Assertions (1) and (2) now follow from Remark 5.1.5.7.

Proposition 5.1.5.14. Let \(\kappa\) be an uncountable regular cardinal and let \(q: X \rightarrow S\) be 047P a locally cartesian fibration of simplicial sets. Then \(q\) is locally \(\kappa\)-small (in the sense of Definition 4.7.9.1) if and only if, for every vertex \(s \in S\), the \(\infty\)-category \(X_{s}=\{s\} \times_{S} X\) is locally \(\kappa\)-small.

Proof. Assume that, for every vertex \(s \in S\), the \(\infty\)-category \(X_{s}\) is locally \(\kappa\)-small; we will show that \(q\) is locally \(\kappa\)-small (the reverse implication is immediate from the definitions). By virtue of Corollary 4.7.9.11 we may assume without loss of generality that \(S=\Delta^{1}\). In this case, \(q\) is a cartesian fibration and we wish to show that \(X\) is locally \(\kappa\)-small. Fix a pair of objects \(x, z \in X\); we wish to show that the \(\operatorname{Kan}\) complex \(\operatorname{Hom}_{X}(x, z)\) is essentially \(\kappa\)-small. We may assume without loss of generality that \(q(x) \leq q(z)\) (otherwise, the Kan complex \(\operatorname{Hom}_{X}(x, z)\) is empty). If \(q(x)=q(z)\), then the desired result follows from our hypothesis. It will therefore suffice to treat the case where \(q(x)=0\) and \(q(z)=1\). Since \(q\) is a locally cartesian fibration, we can choose a \(q\)-cartesian morphism \(f: y \rightarrow z\) of \(X\), where \(q(y)=0\). In this case, composition with the homotopy class \([f]\) induces a homotopy equivalence of Kan complexes \(\operatorname{Hom}_{X}(x, y) \rightarrow \operatorname{Hom}_{X}(x, z)\) (Corollary 5.1.2.3), so the desired result follows from the local \(\kappa\)-smallness of the \(\infty\)-category \(X_{0}\).

047Q Corollary 5.1.5.15. Let \(\kappa\) be an uncountable regular cardinal and let \(q: X \rightarrow S\) be a locally cartesian fibration of simplicial sets. Then \(q\) is essentially \(\kappa\)-small if and only if, for every vertex \(s \in S\), the \(\infty\)-category \(X_{s}=\{s\} \times_{S} X\) is essentially \(\kappa\)-small.

Proof. Combine Proposition 5.1.5.14 with Remark 4.7.9.4.
05DV Corollary 5.1.5.16. Let \(\kappa\) be an uncountable regular cardinal and let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a locally cartesian fibration of \(\infty\)-categories. Suppose that \(\mathcal{C}\) is essentially \(\kappa\)-small. The following conditions are equivalent:
(1) The \(\infty\)-category \(\mathcal{E}\) is essentially \(\kappa\)-small.
(2) For every vertex \(C \in \mathcal{C}\), the \(\infty\)-category \(\mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E}\) is essentially \(\kappa\)-small.

Proof. Combine Corollaries 5.1.5.15 and 4.7.9.6
05DW Variant 5.1.5.17. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a locally cartesian fibration of \(\infty\)-categories and let \(n \geq-1\) be an integer. Then \(U\) is essentially \(n\)-categorical (in the sense of Definition \(4.8 .6 .1)\) if and only if, for each object \(C \in \mathcal{C}\), the \(\infty\)-category \(\mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E}\) is locally ( \(n-1\) )-truncated (in the sense of Definition 4.8.2.1).

Proof. We proceed as in the proof of Proposition 5.1.5.14. Assume that, for each object \(C \in \mathcal{C}\), the \(\infty\)-category \(\mathcal{E}_{C}\) is locally \((n-1)\)-truncated; we will show that the functor \(U\) is essentially \(n\)-categorical (the reverse implication follows from Proposition 4.8.6.17, and does not require the assumption that \(U\) is locally cartesian). By virtue of Proposition 4.8.5.27, we may assume without loss of generality that \(\mathcal{C}=\Delta^{1}\). Fix a pair of objects \(X, Z \in \mathcal{E}\); we wish to show that the map of \(\operatorname{Kan}\) complexes \(\operatorname{Hom}_{\mathcal{E}}(X, Z) \rightarrow \operatorname{Hom}_{\mathcal{C}}(U(X), U(Z))\) is \(n\)-truncated. We may assume that \(U(X) \leq U(Z)\) (otherwise, both Kan complexes are empty and there is nothing to prove); in this case, we wish to show that the morphism space \(\operatorname{Hom}_{\mathcal{E}}(X, Z)\) is \(n\)-truncated (Example 3.5.9.4). If \(U(X)=U(Z)\), then the desired result follows from our hypothesis on the fibers of \(U\). It will therefore suffice to treat the case where \(U(X)=0\) and \(U(Z)=1\). Since \(U\) is a locally cartesian fibration, we can choose a \(U\)-cartesian morphism \(f: Y \rightarrow Z\) of \(\mathcal{E}\) satisfying \(U(Y)=0\). In this case, composition with the homotopy calss \([f]\) induces a homotopy equivalence of \(\operatorname{Kan}\) complexes \(\operatorname{Hom}_{\mathcal{E}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{E}}(X, Z)\) (Corollary 5.1.2.3). It will therefore suffice to show that the \(\operatorname{Kan}\) complex \(\operatorname{Hom}_{\mathcal{E}}(X, Y)\) is \(n\)-truncated, which follows from our assumption that the fiber \(\mathcal{E}_{0}=U^{-1}\{0\}\) is locally \(n\)-truncated.

05DX Corollary 5.1.5.18. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a right fibration of \(\infty\)-categories and let \(n \geq-2\) be an integer. Then \(U\) is locally n-truncated if and only if, for every object \(C \in \mathcal{C}\), the Kan complex \(\mathcal{E}_{C}\) is \((n+1)\)-truncated.

Proof. Combine Variant 5.1.5.17 with Example 4.8.2.4

One advantage the theory of locally cartesian fibrations holds over the theory of cartesian fibrations is the following "fiberwise" existence criterion:

Proposition 5.1.5.19. Suppose we are given a commutative diagram of simplicial sets

satisfying the following conditions:
(1) The maps \(p\) and \(q\) are locally cartesian fibrations, and \(r\) is an inner fibration.
(2) The map \(r\) carries locally \(p\)-cartesian edges of \(X\) to locally \(q\)-cartesian edges of \(Y\).
(3) For every vertex \(s\) of \(S\), the induced map \(r_{s}: X_{s} \rightarrow Y_{s}\) is a locally cartesian fibration.

Then \(r\) is a locally cartesian fibration.
Warning 5.1.5.20. The analogue of Proposition 5.1.5.19 for cartesian fibrations is false.
Proof of Proposition 5.1.5.19, Choose a vertex \(z \in X\) and an edge \(\bar{h}: \bar{x} \rightarrow r(z)\) of the simplicial set \(Y\). We wish to prove that there exists a locally \(r\)-cartesian edge \(h: x \rightarrow z\) satisfying \(r(h)=\bar{h}\). Since \(p\) is a locally cartesian fibration, we can choose a locally \(p\) cartesian edge \(g: y \rightarrow z\) satisfying \(p(g)=q(\bar{h})\). Assumption (2) guarantees that \(r(g)\) is locally \(q\)-cartesian, so we can choose a 2 -simplex \(\bar{\sigma}\) of \(Y\) satisfying
\[
d_{0}^{2}(\bar{\sigma})=r(g) \quad d_{1}^{2}(\bar{\sigma})=\bar{h} \quad q(\bar{\sigma})=s_{0}^{1}(q(\bar{h})),
\]
as indicated in the diagram

Set \(s=q(\bar{x})\), so that \(\bar{f}\) can be regarded as an edge of the simplicial set \(Y_{s}\). Invoking assumption (3), we conclude that there exists a locally \(r_{s}\)-cartesian edge \(f: x \rightarrow y\) of \(X_{s}\) satisfying \(r(f)=\bar{f}\). Since \(r\) is an inner fibration, we can choose a 2-simplex \(\sigma\) of \(X\) satisfying
\[
d_{0}^{2}(\sigma)=g \quad d_{2}^{2}(\sigma)=f \quad r(\sigma)=\bar{\sigma},
\]
as depicted in the diagram

We will complete the proof by showing that \(h\) is locally \(r\)-cartesian. To prove this, we can replace \(X\) and \(Y\) by their pullbacks along the edge \(\Delta^{1} \xrightarrow{q(\bar{h})} S\), and thereby reduce to the case \(S=\Delta^{1}\). In this case, the morphisms \(p\) and \(q\) are cartesian fibration (Remark 5.1.5.6), so that \(g\) is \(p\)-cartesian and \(r(g)\) is \(q\)-cartesian (Remark 5.1.4.5). Applying Corollary 5.1.2.6 we conclude that \(g\) is \(r\)-cartesian. It follows from Remark 5.1.3.5 that \(f\) is locally \(r\)-cartesian, so that \(h\) is locally \(r\)-cartesian by virtue of Proposition 5.1.3.7.

\subsection*{5.1.6 Fiberwise Equivalence}

023L Let \(\mathcal{D}\) be an \(\infty\)-category. Our primary goal in this section is to show that, when studying \(\infty\)-categories \(\mathcal{C}\) equipped with a cartesian fibration \(\mathcal{C} \rightarrow \mathcal{D}\), equivalence can be detected fiberwise. More precisely, we have the following result:

023M Theorem 5.1.6.1. Suppose we are given a commutative diagram of \(\infty\)-categories

where \(U\) is a cartesian fibration of \(\infty\)-categories, \(U^{\prime}\) is an isofibration of \(\infty\)-categories, and \(\bar{F}\) is an equivalence of \(\infty\)-categories. Then the functor \(F\) is an equivalence of \(\infty\)-categories if and only if it satisfies the following conditions:
(1) For every object \(D \in \mathcal{D}\) having image \(D^{\prime}=\bar{F}(D)\) in \(\mathcal{D}^{\prime}\), the induced functor
\[
F_{D}: \mathcal{C}_{D}=\{D\} \times_{\mathcal{D}} \mathcal{C} \rightarrow\left\{D^{\prime}\right\} \times_{\mathcal{D}^{\prime}} \mathcal{C}^{\prime}=\mathcal{C}_{D^{\prime}}^{\prime}
\]
is an equivalence of \(\infty\)-categories.
(2) The functor \(F\) carries \(U\)-cartesian morphisms of \(\mathcal{C}\) to \(U^{\prime}\)-cartesian morphisms of \(\mathcal{C}^{\prime}\).

Moreover, if these conditions are satisfied, then \(U^{\prime}\) is also a cartesian fibration of \(\infty\)-categories.

We will give the proof of Theorem 5.1.6.1 at the end of this section. First, let us collect some of its consequences.
Corollary 5.1.6.2. Suppose we are given a commutative diagram of \(\infty\)-categories

Assume that \(U\) and \(U^{\prime}\) are isofibrations of \(\infty\)-categories and that \(F\) and \(\bar{F}\) are equivalences of \(\infty\)-categories. Then:
- The functor \(U\) is a cartesian fibration if and only if \(U^{\prime}\) is a cartesian fibration.
- The functor \(U\) is a cocartesian fibration if and only if \(U^{\prime}\) is a cocartesian fibration.

Proof. We will prove the first assertion; the second follows by a similar argument. It follows from Theorem 5.1.6.1 that if \(U\) is a cartesian fibration, then \(U^{\prime}\) is also a cartesian fibration. To prove the converse, choose functors \(G^{\prime}: \mathcal{C}^{\prime} \rightarrow \mathcal{C}\) and \(\bar{G}: \mathcal{D}^{\prime} \rightarrow \mathcal{D}\) which are homotopy inverse to the equivalences \(F\) and \(\bar{F}\), respectively. We then have isomorphisms
\[
U \circ G^{\prime} \circ F \simeq U \simeq \bar{G} \circ \bar{F} \circ U=\bar{G} \circ U^{\prime} \circ F
\]
in the functor \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\). Since \(F\) is an equivalence of \(\infty\)-categories, it follows that there exists an isomorphism \(\bar{\alpha}: U \circ G^{\prime} \rightarrow \bar{G} \circ U^{\prime}\) in the functor \(\infty\)-category \(\operatorname{Fun}\left(\mathcal{C}^{\prime}, \mathcal{D}\right)\). Using our assumption that \(U\) is an isofibration, we can lift \(\bar{\alpha}\) to an isomorphism of functors \(\alpha: G^{\prime} \rightarrow G\) (Proposition 4.4.5.8). Applying Theorem 5.1.6.1 to the commutative diagram

we conclude that if \(U^{\prime}\) is a cartesian fibration, then \(U\) is also a cartesian fibration.
Corollary 5.1.6.3. Suppose we are given a commutative diagram of \(\infty\)-categories

Assume that \(U\) and \(U^{\prime}\) are isofibrations of \(\infty\)-categories and that \(F\) and \(\bar{F}\) are equivalences of \(\infty\)-categories. Then:
- The functor \(U\) is a right fibration if and only if \(U^{\prime}\) is a right fibration.
- The functor \(U\) is a left fibration if and only if \(U^{\prime}\) is a left fibration.

Proof. We will prove the first assertion; the second follows by a similar argument. Assume first that \(U^{\prime}\) is a right fibration of \(\infty\)-categories. Then \(U^{\prime}\) is a cartesian fibration (Proposition 5.1.4.14, so Corollary 5.1.6.2 implies that \(U\) is a cartesian fibration. To prove that \(U\) is a right fibration, it will suffice to show that for every object \(D \in \mathcal{D}\), the fiber \(\mathcal{C}_{D}=\{D\} \times_{\mathcal{D}} \mathcal{C}\) is a Kan complex (Proposition 5.1.4.14). This follows from Remark 4.5.1.21, since the functor \(F\) induces an equivalence of \(\infty\)-categories \(F_{D}: \mathcal{C}_{D} \rightarrow \mathcal{C}_{\bar{F}(D)}^{\prime}\) (Corollary 4.5.2.32).

We now prove the reverse implication. Arguing as in the proof of Corollary 5.1.6.2, we can construct a commutative diagram

where \(G\) and \(\bar{G}\) are homotopy inverses of the equivalences \(F\) and \(\bar{F}\), respectively. It then follows from the preceding argument that if \(U\) is a right fibration of \(\infty\)-categories, then \(U^{\prime}\) is also a right fibration of \(\infty\)-categories.

\section*{01VE Corollary 5.1.6.4. Suppose we are given a commutative diagram of \(\infty\)-categories}

where \(U\) and \(U^{\prime}\) are right fibrations and the functor \(\bar{F}\) is an equivalence of \(\infty\)-categories. Then \(F\) is an equivalence of \(\infty\)-categories if and only if, for every object \(D \in \mathcal{D}\) having image \(D^{\prime}=\bar{F}(D) \in \mathcal{D}^{\prime}\), the induced map of fibers \(F_{D}: \mathcal{C}_{D} \rightarrow \mathcal{C}_{D^{\prime}}^{\prime}\) is a homotopy equivalence of Kan complexes.

The proof of Theorem 5.1.6.1 will require some preliminaries. Our first step is to show that if \(U: \mathcal{C} \rightarrow \mathcal{D}\) is an isofibration of \(\infty\)-categories, then the collection of \(U\)-cartesian morphisms of \(\mathcal{C}\) is invariant under categorical equivalence.

Lemma 5.1.6.5. Suppose we are given a commutative diagram of \(\infty\)-categories

where the functors \(U\) and \(U^{\prime}\) are inner fibrations and the functors \(F\) and \(\bar{F}\) are fully faithful. Let \(g: Y \rightarrow Z\) be a morphism in \(\mathcal{C}\). If \(F(g)\) is a \(U^{\prime}\)-cartesian morphism of \(\mathcal{C}^{\prime}\), then \(g\) is a \(U\)-cartesian morphism of \(\mathcal{C}\).

Proof. By virtue of Proposition 5.1.2.1, it will suffice to show that for every object \(X \in \mathcal{C}\), the diagram of Kan complexes

is a homotopy pullback square. Set \(X^{\prime}=F(X), Y^{\prime}=F(Y), Z^{\prime}=F(Z)\), and \(g^{\prime}=F(g)\). Since the functors \(F\) and \(\bar{F}\) are fully faithful, (5.6) is homotopy equivalent to the diagram

Our assumption that \(g^{\prime}\) is \(U^{\prime}\)-cartesian guarantees that (5.7) is a homotopy pullback square of Kan complexes (Proposition 5.1.2.1), so that (5.6) is also a homotopy pullback square (Corollary 3.4.1.12).

023R Proposition 5.1.6.6. Suppose we are given a commutative diagram of \(\infty\)-categories

where the functors \(U\) and \(U^{\prime}\) are isofibrations and the functors \(F\) and \(\bar{F}\) are equivalences of \(\infty\)-categories. Let \(g: Y \rightarrow Z\) be a morphism in \(\mathcal{C}\). Then \(g\) is \(U\)-cartesian if and only if \(F(g)\) is \(U^{\prime}\)-cartesian.

Proof. It follows from Lemma 5.1.6.5 that if \(F(g)\) is \(U^{\prime}\)-cartesian, then \(g\) is \(U\)-cartesian. For the converse, suppose that \(g\) is \(U\)-cartesian. Arguing as in the proof of Corollary 5.1.6.2, we can construct a commutative diagram

where \(G\) and \(\bar{G}\) are homotopy inverses of the equivalences \(F\) and \(\bar{F}\), respectively. Then \(G(F(g))\) is isomorphic to \(g\) as an object of the arrow \(\infty\)-category \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)\). Invoking Corollary 5.1.2.5, we conclude that \(G(F(g))\) is \(U\)-cartesian, so that \(F(g)\) is \(U^{\prime}\)-cartesian by virtue of Lemma 5.1.6.5

01VB Proposition 5.1.6.7. Suppose we are given a commutative diagram of \(\infty\)-categories

Assume that:
(1) The functors \(q\) and \(q^{\prime}\) are inner fibrations.
(2) The inner fibration \(q\) is a cartesian fibration and the functor \(F\) carries \(q\)-cartesian morphisms of \(\mathcal{C}\) to locally \(q^{\prime}\)-cartesian morphisms of \(\mathcal{C}^{\prime}\).
(3) The functor \(\bar{F}: \mathcal{D} \rightarrow \mathcal{D}^{\prime}\) is fully faithful.

Then \(F\) is fully faithful if and only if, for every object \(D \in \mathcal{D}\) having image \(D^{\prime}=\bar{F}(D) \in \mathcal{D}^{\prime}\), the induced map of fibers \(F_{D}: \mathcal{C}_{D} \rightarrow \mathcal{C}_{D^{\prime}}^{\prime}\) is fully faithful.

Proof. The "only if" direction follows from Proposition 4.6.2.8. For the converse, assume that each of the functors \(F_{D}\) is fully faithful; we will show that \(F\) is fully faithful. Let \(X\) and \(Z\) be objects of \(\mathcal{C}\) having images \(\bar{X}, \bar{Z} \in \mathcal{D}\); we wish to show that the upper horizontal map in the diagram of Kan complexes

is a homotopy equivalence. Since \(q\) and \(q^{\prime}\) are inner fibrations, the vertical maps are Kan fibrations (Proposition 4.6.1.21). Assumption (3) guarantees that the lower horizontal map is a homotopy equivalence. By virtue of Proposition 3.2.8.1, it will suffice to show that for every morphism \(\bar{e}: \bar{X} \rightarrow \bar{Z}\) in \(\mathcal{D}\), the induced map of fibers
\[
\theta: \operatorname{Hom}_{\mathcal{C}}(X, Z)_{\bar{e}} \rightarrow \operatorname{Hom}_{\mathcal{C}^{\prime}}(F(X), F(Z))_{\bar{F}(\bar{e})}
\]
is a homotopy equivalence.
Let \([\theta]\) denote the homotopy class of \(\theta\), regarded as a morphism in the homotopy category hKan. Since \(q\) is a cartesian fibration, there exists a \(q\)-cartesian morphism \(g: Y \rightarrow Z\) of \(\mathcal{C}\) satisfying \(q(g)=\bar{e}\). We then have a commutative diagram

in hKan, where the vertical maps are given by the composition law of Notation 5.1.3.10. Assumption (2) guarantees that \(F(g)\) is locally \(q^{\prime}\)-cartesian, so that the vertical maps in this diagram are isomorphisms in hKan (Proposition 5.1.3.11). It will therefore suffice to show that the functor \(F_{\bar{X}}\) induces a homotopy equivalence of mapping spaces \(\operatorname{Hom}_{\mathcal{C}_{\bar{X}}}(X, Y) \rightarrow\) \(\operatorname{Hom}_{\mathcal{C}_{\bar{F}(\bar{X})}^{\prime}}(F(X), F(Y))\), which follows from our assumption that \(F_{\bar{X}}\) is fully faithful.

023 S Remark 5.1.6.8. In the situation of Proposition 5.1.6.7, we can replace (2) with the following a priori weaker assumption:
(2') For every object \(Z \in \mathcal{C}\) and every morphism \(\bar{u}: \bar{Y} \rightarrow q(Z)\) in \(\mathcal{D}\), there exists a \(q\)-cartesian \(u: Y \rightarrow Z\) of \(\mathcal{C}\) satisfying \(q(u)=\bar{u}\) and for which \(F(u)\) is locally \(q^{\prime}\)-cartesian.

Assume that (2) is satisfied and let \(v: X \rightarrow Z\) be any \(q\)-cartesian morphism in \(\mathcal{C}\); we wish to show that \(F(v)\) is locally \(q^{\prime}\)-cartesian. To prove this, we can assume without loss of generality that \(\mathcal{D}=\Delta^{1}=\mathcal{D}^{\prime}\) and that \(\bar{F}\) is the identity map. Using (2'), we can choose another \(q\)-cartesian morphism \(u: Y \rightarrow Z\) satisfying \(q(u)=q(v)\) for which \(F(u)\) is \(q^{\prime}\)-cartesian. Applying Remark 5.1.3.8, we see that \(v\) can be obtained as a composition of \(u\) with an isomorphism in the \(\infty\)-category \(\mathcal{C}\). Then \(F(v)\) can be obtained as the composition of \(F(u)\) with an isomorphism in the \(\infty\)-category \(\mathcal{C}^{\prime}\), and is therefore \(q\)-cartesian by virtue of Corollary 5.1.2.4 (and Proposition 5.1.1.8).

Proof of Theorem 5.1.6.1. Suppose we are given a commutative diagram of \(\infty\)-categories

where \(U\) is a cartesian fibration of \(\infty\)-categories, \(U^{\prime}\) is an isofibration of \(\infty\)-categories, and \(\bar{F}\) is an equivalence of \(\infty\)-categories. If \(F\) satisfies conditions (1) and (2) of Theorem 5.1.6.1. then it is fully faithful (Proposition 5.1.6.7) and essentially surjective (Remark 4.6.2.19), hence an equivalence of \(\infty\)-categories by virtue of Theorem 4.6.2.20. Conversely, if \(F\) is an equivalence of \(\infty\)-categories, then it satisfies conditions (1) and (2) by virtue of Corollary 4.5.2.32 and Proposition 5.1.6.7. respectively. To complete the proof, we must show that if these conditions are satisfied, then \(U^{\prime}\) is also a cartesian fibration of \(\infty\)-categories.

Let \(Z^{\prime}\) be an object of \(\mathcal{C}^{\prime}\) and let \(\bar{g}^{\prime}: \bar{Y}^{\prime} \rightarrow U^{\prime}\left(Z^{\prime}\right)\) be a morphism in \(\mathcal{D}^{\prime}\); we wish to show that \(\bar{g}^{\prime}\) can be lifted to a \(U^{\prime}\)-cartesian morphism \(Y^{\prime} \rightarrow Z^{\prime}\) in \(\mathcal{C}^{\prime}\). Since \(F\) is essentially surjective, we can choose an object \(Z \in \mathcal{C}\) and an isomorphism \(v: F(Z) \rightarrow Z^{\prime}\) in the \(\infty\)-category \(\mathcal{C}^{\prime}\). Since \(\bar{F}\) is essentially surjective, we can choose an object \(\bar{Y} \in \mathcal{D}\) and an isomorphism \(\bar{u}: \bar{F}(\bar{Y}) \rightarrow \bar{Y}^{\prime}\) in the \(\infty\)-category \(\mathcal{D}^{\prime}\). Since \(\bar{F}\) is fully faithful at the level of
homotopy categories, we can choose a morphism \(\bar{g}: \bar{Y} \rightarrow U(Z)\) in \(\mathcal{D}\) for which the diagram

commutes in the homotopy category \(\mathrm{h} \mathcal{D}^{\prime}\), and can therefore be lifted to a commutative diagram \(\bar{\sigma}\) in \(\infty\)-category \(\mathcal{D}^{\prime}\) (see Exercise 1.5.2.10). Using our assumption that \(U\) is a cartesian fibration, we can lift \(\bar{g}\) to a \(U\)-cartesian morphism \(g: Y \rightarrow Z\) of \(\mathcal{C}\). Since \(U^{\prime}\) is an isofibration, Corollary 4.4.5.9 guarantees that we can lift \(\bar{\sigma}\) to a commutative diagram \(\sigma\) :

in the \(\infty\)-category \(\mathcal{C}^{\prime}\), where the vertical maps are isomorphisms. To complete the proof, it will suffice to show that the morphism \(g^{\prime}\) is \(U^{\prime}\)-cartesian. This follows from Corollary 5.1.2.5 since the morphism \(F(g)\) is \(U^{\prime}\)-cartesian (Proposition 5.1.6.6).

\subsection*{5.1.7 Equivalence of Inner Fibrations}

Let \(\mathcal{C}\) and \(\mathcal{D}\) be \(\infty\)-categories. Recall that a functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) is an equivalence of \(\infty\)-categories if there exists a functor \(G: \mathcal{D} \rightarrow \mathcal{C}\) such that \(G \circ F\) and \(F \circ G\) are isomorphic to \(\mathrm{id}_{\mathcal{C}}\) and \(\mathrm{id}_{\mathcal{D}}\) as objects of the \(\infty\)-categories \(\operatorname{Fun}(\mathcal{C}, \mathcal{C})\) and \(\operatorname{Fun}(\mathcal{D}, \mathcal{D})\), respectively (Definition 4.5.1.10. In this section, we study a relative version of this notion, where \(\mathcal{C}\) and \(\mathcal{D}\) are simplicial sets equipped with inner fibrations \(U: \mathcal{C} \rightarrow \mathcal{E}\) and \(V: \mathcal{D} \rightarrow \mathcal{E}\) over the same base simplicial set \(\mathcal{E}\) (which need not be an \(\infty\)-category). Recall that, in this case, the simplicial set
\[
\operatorname{Fun}_{/ \mathcal{E}}(\mathcal{C}, \mathcal{D})=\{U\} \times_{\operatorname{Fun}(\mathcal{C}, \mathcal{E})} \operatorname{Fun}(\mathcal{C}, \mathcal{D})
\]
is also an \(\infty\)-category (Corollary 4.1.4.8).

0281 Definition 5.1.7.1. Suppose we are given a commutative diagram of simplicial sets

where \(U\) and \(V\) are inner fibrations. Let \(G: \mathcal{D} \rightarrow \mathcal{C}\) be a morphism of simplicial sets. We say that \(G\) is a homotopy inverse of \(F\) relative to \(\mathcal{E}\) if the following conditions are satisfied:
- The composition \(U \circ G\) is equal to \(V\) : that is, the diagram

is commutative.
- The composite morphisms \(G \circ F\) and \(F \circ G\) are isomorphic to \(\operatorname{id}_{\mathcal{C}}\) and \(\operatorname{id}_{\mathcal{D}}\) as objects of the \(\infty\)-categories Fun \(/ \mathcal{E}(\mathcal{C}, \mathcal{C})\) and Fun \(/ \mathcal{E}(\mathcal{D}, \mathcal{D})\), respectively.

We say that \(F\) is an equivalence of inner fibrations over \(\mathcal{E}\) if there exists a morphism of simplicial sets \(G: \mathcal{D} \rightarrow \mathcal{C}\) which is a homotopy inverse of \(F\) relative to \(\mathcal{E}\). We say that inner fibrations \(U: \mathcal{C} \rightarrow \mathcal{E}\) and \(V: \mathcal{D} \rightarrow \mathcal{E}\) are equivalent if there exists a morphism of simplicial sets \(F: \mathcal{C} \rightarrow \mathcal{D}\) which is an equivalence of inner fibrations over \(\mathcal{E}\) (so that, in particular, we have \(U=V \circ F\) ).

0282 Example 5.1.7.2. Let \(\mathcal{C}\) and \(\mathcal{D}\) be \(\infty\)-categories, so that the projection maps \(U: \mathcal{C} \rightarrow \Delta^{0}\) and \(V: \mathcal{D} \rightarrow \Delta^{0}\) are inner fibrations. Then a functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) is an equivalence of \(\infty\)-categories if and only if it is an equivalence of inner fibrations over \(\Delta^{0}\). In particular, the inner fibrations \(U\) and \(V\) are equivalent (in the sense of Definition 5.1.7.1) if and only if the \(\infty\)-categories \(\mathcal{C}\) and \(\mathcal{D}\) are equivalent (in the sense of Definition 4.5.1.10).
0283 Remark 5.1.7.3 (Two-out-of-Three). Suppose we are given a commutative diagram of simplicial sets

where the vertical maps are inner fibrations. If any two of the morphisms \(F, F^{\prime}\), and \(F^{\prime} \circ F\) are equivalences of inner fibrations over \(\mathcal{E}\), then so is the third. In particular, the collection of equivalences of inner fibrations over \(\mathcal{E}\) is closed under composition.

Remark 5.1.7.4 (Functoriality). Let \(U: \mathcal{C} \rightarrow \mathcal{E}\) and \(V: \mathcal{D} \rightarrow \mathcal{E}\) be inner fibrations
0284 of simplicial sets, and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an equivalence of inner fibrations over \(\mathcal{E}\). For every morphism of simplicial sets \(\mathcal{E}^{\prime} \rightarrow \mathcal{E}\), the induced map \(F^{\prime}: \mathcal{E}^{\prime} \times{ }_{\mathcal{E}} \mathcal{C} \rightarrow \mathcal{E}^{\prime} \times{ }_{\mathcal{E}} \mathcal{D}\) is an equivalence of inner fibrations over \(\mathcal{E}^{\prime}\). In particular, for every object \(E \in \mathcal{E}\), the induced \(\operatorname{map} F_{E}:\{E\} \times_{\mathcal{E}} \mathcal{C} \rightarrow\{E\} \times_{\mathcal{E}} \mathcal{D}\) is an equivalence of \(\infty\)-categories.

Proposition 5.1.7.5. Suppose we are given a commutative diagram of simplicial sets

Then:
(1) If \(U\) and \(V\) are inner fibrations and \(F\) is an equivalence of inner fibrations over \(\mathcal{E}\), then \(F\) is a categorical equivalence of simplicial sets.
(2) If \(U\) and \(V\) are isofibrations and \(F\) is a categorical equivalence of simplicial sets, then it is an equivalence of inner fibrations over \(\mathcal{E}\).

Proof. We first prove (1). Assume that \(U\) and \(V\) are inner fibration and that \(F\) is an equivalence of inner fibrations over \(\mathcal{E}\). We wish to show that \(F\) is a categorical equivalence of simplicial sets. Fix an \(\infty\)-category \(\mathcal{K}\), and let \(\theta_{F}: \pi_{0}(\operatorname{Fun}(\mathcal{D}, \mathcal{K}) \simeq) \rightarrow \pi_{0}\left(\operatorname{Fun}(\mathcal{C}, \mathcal{K})^{\simeq}\right)\) be the map given by precomposition with \(F\). We wish to show that \(\theta_{F}\) is a bijection. Let \(G: \mathcal{D} \rightarrow \mathcal{C}\) be a homotopy inverse of \(F\) relative to \(\mathcal{E}\), so that precomposition with \(G\) determines a map \(\theta_{G}: \pi_{0}\left(\operatorname{Fun}(\mathcal{D}, \mathcal{K})^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}(\mathcal{C}, \mathcal{K})^{\simeq}\right)\). We claim that \(\theta_{G}\) is an inverse of \(\theta_{F}\). We will show that \(\theta_{G}\) is a left inverse of \(\theta_{F}\); a similar argument will show that \(\theta_{G}\) is a right inverse of \(\theta_{F}\). Fix a morphism \(H: \mathcal{C} \rightarrow \mathcal{K}\); we wish to show that \(H\) is isomorphic to \(H \circ G \circ F\) as an object of the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{K})\). This is clear, since postcomposition with \(H\) determines a functor of \(\infty\)-categories Fun \(/ \mathcal{E}(\mathcal{C}, \mathcal{C}) \rightarrow \operatorname{Fun}(\mathcal{C}, \mathcal{K})\).

We now prove (2). Let \(Q\) be a contractible Kan complex containing a pair of distinct
vertices \(x\) and \(y\), and form a pushout diagram of simplicial sets

Since the vertical maps are monomorphisms, this diagram is also a categorical pushout square (Proposition 4.5.4.11). In particular, if \(F\) is a categorical equivalence, then the map \(Q \times \mathcal{C} \rightarrow \mathcal{M}\) is also a categorical equivalence (Proposition 4.5.4.10). Since \(Q\) is contractible, the inclusion \(\{y\} \times \mathcal{C} \hookrightarrow Q \times \mathcal{C}\) is a categorical equivalence (Remark 4.5.3.7), so the inclusion \(\{y\} \times \mathcal{C} \hookrightarrow \mathcal{M}\) is also a categorical equivalence. If \(U\) is an isofibration, then the lifting problem

admits a solution, which we can identify with a pair of morphisms \(G: \mathcal{D} \rightarrow \mathcal{C}\) and \(u: Q \rightarrow \operatorname{Fun}_{/ \mathcal{E}}(\mathcal{C}, \mathcal{C})\) satisfying \(u(x)=G \circ F\) and \(u(y)=\operatorname{id}_{\mathcal{C}}\). It follows that \(G \circ F\) is isomorphic to \(\operatorname{id}_{\mathcal{C}}\) as an object of the \(\infty\)-category Fun \(/ \mathcal{E}(\mathcal{C}, \mathcal{C})\).

Repeating the above argument with \(F\) replaced by \(G\), we conclude that there exists a morphism \(H: \mathcal{C} \rightarrow \mathcal{D}\) in \(\left(\operatorname{Set}_{\Delta}\right)_{/ S}\) such that \(H \circ G\) is isomorphic to \(\operatorname{id}_{\mathcal{D}}\) as an object of the \(\infty\)-category Fun \(/ \mathcal{E}(\mathcal{D}, \mathcal{D})\). Then \(F\) and \(H\) are both isomorphic to \(H \circ G \circ F\) as objects of the \(\infty\)-category \(\operatorname{Fun}_{/ \mathcal{E}}(\mathcal{C}, \mathcal{D})\), and are therefore isomorphic to each other. We may therefore assume without loss of generality that \(H=F\), so that \(G\) is a homotopy inverse of \(F\) relative to \(\mathcal{E}\). In particular, \(F\) is an equivalence of inner fibrations over \(\mathcal{E}\).

0286 Warning 5.1.7.6. Assertion (2) of Proposition 5.1.7.5 need not be true if \(U\) and \(V\) are only assumed to be inner fibrations. For example, let \(\mathcal{E}\) be an \(\infty\)-category and let \(\mathcal{E}^{\prime} \subseteq \mathcal{E}\) be a full subcategory for which the inclusion \(\operatorname{map} \iota: \mathcal{E}^{\prime} \hookrightarrow \mathcal{E}\) is an equivalence. Then we have a commutative diagram of \(\infty\)-categories

where the vertical maps are inner fibrations. However, \(\iota\) is not an equivalence of inner fibrations over \(\mathcal{E}\) unless \(\mathcal{E}^{\prime}=\mathcal{E}\).

Example 5.1.7.7. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(F: K \rightarrow \mathcal{C}\) be a diagram. It follows from Theorem 4.6.4.17 and Proposition 5.1.7.5 that the slice and coslice diagonal morphisms
\[
\delta_{/ F}: \mathcal{C}_{/ F} \hookrightarrow \mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{F\} \quad \delta_{F /}: \mathcal{C}_{F /} \hookrightarrow\{F\} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})} \mathcal{C}
\]
are equivalences of right and left fibrations over \(\mathcal{C}\), respectively. In particular, for every morphism of simplicial sets \(\mathcal{D} \rightarrow \mathcal{C}\), the induced maps
\[
\mathcal{D} \times_{\mathcal{C}} \mathcal{C}_{/ F} \hookrightarrow \mathcal{D} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{F\} \quad \mathcal{D} \times_{\mathcal{C}} \mathcal{C}_{F /} \hookrightarrow\{F\} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})} \mathcal{D}
\]
are equivalences of inner fibrations over \(\mathcal{D}\) (Remark 5.1.7.4); in particular, they are categorical equivalences of simplicial sets (Proposition 5.1.7.5).

Corollary 5.1.7.8. Suppose we are given a commutative diagram of simplicial sets

where \(U\) and \(V\) are inner fibrations and \(\mathcal{E}=\Delta^{n}\) is a standard simplex. Then \(F\) is an equivalence of inner fibrations over \(\mathcal{E}\) if and only if it an equivalence of \(\infty\)-categories.

Proof. Our assumption that \(\mathcal{E}=\Delta^{n}\) is a standard simplex guarantees that the inner fibrations \(U\) and \(V\) are isofibrations (Example 4.4.1.6), so the desired result follows from Proposition 5.1.7.5.

Proposition 5.1.7.9. Suppose we are given a commutative diagram of simplicial sets

where \(U\) and \(V\) are inner fibrations. The following conditions are equivalent:
(1) For every morphism of simplicial sets \(B \rightarrow \mathcal{E}\), postcomposition with \(F\) induces a homotopy equivalence of Kan complexes \(\operatorname{Fun}_{/ \mathcal{E}}(B, \mathcal{C})^{\simeq} \rightarrow \operatorname{Fun}_{/ \mathcal{E}}(B, \mathcal{D})^{\simeq}\).
(2) For every morphism of simplicial sets \(B \rightarrow \mathcal{E}\), postcomposition with \(F\) induces an equivalence of \(\infty\)-categories Fun \(/ \mathcal{E}(B, \mathcal{C}) \rightarrow\) Fun \(_{/ \mathcal{E}}(B, \mathcal{D})\).
(3) The morphism \(F\) is an equivalence of inner fibrations over \(\mathcal{E}\).
(4) For every simplex \(\sigma: \Delta^{n} \rightarrow \mathcal{E}\), the induced map \(F_{\sigma}: \Delta^{n} \times_{\mathcal{E}} \mathcal{C} \rightarrow \Delta^{n} \times_{\mathcal{E}} \mathcal{D}\) is an equivalence of \(\infty\)-categories.

Proof. We first show that (1) implies (2). Assume that (1) is satisfied and let \(B \rightarrow \mathcal{E}\) be a morphism of simplicial sets; we wish to show that the induced map Fun/ \(\mathcal{E}(B, \mathcal{C}) \rightarrow\) \(\operatorname{Fun}_{/ \mathcal{E}}(B, \mathcal{D})\) is an equivalence of \(\infty\)-categories. By virtue of Theorem 4.5.7.1. it will suffice to show that for every simplicial set \(A\), the induced map
\[
\operatorname{Fun}\left(B^{\prime}, \operatorname{Fun}_{/ \mathcal{E}}(B, \mathcal{C})\right)^{\simeq} \rightarrow \operatorname{Fun}\left(B^{\prime}, \operatorname{Fun}_{/ \mathcal{E}}(B, \mathcal{D})\right)^{\simeq}
\]
is a homotopy equivalence of Kan complexes. This follows by applying (1) to the composite \(\operatorname{map} B^{\prime} \times B \rightarrow B \rightarrow \mathcal{E}\).

We now prove that (2) implies (3). Assume that condition (2) is satisfied. Setting \(B=\mathcal{D}\), we deduce that composition with \(F\) induces an equivalence of \(\infty\)-categories Fun/ \(\mathcal{E}(\mathcal{D}, \mathcal{C}) \rightarrow\) \(\operatorname{Fun}_{/ \mathcal{E}}(\mathcal{D}, \mathcal{D})\). In particular, there exists a morphism \(G: \mathcal{D} \rightarrow \mathcal{C}\) in \(\left(\operatorname{Set}_{\Delta}\right) / \mathcal{E}\) such that \(F \circ G\) is isomorphic to \(\mathrm{id}_{\mathcal{D}}\) as an object of the \(\infty\)-category \(\operatorname{Fun}_{/ \mathcal{E}}(\mathcal{D}, \mathcal{D})\). It follows that \(F \circ G \circ F\) is isomorphic to \(F\) as an object of the \(\infty\)-category Fun \(/ \mathcal{E}(\mathcal{C}, \mathcal{D})\). Applying condition (2) in the case \(B=\mathcal{C}\), we see that postcomposition with \(F\) induces an equivalence of \(\infty\)-categories Fun \(_{/ \mathcal{E}}(\mathcal{C}, \mathcal{C}) \rightarrow\) Fun \(_{/ \mathcal{E}}(\mathcal{C}, \mathcal{D})\), so that \(G \circ F\) is isomorphic to id \(\mathcal{C}_{\mathcal{C}}\) as an object of \(\mathrm{Fun}_{/ \mathcal{E}}(\mathcal{C}, \mathcal{C})\). It follows that \(G\) is a homotopy inverse of \(F\) relative to \(\mathcal{E}\). In particular, \(F\) is an equivalence of inner fibrations over \(\mathcal{E}\).

The implication \((3) \Rightarrow(4)\) follows by combining Remark 5.1.7.4 with Corollary 5.1.7.8. We will complete the proof by showing that (4) implies (1). Assume that condition (4) is satisfied, and let \(B\) be a simplicial set equipped with a morphism \(B \rightarrow \mathcal{E}\). We wish to show that composition with \(F\) induces a homotopy equivalence of Kan complexes \(\theta_{B}\) : Fun \(_{/ \mathcal{E}}(B, \mathcal{C})^{\simeq} \rightarrow \operatorname{Fun}_{/ \mathcal{E}}(B, \mathcal{D})^{\simeq}\). Assume first that the simplicial set \(B\) has dimension \(\leq n\), for some integer \(n \geq-1\). Our proof proceeds by induction on \(n\). If \(n=-1\), then \(B\) is empty and there is nothing to prove. We may therefore assume without loss of generality that \(n \geq 0\). Let \(A\) be the \((n-1)\)-skeleton of \(B\). Our inductive hypothesis guarantees that \(\theta_{A}\) is a homotopy equivalence. By virtue of Proposition 3.2.8.1, it will suffice to verify the following:
(*) The restriction maps
\[
\operatorname{Fun}_{/ \mathcal{E}}(B, \mathcal{C}) \rightarrow \operatorname{Fun}_{/ \mathcal{E}}(A, \mathcal{C}) \quad \operatorname{Fun}_{/ \mathcal{E}}(B, \mathcal{D}) \rightarrow \operatorname{Fun}_{/ \mathcal{E}}(A, \mathcal{D})
\]
are isofibrations of \(\infty\)-categories, and therefore induce Kan fibrations
\[
\text { Fun }_{\mathcal{E}}(B, \mathcal{C})^{\simeq} \rightarrow \text { Fun }_{/ \mathcal{E}}(A, \mathcal{C})^{\simeq} \quad \text { Fun }_{/ \mathcal{E}}(B, \mathcal{D})^{\simeq} \rightarrow \operatorname{Fun}_{/ \mathcal{E}}(A, \mathcal{D})^{\simeq}
\]
see Proposition 4.4.3.7.
( \(*^{\prime}\) ) For every object \(T \in \operatorname{Fun}_{\mathcal{E}}(A, \mathcal{C})\), the induced map of fibers
\[
\{T\} \times_{\text {Fun }_{/ \mathcal{E}}(A, \mathcal{C})} \operatorname{Fun}_{/ \mathcal{E}}(B, \mathcal{C}) \rightarrow\{F \circ T\} \times_{\text {Fun }_{/ \mathcal{E}}(A, \mathcal{D})} \text { Fun }_{/ \mathcal{E}}(B, \mathcal{D})
\]
is an equivalence of \(\infty\)-categories, and therefore induces a homotopy equivalence of Kan complexes
(see Remark 4.5.1.19).
Let \(J\) denote the set of all nondegenerate \(n\)-simplices of \(B\). Proposition 1.1.4.12 supplies a pushout diagram of simplicial sets

Consequently, to verify ( \(*\) ) and ( \(*^{\prime}\) ), we can assume without loss of generality that \(B=\Delta^{n}\) is a standard simplex and that \(A=\partial \Delta^{n}\) is its boundary. Replacing \(\mathcal{C}\) and \(\mathcal{D}\) by the fiber products \(\Delta^{n} \times_{\mathcal{E}} \mathcal{C}\) and \(\Delta^{n} \times_{\mathcal{E}} \mathcal{D}\), we can reduce further to the case where \(\mathcal{E}=\Delta^{n}\) is a standard simplex. Applying Example 4.4.1.6, we deduce that \(U\) and \(V\) are isofibrations, so that assertion \((*)\) follows from Proposition 4.4.5.1. Invoking assumption (4), we deduce that \(F\) is an equivalence of \(\infty\)-categories, and therefore induces equivalences
\[
\operatorname{Fun}(A, \mathcal{C}) \rightarrow \operatorname{Fun}(A, \mathcal{D}) \quad \operatorname{Fun}(B, \mathcal{C}) \rightarrow \operatorname{Fun}(B, \mathcal{D})
\]

Assertion ( \(*^{\prime}\) ) now follows from Corollary 4.5.2.32.
We now treat the case where \(B\) is a general simplicial set. For each \(n \geq 0\), let \(\mathrm{sk}_{n}(B)\) denote the \(n\)-skeleton of \(B\) (Construction 1.1.4.1). Using \((*)\) and Corollary 4.5.6.22, we see that \(\theta_{B}\) can be realized as the inverse limit of a tower

where each of the transition maps is a Kan fibration. The preceding arguments show that each of the vertical maps \(\theta_{\text {sk }_{n}(B)}\) is a homotopy equivalence of Kan complexes. Invoking Example 4.5.6.18, we deduce that \(\theta_{B}\) is a homotopy equivalence of Kan complexes.

Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets. Then \(F\) determines a pullback functor \(F^{*}:\left(\operatorname{Set}_{\Delta}\right)_{/ \mathcal{D}} \rightarrow\left(\operatorname{Set}_{\Delta}\right) / \mathcal{C}\), given on objects by the formula \(F^{*}(\widetilde{\mathcal{D}})=\mathcal{C} \times{ }_{\mathcal{D}} \widetilde{\mathcal{D}}\).
028 E Proposition 5.1.7.10. Let \(V: \widetilde{\mathcal{D}} \rightarrow \mathcal{D}\) be an isofibration of \(\infty\)-categories, let \(\mathcal{C}\) be a simplicial set, and let \(F, G: \mathcal{C} \rightarrow \mathcal{D}\) be morphisms of simplicial sets which are isomorphic when viewed as objects of the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\). Then the isofibrations \(F^{*}(\widetilde{\mathcal{D}}) \rightarrow \mathcal{C}\) and \(G^{*}(\widetilde{\mathcal{D}}) \rightarrow \mathcal{C}\) are equivalent (in the sense of Definition 5.1.7.1).

028F Warning 5.1.7.11. The conclusion of Proposition 5.1.7.10 does not necessarily hold if \(V: \widetilde{\mathcal{D}} \rightarrow \mathcal{D}\) is assumed only to be an inner fibration of simplicial sets. See Warning 5.1.7.6. Proof of Proposition 5.1.7.10. Since \(F\) and \(G\) are isomorphic as objects of \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\), there exists a contractible Kan complex \(X\) containing vertices \(f\) and \(g\) and a functor \(H: X \rightarrow\) \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\) satisfying \(H(f)=F\) and \(H(g)=G\). Let us identify \(H\) with a morphism of simplicial sets \(X \times \mathcal{C} \rightarrow \mathcal{D}\), and let \(\widetilde{\mathcal{C}}\) denote the fiber product \((X \times \mathcal{C}) \times_{\mathcal{D}} \widetilde{\mathcal{D}}\). We will show that the inclusion maps
\[
F^{*}(\widetilde{\mathcal{D}})=\{f\} \times_{X} \widetilde{\mathcal{C}} \hookrightarrow \widetilde{\mathcal{C}} \hookleftarrow\{g\} \times_{X} \widetilde{\mathcal{C}}=G^{*}(\widetilde{\mathcal{D}})
\]
are equivalences of inner fibrations over \(\mathcal{C}\). To prove this, we may assume without loss of generality that \(\mathcal{C}=\Delta^{n}\) is a standard simplex (Proposition 5.1.7.9); in this case, we wish to show that both inclusion maps are equivalences of \(\infty\)-categories (Corollary 5.1.7.8). This follows by applying Corollary 4.5.2.29 to the diagram of pullback squares

here the vertical maps are isofibrations (since they are pullbacks of \(V\) ) and the lower horizontal maps are equivalences of \(\infty\)-categories (since \(X\) is a contractible Kan complex).

We now study properties of inner fibrations that are invariant under equivalence.
0289 Lemma 5.1.7.12. Let \(U: \mathcal{D} \rightarrow \mathcal{E}\) be an isofibration of simplicial sets and \(F: \mathcal{C} \hookrightarrow \mathcal{D}\) be a monomorphism of simplicial sets. The following conditions are equivalent:
(1) The restriction \((U \circ F): \mathcal{C} \rightarrow \mathcal{E}\) is an inner fibration and \(F\) is an equivalence of inner fibrations over \(\mathcal{E}\).
(2) There exists a morphism \(G: \mathcal{D} \rightarrow \mathcal{C}\) in \(\left(\operatorname{Set}_{\Delta}\right)_{/ \mathcal{E}}\) satisfying \(G \circ F=\mathrm{id}_{\mathcal{C}}\) and an isomorphism \(u: \operatorname{id}_{\mathcal{D}} \rightarrow F \circ G\) in the \(\infty\)-category \(\operatorname{Fun}_{/ \mathcal{E}}(\mathcal{D}, \mathcal{D})\) whose image in \(\operatorname{Fun}_{/ \mathcal{E}}(\mathcal{C}, \mathcal{D})\) is the identity morphism \(\operatorname{id}_{F}: F \rightarrow F \circ G \circ F=F\).

Proof. We first show that (2) implies (1). Suppose that there exists a morphism \(G: \mathcal{D} \rightarrow \mathcal{C}\) satisfying \(G \circ F=\operatorname{id}_{\mathcal{C}}\). Then \(F\) and \(G\) exhibit \(\mathcal{C}\) as a retract of \(\mathcal{D}\) in the category \(\left(\operatorname{Set}_{\Delta}\right) / \mathcal{E}\). Since \(U: \mathcal{D} \rightarrow \mathcal{E}\) is an isofibration, it follows that \((U \circ F): \mathcal{C} \rightarrow \mathcal{E}\) is an isofibration (Remark 4.5.5.10). In particular, \(U \circ F\) is an inner fibration (Remark 4.5.5.7). If there exists an isomorphism \(u: \operatorname{id}_{\mathcal{D}} \rightarrow F \circ G\) in the \(\infty\)-category Fun \(/ \mathcal{E}(\mathcal{D}, \mathcal{D})\), then \(G\) is a homotopy inverse of \(F\) relative to \(\mathcal{E}\), so that \(F\) is an equivalence of inner fibrations over \(\mathcal{E}\).

We now show that (1) implies (2). Assume that \(U \circ F\) is an inner fibration and that \(F\) is an equivalence of inner fibrations over \(\mathcal{E}\). Let \(G^{\prime}: \mathcal{D} \rightarrow \mathcal{C}\) be a homotopy inverse of \(F\) relative to \(\mathcal{E}\), so that there exists an isomorphism \(e: \mathrm{id}_{\mathcal{C}} \rightarrow G^{\prime} \circ F\) in the \(\infty\)-category \(\operatorname{Fun}_{/ \mathcal{E}}(\mathcal{C}, \mathcal{C})\). Applying Proposition 4.4.5.8, we can lift \(e\) to an isomorphism \(\widetilde{e}: G \rightarrow G^{\prime}\) in the \(\infty\)-category \(\operatorname{Fun}_{/ \mathcal{E}}(\mathcal{D}, \mathcal{C})\), where \(G: \mathcal{D} \rightarrow \mathcal{C}\) satisfies \(G \circ F=\mathrm{id}_{\mathcal{C}}\). Note that \(F\) is a categorical equivalence of simplicial sets (Proposition 5.1.7.5), and therefore induces a categorical equivalence
\[
\left(\Delta^{1} \times \mathcal{C}\right) \coprod_{\left(\partial \Delta^{1} \times \mathcal{C}\right)}\left(\partial \Delta^{1} \times \mathcal{D}\right) \hookrightarrow \Delta^{1} \times \mathcal{D}
\]

Since \(U\) is an isofibration, every lifting problem

admits a solution. In particular, there exists a morphism \(u: \operatorname{id}_{\mathcal{D}} \rightarrow F \circ G\) in the \(\infty\)-category \(\operatorname{Fun}_{/ \mathcal{E}}(\mathcal{D}, \mathcal{D})\) whose image in \(\operatorname{Fun}_{/ \mathcal{E}}(\mathcal{C}, \mathcal{D})\) is the identity map \(\mathrm{id}_{F}\). We will complete the proof by showing that \(u\) is an isomorphism in the \(\infty\)-category Fun \(/ \mathcal{E}(\mathcal{D}, \mathcal{D})\). Using the criterion of Proposition 4.4.4.9, we are reduced to checking that, for each vertex \(D \in \mathcal{D}\) having image \(E=U(D) \in \mathcal{E}\), the induced map \(u_{D}: D \rightarrow(F \circ G)(D)\) is an isomorphism in the \(\infty\)-category \(\mathcal{D}_{E}=\{E\} \times_{\mathcal{E}} \mathcal{D}\). This is clear, since \(D\) is isomorphic (in the \(\infty\)-category \(\mathcal{D}_{E}\) ) to an object of the form \(F(C)\) for \(C \in \mathcal{C}_{E}\), and the morphism \(u_{F(C)}\) is equal to the identity \(\operatorname{id}_{F(C)}\).

Proposition 5.1.7.13. Let \(U: \mathcal{C} \rightarrow \mathcal{E}\) and \(V: \mathcal{D} \rightarrow \mathcal{E}\) be inner fibrations of simplicial sets 028A which are equivalent to one another. Then:
(1) The morphism \(U\) is an isofibration if and only if \(V\) is an isofibration.
(2) The morphism \(U\) is a cartesian fibration if and only if \(V\) is a cartesian fibration.
(3) The morphism \(U\) is a right fibration if and only if \(V\) is a right fibration.
(4) The morphism \(U\) is a cocartesian fibration if and only if \(V\) is a cocartesian fibration.
(5) The morphism \(U\) is a left fibration if and only if \(V\) is a left fibration.
(6) The morphism \(U\) is a Kan fibration if and only if \(V\) is a Kan fibration.

Proof. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an equivalence of inner fibrations over \(\mathcal{E}\). We first prove (1). Assume that \(V\) is an isofibration; we will show that \(U\) is also an isofibration. Choose a monomorphism of simplicial sets \(\mathcal{C} \hookrightarrow \mathcal{Q}\), where \(\mathcal{Q}\) is a contractible Kan complex (Exercise 3.1.7.11. Replacing \(\mathcal{D}\) by the product \(\mathcal{D} \times \mathcal{Q}\), we can assume that \(F\) is a monomorphism of simplicial sets. In this case, Lemma 5.1.7.12 guarantees that \(F\) exhibits \(\mathcal{C}\) as a retract of \(\mathcal{D}\) in the category \(\left(\operatorname{Set}_{\Delta}\right)_{/ \mathcal{E}}\), so that \(U\) is an isofibration by virtue of Remark 4.5.5.10

To prove (2), we may assume without loss of generality that \(\mathcal{E}=\Delta^{n}\) is a standard simplex (Proposition 5.1.4.7). In this case, \(U\) and \(V\) are isofibrations (Example 4.4.1.6) and \(F\) is an equivalence of \(\infty\)-categories (Corollary 5.1.7.8). It follows from Corollary 5.1.6.2 that \(U\) is a cartesian fibration if and only if \(V\) is a cartesian fibration.

To prove (3), suppose that \(U\) is a right fibration; we will show that \(V\) is a right fibration. It follows from (2) that \(V\) is a cartesian fibration. It will therefore suffice to show that, for each vertex \(E \in \mathcal{E}\), the \(\infty\)-category \(\{E\} \times_{\mathcal{E}} \mathcal{D}\) is a Kan complex (Proposition 5.1.4.14). By virtue of Remark 5.1.7.4, the morphism \(F\) induces an equivalence of \(\infty\)-categories \(F_{E}:\{E\} \times_{\mathcal{E}} \mathcal{C} \rightarrow\{E\} \times_{\mathcal{E}} \mathcal{D}\). It will therefore suffice to show that \(\{E\} \times_{\mathcal{E}} \mathcal{C}\) is a Kan complex (Remark 4.5.1.21), which follows from our assumption that \(U\) is a right fibration.

Assertions (4) and (5) follow by similar arguments. Assertion (6) follows by combining (3) and (5) (see Example 4.2.1.5).

028B Proposition 5.1.7.14. Suppose we are given a commutative diagram of simplicial sets

where \(U\) and \(V\) are cartesian fibrations. Then \(F\) is an equivalence of inner fibrations over \(\mathcal{E}\) if and only if the following conditions are satisfied:
(1) For every vertex \(E \in \mathcal{E}\), the induced map \(F_{E}:\{E\} \times_{\mathcal{E}} \mathcal{C} \rightarrow\{E\} \times_{\mathcal{E}} \mathcal{D}\) is an equivalence of \(\infty\)-categories.
(2) The morphism \(F\) carries \(U\)-cartesian edges of \(\mathcal{C}\) to \(V\)-cartesian edges of \(\mathcal{D}\).

Proof. By virtue of Proposition 5.1.7.9, we may assume without loss of generality that \(\mathcal{E}=\Delta^{n}\) is a standard simplex, so that \(F\) is an equivalence of inner fibrations over \(\mathcal{E}\) if and only if it is an equivalence of \(\infty\)-categories (Corollary 5.1.7.8). Since \(U\) and \(V\) are isofibrations (Example 4.4.1.6), the desired result follows from Theorem 5.1.6.1.

Corollary 5.1.7.15. Suppose we are given a commutative diagram of simplicial sets

where \(U\) and \(V\) are right fibrations. Then \(F\) is an equivalence of inner fibrations if and only if, for every vertex \(E \in \mathcal{E}\), the induced map \(F_{E}:\{E\} \times_{\mathcal{E}} \mathcal{C} \rightarrow\{E\} \times_{\mathcal{E}} \mathcal{D}\) is a homotopy equivalence of Kan complexes.

Proof. Combine Proposition 5.1.7.14 with Proposition 5.1.4.14.

\subsection*{5.2 Covariant Transport}

Let \(X \rightarrow S\) be a covering map of topological spaces. For every point \(s \in S\), the fiber
019A
\(X_{s}=\{s\} \times{ }_{S} X\) is equipped with an action of the fundamental group \(\pi_{1}(S, s)\). More generally, the construction \(s \mapsto X_{s}\) determines a functor from the fundamental groupoid \(\pi_{\leq 1}(S)\) to the category of sets, which will refer to as the monodromy representation of the covering map \(X \rightarrow S\) (see Example 5.2.0.5 below).

It will be convenient to place monodromy in a more general context. Recall that if \(X \rightarrow S\) is a covering map of topological spaces, then the induced map Sing. \((X) \rightarrow \operatorname{Sing} .(S)\) is a covering map of simplicial sets (Proposition 3.1.4.9). In particular, it is a left covering map of simplicial sets (Definition 4.2.3.8).
Construction 5.2.0.1 (Covariant Transport for Left Covering Maps). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a
left covering map of simplicial sets. For each vertex \(C \in \mathcal{C}\), the fiber \(\mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E}\) is a discrete simplicial set, which we will identify with its underlying set of vertices (Remark 4.2.3.17). If \(\widetilde{C}\) is a vertex of \(\mathcal{E}_{C}\) and \(f: C \rightarrow D\) is an edge of \(\mathcal{C}\), then our assumption that \(U\) is a left covering map guarantees that there is a unique edge \(\widetilde{f}: \widetilde{C} \rightarrow f_{!}(\widetilde{C})\) of \(\mathcal{E}\) satisfying \(U(\widetilde{f})=f\). The construction \(\widetilde{C} \mapsto f_{!}(\widetilde{C})\) then determines a function \(f_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\), which we will refer to as covariant transport along \(f\).
Example 5.2.0.2. In the situation of Construction 5.2.0.1, suppose that \(e=\mathrm{id}_{C}\) is a degenerate edge of \(\mathcal{C}\). Then the covariant transport function \(e_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{C}\) is the identity function.

0352 Proposition 5.2.0.3. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a left covering map of simplicial sets. Then there is a unique functor
\[
\mathrm{h} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}: \mathrm{hC} \rightarrow \text { Set }
\]
with the following properties:
- For each vertex \(C \in \mathcal{C}\), we have \(\mathrm{hTr}_{\mathcal{E} / \mathcal{C}}(C)=\mathcal{E}_{C}\).
- Let \(f: C \rightarrow D\) be an edge of \(\mathcal{C}\), and let \([f]\) denote the corresponding morphism in the homotopy category hC . Then \(\mathrm{h}^{\operatorname{E} / \mathcal{C}}([f])\) is the covariant transport function \(f_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) of Construction 5.2.0.1.

Proof. By virtue of Example 5.2.0.2 (and the proof of Proposition 1.3.6.4), it will suffice to show that if \(\sigma\) is a 2 -simplex \(\sigma\) of \(\mathcal{C}\) as indicated in the diagram

then the covariant transport function \(h_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{E}\) is equal to the composition \(g_{!} \circ f!\). Fix a vertex \(X \in \mathcal{E}_{C}\). By construction, there is an edge \(\tilde{f}: X \rightarrow f_{!}(X)\) satisfying \(U(\tilde{f})=f\) and an edge \(\widetilde{h}: X \rightarrow h_{!}(X)\) satisfying \(U(\widetilde{h})=h\). Since \(U\) is a left covering map, we can lift \(\sigma\) (uniquely) to a 2 -simplex of \(\mathcal{E}\) with boundary indicated in the diagram

The edge \(\widetilde{g}\) then satisfies \(U(\widetilde{g})=g\), and therefore witnesses the identity \(g_{!}\left(f_{!}(X)\right)=\) \(h_{!}(X)\).

0353 Definition 5.2.0.4. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a left covering morphism of simplicial sets and let \(\mathrm{h} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}: \mathrm{h} \mathrm{\mathcal{C}} \rightarrow\) Set be the functor of Proposition 5.2.0.3. We will refer to \(\mathrm{h} \mathrm{Tr}_{\mathcal{E} / \mathcal{C}}\) as the homotopy transport representation of \(U\).
027 T Example 5.2.0.5 (The Monodromy Representation). Let \(f: X \rightarrow S\) be a covering map of topological spaces. Applying Proposition 5.2.0.3 to the induced map Sing. \((X) \rightarrow \operatorname{Sing} .(S)\), we obtain a functor from the fundamental groupoid \(\pi_{\leq 1}(S)\) to the category of sets, which we will denote by \(\operatorname{hTr}_{X / S}: \pi_{\leq 1}(S) \rightarrow\) Set and refer to as the monodromy representation of \(f\). Concretely, it is given on objects by the formula \(h \operatorname{Tr}_{X / S}(s)=\{s\} \times_{S} X\).

Example 5.2.0.6. Let \(\mathrm{Set}_{*}\) denote the category of pointed sets, so that the forgetful functor \(\operatorname{Set}_{*} \rightarrow\) Set induces a left covering morphism of simplicial sets \(\mathrm{N}_{\bullet}\left(\operatorname{Set}_{*}\right) \rightarrow \mathrm{N}_{\bullet}(\) Set \()\) (Example 4.2.3.3). Then the homotopy transport functor \(\mathrm{hTr}_{\mathrm{N}_{\bullet}\left(\mathrm{Set}_{*}\right) / \mathrm{N}_{\bullet} \text { (Set) } \text { is isomorphic }}\) to the identity functor id \({ }_{\text {Set }}\) : Set \(\rightarrow\) Set.

Our first goal in this section is to generalize the definition of the homotopy transport representation \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) to the case where \(U: \mathcal{E} \rightarrow \mathcal{C}\) is a cocartesian fibration of simplicial sets. In \(\S 5.2 .2\), we associate to each edge \(f: C \rightarrow D\) of the simplicial set \(\mathcal{C}\) a functor of \(\infty\)-categories \(f_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\), which we refer to as the covariant transport functor associated to \(f\) (Definition 5.2 .2 .4 . Unlike the covariant transport function of Construction 5.2.0.1, the functor \(f_{!}\)is not uniquely determined: it is well-defined only up to isomorphism (Proposition 5.2.2.8). To construct it (and to establish its uniqueness up to isomorphism), we will exploit the fact that postcomposition with \(U\) induces a cocartesian fibration \(\operatorname{Fun}\left(\mathcal{E}_{C}, \mathcal{E}\right) \rightarrow \operatorname{Fun}\left(\mathcal{E}_{C}, \mathcal{C}\right)\), which we prove in \(\$ 5.2 .1\) (see Theorem 5.2.1.1).

In \(\S 5.2 .5\), we study the behavior of covariant transport with respect to composition. Suppose we are given a 2 -simplex \(\sigma\) of the \(\operatorname{simplicial}\) set \(\mathcal{C}\), which we view as a commutative diagram

In this case, we will show that there is an isomorphism of covariant transport functors \(h_{!} \simeq g_{!} \circ f_{!}\)(Proposition 5.2.5.1). As a consequence, we can regard the construction \(C \mapsto \mathcal{E}_{C}\) as a functor from the homotopy category hC to the homotopy category hQCat of Construction 4.5.1.1. which we denote by \(\operatorname{hr}_{\mathcal{E} / \mathcal{C}}: \mathrm{hC} \rightarrow \mathrm{hQCat}\) and refer to as the homotopy transport representation of the cocartesian fibration \(U\) (Construction 5.2.5.2).

The remainder of this section is devoted to the following:
Question 5.2.0.7. Let \(\mathcal{C}\) be a simplicial set and let \(\mathscr{F}: \mathrm{hC} \rightarrow \mathrm{hQCat}\) be a functor. Can \(\mathscr{F} 023 \mathrm{~V}\) be obtained as the homotopy transport representation of a cocartesian fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\) ?

The answer to Question 5.2.0.7 is "no" in general. However, there are two important special cases where the answer is "yes":
- In \(\$ 5.2 .7\), we show that any set-valued functor \(\mathrm{hC} \rightarrow\) Set can be realized as the homotopy transport representation of a cocartesian fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\). Moreover, we can arrange that \(U\) is a left covering map. In this case, the \(\operatorname{simplicial}\) set \(\mathcal{E}\) is uniquely determined up to isomorphism (Corollary 5.2.7.3) and can be described explicitly using the classical category of elements construction, which we review in \(\$ 5.2 .6\).
- Every functor of \(\infty\)-categories \(\mathcal{E}_{0} \rightarrow \mathcal{E}_{1}\) can be realized as the covariant transport functor associated to a cocartesian fibration \(U: \mathcal{E} \rightarrow \Delta^{1}\) : that is, Question 5.2.0.7 has an affirmative answer in the case \(\mathcal{C}=\Delta^{1}\) (see Proposition 5.2.3.15). We prove this in \(\$ 5.2 .3\) using an explicit construction which generalizes the join operation on simplicial sets (Construction 5.2.3.1). In \(\S 5.2 .4\), we show that the \(\infty\)-category \(\mathcal{E}\) is determined uniquely up to equivalence (see Remark 5.2.4.3).

We will eventually give a complete answer to Question 5.2.0.7. a functor between ordinary categories \(\mathscr{F}: \mathrm{hC} \rightarrow \mathrm{hQCat}\) is (isomorphic to) the homotopy transport representation of a cocartesian fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\) if and only if it can be promoted to a diagram \(\widetilde{\mathscr{F}}: \mathcal{C} \rightarrow \mathcal{Q C}\) (Remark 5.6.5.15), where \(\mathcal{Q C}\) denotes the \(\infty\)-category of small \(\infty\)-categories (Construction 5.5.4.1). In \(\$ 5.2 .8\), we prove a preliminary result in this direction by showing that if \(\mathcal{C}\) is an \(\infty\)-category, then the homotopy transport representation of any cocartesian fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\) can always be promoted to an enriched functor, where we regard hC and QCat as enriched over the homotopy category of Kan complexes hKan (Construction 5.2.8.9).

023X Remark 5.2.0.8. In the preceding discussion, we have confined our attention to the case of cocartesian fibrations \(U: \mathcal{E} \rightarrow \mathcal{C}\). Of course, all of our results have counterparts for cartesian fibrations, which can be obtained from passing to opposite \(\infty\)-categories.

\subsection*{5.2.1 Exponentiation for Cartesian Fibrations}

01 VF In this section, we study the behavior of (co)cartesian fibrations with respect to the formation of functor \(\infty\)-categories. Our main result can be stated as follows:

01VG Theorem 5.2.1.1. Let \(q: X \rightarrow S\) be a morphism of simplicial sets, let \(B\) be a simplicial set, and let \(q^{\prime}: \operatorname{Fun}(B, X) \rightarrow \operatorname{Fun}(B, S)\) be the morphism given by postcomposition with \(q\). Then:
(1) If \(q\) is a cartesian fibration of simplicial sets, then \(q^{\prime}\) is also a cartesian fibration of simplicial sets.
(2) Assume that \(q\) is a cartesian fibration, and let e be an edge of the simplicial set \(\operatorname{Fun}(B, X)\). Then \(e\) is \(q^{\prime}\)-cartesian if and only if, for every vertex \(b \in B\), the evaluation map \(\operatorname{ev}_{b}: \operatorname{Fun}(B, X) \rightarrow \operatorname{Fun}(\{b\}, X) \simeq X\) carries e to a \(q\)-cartesian edge of \(X\).
(1') If \(q\) is a cocartesian fibration of simplicial sets, then \(q^{\prime}\) is also a cocartesian fibration of simplicial sets.
(2') Assume that \(q\) is a cocartesian fibration, and let \(e\) be an edge of the simplicial set \(\operatorname{Fun}(B, X)\). Then \(e\) is \(q^{\prime}\)-cocartesian if and only if, for every vertex \(b \in B\), the evaluation map \(\mathrm{ev}_{b}: \operatorname{Fun}(B, X) \rightarrow \operatorname{Fun}(\{b\}, X) \simeq X\) carries e to a \(q\)-cocartesian edge of \(X\).

Remark 5.2.1.2. Let \(\mathcal{C}\) be an \(\infty\)-category, so that the projection map \(q: \mathcal{C} \rightarrow \Delta^{0}\) is a
01VH cartesian fibration (Example 5.1.4.3). In this case, part (1) of Theorem 5.2.1.1 is equivalent to the assertion that for every simplicial set \(B\), the simplicial set \(\operatorname{Fun}(B, \mathcal{C})\) is also an \(\infty\)-category (Theorem 1.5.3.7). By virtue of Proposition 5.1.4.11, part (2) is equivalent to the assertion that a morphism of \(\operatorname{Fun}(B, \mathcal{C})\) is an isomorphism if and only if, for every vertex \(b \in B\), its image under the evaluation functor \(\mathrm{ev}_{b}: \operatorname{Fun}(B, \mathcal{C}) \rightarrow \mathcal{C}\) is an isomorphism in \(\mathcal{C}\) (Theorem 4.4.4.4).

The proof of Theorem 5.2.1.1 will require some preliminaries. Let \(q: X \rightarrow S\) be an inner fibration of simplicial sets. By definition, \(q\) is a cartesian fibration if and only if for every vertex \(z \in X\) and every edge \(\bar{e}: s \rightarrow q(z)\) of \(S\), there exists a \(q\)-cartesian edge \(e: y \rightarrow z\) in \(X\) satisfying \(q(e)=\bar{e}\). To prove Theorem 5.2.1.1, we need to show that the edge \(e\) can be chosen to depend functorially on \(z\).
Proposition 5.2.1.3. Let \(q: X \rightarrow S\) be an inner fibration of simplicial sets and let 01 VK \(Y \subseteq \operatorname{Fun}\left(\Delta^{1}, X\right)\) be the full simplicial subset of \(\operatorname{Fun}\left(\Delta^{1}, X\right)\) spanned by those edges \(e\) : \(\Delta^{1} \rightarrow X\) which are \(q\)-cartesian (see Definition 4.1.2.17). Let \(\theta: Y \rightarrow \operatorname{Fun}\left(\Delta^{1}, S\right) \times \operatorname{Fun}(\{1\}, S)\) \(\operatorname{Fun}(\{1\}, X)\) denote the restriction map, and let \(Z \subseteq \operatorname{Fun}\left(\Delta^{1}, S\right) \times_{\operatorname{Fun}(\{1\}, S)} \operatorname{Fun}(\{1\}, X)\) be the full simplicial subset spanned by those vertices which belong to the image of \(\theta\). Then \(\theta: Y \rightarrow Z\) is a trivial Kan fibration of simplicial sets.
Remark 5.2.1.4. In the situation of Proposition 5.2.1.3 the simplicial set \(Z\) coincides with \(\operatorname{Fun}\left(\Delta^{1}, S\right) \times_{\text {Fun }(\{1\}, S)} \operatorname{Fun}(\{1\}, X)\) if and only if \(q\) is a cartesian fibration. If this condition is satisfied, then Proposition 5.2.1.3 asserts that \(\theta: Y \rightarrow \operatorname{Fun}\left(\Delta^{1}, S\right) \times{ }_{\text {Fun }(\{1\}, S)} \operatorname{Fun}(\{1\}, X)\) is a trivial Kan fibration.

Proof of Proposition 5.2.1.3. Let \(n>0\) be an integer; we wish to show that every lifting problem of the form

01VL
admits a solution. Unwinding the definitions, we can rephrase (5.8) as a lifting problem

where the morphism \(h_{0}\) has the property that \(\left.h_{0}\right|_{\Delta^{1} \times\{i\}}\) is a \(q\)-cartesian edge of \(X\) for \(0 \leq i \leq n\). Let
\[
\left(\Delta^{1} \times \partial \Delta^{n}\right) \cup\left(\{1\} \times \Delta^{n}\right)=Y(0) \subset Y(1) \subset X(2) \subset \cdots \subset Y(n+1)=\Delta^{1} \times \Delta^{n}
\]
be the sequence of simplicial subsets appearing in the proof of Lemma 3.1.2.12, so that \(h_{0}\) can be identified with a morphism of simplicial sets from \(Y(0)\) to \(X\). We will show that, for \(0 \leq j \leq n+1\), there exists a morphism of simplicial sets \(h_{j}: Y(j) \rightarrow X\) satisfying \(\left.h_{j}\right|_{Y(0)}=h_{0}\) and \(q \circ h_{j}=\left.\bar{h}\right|_{Y(j)}\) (taking \(j=n+1\), this will complete the proof of Proposition 5.2.1.3. We proceed by induction on \(j\), the case \(j=0\) being vacuous. Assume that \(j>0\) and that we have already constructed a morphism \(h_{j-1}: Y(j-1) \rightarrow X\) satisfying \(\left.h_{j-1}\right|_{Y(0)}=h_{0}\) and \(q \circ h_{j-1}=\left.\bar{h}\right|_{Y(j-1)}\). By virtue of Lemma 3.1.2.12, we have a pushout diagram of simplicial sets

Consequently, to prove the existence of \(h_{i}\), it suffices to solve the lifting problem

For \(0<j<n+1\), the existence of the desired solution follows from our assumption that \(q\) is an inner fibration. In the case \(j=n+1\), the existence follows from the fact that the composite map
\[
\Delta^{1} \simeq \mathrm{~N}_{\bullet}(\{n<n+1\}) \hookrightarrow \Lambda_{j}^{n+1} \xrightarrow{\sigma_{0}} Y(n) \xrightarrow{h_{n}} X
\]
is the edge of \(X\) given by the restriction \(\left.h_{0}\right|_{\Delta^{1} \times\{n\}}\), and is therefore \(q\)-cartesian.
01VM Lemma 5.2.1.5. Let \(q: X \rightarrow S\) be an inner fibration of simplicial sets, let \(B\) be a simplicial set, and let \(q^{\prime}: \operatorname{Fun}(B, X) \rightarrow \operatorname{Fun}(B, S)\) be the map given by postcomposition with \(q\) (so that \(q^{\prime}\) is also an inner fibration; see Corollary 4.1.4.3). Let \(e\) be an edge of the simplicial set \(\operatorname{Fun}(B, X)\).
(1) Suppose that, for every vertex \(b \in B\), the evaluation map
\[
\operatorname{ev}_{b}: \operatorname{Fun}(B, X) \rightarrow \operatorname{Fun}(\{b\}, X) \simeq X
\]
carries e to a \(q\)-cartesian edge of \(X\). Then \(e\) is \(q^{\prime}\)-cartesian.
(2) Suppose that, for every vertex \(b \in B\), the evaluation map
\[
\operatorname{ev}_{b}: \operatorname{Fun}(B, X) \rightarrow \operatorname{Fun}(\{b\}, X) \simeq X
\]
carries e to a \(q\)-cocartesian edge of \(X\). Then e is \(q^{\prime}\)-cocartesian.
Proof. We will give a proof of (2); assertion (1) follows by a similar argument. We proceed as in the proof of Lemma 4.4.4.8. Suppose we are given an integer \(n \geq 2\); we wish to show that every lifting problem

admits a solution, provided that the composite map
\[
\Delta^{1} \simeq \mathrm{~N}_{\bullet}(\{0<1\}) \hookrightarrow \Lambda_{0}^{n} \xrightarrow{\sigma_{0}} \operatorname{Fun}(B, X)
\]
is the edge \(e\). Unwinding the definitions, we can rewrite this as a lifting problem

Let \(P\) denote the collection of all pairs \(\left(A, F_{A}\right)\), where \(A \subseteq B\) is a simplicial subset and \(F_{A}: A \times \Delta^{n} \rightarrow X\) is a morphism of simplicial sets satisfying
\[
\left.F_{A}\right|_{A \times \Lambda_{0}^{n}}=\left.F_{0}\right|_{A \times \Lambda_{0}^{n}} \quad q \circ F_{A}=\left.\bar{F}\right|_{A \times \Delta^{n}}
\]

We regard \(P\) as partially ordered set, where \(\left(A, F_{A}\right) \leq\left(A^{\prime}, F_{A^{\prime}}\right)\) if \(A \subseteq A^{\prime}\) and \(F_{A}=\left.F_{A^{\prime}}\right|_{A \times \Delta^{n}}\). The partially ordered set \(P\) satisfies the hypotheses of Zorn's lemma, and therefore has a maximal element \(\left(A_{\max }, F_{A_{\max }}\right)\). We will complete the proof by showing that \(A_{\max }=B\). Assume otherwise. Then there exists some nondegenerate \(m\)-simplex \(\tau: \Delta^{m} \rightarrow B\) whose image is not contained in \(A_{\max }\). Choosing \(m\) as small as possible, we can assume that \(\tau\) carries the boundary \(\partial \Delta^{m}\) into \(A_{\max }\). Let \(A^{\prime} \subseteq B\) be the union of \(A_{\max }\) with the image of
\(\tau\), so that we have a pushout diagram of simplicial sets

We will complete the proof by showing that the lifting problem

admits a solution (contradicting the maximality of the pair \(\left(A_{\max }, F_{A_{\max }}\right)\) ).
Choose a sequence of simplicial subsets
\[
Y(0) \subset Y(1) \subset Y(2) \subset \cdots \subset Y(t)=\Delta^{m} \times \Delta^{n}
\]
satisfying the requirements of Lemma 4.4.4.7, so that \(F_{A_{\max }}\) determines a map of simplicial sets \(G_{0}: Y(0) \rightarrow X\). We will show that, for \(0 \leq s \leq t\), there exists a morphism of simplicial sets \(G_{s}: Y(s) \rightarrow X\) satisfying \(\left.G_{s}\right|_{Y(0)}=G_{0}\) and \(q \circ G_{s}=\left.\bar{F}\right|_{Y(s)}\) (in the case \(s=t\), this will complete the proof of Lemma 5.2.1.5). We proceed by induction on \(s\), the case \(s=0\) being vacuous. Assume that \(s>0\) and that we have already constructed a morphism \(G_{s-1}: Y(s-1) \rightarrow X\) satisfying \(\left.G_{s-1}\right|_{Y(0)}=F_{0}\) and \(q \circ G_{s-1}=\left.\bar{F}\right|_{Y(s-1)}\). By construction, there exist integers \(\ell \geq 2,0 \leq k<\ell\) and a pushout diagram of simplicial sets

Moreover, in the special case \(k=0\), we can assume that \(\tau(0)=(0,0)\) and \(\tau(1)=(0,1)\), so that the composite map
\[
\Delta^{1} \simeq \mathrm{~N}_{\bullet}(\{0<1\}) \hookrightarrow \Lambda_{k}^{\ell} \xrightarrow{\sigma_{0}} Y(s-1) \xrightarrow{G_{s-1}} X
\]
corresponds to a \(q\)-cocartesian edge \(e^{\prime}\) of \(X\). To construct the desired extension \(F_{s}\), it suffices to solve the lifting problem

For \(0<k<\ell\), the existence of the desired solution follows from our assumption that \(q\) is an inner fibration; when \(k=0\), it follows from the fact that \(e^{\prime}\) is \(q\)-cocartesian.

Proof of Theorem 5.2.1.1. Assume that \(q: X \rightarrow S\) is a cartesian fibration of simplicial sets (the case where \(q\) is a cocartesian fibration can be handled by a similar argument). Let \(B\) be any simplicial set and let \(q^{\prime}: \operatorname{Fun}(B, X) \rightarrow \operatorname{Fun}(B, S)\) be the map given by postcomposition with \(q\). Then \(q^{\prime}\) is an inner fibration (Corollary 4.1.4.3). Let us say that an edge \(e\) of the simplicial set \(\operatorname{Fun}(B, X)\) is special if, for every vertex \(b \in B\), the evaluation map \(\operatorname{ev}_{b}: \operatorname{Fun}(B, X) \rightarrow \operatorname{Fun}(\{b\}, X) \simeq X\) carries \(e\) to a \(q\)-cartesian edge of \(X\). By virtue of Lemma 5.2.1.5, every special edge of \(\operatorname{Fun}(B, X)\) is \(q^{\prime}\)-cartesian. Moreover, Proposition 5.2 .1 .3 guarantees that for every vertex \(z \in \operatorname{Fun}(B, X)\) and every edge \(\bar{e}: \bar{y} \rightarrow q^{\prime}(z)\) of \(\operatorname{Fun}(B, S)\), there exists a special edge \(e: y \rightarrow z\) of \(\operatorname{Fun}(B, X)\) satisfying \(q^{\prime}(e)=\bar{e}\). It follows that \(q^{\prime}\) is a cartesian fibration.

To complete the proof, it will suffice to show that every \(q^{\prime}\)-cartesian edge \(e: x \rightarrow z\) of the simplicial set \(\operatorname{Fun}(B, X)\) is special. By virtue of the preceding argument, there exists a special edge \(e^{\prime}: y \rightarrow z\) of \(\operatorname{Fun}(B, X)\) satisfying \(q^{\prime}\left(e^{\prime}\right)=q^{\prime}(e)\), which is also \(q^{\prime}\)-cartesian. Applying Remark 5.1.3.8, we can choose a 2-simplex \(\sigma\) of \(\operatorname{Fun}(B, X)\) as indicated in the diagram

where \(e^{\prime \prime}\) is an isomorphism in the \(\infty\)-category \(\left\{q^{\prime}(x)\right\} \times_{\operatorname{Fun}(B, S)} \operatorname{Fun}(B, X)\). For each vertex \(b \in B\), the evaluation functor \(\mathrm{ev}_{b}\) carries \(\sigma\) to a 2 -simplex

in the simplicial set \(X\). Since \(e^{\prime}\) is special, the edge \(\mathrm{ev}_{b}\left(e^{\prime}\right)\) is \(q\)-cartesian. The edge \(\mathrm{ev}_{b}\left(e^{\prime \prime}\right)\) is an isomorphism in a fiber of \(q\), and is therfefore also \(q\)-cartesian (Proposition 5.1.4.11). Applying Proposition 5.1.4.12, we deduce that \(\mathrm{ev}_{b}(e)\) is \(q\)-cartesian. Allowing the vertex \(b\) to vary, we conclude that \(e\) is a special edge of \(\operatorname{Fun}(B, X)\), as desired.

\subsection*{5.2.2 Covariant Transport Functors}

019M Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration between categories (Definition 5.0.0.3) and let \(f: C \rightarrow D\) be a morphism in the category \(\mathcal{C}\). If \(X\) is an object of the fiber \(\mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E}\), then our assumption that \(U\) is a cocartesian fibration guarantees that we can choose an object \(f_{!}(X)\) of the fiber \(\mathcal{E}_{D}=\{D\} \times_{\mathcal{C}} \mathcal{E}\) together with a \(U\)-cocartesian morphism \(\widetilde{f}_{X}: X \rightarrow f_{!}(X)\) satisfying \(U\left(\tilde{f}_{X}\right)=f\). In this case, we can view the construction \(X \mapsto f_{!}(X)\) as a functor from the category \(\mathcal{E}_{C}\) to the category \(\mathcal{E}_{D}\) :

01SA Proposition 5.2.2.1. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of categories and let \(f: C \rightarrow D\) be a morphism of \(\mathcal{C}\). For each object \(X \in \mathcal{E}_{C}\), let \(\tilde{f}_{X}\) be a \(U\)-cocartesian morphism of \(\mathcal{E}\) having source \(X\) and satisfying \(U\left(\widetilde{f}_{X}\right)=f\). Then there is a unique functor \(f_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) with the following properties:
- For each object \(X \in \mathcal{E}_{C}\), the object \(f_{!}(X) \in \mathcal{E}_{D}\) is the target of the morphism \(\tilde{f}_{X}\).
- The construction \(X \mapsto \widetilde{f}_{X}\) determines a natural transformation from the inclusion functor \(\mathcal{E}_{C} \rightarrow \mathcal{E}\) to the functor \(f_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D} \subseteq \mathcal{E}\).

Proof. For each object \(X \in \mathcal{E}_{C}\), let \(f_{!}(X)\) denote the target of the morphism \(\tilde{f}_{X}\). Let \(u: X \rightarrow Y\) be a morphism in the category \(\mathcal{E}_{C}\). Invoking our assumption that \(\widetilde{f}_{X}\) is \(U\) cocartesian, we see that there is a unique morphism \(f_{!}(u): f_{!}(X) \rightarrow f_{!}(Y)\) for which the diagram

is commutative (in the category \(\mathcal{E}\) ). Note that if \(v: Y \rightarrow Z\) is another morphism in the category \(\mathcal{E}_{C}\), then the calculation
\[
f_{!}(v) \circ f_{!}(u) \circ \tilde{f}_{X}=f_{!}(v) \circ \widetilde{f}_{Y} \circ u=\widetilde{f}_{Z} \circ v \circ u
\]
shows that \(f_{!}(v \circ u)=f_{!}(v) \circ f_{!}(u)\). Similarly, for each object \(X \in \mathcal{E}_{C}\), the calculation \(\widetilde{f}_{X} \circ \operatorname{id}_{f_{!}(X)}=\widetilde{f}_{X}=\operatorname{id}_{X} \circ \widetilde{f}_{X}\) shows that \(f_{!}\left(\operatorname{id}_{X}\right)=\operatorname{id}_{f_{!}(X)}\). We can therefore regard \(f_{!}\)as a
functor from the category \(\mathcal{E}_{C}\) to \(\mathcal{E}_{D}\), and the commutativity of (5.9) guarantees that the construction \(X \mapsto \widetilde{f}_{X}\) determines a natural transformation from the inclusion \(\mathcal{E}_{C} \hookrightarrow \mathcal{E}\) to the functor \(f_{!}\).

Construction 5.2.2.2. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of categories, let \(f: C \rightarrow D 023 \mathrm{~T}\) be a morphism of the category \(\mathcal{C}\), and let \(f_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) be the functor of Proposition 5.2.2.1. We will refer to \(f\) ! as the functor of covariant transport along \(f\).

Warning 5.2.2.3. In the situation of Construction 5.2 .2 .2 , the covariant transport functor 01 SC \(f_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) depends not only on the cocartesian fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\) and the morphism \(f: C \rightarrow D\), but also on the system of \(U\)-cocartesian lifts \(\left\{\widetilde{f}_{X}: X \rightarrow f_{!}(X)\right\}_{X \in \mathcal{E}_{C}}\). A different system of cocartesian lifts \(\left\{\widetilde{f}_{X}^{\prime}: X \rightarrow f_{!}^{\prime}(X)\right\}_{X \in \mathcal{E}_{C}}\) will give rise to a different covariant transport functor \(f_{!}^{\prime}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\). However, there is a canonical isomorphism of functors \(\alpha: f_{!} \simeq f_{!}^{\prime}\), which is uniquely determined by the requirement that for every object \(X \in \mathcal{E}_{C}\), the diagram

is commutative.
We now apply the results of \(\$ 5.2 .1\) to extend Construction 5.2 .2 .2 to the \(\infty\)-categorical setting.

Definition 5.2.2.4. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an inner fibration of simplicial sets, let \(f: C \rightarrow D\) be 019N an edge of \(\mathcal{C}\), and let \(\mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E}\) and \(\mathcal{E}_{D}=\{D\} \times_{\mathcal{C}} \mathcal{E}\) denote the corresponding fibers of \(U\). We will say that a functor \(F: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) is given by covariant transport along \(f\) if there exists a morphism of simplicial sets \(\widetilde{F}: \Delta^{1} \times \mathcal{E}_{C} \rightarrow \mathcal{E}\) satisfying the following conditions:
(1) The diagram of simplicial sets

commutes.
(2) The restriction \(\left.\widetilde{F}\right|_{\{0\} \times \mathcal{E}_{C}}\) is the identity map id \(\mathcal{E}_{C}\), and the restriction \(\left.\widetilde{F}\right|_{\{1\} \times \mathcal{E}_{C}}\) is equal to \(F\).
(3) For every object \(X\) of the \(\infty\)-category \(\mathcal{E}_{C}\), the composite map
\[
\Delta^{1} \times\{X\} \hookrightarrow \Delta^{1} \times \mathcal{E}_{C} \xrightarrow{\widetilde{F}} \mathcal{E}
\]
is a locally \(U\)-cocartesian edge of the simplicial set \(\mathcal{E}\).
If these conditions are satisfied, we say that the morphism \(\widetilde{F}\) witnesses \(F\) as given by covariant transport along \(f\).

019 P Example 5.2.2.5. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an inner fibration of simplicial sets and let \(C\) be a vertex of \(\mathcal{C}\). Then the projection map
\[
\Delta^{1} \times \mathcal{E}_{C} \rightarrow \mathcal{E}_{C} \hookrightarrow \mathcal{E}
\]
exhibits the identity functor \(\mathrm{id}_{\mathcal{E}_{C}}\) as given by covariant transport along the degenerate edge \(\mathrm{id}_{C}\). See Example 5.1.3.6.

0355 Example 5.2.2.6. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a left covering map of simplicial sets. Then, for every edge \(f: C \rightarrow D\) in \(\mathcal{C}\), there is a unique functor \(\mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) given by covariant transport along \(f\), which can be identified with the covariant transport function given by Construction 5.2.0.1.

01 VR Example 5.2.2.7. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration between ordinary categories, let \(f: C \rightarrow D\) be a morphism in \(\mathcal{C}\), and choose a collection of \(U\)-cocartesian morphisms \(\left\{\widetilde{f}_{X}: X \rightarrow f_{!}(X)\right\}_{X \in \mathcal{E}_{C}}\) satisfying \(U\left(\tilde{f}_{X}\right)=f\). According to Proposition 5.2.2.1, there is a unique functor \(f_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) for which the construction \(X \mapsto \tilde{f}_{X}\) determines a natural transformation of functors \(\widetilde{f}: \mathrm{id}_{\mathcal{E}_{C}} \rightarrow f_{!}\). Passing to nerves, we obtain a natural transformation \(\operatorname{id}_{\mathrm{N}_{\bullet}\left(\mathcal{E}_{C}\right)} \rightarrow \mathrm{N}_{\bullet}\left(f_{!}\right)\), which exhibits the functor
\[
\mathrm{N}_{\bullet}\left(f_{!}\right): \mathrm{N}_{\bullet}\left(\mathcal{E}_{C}\right) \rightarrow \mathrm{N}_{\bullet}\left(\mathcal{E}_{D}\right)
\]
as given by covariant transport along \(f\) (regarded as an edge of the simplicial set \(\mathrm{N}_{\bullet}(\mathcal{C})\) ).
Stated more informally, the covariant transport construction for cocartesian fibrations of ordinary categories (see Construction 5.2.2.2) can be regarded as a special case Definition 5.2.2.4

01 VS Proposition 5.2.2.8. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets and let \(f: C \rightarrow D\) be an edge of \(\mathcal{C}\). Then:
- There exists a functor \(F: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) which is given by covariant transport along \(f\).
- An arbitrary functor \(F^{\prime}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) is given by covariant transport along \(f\) if and only if it is isomorphic to \(F\) (as an object of the \(\infty\)-category \(\operatorname{Fun}\left(\mathcal{E}_{C}, \mathcal{E}_{D}\right)\) ).

Notation 5.2.2.9. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets and let \(f: C \rightarrow D\) be an edge of the simplicial set \(\mathcal{C}\). Applying Proposition 5.2.2.8, we conclude that the collection of functors \(\mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) which are given by covariant transport along \(f\) comprise a single isomorphism class in the \(\infty\)-category \(\operatorname{Fun}\left(\mathcal{E}_{C}, \mathcal{E}_{D}\right)\). We will denote this isomorphism class by \(\left[f_{!}\right]\), which we regard as an element of the set \(\pi_{0}\left(\operatorname{Fun}\left(\mathcal{E}_{C}, \mathcal{E}_{D}\right)^{\simeq}\right)\). We will often use the notation \(f_{\text {! }}\) to denote a particular choice of representative of this isomorphism class: that is, a particular choice of functor \(\mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) which is given by covariant transport along \(f\).

We now explain how to deduce Proposition 5.2.2.8 from Theorem 5.2.1.1. For this purpose, it will be convenient to introduce a bit more terminology.

Definition 5.2.2.10. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets. Let \(K\) be another simplicial set, let \(H: \Delta^{1} \times K \rightarrow \mathcal{E}\) be a morphism. We will say that \(H\) is a \(U\)-cocartesian lift of \(\bar{H}=U \circ H\) if, for every vertex \(x \in K\), the restriction \(\left.H\right|_{\Delta^{1} \times\{x\}}\) is a \(U\)-cocartesian edge of \(\mathcal{E}\).

Remark 5.2.2.11. In the situation of Definition 5.2 .2 .10 , we can identify \(H\) and \(\bar{H}\) with
02R8

\(\square\)
\(\square\)
02R9 edges of the simplicial sets \(\operatorname{Fun}(K, \mathcal{E})\) and \(\operatorname{Fun}(K, \mathcal{C})\), respectively. Then \(H\) is a \(U\)-cocartesian lift of \(\bar{H}\) if and only if it is \(U^{\prime}\)-cocartesian, where \(U^{\prime}: \operatorname{Fun}(K, \mathcal{E}) \rightarrow \operatorname{Fun}(K, \mathcal{C})\) is given by postcomposition with \(U\). (see Theorem 5.2.1.1).

Example 5.2.2.12. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets, let \(f: C \rightarrow D\) 02RA be an edge of \(\mathcal{C}\), let \(\mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E}\) and \(\mathcal{E}_{D}=\{D\} \times_{\mathcal{C}} \mathcal{E}\) denote the corresponding fibers of \(U\). Suppose we are given a commutative diagram of simplicial sets

where the restriction \(\left.\widetilde{F}\right|_{\{0\} \times \mathcal{E}_{C}}\) is the identity map from \(\mathcal{E}_{C}\) to itself, and set \(F=\left.\widetilde{F}\right|_{\{1\} \times \mathcal{E}_{C}} \in\) \(\operatorname{Fun}\left(\mathcal{E}_{C}, \mathcal{E}_{D}\right)\). Then \(\widetilde{F}\) witnesses \(F\) as given by covariant transport along \(f\) (in the sense of Definition 5.2.2.4 if and only if it is a \(U\)-cocartesian lift of \(U \circ \widetilde{F}\) (in the sense of Definition 5.2.2.10.

Lemma 5.2.2.13. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets, let \(K\) be a 02RB
simplicial set, and suppose we are given a lifting problem
02RC

Then:
(1) The lifting problem (5.10) admits a solution \(H: \Delta^{1} \times K \rightarrow \mathcal{E}\) which is a \(U\)-cocartesian lift of \(\bar{H}\).
(2) Let \(F\) be any object of the \(\infty\)-category Fun \(_{\mathcal{C}}(\{1\} \times K, \mathcal{E})\). Then \(F\) is isomorphic to \(\left.H\right|_{\{1\} \times K}(\) as an object of Fun \(/ \mathcal{C}(\{1\} \times K, \mathcal{E}))\) if and only if \(F=\left.H^{\prime}\right|_{\{1\} \times K}\), where \(H^{\prime}\) is another \(U\)-cocartesian lift of \(\bar{H}\) which solves the lifting problem (5.10).

Proof. By virtue of Remark 5.2.2.11 (and Theorem 5.2.1.1), we can replace \(U\) by the induced map \(\operatorname{Fun}(K, \mathcal{E}) \rightarrow \operatorname{Fun}(K, \mathcal{C})\) and thereby reduce to the case where \(K=\Delta^{0}\). In this case, assertion (1) follows immediately from our assumption that \(U\) is a cocartesian fibration, and assertion (2) follows from Remark 5.1.3.8.

Proof of Proposition 5.2.2.8. Apply Lemma 5.2.2.13 in the special case where \(K\) is the \(\infty\)-category \(\mathcal{E}_{C}, H_{0}: K \rightarrow \mathcal{E}\) is the inclusion map, and \(\bar{H}\) is the composite map \(\Delta^{1} \times K \rightarrow\) \(\Delta^{1} \xrightarrow{f} \mathcal{C}\) (see Example 5.2.2.12.

We also have a dual version of Definition 5.2.2.4
01VN Definition 5.2.2.14. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an inner fibration of simplicial sets, let \(C\) and \(D\) be vertices of \(\mathcal{C}\), and let \(f: C \rightarrow D\) be an edge of \(\mathcal{C}\). We say that a functor \(F: \mathcal{E}_{D} \rightarrow \mathcal{E}_{C}\) is given by contravariant transport along \(f\) if there exists a morphism of simplicial sets \(\widetilde{F}: \Delta^{1} \times \mathcal{E}_{D} \rightarrow \mathcal{E}\) satisfying the following conditions:
(1) The diagram of simplicial sets

commutes.
(2) The restriction \(\left.\widetilde{F}\right|_{\{1\} \times \mathcal{E}_{D}}\) is equal to the identity map id \(\mathcal{E}_{D}\), and the restriction \(\left.\widetilde{F}\right|_{\{0\} \times \mathcal{E}_{D}}\) is equal to \(F\).
(3) For every object \(Y\) of the \(\infty\)-category \(\mathcal{E}_{D}\), the composite map
\[
\Delta^{1} \times\{Y\} \hookrightarrow \Delta^{1} \times \mathcal{E}_{D} \xrightarrow{\widetilde{F}} \mathcal{E}
\]
is a locally \(U\)-cartesian edge of the simplicial set \(\mathcal{E}\).
If these conditions are satisfied, we say that the morphism \(\widetilde{F}\) witnesses \(F\) as given by contravariant transport along \(f\).

Remark 5.2.2.15. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an inner fibration of simplicial sets and let \(f: C \rightarrow D 019 \mathrm{~W}\) be an edge of \(\mathcal{C}\). Then a functor \(F: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) is given by covariant transport along \(f\) if and only if the opposite functor \(F^{\mathrm{op}}: \mathcal{E}_{C}^{\mathrm{op}} \rightarrow \mathcal{E}_{D}^{\mathrm{op}}\) is given by contravariant transport along \(f\) with respect to the cartesian fibration \(U^{\mathrm{op}}: \mathcal{E}^{\mathrm{op}} \rightarrow \mathcal{C}^{\mathrm{op}}\).

Proposition 5.2.2.8 has a counterpart for cartesian fibrations:
Proposition 5.2.2.16. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cartesian fibration of simplicial sets and let 019 X \(f: C \rightarrow D\) be an edge of \(\mathcal{C}\). Then:
- There exists a functor \(F: \mathcal{E}_{D} \rightarrow \mathcal{E}_{C}\) which is given by contravariant transport along \(f\).
- An arbitrary functor \(F^{\prime}: \mathcal{E}_{D} \rightarrow \mathcal{E}_{C}\) is given by contravariant transport along \(f\) if and only if it is isomorphic to \(F\) (as an object of the \(\infty\)-category \(\operatorname{Fun}\left(\mathcal{E}_{D}, \mathcal{E}_{C}\right)\) ).

Notation 5.2.2.17. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cartesian fibration of simplicial sets and let \(f: C \rightarrow D\) be an edge of the simplicial set \(\mathcal{C}\). It follows from Proposition 5.2.2.16 that the collection of functors \(\mathcal{E}_{D} \rightarrow \mathcal{E}_{C}\) which are given by contravariant transport along \(f\) comprise a single isomorphism class in the \(\infty\)-category \(\operatorname{Fun}\left(\mathcal{E}_{D}, \mathcal{E}_{C}\right)\). We will denote this isomorphism class by \(\left[f^{*}\right]\), which we regard as an element of the \(\operatorname{set} \pi_{0}\left(\operatorname{Fun}\left(\mathcal{E}_{D}, \mathcal{E}_{C}\right)^{\simeq}\right)\). We will often use the notation \(f^{*}\) to denote a particular choice of representative of this isomorphism class: that is, a particular choice of functor \(\mathcal{E}_{D} \rightarrow \mathcal{E}_{C}\) which is given by contravariant transport along \(f\).

For Kan fibrations, there is a close relationship between covariant and contravariant transport:

Proposition 5.2.2.18. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a Kan fibration of simplicial sets and let 01A1 \(f: C \rightarrow D\) be an edge of \(\mathcal{C}\). Then the covariant and contravariant transport morphisms \(\left[f_{!}\right] \in\) \(\operatorname{Hom}_{\mathrm{hKan}}\left(\mathcal{E}_{C}, \mathcal{E}_{D}\right)\) and \(\left[f^{*}\right] \in \operatorname{Hom}_{\mathrm{hKan}}\left(\mathcal{E}_{D}, \mathcal{E}_{C}\right)\) are inverse to one another (as morphisms in the homotopy category hKan).

Proof. Choose morphisms of Kan complexes \(f_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) and \(f^{*}: \mathcal{E}_{D} \rightarrow \mathcal{E}_{C}\) representing the homotopy classes \(\left[f_{!}\right]\)and \(\left[f^{*}\right]\), respectively. We will show that \(f^{*} \circ f_{!}\)is homotopic to the identity morphism \(\operatorname{id}_{\mathcal{E}_{C}}\); a similar argument will show that \(f_{!} \circ f^{*}\) is homotopic to \(\operatorname{id} \mathcal{E}_{D}\). Let \(\mathcal{D}\) denote the fiber product \(\operatorname{Fun}\left(\mathcal{E}_{C}, \mathcal{E}\right) \times_{\mathrm{Fun}\left(\mathcal{E}_{C}, \mathcal{C}\right)} \mathcal{C}\), and let \(\pi: \mathcal{D} \rightarrow \mathcal{C}\) be the projection map onto the second factor. Since \(U\) is a Kan fibration, it follows from Corollary 3.1.3.2 that \(\pi\) is also a Kan fibration. Let \(\tilde{f}: \Delta^{1} \times \mathcal{E}_{C} \rightarrow \mathcal{E}\) be a morphism witnessing \(f_{!}\)as given by covariant transport along \(f\). Then \(\tilde{f}\) determines an edge \(h\) of the simplicial set \(\mathcal{D}\) satisfying \(\pi(h)=f\). Let \(\tilde{f^{\prime}}: \Delta^{1} \times \mathcal{E}_{D} \rightarrow \mathcal{E}\) be a morphism which witnesses \(f^{*}\) as given by contravariant transport along \(f\), so that the composite morphism
\[
\Delta^{1} \times \mathcal{E}_{C} \xrightarrow{\text { id } \times f_{1}} \Delta^{1} \times \mathcal{E}_{D} \xrightarrow{\widetilde{f^{\prime}}} \mathcal{E}
\]
determines an edge \(h^{\prime}\) of the simplicial set \(\mathcal{D}\) satisfying \(\pi\left(h^{\prime}\right)=f\). The edges \(h\) and \(h^{\prime}\) have the same target (the vertex of \(\mathcal{D}\) corresponding to the morphism \(f_{!}\)). Invoking our assumption that \(\pi\) is a Kan fibration, we deduce that there exists a 2-simplex \(\sigma\) of \(\mathcal{D}\) satisfying \(d_{0}^{2}(\sigma)=h^{\prime}, d_{1}^{2}(\sigma)=h\), and \(\pi(\sigma)=s_{0}^{1}(f)\); we can represent \(\sigma\) as a diagram

We now observe that the edge \(v=d_{2}^{2}(\sigma)\) of \(\mathcal{D}\) can be identified with a map of simplicial sets \(V: \Delta^{1} \times \mathcal{E}_{C} \rightarrow \mathcal{E}_{C}\) which is a homotopy from id \(\mathcal{E}_{C}=\left.V\right|_{\{0\} \times \mathcal{E}_{C}}\) to \(f^{*} \circ f_{!}=\left.V\right|_{\{1\} \times \mathcal{E}_{C}}\).

We close this section by establishing a converse to Proposition 5.2.2.18
01 A 2 Theorem 5.2.2.19. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a morphism of simplicial sets. The following conditions are equivalent:
(1) The morphism \(U\) is a Kan fibration.
(2) The morphism \(U\) is a left fibration and, for every edge \(f: C \rightarrow D\) of the simplicial set \(\mathcal{C}\), the covariant transport morphism \(\left[f_{i}\right]: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) is an isomorphism in the homotopy category hKan.
(3) The morphism \(U\) is a right fibration and, for every edge \(f: C \rightarrow D\) of the simplicial set \(\mathcal{C}\), the contravariant transport morphism \(\left[f^{*}\right]: \mathcal{E}_{D} \rightarrow \mathcal{E}_{C}\) is an isomorphism in the homotopy category hKan.

Proof. We will show that \((1) \Leftrightarrow(2)\); the proof of the equivalence \((1) \Leftrightarrow(3)\) is similar. The implication \((1) \Rightarrow(2)\) is immediate from Proposition 5.2.2.18. For the converse, assume that \(U: \mathcal{E} \rightarrow \mathcal{C}\) is a left fibration of simplicial sets and that, for every edge \(f: C \rightarrow D\) of \(\mathcal{C}\), the covariant transport morphism [ \(f_{!}\)] is an isomorphism in the homotopy category hKan. We wish to show that \(U\) is a Kan fibration. By virtue of Example 4.2.1.5, it will suffice to show that \(U\) is a right fibration. By Proposition 4.2.6.1, this is equivalent to the assertion that the induced map
\[
\theta: \operatorname{Fun}\left(\Delta^{1}, \mathcal{E}\right) \rightarrow \operatorname{Fun}(\{1\}, \mathcal{E}) \times_{\operatorname{Fun}(\{1\}, \mathcal{C})} \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)
\]
is a trivial Kan fibration. Note that our assumption that \(U\) is a left fibration guarantees that \(\theta\) is also a left fibration (Proposition 4.2.5.1).

Fix an edge \(f: C \rightarrow D\) of the simplicial set \(\mathcal{C}\) and let \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{E}\right)_{f}\) denote the fiber \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{E}\right) \times_{\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)}\{f\}\). Then evaluation at the vertex \(1 \in \Delta^{1}\) induces a morphism \(\theta_{f}: \operatorname{Fun}\left(\Delta^{1}, \mathcal{E}\right)_{f} \rightarrow \mathcal{E}_{D}\). Note that \(\theta_{f}\) is a pullback of \(\theta\), and is therefore also a left fibration. Since \(\mathcal{E}_{D}\) is a Kan complex (Corollary 4.4.2.3), Corollary 4.4.3.8 guarantees that \(\theta_{f}\) is a Kan fibration (so \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)_{f}\) is also a Kan complex). Evaluation at the vertex \(0 \in \Delta^{1}\) induces another morphism of simplicial sets \(u: \operatorname{Fun}\left(\Delta^{1}, \mathcal{E}\right)_{f} \rightarrow \mathcal{E}_{C}\). Since \(U\) is a left fibration, the morphism \(u\) is a trivial Kan fibration. By construction, the homotopy class [ \(f_{!}\)] can be represented by the morphism of Kan complexes given by the composition
\[
\mathcal{E}_{C} \xrightarrow{v} \operatorname{Fun}\left(\Delta^{1}, \mathcal{E}\right)_{f} \xrightarrow{\theta_{f}} \mathcal{E}_{D},
\]
where \(v\) is a section of \(u\) (and therefore a homotopy equivalence). Consequently, our assumption that \(\left[f_{!}\right]\)is an isomorphism in hKan guarantees that \(\theta_{f}\) is a homotopy equivalence of Kan complexes (Remark 3.1.6.16). Applying Proposition 3.2.7.2, we deduce that the fibers of \(\theta_{f}\) are contractible Kan complexes. Since every fiber of \(\theta\) can also be viewed as a fiber of \(\theta_{f}\) for some edge \(f\) of the simplicial set \(\mathcal{C}\), it follows that the fibers of \(\theta\) are also contractible Kan complexes. Invoking Proposition 4.4.2.14, we conclude that \(\theta\) is a trivial Kan fibration, as desired.

Corollary 5.2.2.20. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a morphism of simplicial sets. The following conditions are equivalent:
(1) The morphism \(U\) is a covering map (Definition 3.1.4.1).
(2) The morphism \(U\) is a left covering map (Definition4.2.3.8) and, for every edge \(f: C \rightarrow D\) of the simplicial set \(\mathcal{C}\), the covariant transport functor \(f_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) is a bijection.
(3) The morphism \(U\) is a right covering map (Definition 4.2.3.8) and, for every edge \(f: C \rightarrow D\) of the simplicial set \(\mathcal{C}\), the contravariant transport morphism \(f^{*}: \mathcal{E}_{D} \rightarrow \mathcal{E}_{C}\) is a bijection.

Proof. Combine Theorem 5.2.2.19 with Corollary 4.2.3.20.

\subsection*{5.2.3 Example: The Relative Join}

0241 Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Our goal in this section is to show that \(F\) is given by covariant transport, in the sense of Definition 5.2.2.4. More precisely, we will show that there exists a cocartesian fibration of \(\infty\)-categories \(\mathcal{M} \rightarrow \Delta^{1}\) equipped with isomorphisms \(\mathcal{C} \simeq\{0\} \times_{\Delta^{1}} \mathcal{M}\) and \(\mathcal{D}=\{1\} \times_{\Delta^{1}} \mathcal{M}\) carrying \(F\) to a functor
\[
\{0\} \times_{\Delta^{1}} \mathcal{M} \rightarrow\{1\} \times_{\Delta^{1}} \mathcal{M}
\]
which is given by covariant transport along the nondegenerate edge of \(\Delta^{1}\) (Proposition 5.2 .3 .15 . We will prove this by an explicit construction, using a generalization of the join operation studied in \(\S \boxed{4.3}\). (in \(\$ \sqrt[5.2 .4]{ }\), we will show that the \(\infty\)-category \(\mathcal{M}\) is determined up to equivalence by the functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) (see Corollary 5.2.4.2 and Remark 5.2.4.3).
0242 Construction 5.2.3.1 (The Relative Join). Let \(\mathcal{E}\) be a simplicial set. By virtue of Remark 4.3.3.21, there is a unique morphism of simplicial sets \(\rho: \Delta^{1} \times \mathcal{E} \rightarrow \mathcal{E} \star \mathcal{E}\) for which the diagram

is commutative.
Let \(F: \mathcal{C} \rightarrow \mathcal{E}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be morphisms of simplicial sets. We let \(\mathcal{C}{ }_{\star \mathcal{E}} \mathcal{D}\) denote the fiber product \((\mathcal{C} \star \mathcal{D}) \times_{(\mathcal{E} \star \mathcal{E})}\left(\Delta^{1} \times \mathcal{E}\right)\), so that we have a pullback diagram

We will refer to \(\mathcal{C}{ }_{\star \mathcal{E}} \mathcal{D}\) as the join of \(\mathcal{C}\) and \(\mathcal{D}\) relative to \(\mathcal{E}\).
0243 Remark 5.2.3.2. Let \(F: \mathcal{C} \rightarrow \mathcal{E}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be morphisms of simplicial sets, and let \(K\) be a simplicial set. By virtue of Remark 4.3.3.21, morphisms from \(K\) to the relative join \(\mathcal{C}{ }_{\star} \mathcal{D}\) are given by maps \(\pi: K \rightarrow \Delta^{1}\) together with commutative diagrams

Remark 5.2.3.3. Let \(F: \mathcal{C} \rightarrow \mathcal{E}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be morphisms of simplicial sets. Then the 0244 inclusion maps \(\mathcal{C} \hookrightarrow \mathcal{C} \star \mathcal{D} \hookleftarrow \mathcal{D}\) lift uniquely to monomorphisms
\[
\iota_{\mathcal{C}}: \mathcal{C} \hookrightarrow \mathcal{C} \star \mathcal{E} \mathcal{D} \quad \iota_{\mathcal{D}}: \mathcal{D} \hookrightarrow \mathcal{C} \star \mathcal{E} \mathcal{D}
\]
which fit into a commutative diagram

in which both squares are pullbacks. In the future, we will often abuse notation by identifying \(\mathcal{C}\) and \(\mathcal{D}\) with their images under the monomorphisms \(\iota_{\mathcal{C}}\) and \(\iota_{\mathcal{D}}\), respectively (which are full simplicial subsets of the relative join \(\left.\mathcal{C} \star_{\mathcal{E}} \mathcal{D}\right)\).
Example 5.2.3.4. Let \(F: \mathcal{C} \rightarrow \mathcal{E}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be morphisms of simplicial sets. If \(\mathcal{D}\) is 0245 empty, then the inclusion map \(\iota_{\mathcal{C}}: \mathcal{C} \hookrightarrow \mathcal{C} \star_{\mathcal{E}} \mathcal{D}\) is an isomorphism of simplicial sets. If \(\mathcal{C}\) is empty, then the inclusion map \(\iota_{\mathcal{D}}: \mathcal{D} \hookrightarrow \mathcal{C} \star_{\mathcal{E}} \mathcal{D}\) is an isomorphism of simplicial sets.
Example 5.2.3.5. Let \(\mathcal{C}\) and \(\mathcal{D}\) be simplicial sets, so that we have unique morphisms 0246 \(F: \mathcal{C} \rightarrow \Delta^{0}\) and \(G: \mathcal{D} \rightarrow \Delta^{0}\). Then the relative join \(\mathcal{C} \star_{\Delta^{0}} \mathcal{D}\) agrees with the join \(\mathcal{C} \star \mathcal{D}\) introduced in Construction 4.3.3.13.
Example 5.2.3.6. Let \(\mathcal{E}\) be a simplicial set. Then the relative join \(\mathcal{E} \star_{\mathcal{E}} \mathcal{E}\) is isomorphic to 0247 \(\Delta^{1} \times \mathcal{E}\).
Example 5.2.3.7. Let \(\mathcal{E}\) be a simplicial set equipped with a morphism \(\pi: \mathcal{E} \rightarrow \Delta^{1}\), and set 0248 \(\mathcal{C}=\{0\} \times_{\Delta^{1}} \mathcal{E}\) and \(\mathcal{D}=\{1\} \times_{\Delta^{1}} \mathcal{E}\). Then the relative join \(\mathcal{C} \star_{\mathcal{E}} \mathcal{D}\) is isomorphic to \(\mathcal{E}\).
Example 5.2.3.8. Let \(F: \mathcal{C} \rightarrow \mathcal{E}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors between categories. Then the 0249 relative join \(\mathrm{N}_{\bullet}(\mathcal{C}) \star_{\mathrm{N}_{\bullet}}(\mathcal{E}) \mathrm{N}_{\bullet}(\mathcal{D})\) can be identified with the nerve of the category
\[
\mathcal{C} \star \mathcal{E}^{\mathcal{D}}=(\mathcal{C} \star \mathcal{D}) \times_{(\mathcal{E} \star \mathcal{E})}([1] \times \mathcal{E}),
\]
which can be described more concretely as follows:
- The set of objects \(\operatorname{Ob}\left(\mathcal{C} \star \mathcal{E}^{\mathcal{D}}\right)\) is the disjoint union of \(\mathrm{Ob}(\mathcal{C})\) with \(\operatorname{Ob}(\mathcal{D})\).
- For every pair of objects \(X, Y \in \operatorname{Ob}\left(\mathcal{C} \star \mathcal{E}^{\mathcal{D}}\right)\), we have
\[
\operatorname{Hom}_{\mathcal{C} * \mathcal{E}} \mathcal{D}(X, Y)= \begin{cases}\operatorname{Hom}_{\mathcal{C}}(X, Y) & \text { if } X, Y \in \mathrm{Ob}(\mathcal{C}) \\ \operatorname{Hom}_{\mathcal{D}}(X, Y) & \text { if } X, Y \in \operatorname{Ob}(\mathcal{D}) \\ \operatorname{Hom}_{\mathcal{E}}(F(X), G(Y)) & \text { if } X \in \operatorname{Ob}(\mathcal{C}), Y \in \mathrm{Ob}(\mathcal{D}) \\ \emptyset & \text { if } X \in \operatorname{Ob}(\mathcal{D}), Y \in \mathrm{Ob}(\mathcal{C})\end{cases}
\]

024A Remark 5.2.3.9 (Base Change). Suppose we are given a commutative diagram of simplicial sets

where both squares are pullbacks. Then the induced diagram

is also a pullback square.
024B Remark 5.2.3.10. Let \(G: \mathcal{D} \rightarrow \mathcal{E}\) be a fixed morphism of simplicial sets. Then the construction
\[
(F: \mathcal{C} \rightarrow \mathcal{E}) \mapsto \mathcal{C} \not{ }_{\mathcal{E}} \mathcal{D}
\]
carries colimits in the category \(\left(\operatorname{Set}_{\Delta}\right) / \mathcal{E}\) to colimits in the category \(\left(\operatorname{Set}_{\Delta}\right)_{\mathcal{D} /}\). In particular, the construction \(\mathcal{C} \mapsto(\mathcal{C} \star \mathcal{E} \mathcal{D})\) commutes with filtered colimits and carries pushout diagrams to pushout diagrams.

The relative join \(\mathcal{C}{ }_{\star \mathcal{E}} \mathcal{D}\) of Construction 5.2.3.1 is defined for arbitrary diagrams of simplicial sets \(\mathcal{C} \xrightarrow{F} \mathcal{E} \stackrel{G}{\leftarrow} \mathcal{D}\). However, as our notation suggests, we will be primarily interested in the special case where \(\mathcal{C}, \mathcal{D}\), and \(\mathcal{E}\) are \(\infty\)-categories. In this case, we have the following generalization of Corollary 4.3.3.25

024C Proposition 5.2.3.11. Let \(F: \mathcal{C} \rightarrow \mathcal{E}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories. Then the relative join \(\mathcal{C} \star \mathcal{E}^{\mathcal{D}}\) is an \(\infty\)-category.

024D Lemma 5.2.3.12. Let \(U: \mathcal{E} \rightarrow \mathcal{E}^{\prime}\) be an inner fibration of simplicial sets. Then the induced map
\[
\Delta^{1} \times \mathcal{E}=\mathcal{E} \star_{\mathcal{E}} \mathcal{E} \rightarrow \mathcal{E} \star_{\mathcal{E}^{\prime}} \mathcal{E}
\]
is also an inner fibration of simplicial sets.

Proof. Suppose we are given integers \(0<i<n\); we wish to show that every lifting problem

02RE
admits a solution. Let \(\alpha\) denote the composite map
\[
\Delta^{n} \xrightarrow{\bar{\sigma}} \mathcal{E} \star_{\mathcal{E}^{\prime}} \mathcal{E} \rightarrow \Delta^{0} \star_{\Delta^{0}} \Delta^{0} \simeq \Delta^{1} .
\]

If \(\alpha\) is a constant morphism, then the existence of \(\sigma\) is immediate. We may therefore assume without loss of generality that \(\alpha\) is not constant. Write \(\sigma_{0}=\left(\alpha_{0}, \tau_{0}\right)\), where \(\alpha_{0}=\left.\alpha\right|_{\Lambda_{i}^{n}}\) and \(\tau_{0}: \Lambda_{i}^{n} \rightarrow \mathcal{E}\) is a morphism of simplicial sets, and let \(\bar{\tau}\) denote the composite map \(\Delta^{n} \xrightarrow{\bar{\sigma}} \mathcal{E} \star_{\mathcal{E}^{\prime}} \mathcal{E} \rightarrow \mathcal{E}^{\prime}\). Since \(U\) is an inner fibration, the lifting problem

admits a solution. We now observe that the pair \(\sigma=(\alpha, \tau)\) can be regarded as an \(n\)-simplex of \(\Delta^{1} \times \mathcal{E}\) which solves the lifting problem 5.11.

Lemma 5.2.3.13. Suppose we are given a commutative diagram of simplicial sets

in which the vertical morphisms are inner fibrations. Then the induced map
\[
F: \mathcal{C} \star \mathcal{E}^{\mathcal{D}} \rightarrow \mathcal{C}^{\prime} \star_{\mathcal{E}^{\prime}} \mathcal{D}^{\prime}
\]
is also an inner fibration.

Proof. Unwinding the definitions, we see that \(F\) factors as a composition
\[
\mathcal{C} \star \mathcal{E} \mathcal{D} \xrightarrow{G} \mathcal{C} \star_{\mathcal{E}^{\prime}} \mathcal{D} \xrightarrow{H} \mathcal{C}^{\prime} \star_{\mathcal{E}^{\prime}} \mathcal{D}^{\prime},
\]
 pullback of the inner fibration \(\mathcal{C} \star \mathcal{D} \rightarrow \mathcal{C}^{\prime} \star \mathcal{D}^{\prime}\) of Proposition 4.3.3.24.

Proof of Proposition 5.2.3.11. Let \(F: \mathcal{C} \rightarrow \mathcal{E}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories. Applying Lemma 5.2.3.13, we see that the natural map
\[
\mathcal{C} \star \mathcal{E}^{\mathcal{D}} \rightarrow \Delta^{0} \star_{\Delta^{0}} \Delta^{0} \simeq \Delta^{1}
\]
is an inner fibration of simplicial sets. Since \(\Delta^{1}\) is an \(\infty\)-category, it follows that \(\mathcal{C} \star \mathcal{E} \mathcal{D}\) is also an \(\infty\)-category (Remark 4.1.1.9).

024 F Remark 5.2.3.14 (Morphism Spaces in the Relative Join). Let \(F: \mathcal{C} \rightarrow \mathcal{E}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be morphisms of simplicial sets. If \(X\) and \(Y\) are vertices of the relative join \(\mathcal{C} \star \mathcal{E} \mathcal{D}\), then we have canonical isomorphisms of simplicial sets
\[
\operatorname{Hom}_{\mathcal{C} \star \mathcal{E}}(X, Y) \simeq \begin{cases}\operatorname{Hom}_{\mathcal{C}}(X, Y) & \text { if } X, Y \in \mathcal{C} \\ \operatorname{Hom}_{\mathcal{D}}(X, Y) & \text { if } X, Y \in \mathcal{D} \\ \operatorname{Hom}_{\mathcal{E}}(F(X), G(Y)) & \text { if } X \in \mathcal{C}, Y \in \mathcal{D} \\ \emptyset & \text { if } X \in \mathcal{D}, Y \in \mathcal{C}\end{cases}
\]

The pinched morphism spaces \(\operatorname{Hom}_{\mathcal{C} \star \mathcal{E}}^{\mathrm{D}}(X, Y)\) and \(\operatorname{Hom}_{\mathcal{C} \star \mathcal{E}}^{\mathrm{D}} \mathrm{R}(X, Y)\) admit similar descriptions.

We now specialize Construction 5.2.3.1 to the case where \(\mathcal{D}=\mathcal{E}\) and the morphism \(G: \mathcal{D} \rightarrow \mathcal{E}\) is the identity. Our goal is to prove the following:

024J Proposition 5.2.3.15. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Then:
(1) The projection map \(\pi: \mathcal{C} \star_{\mathcal{D}} \mathcal{D} \rightarrow \Delta^{1}\) is a cocartesian fibration of \(\infty\)-categories.
(2) The map
\[
\widetilde{F}: \Delta^{1} \times \mathcal{C} \simeq\left(\mathcal{C} \star_{\mathcal{C}} \mathcal{C}\right) \rightarrow \mathcal{C} \star_{\mathcal{D}} \mathcal{D}
\]
witnesses the functor \(F\) as given by covariant transport along the nondegenerate edge of \(\Delta^{1}\).

The proof of Proposition 5.2.3.15 will require some preliminaries.

Lemma 5.2.3.16. Suppose we are given a commutative diagram of simplicial sets

so that \(U\) and \(V\) induce a morphism \(W: \mathcal{C} \star_{\mathcal{D}} \mathcal{D} \rightarrow \mathcal{C}^{\prime}{ }_{\mathcal{D}^{\prime}} \mathcal{D}^{\prime}\). Let \(e\) be an edge of the simplicial set \(\mathcal{C} \star_{\mathcal{D}} \mathcal{D}\) satisfying the following conditions:
(1) If \(e\) is contained in \(\mathcal{C}\), then it is \(U\)-cocartesian when viewed as an edge of \(\mathcal{C}\).
(2) The image of e under the map
\[
\rho: \mathcal{C} \star_{\mathcal{D}} \mathcal{D} \rightarrow \mathcal{D} \star_{\mathcal{D}} \mathcal{D} \simeq \Delta^{1} \times \mathcal{D} \rightarrow \mathcal{D}
\]
is \(V\)-cocartesian.
Then e is \(W\)-cocartesian.
Proof. Let \(n \geq 2\) be an integer and suppose we are given a lifting problem

where \(\sigma_{0}\) carries \(\mathrm{N}_{\bullet}(\{0<1\}) \subseteq \Lambda_{0}^{n}\) to the edge \(e\). If \(\sigma^{\prime}\) is contained in the simplicial subset \(\mathcal{C}^{\prime} \subseteq \mathcal{C}^{\prime} \star_{\mathcal{D}^{\prime}} \mathcal{D}^{\prime}\), then the lifting problem (5.12) admits a solution by virtue of assumption (1). Let us therefore assume that \(\sigma^{\prime}\) is not contained in \(\mathcal{C}^{\prime}\). Let \(\rho: \mathcal{C} \star_{\mathcal{D}} \mathcal{D} \rightarrow \mathcal{D}\) be as in (2), and define \(\rho^{\prime}: \mathcal{C}^{\prime} \star_{\mathcal{D}^{\prime}} \mathcal{D}^{\prime} \rightarrow \mathcal{D}^{\prime}\) similarly. Unwinding the definitions, we can rewrite 5.12) as a lifting problem

which admits a solution by virtue of assumption (2).

02RH Lemma 5.2.3.17. Suppose we are given a commutative diagram of simplicial sets

Suppose that \(U\) and \(V\) are cocartesian fibrations, and that the morphism \(F\) carries \(U\) cocartesian edges of \(\mathcal{C}\) to \(V\)-cocartesian edges of \(\mathcal{D}\). Then the induced map \(W: \mathcal{C} \star_{\mathcal{D}} \mathcal{D} \rightarrow\) \(\mathcal{C}^{\prime} \star_{\mathcal{D}^{\prime}} \mathcal{D}^{\prime}\) is also a cocartesian fibration. Moreover, an edge e of \(\mathcal{C} \star_{\mathcal{D}} \mathcal{D}\) is \(W\)-cocartesian if and only if it satisfies conditions (1) and (2) of Lemma 5.2.3.16.

Proof. It follows from Lemma 5.2.3.12 that \(W\) is an inner fibration of simplicial sets. Let us say that an edge of \(\mathcal{C} \star_{\mathcal{D}} \mathcal{D}\) is special if it satisfies conditions (1) and (2) of Lemma 5.2.3.16 so that every special edge of \(\mathcal{C} \star_{\mathcal{D}} \mathcal{D}\) is \(W\)-cocartesian. We consider three cases:
- Suppose that \(X\) belongs to \(\mathcal{C}\) and \(\bar{Y}\) belongs to \(\mathcal{C}^{\prime}\). In this case, our assumption that \(U\) is a cocartesian fibration guarantees that we can lift \(\bar{e}\) to \(U\)-cocartesian edge \(e: X \rightarrow Y\) of \(\mathcal{C} \subseteq \mathcal{C} \star_{\mathcal{D}} \mathcal{D}\). Since \(F(e)\) is a \(V\)-cocartesian edge of \(\mathcal{D}\), the edge \(e\) is special.
- Suppose that \(X\) belongs to \(\mathcal{C}\) and \(\bar{Y}\) belongs to \(\mathcal{D}^{\prime}\). In this case, we can identify \(\bar{e}\) with an edge \(\bar{e}_{0}: V(F(X)) \rightarrow \bar{Y}\) of the simplicial set \(\mathcal{D}^{\prime}\). Since \(V\) is a cocartesian fibration, we can lift \(\bar{e}_{0}\) to a \(V\)-cocartesian morphism \(e_{0}: F(X) \rightarrow Y\) of \(\mathcal{D}\), which we can identify with a special edge \(e: X \rightarrow Y\) of the simplicial set \(\mathcal{C} \star_{\mathcal{D}} \mathcal{D}\) satisfying \(W(e)=\bar{e}\).
- Suppose that \(X\) belongs to \(\mathcal{D}\) and \(\bar{Y}\) belongs to \(\mathcal{D}^{\prime}\). In this case, our assumption that \(V\) is a cocartesian fibration guarantees that we can lift \(\bar{e}\) to \(V\)-cocartesian edge \(e: X \rightarrow Y\) of \(\mathcal{D} \subseteq \mathcal{C} \star_{\mathcal{D}} \mathcal{D}\), which is then special when regarded as an edge of \(\mathcal{C} \star_{\mathcal{D}} \mathcal{D}\).

To complete the proof, it will suffice to show that every \(W\)-cocartesian edge \(e: X \rightarrow Y\) of \(\mathcal{C} \star_{\mathcal{D}} \mathcal{D}\) is special. Applying the preceding argument, we can choose a special edge \(e^{\prime}: X \rightarrow Y^{\prime}\) satisfying \(W\left(e^{\prime}\right)=W(e)\). Set \(\bar{Y}=W(Y)=W\left(Y^{\prime}\right)\). Since \(e\) and \(e^{\prime}\) are both \(W\)-cocartesian, Remark 5.1.3.8 supplies a 2 -simplex \(\sigma\) of the \(\operatorname{simplicial} \operatorname{set} \mathcal{C} \star_{\mathcal{D}} \mathcal{D}\) with boundary given by

where \(u\) is an isomorphism in the \(\infty\)-category \(\{\bar{Y}\} \times\left(\mathcal{C}^{\prime}{ }_{\mathcal{D}^{\prime}} \mathcal{D}^{\prime}\right)\left(\mathcal{C} \star_{\mathcal{D}} \mathcal{D}\right)\). Applying Remark 5.1.3.8 to the cocartesian fibrations \(U\) and \(V\), we deduce that the edge \(e\) is also special.

Example 5.2.3.18. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Applying Lemma 5.2.3.17 02RJ to the diagram

we deduce that the projection map
\[
\pi: \mathcal{C} \star_{\mathcal{D}} \mathcal{D} \rightarrow \Delta^{0} \star_{\Delta^{0}} \Delta^{0} \simeq \Delta^{1}
\]
is a cocartesian fibration. Moreover, a morphism \(e: X \rightarrow Y\) of the \(\infty\)-category \(\mathcal{C} \star_{\mathcal{D}} \mathcal{D}\) is \(\pi\)-cocartesian if and only if it satisfies one of the following three conditions:
- The objects \(X\) and \(Y\) belong to \(\mathcal{C}\) and \(e\) is an isomorphism in the \(\infty\)-category \(\mathcal{C}\).
- The objects \(X\) and \(Y\) belong to \(\mathcal{D}\) and \(e\) is an isomorphism in the \(\infty\)-category \(\mathcal{D}\).
- The object \(X\) belongs to \(\mathcal{C}\), the object \(Y\) belongs to \(\mathcal{D}\), and \(e\) corresponds to an isomorphism \(e_{0}: F(X) \rightarrow Y\) in the \(\infty\)-category \(\mathcal{D}\) (under the identification of Remark 5.2.3.14.

Proof of Proposition 5.2.3.15. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, so that the projection map \(\pi: \mathcal{C} \star_{\mathcal{D}} \mathcal{D} \rightarrow \Delta^{1}\) of Example 5.2 .3 .18 is a cocartesian fibration. Note that the morphism
\[
H: \Delta^{1} \times \mathcal{C} \simeq \mathcal{C} \star_{\mathcal{C}} \mathcal{C} \rightarrow \mathcal{C} \star_{\mathcal{D}} \mathcal{D}
\]
satisfies \(\left.H\right|_{\{0\} \times \mathcal{C}}=\operatorname{id}_{\mathcal{C}}\) and \(\left.H\right|_{\{1\} \times \mathcal{C}}=F\). To complete the proof, it will suffice to show that for every object \(C \in \mathcal{C}\), the restriction \(\left.H\right|_{\Delta^{1} \times\{C\}}\) is a \(\pi\)-cocartesian morphism \(e: X \rightarrow F(X)\) in the \(\infty\)-category \(\mathcal{C}{ }_{\star_{\mathcal{D}}} \mathcal{D}\). This follows from the criterion of Example 5.2.3.18, since \(e\) corresponds to the identity morphism \(\operatorname{id}_{F(X)}: F(X) \rightarrow F(X)\) under the identification of Remark 5.2.3.14

Passing to opposite \(\infty\)-categories, we obtain a dual version of Proposition 5.2.3.15
Variant 5.2.3.19. Let \(G: \mathcal{D} \rightarrow \mathcal{C}\) be a functor of \(\infty\)-categories. Then:
(1) The projection map \(\pi: \mathcal{C} \not{ }_{\mathcal{C}} \mathcal{D} \rightarrow \Delta^{1}\) is a cartesian fibration of \(\infty\)-categories.
(2) The map
\[
h: \Delta^{1} \times \mathcal{D} \simeq\left(\mathcal{D} \star_{\mathcal{D}} \mathcal{D}\right) \rightarrow \mathcal{C} \star_{\mathcal{C}} \mathcal{D}
\]
witnesses the functor \(G\) as given by contravariant transport along the nondegenerate edge of \(\Delta^{1}\).

\subsection*{5.2.4 Fibrations over the 1-Simplex}

024 M Let \(\mathcal{M}\) be an \(\infty\)-category equipped with a cocartesian fibration \(\pi: \mathcal{M} \rightarrow \Delta^{1}\). Our goal in this section is to show that \(\mathcal{M}\) is determined (up to equivalence) by the \(\infty\)-categories \(\mathcal{C}=\{0\} \times_{\Delta^{1}} \mathcal{M}, \mathcal{D}=\{1\} \times \times_{\Delta^{1}} \mathcal{M}\), and the functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) given by covariant transport along the nondegenerate edge of \(\Delta^{1}\). This is a consequence of the following:

024N Theorem 5.2.4.1. Let \(U: \mathcal{M} \rightarrow \Delta^{1}\) be a functor of \(\infty\)-categories, and suppose we are given a commutative diagram \(\sigma\) :

in the category \(\left(\operatorname{Set}_{\Delta}\right) / \Delta^{1}\). Then \(\sigma\) is a categorical pushout diagram of simplicial sets (Definition 4.5.4.1) if and only if the following conditions are satisfied:
(1) The restriction \(\left.h\right|_{\{0\} \times \mathcal{C}}: \mathcal{C} \rightarrow\{0\} \times_{\Delta^{1}} \mathcal{M}\) is a categorical equivalence of simplicial sets.
(2) The morphism \(g: \mathcal{D} \rightarrow\{1\} \times_{\Delta^{1}} \mathcal{M}\) is a categorical equivalence of simplicial sets.
(3) For every vertex \(C \in \mathcal{C}\), the restriction \(\left.h\right|_{\Delta^{1} \times\{C\}}\) is a \(U\)-cocartesian morphism of \(\mathcal{M}\).

Moreover, if these conditions are satisfied, then \(U\) is a cocartesian fibration.
024 P Corollary 5.2.4.2. Let \(U: \mathcal{M} \rightarrow \Delta^{1}\) be a cocartesian fibration of \(\infty\)-categories with fibers \(\mathcal{C}=\{0\} \times_{\Delta^{1}} \mathcal{M}\) and \(\mathcal{D}=\{1\} \times_{\Delta^{1}} \mathcal{M}\). Let \(h: \Delta^{1} \times \mathcal{C} \rightarrow \mathcal{M}\) be a functor which witnesses the functor \(F=\left.h\right|_{\{1\} \times \mathcal{C}}\) as given by covariant transport along the nondegenerate edge of \(\Delta^{1}\) (Definition 5.2.2.4). Then \(h\) induces a categorical equivalence of simplicial sets
\[
\left(\Delta^{1} \times \mathcal{C}\right) \coprod_{(\{1\} \times \mathcal{C})} \mathcal{D} \rightarrow \mathcal{M}
\]

Proof. Combine Theorem 5.2.4.1 with Proposition 4.5.4.11.
024 Q Remark 5.2.4.3. Let \(U: \mathcal{M} \rightarrow \Delta^{1}\) be a cocartesian fibration of \(\infty\)-categories. It follows from Corollary 5.2.4.2 that the \(\infty\)-category \(\mathcal{M}\) can be recovered (up to equivalence) from the \(\infty\)-categories \(\mathcal{C}=\{0\} \times_{\Delta^{1}} \mathcal{M}, \mathcal{D}=\{1\} \times_{\Delta^{1}} \mathcal{M}\), and the covariant transport functor \(F: \mathcal{C} \rightarrow \mathcal{D}\). Similarly, if \(U: \mathcal{M} \rightarrow \Delta^{1}\) is a cartesian fibration, then the \(\infty\)-category \(\mathcal{M}\) can be recovered from \(\mathcal{C}, \mathcal{D}\), and the contravariant transport functor \(G: \mathcal{D} \rightarrow \mathcal{C}\).

As an application of Theorem 5.2.4.1, we give an alternative characterization of the covariant transport functors introduced in \(\S 5.2 .2\).

Corollary 5.2.4.4. Let \(U: \mathcal{M} \rightarrow \Delta^{1}\) be a cocartesian fibration of \(\infty\)-categories and let 046W \(F: \mathcal{M}_{0} \rightarrow \mathcal{M}_{1}\) be a functor. The following conditions are equivalent:
(1) The functor \(F\) is given by covariant transport along the nondegenerate edge of \(\Delta^{1}\) (in the sense of Definition 5.2.2.4.
(2) There exists a functor \(R: \mathcal{M} \rightarrow \mathcal{M}_{1}\) such that \(\left.R\right|_{\mathcal{M}_{0}}=F,\left.R\right|_{\mathcal{M}_{1}}=\mathrm{id}\), and \(R\) carries \(U\)-cocartesian morphisms of \(\mathcal{M}\) to isomorphisms in \(\mathcal{M}_{1}\).

Proof. Let \(e\) denote the nondegenerate edge of \(\Delta^{1}\). By virtue of Proposition 5.2.2.8, we can choose a functor \(F^{\prime}: \mathcal{M}_{0} \rightarrow \mathcal{M}_{1}\) and a natural transformation \(H: \Delta^{1} \times \mathcal{M}_{0} \rightarrow \mathcal{M}\) which exhibits \(F^{\prime}\) as given by covariant transport along \(e\). Let \(R: \mathcal{M} \rightarrow \mathcal{M}_{1}\) be a functor satisfying condition (2). Then the composition
\[
\Delta^{1} \times \mathcal{M}_{0} \xrightarrow{H} \mathcal{M} \xrightarrow{R} \mathcal{M}_{1}
\]
can be regarded as a natural transformation from \(\left.R \circ H\right|_{\{0\} \times \mathcal{M}_{0}}=F\) to \(\left.R \circ H\right|_{\{1\} \times \mathcal{M}_{1}}=F^{\prime}\). By assumption, this natural transformation carries each object of \(\mathcal{M}_{0}\) to an isomorphism in the \(\infty\)-category \(\mathcal{M}_{1}\), and is therefore an isomorphism of functors (Theorem 4.4.4.4). It follows that the functor \(F\) is also given by covariant transport along \(e\) (see Proposition 5.2 .2 .8 . This proves the implication \((2) \Rightarrow(1)\).

Now suppose that condition (1) is satisfied. Then we can assume that \(F^{\prime}=F\), so that we have a commutative diagram of simplicial sets

The upper half of the diagram is a pushout square in which the vertical maps are monomorphisms, and therefore a categorical pushout square (Example 4.5.4.12). Theorem 5.2.4.1 guarantees that the outer rectangle is a categorical pushout square, so the lower half of the diagram is also a categorical pushout square (Proposition 4.5.4.8). It follows that the diagram of \(\infty\)-categories

is a categorical pullback square (Proposition 4.5.4.4). Since the vertical maps are isofibrations (Corollary 4.4.5.3), Corollary 4.5.2.32 implies that composition with \(H\) induces an equivalence of \(\infty\)-categories
\[
\left.\{(F, \mathrm{id})\} \times_{\operatorname{Fun}\left(\mathcal{M}_{0}\right.} \amalg \mathcal{M}_{1}, \mathcal{M}_{1}\right) \operatorname{Fun}\left(\mathcal{M}, \mathcal{M}_{1}\right) \xrightarrow{\circ H} \operatorname{Hom}_{\operatorname{Fun}\left(\mathcal{M}_{0}, \mathcal{M}_{1}\right)}(F, F) .
\]

It follows that we can choose a functor \(R: \mathcal{M} \rightarrow \mathcal{M}_{1}\) such that \(\left.R\right|_{\mathcal{M}_{0}}=F,\left.R\right|_{\mathcal{M}_{1}}=\mathrm{id}\), and the composition \(R \circ H\) is homotopic to the identity (when regarded as a morphism from \(F\) to itself in the \(\infty\)-category \(\left.\operatorname{Fun}\left(\mathcal{M}_{0}, \mathcal{M}_{1}\right)\right)\). To complete the proof, it will suffice to show that if \(f: X \rightarrow Y\) is a \(U\)-cocartesian morphism of \(\mathcal{M}\), then \(U(f)\) is an isomorphism. We may assume without loss of generality that \(X\) belongs to \(\mathcal{M}_{0}\) and \(Y\) belongs to \(\mathcal{M}_{1}\) (otherwise, \(f\) is already an isomorphism and there is nothing to prove). In this case, Remark 5.1.3.8 guarantees that \(f\) is isomorphic (as an object of \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{M}\right)\) ) to the edge \(\left.H\right|_{\Delta^{1} \times\{X\}}\). It will therefore suffice to show that \(\left.(R \circ H)\right|_{\Delta^{1} \times\{X\}}\) is an isomorphism in \(\mathcal{M}_{1}\), which is clear (since it is homotopic to the identity morphism from \(F(X)\) to itself).

For any functor of \(\infty\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\), the projection map
\[
\mathcal{C} \star_{\mathcal{D}} \mathcal{D} \rightarrow \Delta^{0} \star_{\Delta^{0}} \Delta^{0} \simeq \Delta^{1}
\]
is a cocartesian fibration (Proposition 5.2.3.15). The commutative diagram of simplicial sets

satisfies the hypotheses of Theorem 5.2.4.1, and is therefore a categorical pushout square. This is a special case of the following more general assertion, which does not require \(\mathcal{C}\) and \(\mathcal{D}\) to be \(\infty\)-categories:

024R Proposition 5.2.4.5. Let \(f: X \rightarrow Y\) be a morphism of simplicial sets. Then the diagram

is a categorical pushout square of simplicial sets. Here the lower horizontal map is given by the composition
\[
\Delta^{1} \times X \simeq X \star_{X} X \xrightarrow{\mathrm{id} \star_{f} f} X \star_{Y} Y .
\]

Example 5.2.4.6. In the special case \(Y=\Delta^{0}\), Proposition 5.2.4.5 asserts that the diagram 024 S

is a categorical pushout square: that is, that the comparison map \(X \diamond \Delta^{0} \rightarrow X \star \Delta^{0}\) of Notation 4.5.8.3 is a categorical equivalence. This is the content of Proposition 4.5.8.12 (which is a special case of Theorem 4.5.8.8).

Corollary 5.2.4.7. Suppose we are given a commutative diagram of simplicial sets

where the vertical maps are categorical equivalences. Then the induced map \(X \star_{Y} Y \rightarrow\) \(X^{\prime} \star_{Y^{\prime}} Y^{\prime}\) is also a categorical equivalence of simplicial sets.

Proof. Combine Propositions 5.2.4.5 and 4.5.4.9.
Proof of Proposition 5.2.4.5. The diagram 5.13) determines a morphism of simplicial sets
\[
\lambda_{X}:\left(\Delta^{1} \times X\right) \coprod_{(\{1\} \times X)} Y \rightarrow X \star_{Y} Y,
\]
and we wish to show that \(\lambda_{X}\) is a categorical equivalence of simplicial sets (obtained by applying Construction 5.3.4.7 to the diagram [1] \(\rightarrow \operatorname{Set}_{\Delta} \operatorname{determined}\) by the morphism \(f\) ). We wish to show that \(\lambda_{X}\) is a categorical equivalence of simplicial sets (Proposition 4.5.4.11). By virtue of Corollary 4.5.7.3, it will suffice to prove that for every map \(\Delta^{n} \rightarrow Y\), the induced map
\[
\Delta^{n} \times_{Y}\left(\left(\Delta^{1} \times X\right) \coprod_{(\{1\} \times X)} Y\right) \rightarrow \Delta^{n} \times_{Y}\left(X \star_{Y} Y\right)
\]
is a categorical equivalence. Using Remark 5.2.3.9, we can replace \(Y\) by \(\Delta^{n}\) and \(X\) by the fiber product \(\Delta^{n} \times_{Y} X\), and thereby reduce the proof of Proposition 5.2.4.5 to the special case where \(Y=\Delta^{n}\) is a standard simplex.

Since the collection of categorical equivalences is closed under the formation of filtered colimits (Corollary 4.5.7.2), we may assume without loss of generality that the simplicial
set \(X\) is finite (see Remark 3.6.1.8). In particular, \(X\) has dimension \(\leq m\) for some integer \(m \geq-1\). We proceed by induction on \(m\). If \(m=-1\), then \(X\) is empty and the morphism \(\lambda_{X}\) is an isomorphism (see Example 5.2.3.4). Assume that \(m \geq 0\); we now proceed by induction on the number of nondegenerate \(m\)-simplices of \(X\). If \(X\) does not have dimension \(\leq m-1\), then a choice of nondegenerate \(m\)-simplex of \(X\) determines a pushout diagram

where the horizontal maps are monomorphisms (Proposition 1.1.4.12). We then obtain a cubical diagram

where the front and back faces are categorical pushout squares (Proposition 4.5.4.11). Our inductive hypothesis guarantees that the morphisms \(\lambda_{X^{\prime}}\) and \(\lambda_{\partial \Delta^{m}}\) are categorical equivalences. Consequently, to show that \(\lambda_{X}\) is a categorical equivalence, it will suffice to show that \(\lambda_{\Delta^{m}}\) is a categorical equivalence. We can therefore replace \(X\) by \(\Delta^{m}\), and thereby reduce the proof of Proposition 5.2.4.5 to the special case where \(f: \Delta^{m} \rightarrow \Delta^{n}\) is a morphism between standard simplices.

Suppose that \(f(m)<n\). In this case, we can identify \(f\) with a morphism from \(X=\Delta^{m}\) to the simplex \(\Delta^{n-1}\) (regarded as a simplicial subset of \(\Delta^{n}\) ), and we can identify \(X \star_{Y} Y\) with the right cone \(\left(X \star_{\Delta^{n-1}} \Delta^{n-1}\right)^{\triangleright}\). Under this identification, \(\lambda_{X}\) corresponds to the
composition
\[
\begin{aligned}
\left(\Delta^{1} \times X\right) \coprod_{(\{1\} \times X)}\left(\Delta^{n-1}\right)^{\triangleright} & \xrightarrow{\lambda^{\prime}}\left(\Delta^{1} \times X\right)^{\triangleright} \coprod_{(\{1\} \times X)^{\triangleright}}\left(\Delta^{n-1}\right)^{\triangleright} \\
& \simeq\left(\Delta^{1} \times X\right) \coprod_{(\{1\} \times X)}\left(\Delta^{n-1}\right)^{\triangleright} \\
& \xrightarrow{\lambda^{\prime \prime}}\left(X \star_{\Delta^{n-1}} \Delta^{n-1}\right)^{\triangleright},
\end{aligned}
\]
where \(\lambda^{\prime}\) is a pushout of the map
\[
\left(\Delta^{1} \times X\right) \coprod_{(\{1\} \times X)}(\{1\} \times X)^{\triangleright} \rightarrow\left(\Delta^{1} \times X\right)^{\triangleright}
\]
and is therefore inner anodyne by virtue of Example 4.3.6.5 (since the inclusion \(\{1\} \times X \hookrightarrow\) \(\Delta^{1} \times X\) is right anodyne; see Proposition 4.2.5.3). Consequently, to show that \(\lambda_{X}\) is a categorical equivalence, it will suffice to show that \(\lambda^{\prime \prime}\) is a categorical equivalence. By virtue of Corollary 4.5.8.9, we are reduced to proving Proposition 5.2.4.5 for the map \(f: X \rightarrow \Delta^{n-1}\). Applying this argument repeatedly, we can reduce to the case where \(f(m)=n\).

Let \(Z(0)\) denote the simplicial subset of \(\Delta^{1} \times \Delta^{m}\) given by the union of \(\Delta^{1} \times \partial \Delta^{m}\) with \(\{1\} \times \Delta^{m}\), and let
\[
Z(0) \subset Z(1) \subset Z(2) \subset \cdots \subset Z(m) \subset Z(m+1)=\Delta^{1} \times \Delta^{m}
\]
be the sequence of simplicial subsets appearing in Lemma 3.1.2.12. Note that \(\lambda_{X}\) carries \(Z(m)\) into the simplicial subset \(\partial \Delta^{m} \star_{Y} Y \subseteq X \star_{Y} Y\). We therefore obtain a cubical diagram of simplicial sets

where the front and back faces are pushout squares and the vertical maps are monomorphisms. It follows that the front and back faces are categorical pushout squares (Example 4.5.4.12). Our inductive hypothesis guarantees that \(\lambda_{\partial \Delta^{m}}\) is a categorical equivalence, and the inclusion \(Z(0) \hookrightarrow Z(m)\) is inner anodyne by construction (see Lemma 3.1.2.12). Applying Proposition 4.5.4.9, we conclude that \(\lambda_{\Delta^{m}}\) is also a categorical equivalence.

Proof of Theorem 5.2.4.1. Let \(U: \mathcal{M} \rightarrow \Delta^{1}\) be a functor of \(\infty\)-categories and suppose we are given a commutative diagram \(\sigma\) :

in the category \(\left(\operatorname{Set}_{\Delta}\right) / \Delta^{1}\). We wish to show that \(\sigma\) is a categorical pushout square if and only if conditions (1) through (3) of Theorem 5.2.4.1 are satisfied.

We first reduce to the case where \(\mathcal{C}\) and \(\mathcal{D}\) are \(\infty\)-categories. Choose inner anodyne morphisms \(\mathcal{C} \hookrightarrow \mathcal{C}^{\prime}\) and \(\mathcal{D} \hookrightarrow \mathcal{D}^{\prime}\), where \(\mathcal{C}^{\prime}\) and \(\mathcal{D}^{\prime}\) are \(\infty\)-categories (Corollary 4.1.3.3). Since the fiber \(\{1\} \times \times_{\Delta^{1}} \mathcal{M}\) is an \(\infty\)-category, we can extend \(g\) to a functor \(g^{\prime}: \mathcal{D}^{\prime} \rightarrow\{1\} \times \Delta_{\Delta^{1}} \mathcal{M}\). Similarly, the composition \(\mathcal{C} \xrightarrow{F} \mathcal{D} \hookrightarrow \mathcal{D}^{\prime}\) extends to a functor of \(\infty\)-categories \(F^{\prime}: \mathcal{C}^{\prime} \rightarrow \mathcal{D}^{\prime}\). Using Exercise 3.1.7.11, we can factor \(F^{\prime}\) as a composition \(\mathcal{C}^{\prime} \xrightarrow{F^{\prime \prime}} \mathcal{D}^{\prime \prime} \xrightarrow{v} \mathcal{D}^{\prime}\), where \(F^{\prime \prime}\) is a monomorphism and \(v\) is a trivial Kan fibration. It follows from Lemma 1.5.7.5 that the inclusion map
\[
\left(\Delta^{1} \times \mathcal{C}\right) \coprod_{(\{1\} \times \mathcal{C})}\left(\{1\} \times \mathcal{C}^{\prime}\right) \hookrightarrow \Delta^{1} \times \mathcal{C}^{\prime}
\]
is inner anodyne, so that we can extend \(h\) to a functor \(h^{\prime}: \Delta^{1} \times \mathcal{C}^{\prime} \rightarrow \mathcal{M}\) satisfying \(\left.h^{\prime}\right|_{\{1\} \times \mathcal{C}^{\prime}}=g^{\prime} \circ F^{\prime}\). By virtue of Proposition 4.5.4.9. \(\sigma\) is a categorical pushout square if and only if the diagram \(\sigma\) :

is a categorical pushout square. We may therefore replace \(\mathcal{C}\) and \(\mathcal{D}\) by \(\mathcal{C}^{\prime}\) and \(\mathcal{D}^{\prime \prime}\), and thereby reduce to the case where \(\mathcal{C}\) and \(\mathcal{D}\) are \(\infty\)-categories and \(F\) is a monomorphism.

The assumption that \(F\) is a monomorphism guarantees that the natural map
\[
\iota:\left(\Delta^{1} \times \mathcal{C}\right) \coprod_{(\{1\} \times \mathcal{C})} \mathcal{D} \rightarrow \mathcal{C} \star_{\mathcal{D}} \mathcal{D}
\]
is also a monomorphism, and Proposition 5.2.4.5 guarantees that \(\iota\) is a categorical equivalence of simplicial sets. Since \(\mathcal{M}\) is an \(\infty\)-category, Lemma 4.5.5.2 guarantees the existence of a functor \(G: \mathcal{C}{\star_{\mathcal{D}}}^{\mathcal{D}} \rightarrow \mathcal{M}\) satisfying \(\left.G\right|_{\Delta^{1} \times \mathcal{C}}=h\) and \(\left.G\right|_{\mathcal{D}}=g\). By virtue of Proposition 4.5.4.9, the diagram \(\sigma\) is a categorical pushout square if and only if the functor \(G\) is an equivalence of \(\infty\)-categories.

Note that the functor \(G\) fits into a commutative diagram

where \(U^{\prime}\) is the cocartesian fibration of Proposition 5.2.3.15, and the functor \(U\) is an isofibration (Example 4.4.1.6). The desired result now follows by applying the criterion of Theorem 5.1.6.1 (and invoking Remark 5.1.6.8).

\subsection*{5.2.5 The Homotopy Transport Representation}

We now study the behavior of the transport functors of \(\$ 5.2 .2\) with respect to composition. 01VT
Proposition 5.2.5.1 (Transitivity). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial \(\qquad\) sets and let \(\sigma\) be a 2-simplex of \(\mathcal{C}\), which we display as a diagram

Let \(f_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) and \(g_{!}: \mathcal{E}_{D} \rightarrow \mathcal{E}_{E}\) be functors which are given by covariant transport along \(f\) and \(g\), respectively. Then the composite functor \(\left(g_{!} \circ f_{!}\right): \mathcal{E}_{C} \rightarrow \mathcal{E}_{E}\) is given by covariant transport along \(h\).

Proof. Without loss of generality, we may replace \(U\) by the projection map \(\Delta^{2} \times_{\mathcal{C}} \mathcal{E} \rightarrow \Delta^{2}\), and thereby reduce to the case where \(\mathcal{C}=\Delta^{2}\) and \(\sigma\) is the unique nondegenerate 2 -simplex of \(\mathcal{C}\). In this case, \(\mathcal{E}\) is an \(\infty\)-category. Let \(u: \operatorname{id}_{\mathcal{E}_{C}} \rightarrow f_{!}\)be a morphism in the \(\infty-\) category \(\operatorname{Fun}\left(\mathcal{E}_{C}, \mathcal{E}\right)\) which witnesses \(f_{\text {! }}\) as given by covariant transport along \(f\), and let \(v: \operatorname{id}_{\mathcal{E}_{D}} \rightarrow g\) ! be a morphism in the \(\infty\)-category \(\operatorname{Fun}\left(\mathcal{E}_{D}, \mathcal{E}\right)\) which witnesses \(g\) ! as given by covariant transport along \(g\). Let \(v^{\prime}: f!\rightarrow g!\circ f!\) denote the image of \(v\) under the functor \(\operatorname{Fun}\left(\mathcal{E}_{D}, \mathcal{E}\right) \rightarrow \operatorname{Fun}\left(\mathcal{E}_{C}, \mathcal{E}\right)\) given by precomposition with \(f_{!}\). Let \(w: \operatorname{id}_{\mathcal{E}_{C}} \rightarrow g_{!} \circ f_{!}\)
be a composition of \(u\) with \(v^{\prime}\) in the \(\infty\)-category \(\operatorname{Fun}\left(\mathcal{E}_{C}, \mathcal{E}\right)\). We will complete the proof by showing that \(w\) witnesses \(g!\circ f\) ! as given by covariant transport along \(h\). To prove this, we must show that for every object \(X \in \mathcal{E}_{C}\), the morphism \(w_{X}: X \rightarrow\left(g_{!} \circ f_{!}\right)(X)\) is \(U\)-cocartesian. This follows from Corollary 5.1.2.4 since \(w_{X}\) is a composition of the \(U\)-cocartesian morphisms \(u_{X}: X \rightarrow f_{!}(X)\) and \(v_{f_{!}(X)}: f_{!}(X) \rightarrow\left(g!\circ f_{!}\right)(X)\).

019U Construction 5.2.5.2 (The Homotopy Transport Representation: Covariant Case). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets and let hQCat denote the homotopy category of \(\infty\)-categories. It follows from Proposition 5.2.5.1 and Example 5.2.2.5 that there is a unique functor \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}: \mathrm{hC} \rightarrow \mathrm{hQCat}\) with the following properties:
- For each vertex \(C\) of the simplicial set \(\mathcal{C}, h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}(C)\) is the \(\infty\)-category \(\mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E}\) (regarded as an object of hQCat).
- For each edge \(f: C \rightarrow D\) of the simplicial set \(\mathcal{C}\) representing a morphism \([f] \in\) \(\operatorname{Hom}_{\mathrm{h} \mathcal{C}}(C, D)\), we have \(\operatorname{hTr}_{\mathcal{E} / \mathcal{C}}([f])=\left[f_{i}\right]\). Here \(\left[f_{!}\right]\)denotes the isomorphism class of the covariant transport functor of Notation 5.2.2.9, which we regarded as an element of the set
\[
\operatorname{Hom}_{\mathrm{hQCat}}\left(\mathcal{E}_{C}, \mathcal{E}_{D}\right)=\pi_{0}\left(\operatorname{Fun}\left(\mathcal{E}_{C}, \mathcal{E}_{D}\right)^{\simeq}\right) .
\]

We will refer to \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) as the homotopy transport representation of the cocartesian fibration \(U\).

0358 Example 5.2.5.3. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a left covering map of simplicial sets. Then the homotopy transport representation \(\mathrm{hTr}_{\mathcal{E} / \mathcal{C}}\) of Construction 5.2.5.2 coincides with the functor \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}: \mathrm{hC} \rightarrow\) Set of Proposition 5.2.0.3 (here we abuse notation by identifying the category of sets with the full subcategory of hKan spanned by the discrete simplicial sets).

01VY Remark 5.2.5.4. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets, and let \(\mathrm{hTr} \mathcal{E} / \mathcal{C}: \mathrm{hC} \rightarrow \mathrm{hQCat}\) be the homotopy transport representation of Construction 5.2.5.2. It follows from Proposition 5.1.4.14 that \(U\) is a left fibration if and only if the functor \(h \operatorname{Tr}_{\mathcal{E}} / \mathcal{C}\) factors through the full subcategory hKan \(\subseteq h\) hCat. In particular, if \(U\) is a left fibration, then Construction 5.2.5.2 determines a functor \(\mathrm{hC} \rightarrow \mathrm{hKan}\) which we will also refer to as the homotopy transport representation of the left fibration \(U\).

02RD Remark 5.2.5.5. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of \(\infty\)-categories, let \(f: C \rightarrow D\) be a morphism of \(\mathcal{C}\), and let \(f_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) be given by covariant transport along \(f\). If \(f\) is an isomorphism in the \(\infty\)-category \(\mathcal{C}\), then \(f_{!}\)is an equivalence of \(\infty\)-categories. This follows from the observation that the homotopy transport functor \(\mathrm{hTr}_{\mathcal{E} / \mathcal{C}}: \mathrm{hC} \rightarrow \mathrm{hQCat}\) carries isomorphisms to isomorphisms.

Remark 5.2.5.6 (Base Change). Suppose we are given a pullback diagram of simplicial sets 0359

where \(U\) and \(U^{\prime}\) are cocartesian fibrations. Then the homotopy transport representation \(\mathrm{h} \operatorname{Tr}_{\mathcal{E}^{\prime} / \mathcal{C}^{\prime}}\) is isomorphic to the composite functor
\[
\mathrm{hC}^{\prime} \rightarrow \mathrm{hC} \xrightarrow{\mathrm{~h} \operatorname{Tr}_{\mathcal{E}} / \mathcal{C}} \mathrm{hQCat} .
\]

Construction 5.2.5.2 has an analogue for cartesian fibrations:
Construction 5.2.5.7 (The Homotopy Transport Representation: Contravariant Case). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cartesian fibration of simplicial sets and let hQCat denote the homotopy 019 z category of \(\infty\)-categories (Construction 4.5.1.1). It follows from Proposition 5.2.5.1 and Example 5.2.2.5 that there is a unique functor \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}: \mathrm{h} \mathcal{C}^{\mathrm{op}} \rightarrow \mathrm{hQCat}\) satisfying the following conditions:
- For each vertex \(C\) of the simplicial set \(\mathcal{C}, \operatorname{hTr}_{\mathcal{E} / \mathcal{C}}(C)\) is the \(\infty\)-category \(\mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E}\) (regarded as an object of hQCat).
- For each edge \(f: C \rightarrow D\) of the simplicial set \(\mathcal{C}\) representing a morphism \([f] \in\) \(\operatorname{Hom}_{\mathrm{hC}}(C, D)\), we have \(\mathrm{h} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}([f])=\left[f^{*}\right]\), where \(\left[f^{*}\right]\) denotes the isomorphism class of the contravariant transport functor of Notation 5.2.2.17.

We will refer to \(\operatorname{hTr}_{\mathcal{E} / \mathcal{C}}\) as the homotopy transport representation of the cartesian fibration \(U\).

Warning 5.2.5.8. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a morphism of simplicial sets which is both a cartesian
01VZ fibration and a cocartesian fibration. Then Constructions 5.2.5.2 and 5.2.5.7 supply functors \(\mathrm{hC} \rightarrow \mathrm{hQCat}\) and \(\mathrm{hC}^{\mathrm{op}} \rightarrow \mathrm{hQCat}\) respectively, which are both referred to as the homotopy transport representation of \(U\) and both denoted by \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\). We will see later that these two functors are interchangeable data: either can be recovered from the other (see Proposition 6.2.3.5).

Example 5.2.5.9. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a morphism of simplicial sets. Combining Remark 01W0 5.2 .5 .4 with Theorem 5.2.2.19, we deduce that the following conditions are equivalent:
- The morphism \(U\) is a Kan fibration.
- The morphism \(U\) is a cocartesian fibration and the homotopy transport representation \(\mathrm{hTr}_{\mathcal{E} / \mathcal{C}}: \mathrm{hC} \rightarrow \mathrm{hQCat}\) of Construction 5.2 .5 .2 factors through the subcategory \(\mathrm{hKan}^{\simeq} \subseteq \mathrm{hQCat}\).
- The morphism \(U\) is a cartesian fibration and the homotopy transport representation \(\mathrm{h} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}^{\prime}: \mathrm{hC}{ }^{\mathrm{op}} \rightarrow \mathrm{hQCat}\) of Construction 5.2 .5 .7 factors through the subcategory \(\mathrm{hKan}^{\simeq} \subseteq \mathrm{hQCat}\).

If these conditions are satisfied, then \(\operatorname{Tr}_{\mathcal{E} / \mathcal{C}}^{\prime}\) is given by the composition
\[
\mathrm{hC}^{\mathrm{op}} \xrightarrow{\mathrm{hTr}_{\mathcal{E}}^{\mathrm{op}} / \mathcal{C}}\left(\mathrm{hKan}^{\simeq}\right)^{\mathrm{op}} \xrightarrow{\iota} \mathrm{hKan}^{\simeq},
\]
where \(\iota\) is the isomorphism which carries each morphism in hKan \(\simeq\) to its inverse.

\subsection*{5.2.6 Elements of Set-Valued Functors}

01 Q7 Throughout this section, we let Set denote the category of sets.
01Q8 Construction 5.2.6.1 (The Category of Elements). Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow\) Set be a functor. We define a category \(\int_{\mathcal{C}} \mathscr{F}\) as follows:
- The objects of \(\int_{\mathcal{C}} \mathscr{F}\) are pairs \((C, x)\), where \(C\) is an object of \(\mathcal{C}\) and \(x\) is an element of the set \(\mathscr{F}(C)\).
- If \((C, x)\) and \(\left(C^{\prime}, x^{\prime}\right)\) are objects of \(\int_{\mathcal{C}} \mathscr{F}\), then a morphism from \((C, x)\) to \(\left(C^{\prime}, x^{\prime}\right)\) in the category \(\int_{\mathcal{C}} \mathscr{F}\) is a morphism \(f: C \rightarrow C^{\prime}\) in the category \(\mathcal{C}\) for which the induced map \(\mathscr{F}(f): \mathscr{F}(C) \rightarrow \mathscr{F}\left(C^{\prime}\right)\) carries \(x\) to \(x^{\prime}\).
- Composition of morphisms in \(\int_{\mathcal{C}} \mathscr{F}\) is given by composition of morphisms in \(\mathcal{C}\).

We will refer to \(\int_{\mathcal{C}} \mathscr{F}\) as the category of elements of the functor \(\mathscr{F}\). Note that the construction \((C, x) \mapsto C\) determines a functor \(\int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\), which we will refer to as the forgetful functor.
01 Q 9 Variant 5.2.6.2. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C}^{\mathrm{op}} \rightarrow\) Set be a functor. We define a category \(\int^{\mathcal{C}} \mathscr{F}\) as follows:
- The objects of \(\int^{\mathcal{C}} \mathscr{F}\) are pairs \((C, x)\), where \(C\) is an object of \(\mathcal{C}\) and \(x\) is an element of the set \(\mathscr{F}(C)\).
- If \((C, x)\) and \(\left(C^{\prime}, x^{\prime}\right)\) are objects of \(\int^{\mathcal{C}} \mathscr{F}\), then a morphism from \((C, x)\) to \(\left(C^{\prime}, x^{\prime}\right)\) in the category \(\int^{\mathcal{C}} \mathscr{F}\) is a morphism \(f: C \rightarrow C^{\prime}\) in the category \(\mathcal{C}\) for which the induced map \(\mathscr{F}(f): \mathscr{F}\left(C^{\prime}\right) \rightarrow \mathscr{F}(C)\) carries \(x^{\prime}\) to \(x\).
- Composition of morphisms in \(\int^{\mathcal{C}} \mathscr{F}\) is given by composition of morphisms in \(\mathcal{C}\).

We will refer to \(\int^{\mathcal{C}} \mathscr{F}\) as the category of elements of the functor \(\mathscr{F}\). Note that the construction \((C, x) \mapsto C\) determines a functor \(U: \int^{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\), which we will refer to as the forgetful functor.
Remark 5.2.6.3. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow\) Set be a functor. Then we have a 01QA canonical isomorphism of categories
\[
\left(\int_{\mathcal{C}} \mathscr{F}\right)^{\mathrm{op}} \simeq\left(\int^{\mathcal{C}^{\mathrm{Op}}} \mathscr{F}\right)
\]
where \(\int_{\mathcal{C}} \mathscr{F}\) is the category of elements introduced in Construction 5.2.6.1 and \(\int^{\mathcal{C} \text { op }} \mathscr{F}\) is the category of elements introduced in Variant 5.2.6.2.
Example 5.2.6.4. Let \(X: \boldsymbol{\Delta}^{\mathrm{op}} \rightarrow\) Set be a simplicial set. Then \(\int^{\boldsymbol{\Delta}} X\) is the category of 01 QB simplices \(\boldsymbol{\Delta}_{X}\) introduced in Construction 1.1.3.9.
Example 5.2.6.5. Let \(\mathcal{C}\) be a category, let \(X\) be an object of \(\mathcal{C}\), and let \(h^{X}: \mathcal{C} \rightarrow\) Set denote 01QC the functor corepresented by \(X\) (given on objects by the formula \(h^{X}(Y)=\operatorname{Hom}_{\mathcal{C}}(X, Y)\) ). Then the category of elements \(\int_{\mathcal{C}} h^{X}\) can be identified with the coslice category \(\mathcal{C}_{X /}\) of Variant 4.3.1.4. Similarly, if \(h_{X}: \mathcal{C}^{\mathrm{op}} \rightarrow\) Set is the functor represented by \(X\) (given on objects by \(h_{X}(Y)=\operatorname{Hom}_{\mathcal{C}}(Y, X)\) ), then the category of elements \(\int^{\mathcal{C}} h_{X}\) can be identified with the slice category \(\mathcal{C}_{/ X}\).
Remark 5.2.6.6. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow\) Set be a functor. Then the category 01QD of elements \(\int_{\mathcal{C}} \mathscr{F}\) fits into a pullback diagram

Here \(\mathrm{Set}_{*}\) denotes the category of pointed sets (see Example 4.2.3.3).
Remark 5.2.6.7. Let \(\mathcal{C}\) be a small category, let \(\operatorname{Fun}\left(\mathcal{C}^{\text {op }}, S e t\right)\) be the category of set- 01QE valued functors on \(\mathcal{C}^{\text {op }}\), and let \(h: \mathcal{C} \rightarrow \operatorname{Fun}\left(\mathcal{C}^{\text {op }}\right.\), Set) be the Yoneda embedding (so that \(h\) carries each object \(C \in \mathcal{C}\) to the representable functor \(h_{C}=\operatorname{Hom}_{\mathcal{C}}(\bullet, C)\) ). For any object \(\mathscr{F} \in \operatorname{Fun}\left(\mathcal{C}^{\text {op }}\right.\), Set \()\), the category of elements \(\int^{\mathcal{C}} \mathscr{F}\) fits into a pullback diagram

This is essentially a reformulation of Yoneda's lemma (see Corollary 8.4.2.7 for an \(\infty\) categorical counterpart).

We now show that, up to isomorphism, every functor \(\mathscr{F}: \mathcal{C} \rightarrow\) Set can be recovered from the category of elements \(\int_{\mathcal{C}} \mathscr{F}\) (together with the forgetful functor \(\int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) ). Let Cat denote the category of (small) categories.
\(01 Q F\) Proposition 5.2.6.8. Let \(\mathcal{C}\) be a small category. Then:
- Construction 5.2.6.1 determines a fully faithful functor
\[
\operatorname{Fun}(\mathcal{C}, \text { Set }) \rightarrow \text { Cat } / \mathcal{C} \quad \mathscr{F} \mapsto \int_{\mathcal{C}} \mathscr{F} .
\]
- Variant 5.2.6.2 determines a fully faithful functor
\[
\operatorname{Fun}\left(\mathcal{C}^{\text {op }}, \text { Set }\right) \rightarrow \mathrm{Cat} / \mathcal{C} \quad \mathscr{F} \mapsto \int^{\mathcal{C}} \mathscr{F} .
\]

Proof. We will prove the first assertion; the second follows by a similar argument. Let \(\mathscr{F}\) and \(\mathscr{G}\) be functors from \(\mathcal{C}\) to the category of sets, and let \(T:\left(\int_{\mathcal{C}} \mathscr{F}\right) \rightarrow\left(\int_{\mathcal{C}} \mathscr{G}\right)\) be a functor for which the diagram

is strictly commutative, where the vertical maps are the forgetful functors. We wish to show that there is a unique natural transformation of functors
\[
f: \mathscr{F} \rightarrow \mathscr{G} \quad\left\{f_{C}: \mathscr{F}(C) \rightarrow \mathscr{G}(C)\right\}_{C \in \mathcal{C}}
\]
for which the functor \(T\) is given on objects by the construction \(T(C, x)=\left(C, f_{C}(x)\right)\). Note that this requirement uniquely determines the function \(f_{C}: \mathscr{F}(C) \rightarrow \mathscr{G}(C)\) for each object \(C \in \mathcal{C}\). We must show that the resulting collection \(\left\{f_{C}\right\}_{C \in \mathcal{C}}\) is a natural transformation: that is, for every morphism \(u: C \rightarrow D\) in the category \(\mathcal{C}\), the diagram of sets

is commutative. Fix an element \(x \in \mathscr{F}(C)\), so that \(u\) can be regarded as a morphism from \((C, x)\) to \((D, \mathscr{F}(u)(x))\) in the category \(\int_{\mathcal{C}} \mathscr{F}\). Applying the functor \(T\), we deduce that \(u\) can also be regarded as a morphism from \(\left(C, f_{C}(x)\right)\) to \(\left(D, f_{D}(\mathscr{F}(u)(x))\right)\) in the category \(\int_{\mathcal{C}} \mathscr{G}\). It follows that \(\mathscr{G}(u)\left(f_{C}(x)\right)=f_{D}(\mathscr{F}(u)(x))\), as desired.

Remark 5.2.6.9. Let \(\mathcal{C}\) be a category, let \(\mathscr{F}: \mathcal{C} \rightarrow\) Set be a functor, and let \(\int_{\mathcal{C}} \mathscr{F}\) denote 01QP the category of elements of \(\mathscr{F}\) (Construction 5.2.6.1). Then the forgetful functor \(\int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) is a left covering functor, in the sense of Definition 4.2.3.1. This follows from the pullback diagram

of Remark 5.2.6.6, together with Remark 4.2.3.6 and Example 4.2.3.3. We will see in \(\S 5.2 .7\) that the converse is also true: for every left covering functor \(U: \mathcal{E} \rightarrow \mathcal{C}\), there exists a functor \(\mathscr{F}: \mathcal{C} \rightarrow\) Set and isomorphism \(\mathcal{E} \simeq \int_{\mathcal{C}} \mathscr{F}\) which is compatible with the functor \(U\) (Corollary 5.2.7.5). By virtue of Proposition 5.2.6.8, the functor \(\mathscr{F}\) is unique up to canonical isomorphism.

\subsection*{5.2.7 Covering Space Theory}

Let \(S\) be a topological space. Every covering map \(f: X \rightarrow S\) determines a functor 01QG from the fundamental groupoid \(\pi_{\leq 1}(S)\) to the category of sets, given by the monodromy representation of Example 5.2.0.5. Under some mild assumptions on the topological space \(S\), the converse is also true: every functor \(\pi_{\leq 1}(S) \rightarrow\) Set can be obtained as the monodromy representation of an essentially unique covering map \(f: X \rightarrow S\). More precisely, we have the following:

Theorem 5.2.7.1 (The Fundamental Theorem of Covering Space Theory). Let \(S\) be a 027R topological space which is semilocally simply connected. Then the construction \(X \mapsto \mathrm{hTr}_{X / S}\) determines an equivalence of categories
\[
\{\text { Covering maps } f: X \rightarrow S\} \rightarrow \operatorname{Fun}\left(\pi_{\leq 1}(S), \text { Set }\right)
\]

The proof of Theorem 5.2.7.1 can be broken into two parts:
(a) If \(S\) is a topological space which is semilocally simply connected, then the construction
\(X \mapsto \operatorname{Sing}\). \((X)\) induces an equivalence of categories
\(\{\) Covering maps of topological spaces \(f: X \rightarrow S\}\)
\(\{\) Covering maps of simplicial sets \(\mathcal{E} \rightarrow\) Sing. \((S)\}\).
(b) For every Kan complex \(\mathcal{C}\), the formation of monodromy representations determines an equivalence of categories
\[
\{\text { Covering maps } \mathcal{E} \rightarrow \mathcal{C}\} \rightarrow \operatorname{Fun}\left(\pi_{\leq 1}(\mathcal{C}), \text { Set }\right) \quad \mathcal{E} \mapsto \mathrm{h} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}} .
\]

The proof of ( \(a\) ) requires some point-set topology; we defer a discussion to \(\S[?]\). Our goal in this section is to give a proof of (b) (see Corollary 5.2.7.6). We will deduce (b) from a more general statement, which classifies left coverings of an arbitrary simplicial set \(\mathcal{C}\) (Corollary 5.2.7.3).

027 V Proposition 5.2.7.2. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a left covering map of simplicial sets, and let \(\mathrm{h} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}: \mathrm{hC} \rightarrow\) Set be the homotopy transport representation of Proposition 5.2.0.3. Then there is a canonical isomorphism of simplicial sets
\[
\mathcal{E} \simeq \mathcal{C} \times_{\mathrm{N}_{\bullet}(\mathrm{hC})} \mathrm{N}_{\bullet}\left(\int_{\mathrm{h} \mathrm{\mathcal{C}}} \mathrm{~h} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\right) .
\]

Proof. Every vertex \(X \in \mathcal{E}\) can be regarded as an element of the set \(\operatorname{hTr}_{\mathcal{E} / \mathcal{C}}(U(X)\) ), and the construction \((X \in \mathcal{E}) \mapsto\left(\mathcal{E}_{U(X)}, X\right)\) determines a functor \(\widetilde{\mathrm{hTr}}_{\mathcal{E} / \mathcal{C}}: \mathrm{h} \mathrm{\mathcal{E}} \rightarrow \operatorname{Set}_{*}\). Let us identify \(\operatorname{hTr}_{\mathcal{E} / \mathcal{C}}\) with a morphism of simplicial sets from \(\mathcal{C}\) to \(\mathrm{N}_{\bullet}(\mathrm{Set})\) and \(\widetilde{\mathrm{hTr}}_{\mathcal{E} / \mathcal{C}}\) with a morphism of simplicial sets from \(\mathcal{E}\) to \(\mathrm{N}_{\bullet}\left(\operatorname{Set}_{*}\right)\), so that we have a commutative diagram of simplicial sets

which we can identify with a morphism of simplicial sets \(V: \mathcal{E} \rightarrow \mathcal{C} \times{ }_{\mathrm{N}_{\bullet}(\mathrm{hC})} \mathrm{N}_{\bullet}\left(\int_{\mathrm{h} \mathrm{\mathcal{C}}} \mathrm{hTr}_{\mathcal{E} / \mathcal{C}}\right)\). Since \(U\) and the projection map \(\int_{\mathcal{C}} \mathrm{h}^{\mathcal{E} / \mathcal{C}} \rightarrow \mathrm{h} \mathcal{C}\) are both left covering maps (Remark 5.2 .6 .9 ), it follows that \(V\) is a left covering map (Remark 4.2.3.14). By construction, \(V\) is bijective at the level of vertices, and is therefore an isomorphism of simplicial sets (Proposition 4.2.3.19.

Corollary 5.2.7.3. Let \(\mathcal{C}\) be a simplicial set, and let \(\mathrm{LCov}(\mathcal{C})\) denote the full subcategory 027 W of \(\left(\operatorname{Set}_{\Delta}\right)_{/ \mathcal{C}}\) spanned by the left covering maps \(U: \mathcal{E} \rightarrow \mathcal{C}\). Then the formation of homotopy transport representations supplies an equivalence of categories
\[
\operatorname{LCov}(\mathcal{C}) \rightarrow \operatorname{Fun}(\mathrm{hC}, \text { Set }) \quad(U: \mathcal{E} \rightarrow \mathcal{C}) \mapsto \operatorname{hTr}_{\mathcal{E} / \mathcal{C}}
\]

Proof. Proposition 5.2.7.2 shows that the functor
\[
(\mathscr{F} \in \operatorname{Fun}(\mathrm{hC}, \operatorname{Set})) \mapsto \mathcal{C} \times_{\mathrm{N} \bullet(\mathrm{hC})} \mathrm{N}_{\bullet}\left(\int_{\mathrm{hC}} \mathscr{F}\right) \in \operatorname{LCov}(\mathcal{C})
\]
is a left homotopy inverse to the functor \(\mathcal{E} \mapsto \mathrm{hTr}_{\mathcal{E} / \mathcal{C}}\). By virtue of Example 5.2.0.6 and Remark 5.2.5.6, it is also a right homotopy inverse.

Corollary 5.2.7.4. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a morphism of simplicial sets. The following conditions 027 X are equivalent:
(1) There exists a pullback diagram of simplicial sets

where \(V: \mathcal{D} \rightarrow \mathrm{hC}\) is a left covering functor (in the sense of Definition 4.2.3.1).
(2) For every category \(\mathcal{C}^{\prime}\) and every morphism of simplicial sets \(\mathrm{N}_{\bullet}\left(\mathcal{C}^{\prime}\right) \rightarrow \mathcal{C}\), the fiber product \(\mathrm{N}_{\bullet}\left(\mathcal{C}^{\prime}\right) \times_{\mathcal{C}} \mathcal{E}\) is isomorphic to the nerve of a category \(\mathcal{E}^{\prime}\) and the projection \(\mathcal{E}^{\prime} \rightarrow \mathcal{C}^{\prime}\) is left covering functor (in the sense of Definition 4.2.3.1).
(3) For every \(n\)-simplex \(\sigma: \Delta^{n} \rightarrow \mathcal{C}\), the fiber product \(\Delta^{n} \times_{\mathcal{C}} \mathcal{E}\) is isomorphic to the nerve of a category \(\mathcal{E}^{\prime}\) and the projection \(\mathcal{E}^{\prime} \rightarrow[n]\) is a left covering functor (in the sense of Definition 4.2.3.1.
(4) The morphism \(U\) is a left covering map of simplicial sets (in the sense of Definition 4.2.3.8.

Proof. The implication \((1) \Rightarrow(2)\) follows from Remark 4.2.3.6, the implication \((2) \Rightarrow(3)\) is trivial, and the implication \((3) \Rightarrow(4)\) follows by combining Remark 4.2.3.15 with Proposition 4.2.3.16. The implication \((4) \Rightarrow(1)\) follows from Proposition 5.2.7.2.

Corollary 5.2.7.5. Let \(\mathcal{C}\) be a category. Then:
- Construction 5.2.6.1 determines a fully faithful functor
\[
\operatorname{Fun}(\mathcal{C}, \text { Set }) \rightarrow \mathrm{Cat}_{/ \mathcal{C}} \quad \mathscr{F} \mapsto \int_{\mathcal{C}} \mathscr{F},
\]
whose essential image consists of the left covering functors \(U: \mathcal{E} \rightarrow \mathcal{C}\).
- Variant 5.2.6.2 determines a fully faithful functor
\[
\operatorname{Fun}\left(\mathcal{C}^{\text {op }}, \text { Set }\right) \rightarrow \mathrm{Cat}_{/ \mathcal{C}} \quad \mathscr{F} \mapsto \int^{\mathcal{C}} \mathscr{F},
\]
whose essential image consists of the right covering functors \(U: \mathcal{E} \rightarrow \mathcal{C}\).
\(027 Z\) Corollary 5.2.7.6. Let \(\mathcal{C}\) be a Kan complex. Then the construction \((U: \mathcal{E} \rightarrow \mathcal{C}) \mapsto h \operatorname{Tr}_{\mathcal{E}} / \mathcal{C}\) induces an equivalence of categories
\[
\{\text { Covering maps } \mathcal{E} \rightarrow \mathcal{C}\} \rightarrow \operatorname{Fun}\left(\pi_{\leq 1}(\mathcal{C}), \text { Set }\right)
\]

Proof. Combine Corollaries 5.2.7.3 and 4.4.3.9.

\subsection*{5.2.8 Parametrized Covariant Transport}

02RL Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of \(\infty\)-categories. To every morphism \(f: C \rightarrow D\) in the \(\infty\)-category \(\mathcal{C}\), Definition 5.2.2.4 associates a covariant transport functor \(f_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\), which is uniquely determined up to isomorphism (see Proposition 5.2.2.8). Our goal in this section is to show that the functor \(f_{!}\)can be chosen to depend functorially on the morphism \(f\) : that is, the construction \(f \mapsto f_{!}\)can be promoted to a functor from the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(C, D)\) to the \(\infty\)-category \(\operatorname{Fun}\left(\mathcal{E}_{C}, \mathcal{E}_{D}\right)\). We begin by introducing a more elaborate version of Definition 5.2.2.4.
02RM Definition 5.2.8.1 (Parametrized Covariant Transport). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets and let \(C\) and \(D\) be vertices of \(\mathcal{C}\). We will say that a morphism \(F: \operatorname{Hom}_{\mathcal{C}}(C, D) \times \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) is given by parametrized covariant transport if there exists a morphism of simplicial sets \(\widetilde{F}: \Delta^{1} \times \operatorname{Hom}_{\mathcal{C}}(C, D) \times \mathcal{E}_{C} \rightarrow \mathcal{E}\) satisfying the following conditions:
(1) The diagram of simplicial sets

commutes (where the lower horizontal map is induced by the inclusion \(\operatorname{Hom}_{\mathcal{C}}(C, D) \hookrightarrow\) \(\left.\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)\right)\).
(2) The restriction \(\left.\widetilde{F}\right|_{\{0\} \times \operatorname{Hom}_{\mathcal{C}}(C, D) \times \mathcal{E}_{C}}\) is given by projection onto \(\mathcal{E}_{C}\), and the restriction \(\left.\widetilde{F}\right|_{\{1\} \times \operatorname{Hom}_{\mathcal{C}}(C, D) \times \mathcal{E}_{C}}\) is equal to \(F\).
(3) For every edge \(f: C \rightarrow D\) of \(\mathcal{C}\) and every object \(X \in \mathcal{E}_{C}\), the composite map
\[
\Delta^{1} \times\{f\} \times\{X\} \hookrightarrow \Delta^{1} \times \operatorname{Hom}_{\mathcal{C}}(C, D) \times \mathcal{E}_{C} \xrightarrow{\widetilde{F}} \mathcal{E}
\]
is a \(U\)-cocartesian edge of \(\mathcal{E}\).
If these conditions are satisfied, we say that the morphism \(\widetilde{F}\) witnesses \(F\) as given by parametrized covariant transport.

Remark 5.2.8.2. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets, let \(C\) and \(D\) be vertices of \(\mathcal{C}\), and let \(F: \operatorname{Hom}_{\mathcal{C}}(C, D) \times \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) be given by parametrized covariant transport. Then, for every edge \(f: C \rightarrow D\), the composite map
\[
\{f\} \times \mathcal{E}_{C} \hookrightarrow \operatorname{Hom}_{\mathcal{C}}(C, D) \times \mathcal{E}_{C} \xrightarrow{F} \mathcal{E}_{D}
\]
is given by covariant transport along \(f\), in the sense of Definition 5.2.2.4. In other words, we can identify \(F\) with a diagram \(\operatorname{Hom}_{\mathcal{C}}(C, D) \rightarrow \operatorname{Fun}\left(\mathcal{E}_{C}, \mathcal{E}_{D}\right)\), which carries each edge \(f \in \operatorname{Hom}_{\mathcal{C}}(C, D)\) to the covariant transport functor \(f_{!}\)of Notation 5.2.2.9.

Example 5.2.8.3. Let \(\mathrm{Set}_{*}\) denote the category of pointed sets (Example 4.2.3.3, and 02RP let \(V:\) Set \(_{*} \rightarrow\) Set denote the forgetful functor \((X, x) \mapsto X\). Then the induced map \(\mathrm{N}_{\bullet}(V): \mathrm{N}_{\bullet}\left(\operatorname{Set}_{*}\right) \rightarrow \mathrm{N}_{\bullet}(\) Set \()\) is a cocartesian fibration (in fact, it is a left covering map), whose fiber over an object \(X \in \mathrm{~N}_{\bullet}\).(Set) can be identified with the set \(X\). For every pair of sets \(X\) and \(Y\), the evaluation map
\[
\text { ev : } \operatorname{Hom}_{\mathrm{Set}}(X, Y) \times X \rightarrow Y \quad(f, x) \mapsto f(x)
\]
is given by parametrized covariant transport (in the sense of Definition 5.2.8.1).
Proposition 5.2.8.4. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets, and let \(C\) 02RQ and \(D\) be vertices of \(\mathcal{C}\). Then:
- There exists a morphism \(F: \operatorname{Hom}_{\mathcal{C}}(C, D) \times \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) which is given by parametrized covariant transport.
- An arbitrary diagram \(F^{\prime}: \operatorname{Hom}_{\mathcal{C}}(C, D) \times \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) is given by parametrized covariant transport if and only if it is isomorphic to \(F\) (as an object of the \(\infty\)-category \(\left.\operatorname{Fun}\left(\operatorname{Hom}_{\mathcal{C}}(C, D) \times \mathcal{E}_{C}, \mathcal{E}_{D}\right)\right)\).

Proof. Apply Lemma 5.2 .2 .13 to the simplicial set \(K=\operatorname{Hom}_{\mathcal{C}}(C, D) \times \mathcal{E}_{C}\).

02RR Remark 5.2.8.5 (Functoriality). Suppose we are given a commutative diagram of simplicial sets

where \(U\) and \(U^{\prime}\) are cocartesian fibrations. Let \(C\) and \(D\) be vertices of \(\mathcal{C}\) having images \(C^{\prime}=\bar{G}(C)\) and \(D^{\prime}=\bar{G}(D)\), respectively, so that \(G\) induces functors \(G_{C}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{C^{\prime}}^{\prime}\) and \(G_{D}: \mathcal{E}_{D} \rightarrow \mathcal{E}_{D^{\prime}}^{\prime}\). Let \(\varphi: \operatorname{Hom}_{\mathcal{C}}(C, D) \rightarrow \operatorname{Hom}_{\mathcal{C}^{\prime}}\left(C^{\prime}, D^{\prime}\right)\) be the morphism induced by \(\bar{G}\), and let
\[
F: \operatorname{Hom}_{\mathcal{C}}(C, D) \times \mathcal{E}_{C} \rightarrow \mathcal{E}_{D} \quad F^{\prime}: \operatorname{Hom}_{\mathcal{C}^{\prime}}\left(C^{\prime}, D^{\prime}\right) \times \mathcal{E}_{C^{\prime}}^{\prime} \rightarrow \mathcal{E}_{D^{\prime}}^{\prime}
\]
be given by parametrized covariant transport with respect to \(U\) and \(U^{\prime}\). Suppose that the morphism \(G\) carries \(U\)-cocartesian edges of \(\mathcal{E}\) to \(U^{\prime}\)-cocartesian edges of \(\mathcal{E}^{\prime}\). Then the diagram

commutes up to isomorphism: that is, \(G_{D} \circ F\) and \(F^{\prime} \circ\left(\varphi \times G_{C}\right)\) are isomorphic as objects of the \(\infty\)-category \(\operatorname{Fun}\left(\operatorname{Hom}_{\mathcal{C}}(C, D) \times \mathcal{E}_{C}, \mathcal{E}_{D^{\prime}}^{\prime}\right)\). This follows by applying the uniqueness assertion of Lemma 5.2.2.13 to the lifting problem

02RS Variant 5.2.8.6 (Parametrized Contravariant Transport). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cartesian fibration of simplicial sets and let \(C\) and \(D\) be vertices of \(\mathcal{C}\). Applying Proposition 5.2.8.4 to the opposite cocartesian fibration \(U^{\mathrm{op}}: \mathcal{E}^{\mathrm{op}} \rightarrow \mathcal{C}^{\mathrm{op}}\), we obtain a diagram \(\operatorname{Hom}_{\mathcal{C}}(C, D) \rightarrow\) \(\operatorname{Fun}\left(\mathcal{E}_{D}, \mathcal{E}_{C}\right)\), carrying each edge \(f: C \rightarrow D\) to a functor \(f^{*}: \mathcal{E}_{D} \rightarrow \mathcal{E}_{C}\) given by contravariant transport along \(f\).

Let \(\mathcal{C}\) be an \(\infty\)-category. Recall that, for every pair of objects \(X, Y \in \mathcal{C}\), the morphism space \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) can be identified with the fiber over \(Y\) of the left fibration \(\{X\} \tilde{x}_{\mathcal{C}} \mathcal{C} \rightarrow \mathcal{C}\) of Proposition 4.6.4.11, or with the fiber over \(X\) of the right fibration \(\mathcal{C} \tilde{x}_{\mathcal{C}}\{Y\}\). In either case, parametrized transport recovers the composition law of \(\mathcal{C}\) :
Proposition 5.2.8.7. Let \(\mathcal{C}\) be an \(\infty\)-category containing objects \(C\), \(D\), and \(E\). Then the 02GT composition law
\[
\circ: \operatorname{Hom}_{\mathcal{C}}(D, E) \times \operatorname{Hom}_{\mathcal{C}}(C, D) \rightarrow \operatorname{Hom}_{\mathcal{C}}(C, E)
\]
of Construction 4.6.9.9 is given by parametrized covariant transport for the left fibration \(U:\{C\} \tilde{x}_{\mathcal{C}} \mathcal{C} \rightarrow \mathcal{C}\) (in the sense of Definition 5.2.8.1), and also by parametrized contravariant transport for the right fibration \(V: \mathcal{C} \tilde{x}_{\mathcal{C}}\{E\} \rightarrow \mathcal{C}\).

Proof. We will prove the first assertion; the second follows by a similar argument. Let \(S: \Delta^{1} \times \Delta^{1} \rightarrow \Delta^{2}\) be the morphism given on vertices by the formula \(T(i, j)=i(j+1)\), and let \(T\) be a section of the trivial Kan fibration \(\operatorname{Hom}_{\mathcal{C}}(C, D, E) \rightarrow \operatorname{Hom}_{\mathcal{C}}(D, E) \times \operatorname{Hom}_{\mathcal{C}}(C, D)\) (see Corollary 4.6.9.5). Then the composite map
\[
\Delta^{1} \times \Delta^{1} \times \operatorname{Hom}_{\mathcal{C}}(D, E) \times \operatorname{Hom}_{\mathcal{C}}(C, D) \xrightarrow{S \times T} \Delta^{2} \times \operatorname{Hom}_{\mathcal{C}}(C, D, E) \rightarrow \mathcal{C}
\]
carries \(\{0\} \times \Delta^{1} \times \operatorname{Hom}_{\mathcal{C}}(D, E) \times \operatorname{Hom}_{\mathcal{C}}(C, D)\) to the vertex \(C\), and can therefore be identified with a functor
\[
\tilde{F}: \Delta^{1} \times \operatorname{Hom}_{\mathcal{C}}(D, E) \times \operatorname{Hom}_{\mathcal{C}}(C, D) \rightarrow\{C\} \tilde{x}_{\mathcal{C}} \mathcal{C}
\]
which exhibits the composition law as given by parametrized covariant transport for the left fibration \(U\).

Proposition 5.2.5.1 has a counterpart for parametrized covariant transport:
Proposition 5.2.8.8. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of \(\infty\)-categories. Let \(C, D\), 02GU and \(E\) be objects of \(\mathcal{C}\), and let
\[
\begin{aligned}
F: \operatorname{Hom}_{\mathcal{C}}(C, D) \times \mathcal{E}_{C} \rightarrow \mathcal{E}_{D} \quad G: \operatorname{Hom}_{\mathcal{C}}(D, E) \times \mathcal{E}_{D} \rightarrow \mathcal{E}_{E} \\
H: \operatorname{Hom}_{\mathcal{C}}(C, E) \times \mathcal{E}_{C} \rightarrow \mathcal{E}_{E}
\end{aligned}
\]
be given by parametrized covariant transport. Then the diagram

commutes in the homotopy category hQCat; here the left vertical map is given by the composition law of Construction 4.6.9.9.

Proof. Let \(\operatorname{Hom}_{\mathcal{C}}(C, D, E)\) be the Kan complex defined in Notation 4.6.9.1. let \(H^{\prime}\) denote the composite map
\[
\operatorname{Hom}_{\mathcal{C}}(C, D, E) \times \mathcal{E}_{C} \rightarrow \operatorname{Hom}_{\mathcal{C}}(C, E) \times \mathcal{E}_{C} \xrightarrow{H} \mathcal{E}_{E},
\]
and let \(H^{\prime \prime}\) denote the composition
\[
\begin{aligned}
\operatorname{Hom}_{\mathcal{C}}(C, D, E) \times \mathcal{E}_{C} & \rightarrow \\
& \xrightarrow{\rightarrow} \\
& \operatorname{Hom}_{\mathcal{C}}(D, E) \times \operatorname{Hom}_{\mathcal{C}}(D, E) \times \mathcal{E}_{D} \\
& \xrightarrow{G} \mathcal{E}_{E} .
\end{aligned}
\]

We will show that \(H^{\prime}\) and \(H^{\prime \prime}\) are isomorphic when regarded as objects of the \(\infty\)-category \(\operatorname{Fun}\left(\operatorname{Hom}_{\mathcal{C}}(C, D, E) \times \mathcal{E}_{C}, \mathcal{E}_{E}\right)\). The homotopy commutativity of the diagram (5.14) will then follow by precomposing with any section of the trivial Kan fibration \(\operatorname{Hom}_{\mathcal{C}}(C, D, E) \rightarrow\) \(\operatorname{Hom}_{\mathcal{C}}(D, E) \times \operatorname{Hom}_{\mathcal{C}}(C, D)\).

Choose morphisms
\[
\begin{aligned}
& \widetilde{F}: \mathrm{N}_{\bullet}(\{0<1\}) \times \operatorname{Hom}_{\mathcal{C}}(C, D) \times \mathcal{E}_{C} \rightarrow \mathcal{E} \\
& \widetilde{G}: \mathrm{N}_{\bullet}(\{1<2\}) \times \operatorname{Hom}_{\mathcal{C}}(D, E) \times \mathcal{E}_{D} \rightarrow \mathcal{E} \\
& \widetilde{H}: \mathrm{N}_{\bullet}(\{0<2\}) \times \operatorname{Hom}_{\mathcal{C}}(C, E) \times \mathcal{E}_{C} \rightarrow \mathcal{E}
\end{aligned}
\]
which witness \(F, G\), and \(H\) as given by parametrized covariant transport, respectively. Composing with the projection maps
\[
\operatorname{Hom}_{\mathcal{C}}(C, D) \leftarrow \operatorname{Hom}_{\mathcal{C}}(C, D, E) \rightarrow \operatorname{Hom}_{\mathcal{C}}(C, E)
\]
we obtain morphisms
\[
\begin{gathered}
\widetilde{F}^{\prime}: \mathrm{N}_{\bullet}(\{0<1\}) \times \operatorname{Hom}_{\mathcal{C}}(C, D, E) \times \mathcal{E}_{C} \rightarrow \mathcal{E} \\
\widetilde{H}^{\prime}: \mathrm{N}_{\bullet}(\{0<2\}) \times \operatorname{Hom}_{\mathcal{C}}(C, D, E) \times \mathcal{E}_{C} \rightarrow \mathcal{E}
\end{gathered}
\]

Let \(\widetilde{G}^{\prime}\) denote the composite map
\[
\begin{aligned}
& \mathrm{N}_{\bullet}(\{1<2\}) \times \operatorname{Hom}_{\mathcal{C}}(C, D, E) \times \mathcal{E}_{C} \rightarrow \\
& \mathrm{~N}_{\bullet}(\{1<2\}) \times \operatorname{Hom}_{\mathcal{C}}(D, E) \times \operatorname{Hom}_{\mathcal{C}}(C, D) \times \mathcal{E}_{C} \\
& \xrightarrow{F} \mathrm{~N}_{\bullet}(\{1<2\}) \times \operatorname{Hom}_{\mathcal{C}}(D, E) \times \mathcal{E}_{D} \\
& \xrightarrow{\widetilde{G}} \\
& \mathcal{E} .
\end{aligned}
\]

Since \(U\) is an inner fibration, the lifting problem

admits a solution \(\Phi: \Delta^{2} \times \operatorname{Hom}_{\mathcal{C}}(C, D, E) \times \mathcal{E}_{C} \rightarrow \mathcal{E}\). Let \(\widetilde{H}^{\prime \prime}\) denote the restriction of \(\Phi\) to the product \(\mathrm{N}_{\bullet}(\{0,2\}) \times \operatorname{Hom}_{\mathcal{C}}(C, D, E) \times \mathcal{E}_{C}\). Using Proposition 5.1.4.12, we see that \(\widetilde{H}^{\prime \prime}\) is a \(U\) cocartesian lift of \(U \circ \widetilde{H}^{\prime \prime}=U \circ \widetilde{H}^{\prime}\), in the sense of Definition 5.2.2.10. Applying the uniqueness assertion of Lemma 5.2.2.13, we conclude that the restrictions \(H^{\prime}=\left.\widetilde{H}^{\prime}\right|_{\{2\} \times \operatorname{Hom}_{\mathcal{C}}(C, D, E) \times \mathcal{E}_{C}}\) and \(H^{\prime \prime}=\left.\widetilde{H}^{\prime \prime}\right|_{\{2\} \times \operatorname{Hom}_{\mathcal{C}}(C, D, E) \times \mathcal{E}_{C}}\) are isomorphic when regarded as objects of the \(\infty\)-category \(\operatorname{Fun}\left(\operatorname{Hom}_{\mathcal{C}}(C, D, E) \times \mathcal{E}_{C}, \mathcal{E}_{E}\right)\), as desired.

Using Proposition 5.2.8.8, we obtain the following refinement of Construction 5.2.5.2
Construction 5.2.8.9 (Enriched Homotopy Transport: Covariant Case). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of \(\infty\)-categories and let us regard the homotopy category hC as enriched over the homotopy category hKan of Kan complexes (Construction 4.6.9.13). It follows from Proposition 5.2.8.8 (and Example 5.2.2.5 that there is a unique hKan-enriched functor \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}: \mathrm{hC} \rightarrow \mathrm{hQCat}\) with the following properties:
- For each object \(C\) of the \(\infty\)-category \(\mathcal{C}, \operatorname{hTr}_{\mathcal{E} / \mathcal{C}}(C)\) is the \(\infty\)-category \(\mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E}\) (regarded as an object of hQCat).
- For every pair of objects \(C, D \in \mathcal{C}\), the induced map
\[
\operatorname{hTr}_{\mathcal{E} / \mathcal{C}}: \operatorname{Hom}_{\mathcal{C}}(C, D) \rightarrow \operatorname{Fun}\left(\mathcal{E}_{C}, \mathcal{E}_{D}\right)^{\simeq}
\]
in hKan corresponds to the parametrized covariant transport functor \(\operatorname{Hom}_{\mathcal{C}}(C, D) \times\) \(\mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) of supplied by Proposition 5.2.8.4 (which is well-defined up to isomorphism).

We will refer to \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) as the enriched homotopy transport representation of the cocartesian fibration \(U\). Note that the underlying functor of ordinary categories \(\mathrm{hC} \rightarrow \mathrm{hQCat}\) coincides with homotopy transport representation of Construction 5.2.5.2.

Remark 5.2.8.10 (Functoriality). Suppose we are given a commutative diagram of \(\infty\) - 02RU
categories
02RV

where \(U\) and \(U^{\prime}\) are cocartesian fibrations and the functor \(G\) carries \(U\)-cocartesian morphisms of \(\mathcal{E}\) to \(U^{\prime}\)-cocartesian morphisms of \(\mathcal{E}^{\prime}\). For each object \(C \in \mathcal{C}\) having image \(C^{\prime}=\bar{G}(C), G\) restricts to a functor \(G_{C}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{C^{\prime}}^{\prime}\). It follows from Remark 5.2.8.5 that the construction \(C \mapsto G_{C}\) determines a natural transformation of hKan-enriched functors \(\alpha: \mathrm{h} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}} \rightarrow\) \(\mathrm{h} \operatorname{Tr}_{\mathcal{E}^{\prime} / \mathcal{C}^{\prime}}\) oh \(\bar{G}\) from hC to hQCat. Moreover, if (5.15) is a pullback square, then \(\alpha\) is an isomorphism of hKan-enriched functors.

02RW Variant 5.2.8.11 (Enriched Homotopy Transport: Left Fibrations). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a left fibration of \(\infty\)-categories. Applying Construction 5.2.8.9, we obtain an hKan-enriched functor
\[
\mathrm{h} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}: \mathrm{hC} \rightarrow \mathrm{hKan},
\]
given on objects by the formula \(\operatorname{hTr}_{\mathcal{E} / \mathcal{C}}(C)=\{C\} \times_{\mathcal{C}} \mathcal{E}\).
02GX Variant 5.2.8.12 (Enriched Homotopy Transport: Contravariant Case). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cartesian fibration of \(\infty\)-categories. Applying Construction 5.2.8.9 to the opposite functor \(U^{\mathrm{op}}\), we deduce that there is a unique hKan -enriched functor \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}: \mathrm{h} \mathcal{C}^{\mathrm{op}} \rightarrow \mathrm{hQCat}\) with the following properties:
- For each object \(C\) of the \(\infty\)-category \(\mathcal{C}, \operatorname{hTr}_{\mathcal{E} / \mathcal{C}}(C)\) is the \(\infty\)-category \(\mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E}\) (regarded as an object of hQCat).
- For every pair of objects \(C, D \in \mathcal{C}\), the induced map
\[
\operatorname{hTr}_{\mathcal{E} / \mathcal{C}}: \operatorname{Hom}_{\mathcal{C}}(C, D) \rightarrow \operatorname{Fun}\left(\mathcal{E}_{D}, \mathcal{E}_{C}\right)^{\simeq}
\]
is given by the parametrized contravariant transport functor \(\mathcal{E}_{D} \times \operatorname{Hom}_{\mathcal{C}}(C, D) \rightarrow \mathcal{E}_{C}\) of Variant 5.2.8.6

We will refer to \(\mathrm{h} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) as the enriched homotopy transport representation of the cartesian fibration \(U\). If \(U\) is a right fibration, then \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) takes values in the full subcategory hKan \(\subseteq\) hQCat.

02GY Example 5.2.8.13. Let \(\mathcal{C}\) be an \(\infty\)-category and let hC denote its homotopy category, which we regard as enriched over the homotopy category hKan of Kan complexes. Applying Proposition 5.2.8.7, we obtain the following:
- For every object \(C \in \mathcal{C}\), the corepresentable hKan-enriched functor
\[
\mathrm{hC} \rightarrow \text { hKan } \quad D \mapsto \operatorname{Hom}_{\mathcal{C}}(C, D)
\]
is the enriched homotopy transport representation for the left fibration \(\{C\} \tilde{x}_{\mathcal{C}} \mathcal{C} \rightarrow \mathcal{C}\).
- For every object \(D \in \mathcal{C}\), the representable hKan-enriched functor
\[
\mathrm{hC}^{\mathrm{op}} \rightarrow \mathrm{hKan} \quad C \mapsto \operatorname{Hom}_{\mathcal{C}}(C, D)
\]
is the enriched homotopy transport representation for the right fibration \(\mathcal{C} \tilde{x}_{\mathcal{C}}\{D\} \rightarrow \mathcal{C}\).

\subsection*{5.3 Fibrations over Ordinary Categories}

Let \(\operatorname{Set}_{\Delta}\) denote the category of simplicial sets, let QCat \(\subset \operatorname{Set}_{\Delta}\) denote the full subcate-
gory spanned by the \(\infty\)-categories, and let hQCat denote its homotopy category (Construction 4.5.1.1. In \(\S 5.2 .5\) we associated to every cocartesian fibration of simplicial sets \(U: \mathcal{E} \rightarrow S\) a functor \(\mathrm{h}^{\operatorname{T}} \mathrm{E}_{/ S}: \mathrm{h} S \rightarrow \mathrm{hQCat}\) called the homotopy transport representation of \(U\), given on objects by the formula \(h \operatorname{Tr}_{\mathcal{E} / S}(s)=\{s\} \times_{S} \mathcal{E}(\) Construction 5.2.5.2. In \(\$ 5.3 .1\) we specialize to the situation where \(S=\mathrm{N}_{\bullet}(\mathcal{C})\) is the nerve of an ordinary category \(\mathcal{C}\). In this case, we show that \(\operatorname{hTr}_{\mathcal{E} / \mathrm{N}_{\mathbf{\bullet}}(\mathcal{C})}\) can be lifted to a functor taking values in the category QCat. More precisely, we introduce a functor \(\operatorname{sir}_{\mathcal{E} / \mathcal{C}}: \mathcal{C} \rightarrow \mathrm{QCat}\) which we refer to as the strict transport representation of \(U\) (Construction 5.3.1.5), and show that the diagram

commutes up to canonical isomorphism (Corollary 5.3.1.8).
Our primary goal in this section is to show that a cocartesian fibration \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) can be recovered, up to equivalence, from its strict transport representation \(\mathrm{sTr} \operatorname{Tr}_{\mathcal{E}}\). To formulate this precisely, we need another construction. In \(\$ 5.3 .3\), we associate to every diagram \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) a simplicial set \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\), which we will refer to as the \(\mathscr{F}\)-weighted nerve of \(\mathcal{C}\) (Definition 5.3.3.1). The weighted nerve is equipped with a projection map \(V: \mathrm{N}_{\bullet}^{\mathscr{\mathscr { }}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\), whose fiber over an object \(C \in \mathcal{C}\) can be identified with the simplicial set \(\mathscr{F}(C)\) (Example 5.3.3.8). If each of these simplicial sets is an \(\infty\)-category, then \(V\) is a cocartesian fibration of \(\infty\)-categories (Corollary 5.3.3.16). Our main results can be summarized as follows:
(1) Let \(\mathscr{F}: \mathcal{C} \rightarrow\) QCat be a diagram of \(\infty\)-categories having weighted nerve \(\mathcal{E}=\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\). Then there is a natural transformation from \(\mathscr{F}\) to the strict transport representation \(\operatorname{sir}_{\mathcal{E} / \mathcal{C}}\), which carries each object \(C \in \mathcal{C}\) to an equivalence of \(\infty\)-categories \(\mathscr{F}(C) \rightarrow\) \(\operatorname{sTr}_{\mathcal{E} / \mathcal{C}}(C)\) (Corollary 5.3.4.19).
(2) Let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a cocartesian fibration of \(\infty\)-categories having strict transport representation \(\mathscr{F}=\operatorname{sTr}_{\mathcal{E} / \mathcal{C}}\). Then \(U\) is equivalent (in the sense of Definition 5.1.7.1) to the cocartesian fibration \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) (Theorem 5.3.5.6).

The proof of (1) is relatively straightforward. However, the proof of (2) is somewhat more difficult: given a cocartesian fibration \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) there is no obvious comparison map between the simplicial sets \(\mathcal{E}\) and \(\mathrm{N}_{\bullet}^{\mathrm{sTr}} / \mathcal{C}(\mathcal{C})\). To relate them, we need an auxiliary construction. In \(\S 5.3 .2\), we associate to every diagram \(\mathscr{F}: \mathcal{C} \rightarrow\) Set \(_{\Delta}\) a simplicial set \(\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F})\), which we refer to as the homotopy colimit of \(\mathscr{F}\) (Construction 5.3.2.1). The formation of homotopy colimits plays an important role in the classical homotopy theory of simplicial sets: it can be regarded as a replacement for the usual notion of colimit (see Remark 5.3.2.9) which is compatible with weak homotopy equivalence (Proposition 5.3.2.18). Beware that the homotopy colimit holim\((\mathscr{F})\) is generally not an \(\infty\)-category (even in the special case where \(\mathscr{F}\) is a diagram of \(\infty\)-categories). Nevertheless, it is equipped with a projection map \(\underset{\rightarrow}{\text { holim }}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\), whose fiber over each object \(C \in \mathcal{C}\) can be identified with the simplicial set \(\mathscr{F}(C)\), and which behaves in certain respects like a cocartesian fibration. In \(\$ 5.3 .4\) we make this heuristic precise by introducing the notion of a scaffold. If \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is a cocartesian fibration of \(\infty\)-categories, we define a scaffold of \(U\) to be a commutative diagram

where \(\lambda\) restricts to a categorical equivalence \(\mathscr{F}(C) \rightarrow \mathcal{E}_{C}\) for each \(C \in \mathcal{C}\) and behaves well with respect to the collection of \(U\)-cocartesian morphisms of \(\mathcal{E}\) (Definition 5.3.4.2). We are primarily interested in two examples:
- To any cocartesian fibration \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\), we associate a universal scaffold \(\lambda_{u}\) : \(\xrightarrow{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathcal{E}\), where \(\mathscr{F}=\operatorname{sTr}_{\mathcal{E} / \mathcal{C}}\) is the strict transport representation of \(U\) (see \(\overrightarrow{\text { Construction 5.3.4.7 and Proposition 5.3.4.8. }}\)
- To any diagram of \(\infty\)-categories \(\mathscr{F}: \mathcal{C} \rightarrow\) QCat, we associate a taut scaffold \(\lambda\) : \(\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathcal{E}\), where \(\mathcal{E}=\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) is the \(\mathscr{F}\)-weighted nerve of \(\mathcal{C}\) (see Construction 5.3.4.11 and Proposition 5.3.4.17).

In \(\S 5.3 .5\), we show that every scaffold \(\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathcal{E}\) is a categorical equivalence of simplicial sets (Theorem 5.3.5.7). In particular, if \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is a cocartesian fibration with strict transport representation \(\mathscr{F}=s \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\), then we can exploit the tait and universal scaffolds
\[
\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \stackrel{\lambda}{\leftarrow} \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \xrightarrow{\lambda_{u}} \mathcal{E},
\]
to deduce the existence of an equivalence of \(\infty\)-categories \(\mathcal{E} \simeq \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) (compatible with the projection \(\mathrm{N}_{\bullet}(\mathcal{C})\) ), thereby obtaining a proof of (2) (see Theorem 5.3.5.6).

We close this section by describing some other applications of our theory of scaffolds. Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be a morphism of simplicial sets, let \(\mathcal{D}\) be an \(\infty\)-category, and let \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\) be the relative exponential of Construction 4.5.9.1. In \(\$ \sqrt[5.3 .6]{ }\), we show that if \(U\) is a cocartesian fibration, then the projection map \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D}) \rightarrow \mathcal{B}\) is a cartesian fibration. More generally, for every cocartesian fibration of simplicial sets \(V: \mathcal{D} \rightarrow \mathcal{E}\), the induced map
\[
\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D}) \xrightarrow{V_{0}} \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})
\]
is also a cocartesian fibration (Proposition 5.3.6.6). In \(\$ 5.3 .7\), we apply this result to study the oriented fiber product of Definition 4.6.4.1. For any functor of \(\infty\)-categories \(F: \mathcal{A} \rightarrow \mathcal{B}\), projection onto the second factor determines a cocartesian fibration \(\mathcal{A} \tilde{x}_{\mathcal{B}} \mathcal{B} \rightarrow \mathcal{B}\) (Corollary 5 5.3.7.3 which is, in some sense, freely generated by the \(\infty\)-category \(\mathcal{A}\) (Theorem 5.3.7.6).
Remark 5.3.0.1. There is a close analogy between the homotopy colimit construction 035B (studied in \(\$ 5.3 .2\) ) and the weighted nerve construction (studied in \(\$ 5.3 .3\) ).
- The formation of homotopy colimits determines a functor
\[
\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right) \rightarrow\left(\operatorname{Set}_{\Delta}\right) / \mathrm{N}_{\bullet}(\mathcal{C}) \quad \mathscr{F} \mapsto \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) .
\]

This functor has a right adjoint, which carries an object \(\mathcal{E} \in\left(\operatorname{Set}_{\Delta}\right) / \mathrm{N}_{\bullet}(\mathcal{C})\) to the diagram
\[
\mathcal{C} \rightarrow \operatorname{Set}_{\Delta} \quad C \mapsto \text { Fun }_{/ \mathrm{N}_{\bullet}(\mathcal{C})}\left(\mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right), \mathcal{E}\right) .
\]

See Corollary 5.3.2.24
- The formation of weighted nerves determines a functor
\[
\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right) \rightarrow\left(\operatorname{Set}_{\Delta}\right) / \mathrm{N}_{\bullet}(\mathcal{C}) \quad \mathscr{F} \mapsto \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) .
\]

This functor has a left adjoint, which carries an object \(\mathcal{E} \in\left(\operatorname{Set}_{\Delta}\right) / \mathrm{N}_{\bullet}(\mathcal{C})\) to the diagram
\[
\mathcal{C} \rightarrow \operatorname{Set}_{\Delta} \quad C \mapsto \mathrm{~N}_{\bullet}(\mathcal{C} / C) \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathcal{E} .
\]

See Corollary 5.3.3.25

035C Remark 5.3.0.2. After restricting to diagrams of Kan complexes, the results of this section supply a dictionary

This dictionary was formulated in work of Heuts and Moerdijk (using the language of model categories) which is closely related to the contents of this section. For more details, we refer the reader to [28].

\subsection*{5.3.1 The Strict Transport Representation}

035D Let \(\mathcal{C}\) be a category and let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a cocartesian fibration of \(\infty\)-categories. To each morphism \(f: C \rightarrow D\) of \(\mathcal{C}\), the homotopy transport representation \(\mathrm{hTr}_{\mathcal{E} / \mathrm{N}_{\bullet}(\mathcal{C})}\) associates the homotopy class [ \(f_{!}\)], where \(f_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) is given by covariant transport along \(f\). Beware that the functor \(f\) ! is only well-defined up to isomorphism. For example, the value of \(f\) ! on an object \(X \in \mathcal{E}_{C}\) depends on an auxiliary choice: namely, the choice of a \(U\)-cocartesian morphism \(\widetilde{f}: X \rightarrow Y\) satisfying \(U(\widetilde{f})=f\) (once we have made this choice, we can take \(f_{!}(X)\) to be the object \(\left.Y \in \mathcal{E}_{D}\right)\). Our goal in this section is to show that, by replacing each fiber \(\mathcal{E}_{C}\) by an equivalent \(\infty\)-category, the ambiguity in the definition of the transport functors can be eliminated. More precisely, we will associate to each object \(C \in \mathcal{C}\) a simplicial set \(\operatorname{sir}_{\mathcal{E} / \mathcal{C}}(C)\) with the following properties:
- There is a trivial Kan fibration of simplicial sets \(\mathrm{ev}_{C}: \operatorname{sTr}_{\mathcal{E} / \mathcal{C}}(C) \rightarrow \mathcal{E}_{C}\) (Proposition 5.3.1.7). In particular, \(\operatorname{sTr}_{\mathcal{E} / \mathcal{C}}(C)\) is an \(\infty\)-category which is equivalent to \(\mathcal{E}_{C}\).
- Every morphism \(f: C \rightarrow D\) in the category \(\mathcal{C}\) determines a functor of \(\infty\)-categories \(s \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}(f): \operatorname{sTr}_{\mathcal{E} / \mathcal{C}}(C) \rightarrow s \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}(D)\), which does not depend on any auxiliary choices. Moreover, the assignment \(f \mapsto \operatorname{sTr}_{\mathcal{E} / \mathcal{C}}(f)\) is compatible with composition, and therefore determines a functor \(\operatorname{sTr}_{\mathcal{E} / \mathcal{C}}: \mathcal{C} \rightarrow \mathrm{QCat}\) which we will refer to as the strict transport representation of \(U\) (Construction 5.3.1.5).
- For every morphism \(f: C \rightarrow D\) in \(\mathcal{C}\), the diagram of \(\infty\)-categories

commutes up to isomorphism. Consequently, the strict transport representation \(\operatorname{sTr}_{\mathcal{E}} / \mathcal{C}\) can be regarded as a refinement of the homotopy transport representation \(h \operatorname{Tr}_{\mathcal{E}} / \mathrm{N} \cdot(\mathcal{C})\) of Construction 5.2.5.2.

We begin by considering a closely related construction.
Construction 5.3.1.1. Let Cat denote the ordinary category whose objects are (small) 035 E categories and whose morphisms are functors. If \(\mathcal{C}\) is a category, then the construction \(C \mapsto \mathcal{C}_{C /}\) determines a functor \(\mathcal{C} \rightarrow(\mathrm{Cat} / \mathcal{C})^{\mathrm{op}}\), carrying each morphism \(f: C \rightarrow D\) in \(\mathcal{C}\) to the functor
\[
\mathcal{C}_{D /} \rightarrow \mathcal{C}_{C /} \quad(g: D \rightarrow E) \mapsto((g \circ f): C \rightarrow E) .
\]

For any morphism of simplicial sets \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\), we let \(\operatorname{wTr}_{\mathcal{E} / \mathcal{C}}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) denote the functor given on objects by the formula
\[
\mathrm{wTr}_{\mathcal{E} / \mathcal{C}}(C)={\operatorname{Fun} / \mathrm{N}_{\bullet}(\mathcal{C})}\left(\mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right), \mathcal{E}\right) .
\]

We will refer to \(\mathrm{wTr}_{\mathcal{E} / \mathcal{C}}\) as the weak transport representation of \(U\).
Remark 5.3.1.2. Let \(\mathcal{C}\) be a category and let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be an inner fibration of 035 F \(\infty\)-categories. Then, for every object \(C \in \mathcal{C}\), the simplicial set
\[
\mathrm{wTr}_{\mathcal{E} / \mathcal{C}}(C)=\operatorname{Fun}_{/ \mathrm{N}_{\bullet}(\mathcal{C})}\left(\mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right), \mathcal{E}\right)
\]
is an \(\infty\)-category (Corollary 4.1.4.8).
Remark 5.3.1.3. Let \(\mathcal{C}\) be a category and let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a morphism of simplicial sets. For each object \(C \in \mathcal{C}\), we can regard the identity morphism \(\mathrm{id}_{C}\) as an object of the coslice \(\infty\)-category \(\mathcal{C}_{C /}\). Evaluation on \(\mathrm{id}_{C}\) determines a morphism of simplicial sets
\[
\mathrm{ev}_{C}: \operatorname{wTr}_{\mathcal{E} / \mathcal{C}}(C) \rightarrow \mathcal{E}_{C} .
\]

Note that \(\mathrm{id}_{C}\) is an initial object of the category \(\mathcal{C}_{C /}\), so the inclusion map \(\left\{\mathrm{id}_{C}\right\} \hookrightarrow \mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right)\) is left anodyne (Corollary 4.6.7.24). If \(U\) is a left fibration of \(\infty\)-categories, then \(\mathrm{ev}_{C}\) is a trivial Kan fibration of simplicial sets. It follows that the simplicial set \(\mathrm{w} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}(C)\) is a \(\operatorname{Kan}\) complex, and that \(\mathrm{ev}_{C}\) is a homotopy equivalence of Kan complexes.
Example 5.3.1.4. Let \(\mathcal{C}\) be a category and let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a left covering map of 035 H simplicial sets. Then, for every object \(C \in \mathcal{C}\), the evaluation map ev \({ }_{C}: \mathrm{wTr}_{\mathcal{E} / \mathcal{C}}(C) \rightarrow \mathcal{E}_{C}\) is an isomorphism of simplicial sets (Exercise 4.2.5.5). It follows that the simplicial set \(\mathrm{w} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}(C)\) is discrete (see Remark 4.2.3.17). We can therefore identify \(\mathrm{w} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) with a functor from \(\mathcal{C}\) to the category of sets, which is isomorphic to the homotopy transport representation \(\mathrm{hTr}_{\mathcal{E} / \mathrm{N}_{\bullet}(\mathcal{C})}: \mathcal{C} \rightarrow\) Set of Definition 5.2.0.4.

Let \(\mathcal{C}\) be a category and let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a cocartesian fibration of \(\infty\)-categories. For an object \(C \in \mathcal{C}\), the evaluation map \(\mathrm{ev}_{C}: \mathrm{wTr}_{\mathcal{E} / \mathcal{C}}(C) \rightarrow \mathcal{E}_{C}\) of Remark 5.3.1.3 is generally not an equivalence of \(\infty\)-categories. By definition, an object of \(\mathrm{wTr} \mathrm{E}_{\mathcal{E}}(C)\) can be identified with a functor of \(\infty\)-categories \(F: \mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right) \rightarrow \mathcal{E}\) for which the diagram

is commutative. This functor carries \(\mathrm{id}_{C}\) to an object \(X=\mathrm{ev}_{C}(F) \in \mathcal{E}_{C}\), and carries each morphism \(f: C \rightarrow D\) of \(\mathcal{C}\) to an object \(Y \in \mathcal{E}_{D}\) equipped with a morphism \(\tilde{f}: X \rightarrow Y\) satisfying \(U(\widetilde{f})=f\). To guarantee that this data can be recovered from \(X\) (at least up to isomorphism), we need to impose an additional condition which guarantees that \(\tilde{f}\) is \(U\)-cocartesian.

035J Construction 5.3.1.5 (The Strict Transport Representation). Let \(\mathcal{C}\) be a category and let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a cocartesian fibration of \(\infty\)-categories. For every object \(C \in \mathcal{C}\), we let \(\mathrm{s} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}(C)\) denote the full subcategory of \(\mathrm{wr}_{\mathcal{E} / \mathcal{C}}(C)=\operatorname{Fun}_{/ \mathrm{N}_{\bullet}(\mathcal{C})}\left(\mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right), \mathcal{E}\right)\) spanned by those commutative diagrams

where \(F\) carries each morphism of \(\mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right)\) to a \(U\)-cocartesian morphism of \(\mathcal{E}\). The construction \(C \mapsto \operatorname{sTr}_{\mathcal{E} / \mathcal{C}}(C)\) determines a functor \(\mathrm{s} \operatorname{Tr}: \mathcal{C} \rightarrow \mathrm{QCat}\), which we will refer to as the strict transport representation of the cocartesian fibration \(U\).

035 K Remark 5.3.1.6. In the situation of Construction 5.3.1.5, suppose that \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is a left fibration of \(\infty\)-categories. It follows that every morphism of \(\mathcal{E}\) is \(U\)-cocartesian (Proposition 5.1.4.14), so the strict transport representation \(\operatorname{sTr}_{\mathcal{E} / \mathcal{C}}: \mathcal{C} \rightarrow\) QCat coincides with the weak transport representation \(w \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\).

We now wish to show that Construction 5.3.1.5 is a refinement of the homotopy transport representation introduced in \(\$ 5.2 .5\). This is a consequence of the following generalization of Remark 5.3.1.3

Proposition 5.3.1.7. Let \(\mathcal{C}\) be a category and let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a cocartesian fibration 035L of \(\infty\)-categories. Then, for every object \(C \in \mathcal{C}\), the evaluation map of Remark 5.3.1.3 induces a trivial Kan fibration of \(\infty\)-categories \(\mathrm{ev}_{C}: \operatorname{sTr}_{\mathcal{E} / \mathcal{C}}(C) \rightarrow \mathcal{E}_{C}\).
Corollary 5.3.1.8. Let \(\mathcal{C}\) be a category and let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a cocartesian fibration of 035 M \(\infty\)-categories. Then the diagram of functors

commutes up to natural isomorphism, given by the construction
\[
(C \in \mathcal{C}) \mapsto\left(\mathrm{ev}_{C}: \operatorname{sTr}_{\mathcal{E} / \mathcal{C}}(C) \rightarrow \operatorname{hTr}_{\mathcal{E} / \mathrm{N}_{\bullet}(\mathcal{C})}(C)=\mathcal{E}_{C}\right)
\]

Proof. It follows from Proposition 5.3.1.7 that for each object \(C \in \mathcal{C}\), the evaluation functor \(\mathrm{ev}_{C}\) is a trivial Kan fibration, and therefore an isomorphism in the homotopy category hQCat. To complete the proof, it will suffice to show that the construction \(C \mapsto \mathrm{ev}_{C}\) is a natural transformation: that is, for every morphism \(f: C \rightarrow D\) of \(\mathcal{C}\), the diagram of \(\infty\)-categories

commutes up to natural isomorphism. Let \(s: \mathcal{E}_{C} \rightarrow \operatorname{sTr}_{\mathcal{E} / \mathcal{C}}(C)\) be a section of the trivial Kan fibration \(\mathrm{ev}_{C}\). Then the homotopy class \([s]\) is an inverse of \(\left[\mathrm{ev}_{C}\right]\) in the homotopy category hQCat. It will therefore suffice to show that the diagram

commutes up to isomorphism: that is, that the composite functor
\[
\mathcal{E}_{C} \xrightarrow{s} \operatorname{sTr}_{\mathcal{E} / \mathcal{C}}(C) \xrightarrow{\mathrm{sTr}_{\mathcal{E}} / \mathcal{C}(f)} \operatorname{sTr}_{\mathcal{E} / \mathcal{C}}(D) \xrightarrow{\mathrm{ev}_{D}} \mathcal{E}_{D}
\]
is given by covariant transport along \(f\).
Unwinding the definitions, we can identify the composition
\[
\mathcal{E}_{C} \xrightarrow{s} \operatorname{sTr}_{\mathcal{E} / \mathcal{C}}(C) \subseteq \mathrm{wTr}_{\mathcal{E} / \mathcal{C}}(C)=\text { Fun }_{/ \mathrm{N}_{\bullet}(\mathcal{C})}\left(\mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right), \mathcal{E}\right)
\]
with a functor \(H: \mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right) \times \mathcal{E}_{C} \rightarrow \mathcal{E}\). Let us regard \(\mathrm{id}_{C}\) and \(f\) as objects of the category \(\mathcal{C}_{C /}\), so that \(f\) lifts to a morphism \(\widetilde{f}: \operatorname{id}_{C} \rightarrow f\) corresponding to an edge \(e: \Delta^{1} \rightarrow \mathrm{~N}_{\bullet}\left(\mathcal{C}_{C /}\right)\). Let \(H_{e}\) denote the composition
\[
\Delta^{1} \times \mathcal{E}_{C} \xrightarrow{e \times \mathrm{id}} \mathrm{~N}_{\bullet}\left(\mathcal{C}_{C /}\right) \times \mathcal{E}_{C} \xrightarrow{H} \mathcal{E} .
\]

Unwinding the definitions, we see that the commutative diagram

witnesses the composite functor \(\operatorname{ev}_{D} \circ \operatorname{sir}_{\mathcal{E} / \mathcal{C}}(f) \circ s\) as given by covariant transport along \(f\), in the sense of Definition 5.2.2.4.

035N Corollary 5.3.1.9 (Functoriality). Suppose we are given a commutative diagram of \(\infty\) categories

where \(U\) and \(U^{\prime}\) are cocartesian fibrations. The following conditions are equivalent:
(1) The functor \(F\) carries \(U\)-cocartesian morphisms of \(\mathcal{E}\) to \(U^{\prime}\)-cocartesian morphisms of \(\mathcal{E}^{\prime}\).
(2) The induced map of weak transport representations \(\mathrm{wTr}_{\mathcal{E} / \mathcal{C}} \rightarrow \mathrm{wTr}_{\mathcal{E}^{\prime} / \mathcal{C}}\) carries \(\mathrm{sTr}_{\mathcal{E} / \mathcal{C}}\) into \(\operatorname{sTr}_{\mathcal{E}^{\prime} / \mathcal{C}}\).

Proof. The implication (1) \(\Rightarrow(2)\) is immediate from the definitions. Conversely, suppose that condition (2) is satisfied, and let \(f: X \rightarrow Y\) be a \(U\)-cocartesian morphism of \(\mathcal{E}\); we wish to show that \(F(f)\) is \(U^{\prime}\)-cocartesian. Set \(C=U(X)\). Using Proposition 5.3.1.7, we can choose an object \(\tilde{X} \in \operatorname{sir}_{\mathcal{E} / \mathcal{C}}(C)\) satisfying \(\operatorname{ev}_{C}(\tilde{X})=X\). Let us identify \(\tilde{X}\) with a
functor of \(\infty\)-categories \(G: \mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right) \rightarrow \mathcal{E}\). Write \(\bar{f}\) for the image \(U(f)\), which we regard as a morphism in the coslice category \(\mathcal{C}_{C /}\). Assumption (2) guarantees that \(F\) carries \(\tilde{X}\) to an object of \(\operatorname{sTr} \mathcal{E}_{\mathcal{E}^{\prime} / \mathcal{C}}(C)\), so that \((F \circ G)(\bar{f})\) is a \(U^{\prime}\)-cocartesian morphism of \(\mathcal{E}^{\prime}\). Since \(f\) is isomorphic to \(G(\bar{f})\) (as an object of the \(\infty\)-category \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{E}\right)\) ), it follows that \(F(f)\) is also \(U^{\prime}\)-cocartesian.

The remainder of this section is devoted to the proof of Proposition 5.3.1.7. With an eye toward future applications, we will formulate a more general result, which can be applied to cocartesian fibrations \(U: \mathcal{E} \rightarrow \mathcal{C}\) where \(\mathcal{C}\) is not given by (the nerve of) an ordinary category.
Notation 5.3.1.10 (Cocartesian Sections). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) and \(U^{\prime}: \mathcal{E}^{\prime} \rightarrow \mathcal{C}\) be cocartesian \(\qquad\) fibrations of simplicial sets. Then the simplicial set
\[
\operatorname{Fun}_{/ \mathcal{C}}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)=\left\{U^{\prime}\right\} \times_{\operatorname{Fun}\left(\mathcal{E}^{\prime}, \mathcal{C}\right)} \operatorname{Fun}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)
\]
is an \(\infty\)-category (see Corollary 4.1.4.8. We let \(\operatorname{Fun}_{/ \mathcal{C}}^{\text {CCart }}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)\) denote the full subcategory of Fun \(/ \mathcal{C}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)\) whose objects are morphisms \(F: \mathcal{E}^{\prime} \rightarrow \mathcal{E}\) which satisfy the identity \(U \circ F=U^{\prime}\) and carry \(U^{\prime}\)-cocartesian edges of \(\mathcal{E}^{\prime}\) to \(U\)-cocartesian edges of \(\mathcal{E}\).
Variant 5.3.1.11 (Cartesian Sections). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) and \(U^{\prime}: \mathcal{E}^{\prime} \rightarrow \mathcal{C}\) be cartesian 02T2 fibrations of simplicial sets. We let \(\operatorname{Fun}_{/ \mathcal{C}}^{\text {Cart }}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)\) denote the full subcategory of \(\mathrm{Fun}_{/ \mathcal{C}}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)\) whose objects are morphisms \(F: \mathcal{E}^{\prime} \rightarrow \mathcal{E}\) which satisfy the identity \(U \circ F=U^{\prime}\) and carry \(U^{\prime}\) cartesian edges of \(\mathcal{E}^{\prime}\) to \(U\)-cartesian edges of \(\mathcal{E}\). Note that we have a canonical isomorphism of simplicial sets
\[
\operatorname{Fun}_{/ \mathcal{C}}^{\text {Cart }}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)^{\mathrm{op}}=\operatorname{Fun}_{/ \mathcal{C}^{\mathrm{op}}}^{\mathrm{CCOrt}}\left(\mathcal{E}^{\prime \mathrm{op}}, \mathcal{E}^{\mathrm{op}}\right) .
\]

In the special case \(\mathcal{E}^{\prime}=\mathcal{C}\), we will refer to \(\operatorname{Fun}_{/ \mathcal{C}}^{\text {Cart }}(\mathcal{C}, \mathcal{E})\) as the \(\infty\)-category of cartesian sections of \(U\).

Remark 5.3.1.12. Suppose we are given a commutative diagram of simplicial sets

where \(U\) and \(U^{\prime}\) are cocartesian fibrations. Let \(e: X \rightarrow Y\) be an edge of \(\mathcal{C}\). The following conditions are equivalent:
(1) For every \(U^{\prime}\)-cocartesian edge \(\widetilde{e}: \widetilde{X} \rightarrow \widetilde{Y}\) of \(\mathcal{E}^{\prime}\) satisfying \(U^{\prime}(\widetilde{e})=e\), the image \(F(\widetilde{e})\) is a \(U\)-cocartesian edge of \(\mathcal{E}\).
(2) For every vertex \(\tilde{X}\) of \(\mathcal{E}^{\prime}\) satisfying \(U^{\prime}(\widetilde{X})=X\), there exists a \(U^{\prime}\)-cocartesian edge \(\widetilde{e}: \widetilde{X} \rightarrow \widetilde{Y}\) of \(\mathcal{E}^{\prime}\) such that \(F(\widetilde{e})\) is \(U\)-cocartesian and \(U^{\prime}(\widetilde{e})=e\).

The implication \((1) \Rightarrow(2)\) is immediate from the definitions, and the implication \((2) \Rightarrow(1)\) follows from Remark 5.1.3.8

Let \(W\) be the collection of edges of \(\mathcal{C}\) which satisfy these conditions. Then \(W\) contains all degenerate edges of \(\mathcal{C}\) and is closed under composition: that is, for every 2 -simplex

of \(\mathcal{C}\), if \(e\) and \(e^{\prime}\) belong to \(W\), then \(e^{\prime \prime}\) also belongs to \(W\) (see Proposition 5.1.4.12).
035P Remark 5.3.1.13. We will be primarily interested in the special case of Notation 5.3.1.10 where \(U^{\prime}: \mathcal{E}^{\prime} \rightarrow \mathcal{C}\) is a left fibration of simplicial sets. In this case, an object \(F \in \operatorname{Fun}_{/ \mathcal{C}}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)\) belongs to the full subcategory \(\operatorname{Fun}_{/ \mathcal{C}}^{\mathrm{C}}{ }^{\text {Cart }}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)\) if and only if it carries every edge of \(\mathcal{E}^{\prime}\) to a \(U\)-cocartesian edge of \(\mathcal{E}\) (Proposition 5.1.4.14).

035Q Example 5.3.1.14. Let \(\mathcal{C}\) be a category and let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a cocartesian fibration of \(\infty\)-categories. Then the strict transport representation \(s \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) of Construction 5.3.1.5 is given on objects by the formula
\[
\operatorname{sTr}_{\mathcal{E} / \mathcal{C}}(C)=\operatorname{Fun}_{/ \mathrm{N} \bullet(\mathcal{C})}^{\mathrm{CCart}}\left(\mathrm{~N}_{\bullet}\left(\mathcal{C}_{C /}\right), \mathcal{E}\right) .
\]

02 T 3 Remark 5.3.1.15. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) and \(U^{\prime}: \mathcal{E}^{\prime} \rightarrow \mathcal{C}\) be cocartesian fibrations of simplicial sets. Then the full subcategory \(\operatorname{Fun}_{/ \mathcal{C}}^{\text {Cart }}\left(\mathcal{E}^{\prime}, \mathcal{E}\right) \subseteq \operatorname{Fun}_{/ \mathcal{C}}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)\) is replete (Example 4.4.1.12). That is, if \(F\) and \(G\) are isomorphic objects of Fun \(/ \mathcal{C}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)\), then \(F\) carries \(U^{\prime}\)-cocartesian edges of \(\mathcal{E}^{\prime}\) to \(U\)-cocartesian edges of \(\mathcal{E}\) if and only if \(G\) has the same property. In fact, we can be more precise: for every particular edge \(e\) of \(\mathcal{E}^{\prime}\), the image \(F(e)\) is \(U\)-cocartesian if and only if \(G(e)\) is \(U\)-cocartesian. To prove this, we can assume without loss of generality that \(\mathcal{C}=\Delta^{1}\), in which case it follows from Corollary 5.1.2.5.

035R Remark 5.3.1.16 (Detecting Isomorphisms). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) and \(U^{\prime}: \mathcal{E}^{\prime} \rightarrow \mathcal{C}\) be cocartesian fibrations of \(\infty\)-categories, and let \(\alpha: F \rightarrow G\) be a morphism in the \(\infty\)-category \(\operatorname{Fun}_{/ \mathcal{C}}^{\text {Cart }}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)\). The following conditions are equivalent:
(1) The morphism \(\alpha\) is an isomorphism in the \(\infty\)-category \(\operatorname{Fun}_{/ \mathcal{C}}^{\mathrm{CCart}}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)\).
(2) The image of \(\alpha\) is an isomorphism in the \(\infty\)-category Fun \(_{/ \mathcal{C}}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)\).
(3) The image of \(\alpha\) is an isomorphism in the \(\infty\)-category \(\operatorname{Fun}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)\).
(4) For each object \(X \in \mathcal{C}\), the induced map \(\alpha_{X}: F(X) \rightarrow G(X)\) is an isomorphism in the \(\infty\)-category \(\mathcal{E}_{X}\).
(5) For each object \(X \in \mathcal{C}\), the induced map \(\alpha_{X}: F(X) \rightarrow G(X)\) is an isomorphism in the \(\infty\)-category \(\mathcal{E}\).

The implications \((1) \Leftrightarrow(2)\) is immediate, the equivalences \((2) \Leftrightarrow(3)\) and \((4) \Leftrightarrow(5)\) follow from Corollary 4.4.3.19, and the equivalence \((3) \Leftrightarrow(5)\) follows from Theorem 4.4.4.4

Remark 5.3.1.17 (Functoriality). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) and \(U^{\prime}: \mathcal{E}^{\prime} \rightarrow \mathcal{C}\) be cocartesian fibrations 02T4 of simplicial sets. Suppose that we are given a morphism of simplicial sets \(F: \mathcal{C}_{0} \rightarrow \mathcal{C}\), and set \(\mathcal{E}_{0}=\mathcal{C}_{0} \times_{\mathcal{C}} \mathcal{E}\) and \(\mathcal{E}_{0}^{\prime}=\mathcal{C}_{0} \times_{\mathcal{C}} \mathcal{E}^{\prime}\). Then pullback along \(F\) determines a morphism of simplicial sets
\[
F^{*}: \operatorname{Fun}_{/ \mathcal{C}}^{\mathrm{CCart}}\left(\mathcal{E}^{\prime}, \mathcal{E}\right) \rightarrow \operatorname{Fun}_{/ \mathcal{C}_{0}}^{\mathrm{Cart}}\left(\mathcal{E}_{0}^{\prime}, \mathcal{E}_{0}\right)
\]
which we will refer to as the restriction map.
Remark 5.3.1.18. In the situation of Remark 5.3.1.17, suppose that \(F: \mathcal{C}_{0} \rightarrow \mathcal{C}\) is 02 T 5 a monomorphism of simplicial sets. Then the restriction map \(F^{*}: \operatorname{Fun}_{/ \mathcal{C}}^{\mathrm{CCart}}\left(\mathcal{E}^{\prime}, \mathcal{E}\right) \rightarrow\) Fun \(/ \mathcal{C}_{0}{ }^{\text {CCart }}\left(\mathcal{E}_{0}^{\prime}, \mathcal{E}_{0}\right)\) is an isofibration. To see this, we first observe that Fun \(/ \mathcal{C}{ }^{\text {Coart }}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)\) can be regarded as a replete subcategory of the fiber product
\[
\operatorname{Fun}_{/ \mathcal{C}_{0}}^{\text {CCart }}\left(\mathcal{E}_{0}^{\prime}, \mathcal{E}_{0}\right) \times_{\text {Fun }_{/ \mathcal{C}_{0}}\left(\mathcal{E}_{0}^{\prime}, \mathcal{E}_{0}\right)} \text { Fun }_{/ \mathcal{C}}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)
\]
(Remark 5.3.1.15). It will therefore suffice to show that the restriction map
\[
\operatorname{Fun}_{/ \mathcal{C}}\left(\mathcal{E}^{\prime}, \mathcal{E}\right) \rightarrow \operatorname{Fun}_{/ \mathcal{C}_{0}}\left(\mathcal{E}_{0}^{\prime}, \mathcal{E}_{0}\right) \simeq \operatorname{Fun}_{/ \mathcal{C}}\left(\mathcal{E}_{0}^{\prime}, \mathcal{E}\right)
\]
is an isofibration, which follows from Proposition 4.5.5.14
Remark 5.3.1.19. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) and \(U^{\prime}: \mathcal{E}^{\prime} \rightarrow \mathcal{C}\) be cocartesian fibrations of simplicial 02T6 sets, and let \(K\) be an arbitrary simplicial set. Then:
- The projection map \(\mathcal{C} \times \times_{\operatorname{Fun}(K, \mathcal{C})} \operatorname{Fun}(K, \mathcal{E}) \rightarrow \mathcal{C}\) is also a cocartesian fibration.
- The canonical isomorphism
\[
\operatorname{Fun}\left(K, \operatorname{Fun}_{/ \mathcal{C}}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)\right) \simeq \operatorname{Fun}_{/ \mathcal{C}}\left(\mathcal{E}^{\prime}, \mathcal{C} \times \times_{\operatorname{Fun}(K, \mathcal{C})} \operatorname{Fun}(K, \mathcal{E})\right)
\]
restricts to an isomorphism of full subcategories
\[
\operatorname{Fun}\left(K, \operatorname{Fun}_{/ \mathcal{C}}^{\mathrm{CCart}}\left(\mathcal{E}^{\prime}, \mathcal{E}\right)\right) \simeq \operatorname{Fun}_{/ \mathcal{C}}^{\text {CCart }}\left(\mathcal{E}^{\prime}, \mathcal{C} \times \operatorname{Fun}(K, \mathcal{C}) \operatorname{Fun}(K, \mathcal{E})\right) .
\]

Both assertions follow immediately from Theorem 5.2.1.1.
\(02 T 7\) Remark 5.3.1.20. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets. Let \(\mathcal{E}^{\circ} \subseteq \mathcal{E}\) be the simplicial subset whose \(n\)-simplices are maps \(\Delta^{n} \rightarrow \mathcal{E}\) which carry each edge of \(\Delta^{n}\) to a \(U\)-cocartesian edge of \(\mathcal{E}\), so that \(U\) restricts to a left fibration \(U^{\circ}: \mathcal{E}^{\circ} \rightarrow \mathcal{C}\) (see Corollary 5.1.4.15). Then \(\operatorname{Fun}_{/ \mathcal{C}}\left(\mathcal{C}, \mathcal{E}^{\circ}\right)\) can be identified with the core of the \(\infty\)-category \(\operatorname{Fun}_{/ \mathcal{C}}^{\text {COart }}(\stackrel{\mathcal{C}}{ }, \mathcal{E})\).

035 S Proposition 5.3.1.21. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets, let \(F: \mathcal{C}_{0} \rightarrow \mathcal{C}\) be a left anodyne morphism of simplicial sets, and set \(\mathcal{E}_{0}=\mathcal{C}_{0} \times_{\mathcal{C}} \mathcal{E}\). Then the restriction map
\[
F^{*}: \operatorname{Fun}_{/ \mathcal{C}}^{\text {CCart }}(\mathcal{C}, \mathcal{E}) \rightarrow \operatorname{Fun}_{/ \mathcal{C}_{0}}^{\text {CCart }}\left(\mathcal{C}_{0}, \mathcal{E}_{0}\right)
\]
of Remark 5.3.1.17 is a trivial Kan fibration.
Proof. Since \(F\) is a monomorphism of simplicial sets, the functor \(F^{*}\) is an isofibration of \(\infty\)-categories (Remark 5.3.1.18). It will therefore suffice to show that \(F^{*}\) is an equivalence of \(\infty\)-categories (see Proposition 4.5.5.20). By virtue of Proposition 4.5.1.22, this is equivalent to the assertion that for simplicial set \(X\), the induced map
\[
\operatorname{Fun}\left(X, \operatorname{Fun}_{/ \mathcal{C}}^{\mathrm{CCart}}(\mathcal{C}, \mathcal{E})\right)^{\simeq} \rightarrow \operatorname{Fun}\left(X, \operatorname{Fun}_{/ \mathcal{C}_{0}}^{\mathrm{CCart}}\left(\mathcal{C}_{0}, \mathcal{E}_{0}\right)\right)^{\simeq}
\]
is a homotopy equivalence of Kan complexes (in fact, it suffices to verify this for \(X=\Delta^{1}\); see Theorem 4.5.7.1). Replacing \(\mathcal{E}\) by the fiber product \(\mathcal{C} \times{ }_{\text {Fun }(X, \mathcal{C})} \operatorname{Fun}(X, \mathcal{E})\) and using Remark 5.3.1.19, we are reduced to proving that \(F^{*}\) restricts to a homotopy equivalence \(F^{*}: \operatorname{Fun}_{/ \mathcal{C}}^{\text {CCart }}(\mathcal{C}, \mathcal{E})^{\simeq} \rightarrow \operatorname{Fun}_{/ \mathcal{C}_{0}}^{\text {CCart }}\left(\mathcal{C}_{0}, \mathcal{E}_{0}\right)^{\simeq}\). Let \(U^{\circ}: \mathcal{E}^{\circ} \rightarrow \mathcal{E}\) denote the underlying left fibration of \(U\). Using Remark 5.3.1.20, we can identify \(\theta\) with the map
\[
\operatorname{Fun}_{/ \mathcal{C}}\left(\mathcal{C}, \mathcal{E}^{\circ}\right) \rightarrow \operatorname{Fun}_{/ \mathcal{C}_{0}}\left(\mathcal{C}_{0}, \mathcal{C}_{0} \times_{\mathcal{C}} \mathcal{E}^{\circ}\right) \simeq \operatorname{Fun}_{/ \mathcal{C}}\left(\mathcal{C}_{0}, \mathcal{E}^{\circ}\right)
\]
given by precomposition with \(F\). Since \(F\) is left anodyne, this map is a trivial Kan fibration (Proposition 4.2.5.4).

035 T Corollary 5.3.1.22. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of \(\infty\)-categories, let \(U^{\prime}: \mathcal{E}^{\prime} \rightarrow \mathcal{C}\) be a left fibration of \(\infty\)-categories, and let \(X\) be an initial object of \(\mathcal{E}^{\prime}\). Then evaluation at \(X\) induces a trivial Kan fibration of \(\infty\)-categories
\[
\operatorname{ev}_{X}: \operatorname{Fun}_{\mathcal{C}}^{\text {CCart }}\left(\mathcal{E}^{\prime}, \mathcal{E}\right) \rightarrow\{X\} \times_{\mathcal{C}} \mathcal{E}
\]

Proof. By virtue of Remark 5.3.1.13, we can replace \(U\) by the projection map \(\mathcal{E}^{\prime} \times_{\mathcal{C}} \mathcal{E} \rightarrow \mathcal{E}^{\prime}\) and thereby reduce to the case where \(U^{\prime}\) is the identity map. In this case, the desired result follows from Proposition 5.3.1.21, since the inclusion map \(\{X\} \hookrightarrow \mathcal{E}^{\prime}\) is left anodyne (Corollary 4.6.7.24).

Proof of Proposition 5.3.1.7. Let \(\mathcal{C}\) be a category and let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a cocartesian fibration of \(\infty\)-categories. By virtue of Example 5.3.1.14, it will suffice to show that the evaluation functor
\[
\operatorname{ev}_{C}: \operatorname{Fun} / \mathrm{Nar}_{\mathbf{\bullet}}(\mathcal{C})\left(\mathrm{N} \cdot\left(\mathcal{C}_{C /}\right), \mathcal{E}\right) \rightarrow \mathcal{E}_{C}
\]
is a trivial Kan fibration. This is a special case of Corollary 5.3.1.22, since the identity morphism \(\operatorname{id}_{C}\) is initial when viewed as an object of the coslice category \(\mathcal{C}_{C /}\).

We conclude by recording another special case of Corollary 5.3.1.22 which will be useful later:

Corollary 5.3.1.23. Let \(\bar{U}: \overline{\mathcal{E}} \rightarrow \mathcal{C}^{\triangleleft}\) be a cocartesian fibration of simplicial sets. Then 02TC evaluation at \(\mathbf{0}\) induces a trivial Kan fibration of simplicial sets
\[
\operatorname{Fun}_{/ \mathcal{C}^{\triangleleft}}^{\text {CCart }}\left(\mathcal{C}^{\triangleleft}, \overline{\mathcal{E}}\right) \rightarrow\{\mathbf{0}\} \times_{\mathcal{C}^{\triangleleft}} \overline{\mathcal{E}}
\]

Proof. Combine Corollary 5.3.1.22 with Example 4.3.7.11.

\subsection*{5.3.2 Homotopy Colimits of Simplicial Sets}

Let \(f_{0}: A \rightarrow A_{0}\) and \(f_{1}: A \rightarrow A_{1}\) be morphisms of simplicial sets. Recall that the 035U homotopy pushout of \(A_{0}\) with \(A_{1}\) along \(A\) is defined to be the simplicial set
\[
A_{0} \coprod_{A}^{\mathrm{h}} A_{1}=A_{0} \coprod_{(\{0\} \times A)}\left(\Delta^{1} \times A\right) \coprod_{(\{1\} \times A)} A_{1}
\]
(see Construction 3.4.2.2. This construction has two essential properties:
(1) The formation of homotopy pushouts is compatible with weak homotopy equivalence. That is, if we are given a commutative diagram of simplicial sets

in which the vertical maps are weak homotopy equivalences, then the induced map \(A_{0} \amalg_{A}^{\mathrm{h}} A_{1} \rightarrow B_{0} \amalg_{B}^{\mathrm{h}} B_{1}\) is also a weak homotopy equivalence (Corollary 3.4.2.15).
(2) The homotopy pushout is equipped with a comparison map \(A_{0} \amalg_{A}^{\mathrm{h}} A_{1} \rightarrow A_{0} \amalg_{A} A_{1}\), which is a weak homotopy equivalence if either \(f_{0}: A_{0} \rightarrow A\) or \(f_{1}: A_{1} \rightarrow A\) is a monomorphism (Corollary 3.4.2.13).

Our goal in this section is to introduce a variant of the homotopy pushout construction which can be applied to more general diagrams of simplicial sets. To every category \(\mathcal{C}\) and every functor \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\), we introduce a simplicial set holim\((\mathscr{F})\) which we refer to as the homotopy colimit of \(\mathscr{F}\) (Construction 5.3.2.1). The homotopy colimit satisfies an analogue of property (1): it is compatible both with weak homotopy equivalence (Proposition 5.3 .2 .18 ) and with categorical equivalence (Variant 5.3.2.19). Moreover, there is a natural epimorphism from the homotopy colimit \(\operatorname{holim}(\mathscr{F})\) to the usual colimit \(\underset{\longrightarrow}{\lim }(\mathscr{F})\) (Remark 5.3.2.9). We will see later that this map is often a weak homotopy equivalence (Corollary 7.5.6.14.

035 V Construction 5.3.2.1. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a functor. For every integer \(n \geq 0\), we let \(\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F})_{n}\) denote the set of all ordered pairs \((\sigma, \tau)\), where \(\sigma:[n] \rightarrow \mathcal{C}\) is an \(n\)-simplex of the nerve \(\mathrm{N}_{\bullet}(\mathcal{C})\) and \(\tau\) is an \(n\)-simplex of the simplicial set \(\mathscr{F}(\sigma(0))\).

If \((\sigma, \tau)\) is an element of \(\underset{\rightarrow}{\operatorname{holim}}(\mathscr{F})_{n}\) and \(\alpha:[m] \rightarrow[n]\) is a nondecreasing function of linearly ordered sets, we set \(\overrightarrow{\alpha^{*}}(\sigma, \tau)=\left(\sigma \circ \alpha, \tau^{\prime}\right) \in \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F})_{m}\), where \(\tau^{\prime}\) is given by the composite map
\[
\Delta^{m} \xrightarrow{\alpha} \Delta^{n} \xrightarrow{\tau} \mathscr{F}(\sigma(0)) \rightarrow \mathscr{F}((\sigma \circ \alpha)(0)) .
\]

By means of this construction, the assignment \([n] \mapsto \underset{\longrightarrow}{\operatorname{holim}(\mathscr{F})_{n}}\) determines a simplicial set \(\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F})=\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F})\) • which we will refer to as the homotopy colimit of the diagram \(\mathscr{F}\). Note that the construction \((\sigma, \tau) \mapsto \sigma\) determines a morphism of simplicial sets \(U: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\), which we will refer to as the projection map.

035W Example 5.3.2.2 (Discrete Diagrams). Let \(\mathcal{C}\) be a category having only identity morphisms, and let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets. Then the homotopy colimit holim \((\mathscr{F})\) can be identified with the disjoint union \(\amalg_{C \in \mathcal{C}} \mathscr{F}(C)\).

035X Remark 5.3.2.3. Let \(T: \mathcal{C}^{\prime} \rightarrow \mathcal{C}\) be a functor between categories, let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets indexed by \(\mathcal{C}\), and let \(\mathscr{F}^{\prime}\) denote the composition \(\mathscr{F} \circ T\). Then we have a pullback diagram of simplicial sets

where \(U\) and \(U^{\prime}\) denote the projection maps of Construction 5.3.2.1. In particular, for every object \(C \in \mathcal{C}\), we have a canonical isomorphism of simplicial sets
\[
\mathscr{F}(C) \simeq\{C\} \times_{\mathrm{N}_{0}}(\mathcal{C}) \xrightarrow{\operatorname{holim}}(\mathscr{F}) .
\]

Example 5.3.2.4 (Constant Diagrams). Let \(\mathcal{C}\) be a category, let \(X\) be a simplicial set, and let 035 Y \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be the constant diagram taking the value \(X\). Combining Remark 5.3.2.3 with Example 5.3 .2 .2 , we obtain a canonical isomorphism of simplicial sets \(\underset{\rightarrow}{\operatorname{holim}}(\mathscr{F}) \simeq \mathrm{N}_{\bullet}(\mathcal{C}) \times X\). In particular, if \(X=\Delta^{0}\), then the projection map \(\underset{\rightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is an isomorphism.

Example 5.3.2.5 (Set-Valued Functors). Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow\) Set be a \(035 z\) diagram of sets indexed by \(\mathcal{C}\). Let us abuse notation by identifying \(\mathscr{F}\) with a diagram of simplicial sets (by identifying each of the sets \(\mathscr{F}(C)\) as a discrete simplicial set). Then there is a canonical isomorphism of simplicial sets
\[
\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \simeq \mathrm{N}_{\bullet}\left(\int_{\mathcal{C}} \mathscr{F}\right) .
\]

Here \(\int_{\mathcal{C}} \mathscr{F}\) denotes the category of elements of of the functor \(\mathscr{F}\) (Construction 5.2.6.1).
Example 5.3.2.6 (Corepresentable Functors). Let \(\mathcal{C}\) be a category and let \(h^{C}: \mathcal{C} \rightarrow\) Set 0360 be the functor corepresented by an object \(C \in \mathcal{C}\), given by \(h^{C}(D)=\operatorname{Hom}_{\mathcal{C}}(C, D)\). Let us abuse notation by regarding \(h^{C}\) as a functor from \(\mathcal{C}\) to the category of simplicial sets (by identifying each morphism set \(\operatorname{Hom}_{\mathcal{C}}(C, D)\) with the corresponding discrete simplicial set). Combining Examples 5.3.2.5 and 5.2.6.5, we obtain a canonical isomorphism of simplicial sets \(\underset{\longrightarrow}{\operatorname{holim}}\left(h^{C}\right) \simeq \mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right)\).

Remark 5.3.2.7. Let \(\mathcal{C}\) be a category, let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets
0361 indexed by \(\mathcal{C}\), and let \(\mathcal{C}_{0} \subseteq \mathcal{C}\) be a full subcategory. Suppose that, for every object \(C \in \mathcal{C}\) which does not belong to \(\mathcal{C}_{0}\), the simplicial set \(\mathscr{F}(C)\) is empty. Then the image of the projection map \(\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is contained in \(\mathrm{N}_{\bullet}\left(\mathcal{C}_{0}\right)\). Setting \(\mathscr{F}_{0}=\left.\mathscr{F}\right|_{\mathcal{C}_{0}}\), we deduce that the canonical map
\[
\underset{\longrightarrow}{\operatorname{holim}}\left(\mathscr{F}_{0}\right) \simeq \mathrm{N}_{\bullet}\left(\mathcal{C}_{0}\right) \times_{\mathrm{N}_{\bullet}}(\mathcal{C}) \xrightarrow{\operatorname{holim}}(\mathscr{F}) \hookrightarrow \operatorname{holim}(\mathscr{F})
\]
is an isomorphism.
Remark 5.3.2.8 (Functoriality). Let \(\mathcal{C}\) be a category. Then the formation of homotopy 0362 colimits determines a functor
\[
\underset{\longrightarrow}{\operatorname{holim}}: \operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right) \rightarrow\left(\operatorname{Set}_{\Delta}\right) / \mathrm{N}_{\bullet}(\mathcal{C}) \quad \mathscr{F} \mapsto \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) .
\]

Moreover, this functor preserves small limits and colimits.
Remark 5.3.2.9 (Comparison with the Colimit). Let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets and let \(\left\{t_{C}: \mathscr{F}(C) \rightarrow X\right\}_{C \in \mathcal{C}}\) be a collection of morphisms which exhibit \(X\) as a colimit of the diagram \(\mathscr{F}\). The morphisms \(t_{C}\) then determine a natural transformation
\(t_{\bullet}: \mathscr{F} \rightarrow \underline{X}\), where \(\underline{X}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) denotes the constant functor taking the value \(X\). Using Example 5.3.2.4, we obtain a morphism of simplicial sets
\[
\theta: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \xrightarrow{\text { holim }\left(t_{\bullet}\right)} \operatorname{holim}_{\longrightarrow}(\underline{X}) \simeq \mathrm{N}_{\bullet}(\mathcal{C}) \times X \rightarrow X,
\]
which we will refer to as the comparison map. Note that, for every vertex \(C \in \mathcal{C}\), the restriction of \(\theta\) to the fiber \(\{C\} \times_{\mathrm{N}_{\mathbf{0}}(\mathcal{C})} \xrightarrow{\operatorname{holim}}(\mathscr{F})\) can be identified with the morphism \(t_{C}\). Since \(X\) is the union of the images of the morphisms \(t_{C}\), it follows that the comparison map \(\theta: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \xrightarrow{\lim }(\mathscr{F})\) is an epimorphism of simplicial sets.

0364 Example 5.3.2.10 (Disjoint Unions). Let \(I\) be a set, which we regard as a category having only identity morphisms. Let \(\mathscr{F}: I \rightarrow \operatorname{Set}_{\Delta}\) be a functor, which we identify with a collection of simplicial sets \(\left\{X_{i}\right\}_{i \in I}\). Then the comparison map
\[
\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \underset{\longrightarrow}{\lim }(\mathscr{F})=\coprod_{i \in I} X_{i}
\]
is an isomorphism of simplicial sets.
0365 Notation 5.3.2.11 (The Mapping Simplex). Suppose we are given a diagram of simplicial sets
\[
X(0) \xrightarrow{f(1)} X(1) \xrightarrow{f(1)} X(2) \xrightarrow{f(3)} \cdots \xrightarrow{f(n)} X(n),
\]
which we will identify with a functor \(\mathscr{F}:[n] \rightarrow \operatorname{Set}_{\Delta}\). We denote the homotopy colimit \(\xrightarrow{\text { holim }}(\mathscr{F})\) by \(\underset{\longrightarrow}{\operatorname{holim}}(X(0) \rightarrow \cdots \rightarrow X(n))\), and refer to it as the mapping simplex of the diagram \(\mathscr{F}\).

Let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be any diagram of simplicial sets and suppose we are given an \(n\)-simplex of \(\mathrm{N}_{\bullet}(\mathcal{C})\), corresponding to a diagram \(C_{0} \rightarrow \cdots \rightarrow C_{n}\) in the category \(\mathcal{C}\). By virtue of Remark 5.3 .2 .3 the fiber product \(\Delta^{n} \times_{\mathrm{N}_{\mathbf{\bullet}}(\mathcal{C})} \xrightarrow{\operatorname{holim}}(\mathscr{F})\) can be identified with the mapping simplex of the diagram \(\mathscr{F}\left(C_{0}\right) \rightarrow \cdots \rightarrow \mathscr{F}\left(C_{n}\right)\). When \(n=0\), this mapping simplex can be identified with the simplicial set \(\mathscr{F}\left(C_{0}\right)\) (Example 5.3.2.4). For larger values of \(n\), the mapping simplex can be computed recursively:

0252 Remark 5.3.2.12. Let \(n \geq 1\) and let \(\mathscr{F}:[n] \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets which we denote by
\[
X(0) \rightarrow X(1) \rightarrow X(2) \rightarrow \cdots \rightarrow X(n) .
\]

Let \(\mathscr{F}^{\prime}:[n] \rightarrow \operatorname{Set}_{\Delta}\) denote the constant diagram taking the value \(X(0)\). Let \(\mathscr{F}_{0} \subseteq \mathscr{F}\) be the subfunctor given by the diagram
\[
\emptyset \rightarrow X(1) \rightarrow X(2) \rightarrow \cdots \rightarrow X(n)
\]
and define \(\mathscr{F}_{0}^{\prime} \subseteq \mathscr{F}^{\prime}\) similarly, so that we have a pushout diagram

in the category \(\operatorname{Fun}\left([n], \operatorname{Set}_{\Delta}\right)\). Applying Remark 5.3.2.8, we deduce that the induced diagram of simplicial sets

is also a pushout square. Using Example 5.3.2.4 and Remark 5.3.2.7, we can rewrite this diagram as

Example 5.3.2.13 (The Mapping Cylinder). Let \(f: X \rightarrow Y\) be a morphism of simplicial 0366 sets, which we identify with a diagram \(\mathscr{F}:[1] \rightarrow \operatorname{Set}_{\Delta}\). We will denote the homotopy colimit \(\operatorname{holim}(\mathscr{F})\) by holim \((f: X \rightarrow Y)\) and refer to it as the mapping cylinder of the morphism \(f\). Applying Remark \(\overrightarrow{5.3 .2 .12}\), we obtain an isomorphism of simplicial sets
\[
\underset{\longrightarrow}{\operatorname{holim}}(f: X \rightarrow Y) \simeq\left(\Delta^{1} \times X\right) \coprod_{(\{1\} \times X)} Y ;
\]
that is, the mapping cylinder \(\underset{\longrightarrow}{\operatorname{holim}}(f: X \rightarrow Y)\) can be identified with the homotopy pushout \(X \amalg_{X}^{\mathrm{h}} Y\) of Construction 3.4.2.2.

Remark 5.3.2.14. Let \(n\) be a nonnegative integer, and suppose we are given a diagram of 0367 simplicial sets
\[
X(0) \rightarrow X(1) \rightarrow X(2) \rightarrow \cdots \rightarrow X(n) .
\]

For each integer \(0 \leq i \leq n\), let \(\Delta_{\geq i}^{n}\) denote the nerve of the linearly ordered set \(\{i<i+1<\) \(\cdots<n\}\), which we regard as a simplicial subset of \(\Delta^{n}\). Applying Remark 5.3.2.12 repeatedly, we can identify the mapping simplex \(\operatorname{holim}(X(0) \rightarrow \cdots \rightarrow X(n))\) with the iterated pushout
\[
\left(\Delta^{n} \times X(0)\right) \coprod_{\left(\Delta_{\geq 1}^{n} \times X(0)\right)}\left(\Delta_{\geq 1}^{n} \times X(1)\right) \coprod_{\left(\Delta_{\geq 2}^{n} \times X(1)\right)} \cdots \coprod_{(\{n\} \times X(n-1))}(\{n\} \times X(n)) .
\]

0368 Example 5.3.2.15 (Homotopy Quotients). Let \(G\) be a group and let \(B G\) denote the associated groupoid (consisting of a single object with automorphism group \(G\) ). Let \(X\) be a simplicial set equipped with an action of \(G\), which we identify with a functor \(\mathscr{F}: B G \rightarrow \operatorname{Set}_{\Delta}\). We will denote the homotopy colimit \(\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F})\) by \(X_{\mathrm{h} G}\), and refer to it as the homotopy quotient of \(X\) by the action of \(G\).

0369 Example 5.3.2.16. Let \(\mathcal{C}\) be the partially ordered set depicted in the diagram

and suppose we are given a functor \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\), which we identify with a diagram of simplicial sets
\[
A_{0} \stackrel{f_{0}}{\stackrel{f_{0}}{f_{1}} A_{1} .}
\]

The homotopy colimit \(\underset{\longrightarrow}{\text { holim }}(\mathscr{F})\) can be identified with the iterated homotopy pushout
\[
\left(A \coprod_{A}^{\mathrm{h}} A_{0}\right) \coprod_{A}^{\mathrm{h}} A_{1} .
\]

In particular, the comparison map \(q_{0}: A \coprod_{A}^{\mathrm{h}} A_{0} \rightarrow A \coprod_{A} A_{0} \simeq A_{0}\) induces an epimorphism of simplicial sets
\[
q: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow A_{0} \coprod_{A}^{\mathrm{h}} A_{1} .
\]

Note that \(q_{0}\) is always a weak homotopy equivalence of simplicial sets (Corollary 3.4.2.13), so that \(q\) is also a weak homotopy equivalence (Corollary 3.4.2.14). Beware that \(q\) is never an isomorphism, except in the trivial case where the simplicial set \(A\) is empty (in which case the homotopy colimit holim \((\mathscr{F})\) and the homotopy pushout \(A_{0} \amalg_{A}^{\mathrm{h}} A_{1}\) can both be identified with the disjoint union \(\overrightarrow{A_{0}} \amalg A_{1}\) ).
036A Exercise 5.3.2.17. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets with the following properties:
- For every object \(C \in \mathcal{C}\), the simplicial set \(\mathscr{F}(C)\) is a Kan complex.
- For every morphism \(u: C \rightarrow C^{\prime}\) in \(\mathcal{C}\), the induced map \(\mathscr{F}(u): \mathscr{F}(C) \rightarrow \mathscr{F}\left(C^{\prime}\right)\) is a Kan fibration.

Show that the projection map \(\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is a left fibration of simplicial sets.

We now apply the preceding analysis to study the homotopy invariance properties of Construction 5.3.2.1.

Proposition 5.3.2.18. Let \(\mathcal{C}\) be a category and let \(\alpha: \mathscr{F} \rightarrow \mathscr{G}\) be a levelwise weak homotopy equivalence between diagrams \(\mathscr{F}, \mathscr{G}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\). Then the induced map \(\operatorname{holim}(\alpha):\) \(\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{G})\) is a weak homotopy equivalence of simplicial sets.

Proof. By virtue of Proposition 3.4.2.16, it will suffice to show that for every \(n\)-simplex \(\Delta^{n} \rightarrow \mathrm{~N}_{\bullet}(\mathcal{C})\), the induced map \(\Delta^{n} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \xrightarrow{\operatorname{holim}}(\mathscr{F}) \rightarrow \Delta^{n} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \xrightarrow{\operatorname{holim}(\mathscr{G})}\) is a weak homotopy equivalence. Using Remark 5.3.2.3, we are reduced to proving Proposition 5.3.2.18 in the special case where \(\mathcal{C}\) is the linearly ordered set \([n]=\{0<1<\cdots<n\}\). We now proceed by induction on \(n\). If \(n=0\), the desired result follows immediately from Example 5.3.2.2. Let us therefore assume that \(n>0\). Let \(\mathscr{F}^{\prime}\) denote the restriction of \(\mathscr{F}\) to the full subcategory \(\{1<2<\cdots<n\}\) and define \(\mathscr{G}^{\prime}\) similarly. The natural transformation \(\alpha\) determines a commutative diagram of simplicial sets

where the left horizontal maps are monomorphisms, the right vertical map is a weak homotopy equivalence by virtue of our inductive hypothesis, and the other vertical maps are weak homotopy equivalences by virtue of our assumption on \(\alpha\). The desired result now follows by combining Corollary 3.4.2.14 with Remark 5.3.2.12.

Using exactly the same argument, we see that the formation of homotopy colimits is compatible with categorical equivalence:

Variant 5.3.2.19. Let \(\mathcal{C}\) be a category and let \(\alpha: \mathscr{F} \rightarrow \mathscr{G}\) be a levelwise categorical equiva036C lence between diagrams \(\mathscr{F}, \mathscr{G}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\). Then the induced map \(\underset{\longrightarrow}{\operatorname{holim}}(\alpha): \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow\) holim \((\mathscr{G})\) is a categorical equivalence of simplicial sets.

Proof. By virtue of Corollary 4.5.7.3, it will suffice to show that for every \(n\)-simplex \(\Delta^{n} \rightarrow \mathrm{~N}_{\bullet}(\mathcal{C})\), the induced map \(\Delta^{n} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \xrightarrow{\operatorname{holim}}(\mathscr{F}) \rightarrow \Delta^{n} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \underset{\longrightarrow}{\operatorname{holim}(\mathscr{G})}\) is a categorical equivalence of simplicial sets. Using Remark \(\overrightarrow{5.3 .2 .3}\), we are reduced to proving Variant 5.3.2.19 in the special case where \(\mathcal{C}\) is the linearly ordered set \([n]=\{0<1<\cdots<n\}\). We now proceed by induction on \(n\). If \(n=0\), the desired result follows immediately from Example 5.3.2.2. Let us therefore assume that \(n>0\). Let \(\mathscr{F}^{\prime}\) denote the restriction of \(\mathscr{F}\) to
the full subcategory \(\{1<2<\cdots<n\}\) and define \(\mathscr{G}^{\prime}\) similarly. The natural transformation \(\alpha\) determines a commutative diagram of simplicial sets

where the left horizontal maps are monomorphisms, the right vertical map is a categorical equivalence by virtue of our inductive hypothesis, and the other vertical maps are categorical equivalences by virtue of our assumption on \(\alpha\). The desired result now follows by combining Corollary 4.5.4.14 with Remark 5.3.2.12.

The homotopy colimit of Construction 5.3.2.1 can be characterized by a universal mapping property.
036D Construction 5.3.2.20. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets indexed by \(\mathcal{C}\). For each object \(C \in \mathcal{C}\), we let
\[
f_{C}: \mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right) \times \mathscr{F}(C) \rightarrow \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F})
\]
denote the morphism of simplicial sets given on \(n\)-simplices by the formula \(f_{C}(\sigma, \tau)=(\bar{\sigma}, \bar{\tau})\), where \(\bar{\sigma}\) denotes the image of \(\sigma\) in \(\mathrm{N}_{\bullet}(\mathcal{C})\) and \(\bar{\tau}\) denote the image of \(\tau\) under the map \(\mathscr{F}(C) \rightarrow \mathscr{F}(\bar{\sigma}(0))\). Note that we can identify \(f_{C}\) with a morphism of simplicial sets
\[
u_{\mathscr{F}, C}: \mathscr{F}(C) \rightarrow \text { Fun }_{/ \mathrm{N}_{\bullet}(\mathcal{C})}\left(\mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right), \operatorname{holim}_{\longrightarrow}(\mathscr{F})\right)=\mathrm{wTr}_{\mathrm{holim}(\mathscr{F}) / \mathcal{C}}(C) .
\]

This morphism depends functorially on \(C\) : that is, the collection \(u_{\mathscr{F}}=\left\{u_{\mathscr{F}, C}\right\}_{C \in \mathcal{C}}\) is a natural transformation from \(\mathscr{F}\) to the weak transport representation \(w \operatorname{Tr}_{\text {holim }}(\mathscr{F}) / \mathcal{C}\).

For every pair of functors \(\mathscr{F}, \mathscr{G}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\), let \(\operatorname{Hom}_{\text {Fun }\left(\mathcal{C}, \text { Set }_{\Delta}\right)}(\mathscr{F}, \mathscr{G})\). denote the simplicial set parametrizing natural transformations from \(\mathscr{F}\) to \(\mathscr{G}\) (Example 2.4.2.2), described concretely by the formula
\[
\operatorname{Hom}_{\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}(\mathscr{F}, \mathscr{G})_{n}=\operatorname{Hom}_{\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}\left(\mathscr{F}, \mathscr{G}^{\Delta^{n}}\right) .
\]

Here \(\mathscr{G}^{\Delta^{n}}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) denotes the functor given by \(\mathscr{G}^{\Delta^{n}}(C)=\operatorname{Fun}\left(\Delta^{n}, \mathscr{G}(C)\right)\).
036 E Proposition 5.3.2.21. Let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets, let \(\mathcal{E}\) be a simplicial set, and define \(\mathscr{G}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) by the formula \(\mathscr{G}(C)=\operatorname{Fun}\left(\mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right), \mathcal{E}\right)\). Then composition with the natural transformation \(u_{\mathscr{F}}\) of Construction5.3.2.20 induces an isomorphism of simplicial sets
\[
\Phi_{\mathscr{F}}: \operatorname{Fun}\left(\operatorname{holim}_{\longrightarrow}(\mathscr{F}), \mathcal{E}\right) \rightarrow \operatorname{Hom}_{\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}(\mathscr{F}, \mathscr{G}) \cdot .
\]

Proof. For every object \(C \in \mathcal{C}\), let \(h^{C}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) denote the functor corepresented by \(C\) (given by \(h^{C}(D)=\operatorname{Hom}_{\mathcal{C}}(C, D)\), regarded as a discrete simplicial set). For every simplicial set \(K\), let \(\underline{K}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) denote the constant functor taking the value \(K\). For every functor \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) we have a coequalizer diagram
\[
\coprod_{C \rightarrow D} h^{D} \times \underline{\mathscr{F}(C)} \rightrightarrows \coprod_{C} h^{C} \times \underline{\mathscr{F}(C)} \rightarrow \mathscr{F}
\]
in the category \(\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)\). Note that, if we regard the simplicial set \(\mathcal{E}\) as fixed, then the construction \(\mathscr{F} \mapsto \Phi_{\mathscr{F}}\) carries colimits in \(\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)\) to limits in the arrow category \(\operatorname{Fun}\left([1], \operatorname{Set}_{\Delta}\right)\). We can therefore assume without loss of generality that the functor \(\mathscr{F}\) factors as a product \(h^{C} \times \underline{K}\), for some object \(C \in \mathcal{C}\) and some simplicial set \(K\).

Fix an integer \(n \geq 0\); we wish to show that \(\Phi_{\mathscr{F}}\) induces a bijection from \(n\)-simplices of Fun \((\underset{\rightarrow}{\operatorname{holim}}(\mathscr{F}), \mathcal{E})\) to \(n\)-simplices of \(\operatorname{Hom}_{\text {Fun }\left(\mathcal{C}, \text { Set }_{\Delta}\right)}(\mathscr{F}, \mathscr{G})\). Replacing \(\mathcal{E}\) by the simplicial set \(\operatorname{Fun}\left(K \times \Delta^{n}, \mathcal{E}\right)\), we are reduced to proving that Construction 5.3.2.20 induces a bijection
\[
\Phi_{0}: \operatorname{Hom}_{\text {Set }_{\Delta}}\left(\underset{\rightarrow}{\operatorname{holim}}\left(h^{C}\right), \mathcal{E}\right) \rightarrow \operatorname{Hom}_{\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}\left(h^{C}, \mathscr{G}\right) .
\]

Let \(\mathscr{G}_{0}: \mathcal{C} \rightarrow\) Set denote the functor given on objects by the formula
\[
\mathscr{G}_{0}(C)=\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\Delta^{0}, \mathscr{G}(C)\right)=\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right), \mathcal{E}\right) .
\]

Under the identification of \(\underset{\rightarrow}{\operatorname{holim}}\left(h^{C}\right) \simeq \mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right)\) of Example 5.3.2.6 the function \(\Phi_{0}\) corresponds to the bijection \(\mathscr{G}_{0}(C) \simeq \operatorname{Hom}_{\operatorname{Fun}(\mathcal{C}, \mathrm{Set})}\left(h^{C}, \mathscr{G}_{0}\right)\) supplied by Yoneda's lemma.

Corollary 5.3.2.22. Let \(\mathcal{C}\) be a small category. Then the homotopy colimit functor
\[
\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right) \rightarrow \operatorname{Set}_{\Delta} \quad \mathscr{F} \mapsto \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F})
\]
admits a right adjoint, given by the construction
\[
\operatorname{Set}_{\Delta} \rightarrow \operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right) \quad \mathcal{E} \mapsto\left(C \mapsto \operatorname{Fun}\left(\mathrm{~N}_{\bullet}\left(\mathcal{C}_{C /}\right), \mathcal{E}\right)\right) .
\]

Corollary 5.3.2.23. Let \(\mathcal{C}\) be a category, let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a morphism of simplicial 036 G sets, and let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a functor. Then composition with the natural transformation \(u_{\mathscr{F}}\) of Construction 5.3.2.20 induces an isomorphism of simplicial sets
\[
\operatorname{Fun}_{/ \mathrm{N}_{\bullet}(\mathcal{C})}\left(\operatorname{holim}_{\longrightarrow}(\mathscr{F}), \mathcal{E}\right) \rightarrow \operatorname{Hom}_{\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}\left(\mathscr{F}, \mathrm{wTr}_{\mathcal{E} / \mathcal{C}}\right)_{\bullet},
\]
where \(\operatorname{wTr}_{\mathcal{E} / \mathcal{C}}\) is the weak transport representation of Construction 5.3.1.1.

Proof. Define \(\mathscr{G}, \mathscr{H}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) by the formulae \(\mathscr{G}(C)=\operatorname{Fun}\left(\mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right), \mathcal{E}\right)\) and \(\mathscr{H}(C)=\) \(\operatorname{Fun}\left(\mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right), \mathrm{N}_{\bullet}(\mathcal{C})\right)\). We have a commutative diagram of simplicial sets

where the horizontal maps are isomorphisms by virtue of Proposition 5.3.2.21. Corollary 5.3.2.23 follows by restricting to fibers of the vertical maps.

036H Corollary 5.3.2.24. Let \(\mathcal{C}\) be a small category. Then the homotopy colimit functor
\[
\xrightarrow[\rightarrow]{\text { holim }}: \operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right) \rightarrow\left(\operatorname{Set}_{\Delta}\right) / N_{\bullet}(\mathcal{C})
\]
admits a right adjoint, given by the functor
\[
\left(\operatorname{Set}_{\Delta}\right)_{/ \mathrm{N}_{\bullet}(\mathcal{C})} \rightarrow \operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right) \quad\left(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\right) \mapsto\left(\operatorname{wTr}_{\mathcal{E} / \mathcal{C}}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\right)
\]
of Construction 5.3.1.1.

\subsection*{5.3.3 The Weighted Nerve}

025W Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow\) Kan be a diagram of Kan complexes indexed by \(\mathcal{C}\). In \(\$ 5.3 .2\), we introduced the homotopy colimit \(\operatorname{holim}(\mathscr{F})\), which is a simplicial set equipped with a projection map \(U: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C}) . \overrightarrow{\text { If }} \mathscr{F}\) carries each morphism of \(\mathcal{C}\) to a Kan fibration, then the projection map \(U\) is a left fibration of simplicial sets (Exercise 5.3.2.17). Beware that \(U\) is not a left fibration in general. In this section, we introduce a variant of the homotopy colimit \(\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F})\) which we will refer to as the \(\mathscr{F}\)-weighted nerve of \(\mathcal{C}\) and denote by \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) (Definition 5.3.3.1. The weighted nerve is equipped with a projection map \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\), which is a left fibration provided that \(\mathscr{F}\) is a diagram of Kan complexes (Corollary 5.3.3.19). In \(\S 5.3 .5\) we will construct a comparison map \(\lambda_{t}: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) (Construction 5.3.4.11) which is a categorical equivalence of simplicial sets (Corollary 5.3.5.9); in particular, it is a weak homotopy equivalence.

025X Definition 5.3.3.1 (The Weighted Nerve). Let \(\mathcal{C}\) be a category equipped with a functor \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\). For every integer \(n \geq 0\), we let \(\mathrm{N}_{n}^{\mathscr{F}}(\mathcal{C})\) denote the collection of all pairs \((\sigma, \tau)\), where \(\sigma:[n] \rightarrow \mathcal{C}\) is an \(n\)-simplex of \(\mathrm{N}_{\bullet}(\mathcal{C})\) which we identify with a diagram
\[
C_{0} \rightarrow C_{1} \rightarrow C_{2} \rightarrow \cdots \rightarrow C_{n-1} \rightarrow C_{n}
\]
and \(\tau\) is a collection of simplices \(\left\{\tau_{j}: \Delta^{j} \rightarrow \mathscr{F}\left(C_{j}\right)\right\}_{0 \leq j \leq n}\) which fit into a commutative diagram of simplicial sets

For every nondecreasing function \(\alpha:[m] \rightarrow[n]\), we define a map \(\alpha^{*}: \mathrm{N}_{n}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{m}^{\mathscr{F}}(\mathcal{C})\) by the formula \(\alpha^{*}(\sigma, \tau)=\left(\sigma \circ \alpha, \tau^{\prime}\right)\), where \(\tau^{\prime}=\left\{\tau_{i}^{\prime}: \Delta^{i} \rightarrow \mathscr{F}(\alpha(i))\right\}_{0 \leq i \leq m}\) is determined by the requirement that each \(\tau_{i}^{\prime}\) is equal to the composition
\[
\Delta^{i} \xrightarrow{\left.\alpha\right|_{\{0<1<\cdots<i\}}} \Delta^{\alpha(i)} \xrightarrow{\tau_{\alpha(i)}} \mathscr{F}(\alpha(i)) .
\]

By means of these restriction maps, we regard the construction \([n] \mapsto \mathrm{N}_{n}^{\mathscr{F}}(\mathcal{C})\) as a simplicial set. We will denote this simplicial set by \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) and refer to it as the \(\mathscr{F}\)-weighted nerve of \(\mathcal{C}\). Note that there is an evident projection map \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\), given on simplices by the construction \((\sigma, \tau) \mapsto \sigma\).

Example 5.3.3.2. Let \(X\) be a simplicial set, which we identify with the constant functor \(025 Y\) \(\mathscr{F}:[0] \rightarrow \operatorname{Set}_{\Delta}\) taking the value \(X\). Then the weighted nerve \(\mathrm{N}_{\bullet}^{\mathscr{F}}([0])\) can be identified with the simplicial set \(X\).

Remark 5.3.3.3 (Vertices of the Weighted Nerve). Let \(\mathcal{C}\) be a category equipped with a functor \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\). Then vertices of the weighted nerve \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) can be identified with pairs \((C, x)\), where \(C\) is an object of \(\mathcal{C}\) and \(x\) is a vertex of the simplicial set \(\mathscr{F}(C)\).
Remark 5.3.3.4 (Edges of the Weighted Nerve). Let \(\mathcal{C}\) be a category equipped with a 0268 functor \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\), and let \((C, x)\) and \((D, y)\) be vertices of the weighted nerve \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) (see Remark 5.3.3.3. Edges of the weighted nerve \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) with source \((C, x)\) and target \((D, y)\) can be identified with pairs \((f, e)\), where \(f: C \rightarrow D\) is a morphism of the category \(\mathcal{C}\) and \(e: \mathscr{F}(f)(x) \rightarrow y\) is an edge of the simplicial set \(\mathscr{F}(D)\).
Remark 5.3.3.5. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a functor. Let \(K\) be an 036J auxiliary simplicial set, and define \(\mathscr{F}^{K}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) by the formula \(\mathscr{F}^{K}(C)=\operatorname{Fun}(K, \mathscr{F}(C))\). Then the weighted nerves of \(\mathscr{F}\) and \(\mathscr{F}^{K}\) are related by a pullback diagram of simplicial sets

036K Example 5.3.3.6. Let \(\mathcal{C}\) be a category, and let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be the functor given on objects by the formula \(\mathscr{F}(C)=\mathrm{N}_{\bullet}\left(\mathcal{C}_{/ C}\right)\). Then there is a canonical isomorphism of simplicial sets
\[
\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \simeq \mathrm{N}_{\bullet}(\operatorname{Fun}([1], \mathcal{C}))=\operatorname{Fun}\left(\Delta^{1}, \mathrm{~N}_{\bullet}(\mathcal{C})\right) .
\]

0261 Remark 5.3.3.7 (Functoriality in \(\mathcal{C}\) ). Let \(\mathcal{C}\) be a category equipped with a functor \(\mathscr{F}\) : \(\mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\), let \(U: \mathcal{C}^{\prime} \rightarrow \mathcal{C}\) be a functor between categories, and let \(\mathscr{F}^{\prime}: \mathcal{C}^{\prime} \rightarrow \operatorname{Set}_{\Delta}\) denote the composition \(\mathscr{F} \circ U\). Then there is a pullback diagram of simplicial sets

0263 Example 5.3.3.8 (Fibers of the Weighted Nerve). Let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be functor. For each object \(C \in \mathcal{C}\), Remark 5.3.3.7 and Example 5.3.3.2 supply an isomorphism of simplicial sets
\[
\mathscr{F}(C) \simeq\{C\} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) .
\]

0262 Example 5.3.3.9 (The Weighted Nerve of a Constant Diagram). Let \(\mathcal{C}\) be a category, let \(X\) be a simplicial set, and let \(\underline{X}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be the constant functor taking the value \(X\). Then Remark 5.3.3.7 and Example 5.3.3.2 supply an isomorphism of simplicial sets \(\mathrm{N}_{\bullet}^{\underline{X}}(\mathcal{C}) \simeq X \times \mathrm{N}_{\bullet}(\mathcal{C})\).
0266 Remark 5.3.3.10 (Functoriality in \(\mathscr{F}\) ). Let \(\mathcal{C}\) be a category. Then the construction \(\mathscr{F} \mapsto \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) determines a functor from the diagram category \(\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)\) to the category \(\left(\operatorname{Set}_{\Delta}\right)_{/ N_{\bullet}(\mathcal{C})}\) of simplicial sets over the nerve \(\mathrm{N}_{\bullet}(\mathcal{C})\). This functor commutes with all limits and with filtered colimits.

036L Exercise 5.3.3.11. Let \(\mathcal{C}\) be a category and let \(\alpha: \mathscr{F} \rightarrow \mathscr{G}\) be a natural transformation between functors \(\mathscr{F}, \mathscr{G}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\). Show that, if \(\alpha\) is a levelwise trivial Kan fibration, then the induced map of weighted nerves \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{G}}(\mathcal{C})\) is a trivial Kan fibration of simplicial sets.

036M Example 5.3.3.12 (The Weighted Nerve of a Cone). Let \(\mathcal{C}\) be a category and let \(\mathcal{C}^{\triangleright}\) denote the right cone on \(\mathcal{C}\) (Example 4.3.2.5), and let \(\mathbf{1} \in \mathcal{C}^{\triangleright}\) denote the final object. Suppose we are given a diagram of simplicial sets \(\overline{\mathscr{F}}: \mathcal{C}^{\triangleright} \rightarrow \operatorname{Set}_{\Delta}\). Set \(\mathscr{F}=\left.\overline{\mathscr{F}}\right|_{\mathcal{C}}\) and \(Y=\overline{\mathscr{F}}(\mathbf{1})\), so that \(\overline{\mathscr{F}}\) determines a natural transformation \(\alpha: \mathscr{F} \rightarrow \underline{Y}\) (where \(\underline{Y}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) denotes the constant functor taking the value \(Y\) ). Combining Remark 5.3.3.10 with Example 5.3.3.9, we obtain morphisms of simplicial sets
\[
\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \xrightarrow{\alpha} \mathrm{N}_{\bullet} \underline{Y}(\mathcal{C}) \simeq Y \times \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow Y .
\]

Unwinding the definitions, there is a canonical isomorphism of simplicial sets
\[
\mathrm{N}_{\bullet}^{\overline{\mathscr{F}}}\left(\mathcal{C}^{\triangleright}\right) \simeq \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \star_{Y} Y,
\]
where the right hand side denotes the relative join of Construction 5.2.3.1.
Example 5.3.3.13. Let \(f: X \rightarrow Y\) be a morphism of simplicial sets, which we identify \(025 Z\) with a functor \(\mathscr{F}:[1] \rightarrow \operatorname{Set}_{\Delta}(\) so that \(X=\mathscr{F}(0)\) and \(Y=\mathscr{F}(1))\). Then Example 5.3.3.12 supplies an isomorphism of simplicial sets \(\mathrm{N}_{\mathscr{F}}^{\mathscr{F}}([1]) \simeq X \star_{Y} Y\).
Example 5.3.3.14. Let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a functor. For every morphism \(f: C \rightarrow D\) in \(\mathcal{C}, 0264\) Remark 5.3.3.7 and Example 5.3.3.13 supply an isomorphism of simplicial sets
\[
\Delta^{1} \times_{\mathrm{N}} \cdot(\mathcal{C}) \mathrm{N}_{\boldsymbol{\theta}}^{\mathscr{F}}(\mathcal{C}) \simeq \mathscr{F}(C) \star_{\mathscr{F}(D)} \mathscr{F}(D) .
\]

Proposition 5.3.3.15. Let \(\mathcal{C}\) be a category and let \(\alpha: \mathscr{F} \rightarrow \mathscr{G}\) be a natural transformation 046X between functors \(\mathscr{F}, \mathscr{G}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\). Assume that:
- For each object \(C \in \mathcal{C}\), the morphism \(\alpha_{C}: \mathscr{F}(C) \rightarrow \mathscr{G}(C)\) is a cocartesian fibration of simplicial sets.
- For each morphism \(u: C \rightarrow D\) of \(\mathcal{C}\), the morphism \(\mathscr{F}(u): \mathscr{F}(C) \rightarrow \mathscr{F}(D)\) carries \(\alpha_{C}\)-cocartesian edges of \(\mathscr{F}(C)\) to \(\alpha_{D}\)-cocartesian edges of \(\mathscr{F}(D)\).
Then:
(1) The induced map \(U: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{G}}(\mathcal{C})\) is a cocartesian fibration of simplicial sets.
(2) Let \((f, e):(C, x) \rightarrow(D, y)\) be an edge of the simplicial set \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) (see Remark 5.3.3.4). Then \((f, e)\) is \(U\)-cocartesian if and only if \(e: \mathscr{F}(f)(x) \rightarrow y\) is an \(\alpha_{D}\)-cocartesian edge of the simplicial set \(\mathscr{F}(D)\).

Proof. By virtue of Proposition 5.1.4.7 and Remark 5.3.3.7, we may assume without loss of generality that \(\mathcal{C}\) is the linearly ordered set \([n]=\{0<1<\cdots<n\}\) for some nonnegative integer \(n\). We proceed by induction on \(n\). If \(n=0\), then \(U\) can be identified with the cocartesian fibration \(\alpha_{0}: \mathscr{F}(0) \rightarrow \mathscr{G}(0)\) (Example 5.3.3.2), so that assertions (1) and (2) are immediate. Let us therefore assume that \(n>0\), so that \(\mathcal{C}\) can be identified with the cone \(\mathcal{C}_{0}^{\triangleright}\) for \(\mathcal{C}_{0}=[n-1]\). Set \(\mathscr{F}_{0}=\left.\mathscr{F}\right|_{\mathcal{C}_{0}}\) and \(\mathscr{G}_{0}=\left.\mathscr{G}\right|_{\mathcal{C}_{0}}\). It follows from our inductive hypothesis that \(U\) restricts to a cocartesian fibration \(U_{0}: \mathrm{N}_{\bullet}^{\mathscr{F}_{0}}\left(\mathcal{C}_{0}\right) \rightarrow \mathrm{N}_{0}^{\mathscr{C}_{0}}\left(\mathcal{C}_{0}\right)\) is a cocartesian fibration of \(\infty\)-categories, and that an edge of \(\mathrm{N}_{\bullet}^{\mathscr{F}_{0}}\left(\mathcal{C}_{0}\right)\) is \(U_{0}\)-cocartesian if and only if it satisfies the criterion described in (2). It follows that the functor \(\mathrm{N}_{\bullet}^{\mathscr{F}_{0}}\left(\mathcal{C}_{0}\right) \rightarrow \mathscr{F}(n)\) described in Example 5.3.3.12 carries \(U_{0}\)-cocartesian morphisms to \(\alpha_{n}\)-cocartesian morphisms of the \(\infty\)-category \(\mathscr{F}(n)\). Unwinding the definitions, we can identify \(U\) with the map of relative joins
\[
\mathrm{N}_{\bullet}^{\mathscr{\mathscr { F } _ { 0 }}}\left(\mathcal{C}_{0}\right) \star_{\mathscr{F}(n)} \mathscr{F}(n) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{G}_{0}}\left(\mathcal{C}_{0}\right) \star_{\mathscr{G}(n)} \mathscr{G}(n) .
\]

Assertions (1) and (2) now follow from Lemma 5.2.3.17.

046 Y Corollary 5.3.3.16. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow\) QCat be a diagram of \(\infty\)-categories indexed by \(\mathcal{C}\). Then:
(1) The projection map \(U: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is a cocartesian fibration of simplicial sets.
(2) Let \((f, e):(C, x) \rightarrow(D, y)\) be an edge of the simplicial set \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) (see Remark5.3.3.4). Then \((f, e)\) is \(U\)-cocartesian if and only if \(e: \mathscr{F}(f)(x) \rightarrow y\) is an isomorphism in the \(\infty\)-category \(\mathscr{F}(D)\).

In particular, \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) is an \(\infty\)-category.
Proof. Apply Proposition 5.3.3.15 in the special case where \(\mathscr{G}\) is the constant diagram taking the value \(\Delta^{0}\).

05DY Exercise 5.3.3.17. Let \(\mathcal{C}\) be a category, let \(n\) be an integer, and let \(\mathscr{F}: \mathcal{C} \rightarrow\) Set \(_{\Delta}\) be a diagram of simplicial sets indexed by \(\mathcal{C}\). Assume that, for each object \(C \in \mathcal{C}\), the simplicial set \(\mathscr{F}(C)\) is an \((n, 1)\)-category (Definition 4.8.1.8). Show that the cocartesian fibration \(U: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is \(n\)-categorical, in the sense of Definition 4.8.6.23.

In particular, if each of the simplicial sets \(\mathscr{F}(C)\) is (isomorphic to) the nerve of an ordinary category, then the weighted nerve \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) is also isomorphic to the nerve of an ordinary category. For a more precise statement, see Example 5.6.1.8.

046 Z Corollary 5.3.3.18. Let \(\mathcal{C}\) be a category and let \(\alpha: \mathscr{F} \rightarrow \mathscr{G}\) be a natural transformation between functors \(\mathscr{F}, \mathscr{G}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\). Suppose that, for every object \(C \in \mathcal{C}\), the morphism \(\alpha_{C}: \mathscr{F}(C) \rightarrow \mathscr{G}(C)\) is a left fibration of simplicial sets. Then the induced map \(U: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow\) \(\mathrm{N}_{\bullet}^{\mathscr{G}}(\mathcal{C})\) is also a left fibration of simplicial sets.

Proof. Combine Propositions 5.1.4.14 and 5.3.3.15.
036 N Corollary 5.3.3.19. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a functor. Suppose that, for every object \(C \in \mathcal{C}\), the simplicial set \(\mathscr{F}(C)\) is a Kan complex. Then the projection map \(U: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is a left fibration.

Proof. Apply Corollary 5.3.3.18 in the special case where \(\mathscr{G}\) is the constant diagram taking the value \(\Delta^{0}\).

036P Corollary 5.3.3.20. Let \(\mathcal{C}\) be a category and let \(\alpha: \mathscr{F} \rightarrow \mathscr{F}^{\prime}\) be a natural transformation between functors \(\mathscr{F}, \mathscr{F}^{\prime}: \mathcal{C} \rightarrow\) Set \(_{\Delta}\). Then \(\alpha\) is a levelwise categorical equivalence if and only if the induced map \(T: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{F}^{\prime}}(\mathcal{C})\) is a categorical equivalence of simplicial sets.

Proof. Assume first that \(\alpha\) is a levelwise categorical equivalence. To prove that \(T\) is a categorical equivalence of simplicial sets, it will suffice to show that for every simplex \(\sigma: \Delta^{n} \rightarrow \mathrm{~N}_{\bullet}(\mathcal{C})\), the induced map \(T_{\sigma}: \Delta^{n} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \Delta^{n} \times \mathrm{N}_{\bullet}(\mathcal{C}) \mathrm{N}_{\bullet}^{\mathscr{F}^{\prime}}(\mathcal{C})\) is a categorical
equivalence of simplicial sets (Corollary 4.5.7.3). Using Remark 5.3.3.7, we can reduce to the special case where \(\mathcal{C}\) is the linearly ordered \([n]=\{0<1<\cdots<n\}\) for some \(n \geq 0\). We now proceed by induction on \(n\). If \(n=0\), the result is immediate from Example 5.3.3.2. The inductive step follows by combining Example 5.3.3.12 with Corollary 5.2.4.7.

We now prove the converse. Using Proposition 4.1.3.2, we can choose a commutative diagram

in the category \(\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)\), where the vertical maps are levelwise categorical equivalences and the simplicial sets \(\mathscr{G}(C)\) and \(\mathscr{G}^{\prime}(C)\) are \(\infty\)-categories for each \(C \in \mathcal{C}\). Using the first part of the proof, we can replace \(\alpha\) by \(\beta\) and thereby reduce to the special case where \(\mathscr{F}\) and \(\mathscr{F}^{\prime}\) are diagrams of \(\infty\)-categories. In this case, the projection maps \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C}) \leftarrow \mathrm{N}_{\bullet}^{\mathscr{F}^{\prime}}(\mathcal{C})\) are cocartesian fibrations of \(\infty\)-categories (Corollary 5.3.3.16). It then follows from Theorem 5.1.6.1 (together with Example 5.3.3.8 that if \(T\) is an equivalence of \(\infty\)-categories, then \(\alpha\) is a levelwise categorical equivalence.

Example 5.3.3.21. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow\) Set \(_{\Delta}\). Suppose that, for every object \(C \in \mathcal{C}\), the simplicial set \(\mathscr{F}(C)\) is an \(\infty\)-category, so that the projection map \(U: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is a cocartesian fibration (Corollary 5.3.3.16). Define \(\mathscr{F} \simeq: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) by the formula \(\mathscr{F} \simeq(C)=\mathscr{F}(C)^{\simeq}\). Then \(\mathrm{N}_{\bullet}^{\mathscr{F} \simeq}(\mathcal{C})\) can be identified with with simplicial subset of \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) spanned by those \(n\)-simplices which carry each edge of \(\Delta^{n}\) to a \(U\)-cocartesian edge of \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\). That is, the projection map \(U^{\simeq}: \mathrm{N}_{\bullet}^{\mathscr{\mathscr { }}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is the underlying left fibration of the cocartesian fibration \(U\) (see Corollary 5.1.4.15).

Remark 5.3.3.22 (The Homotopy Transport Representation). Let \(\mathcal{C}\) be a category equipped with a functor \(\mathscr{F}: \mathcal{C} \rightarrow\) QCat and let \(U: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be the cocartesian fibration of Corollary 5.3.3.16. Then the homotopy transport representation
\[
\mathrm{h} \operatorname{Tr}_{\mathrm{N}_{\bullet}^{\mathscr{Z}}(\mathcal{C}) / \mathrm{N}_{\bullet}(\mathcal{C})}: \mathcal{C} \rightarrow \mathrm{hQCat}
\]
of Construction 5.2.5.2 is canonically isomorphic to the composition \(\mathcal{C} \xrightarrow{\mathscr{F}} \mathrm{QCat} \rightarrow \mathrm{hQCat}\). To prove this, it suffices to observe that for every morphism \(f: C \rightarrow D\) in \(\mathcal{C}\), the functor
\[
\mathscr{F}(f): \mathscr{F}(C) \simeq\{C\} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow\{D\} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\boldsymbol{\mathscr { F }}}^{\mathscr{F}}(\mathcal{C}) \simeq \mathscr{F}(D)
\]
is given by covariant transport along \(f\), which follows immediately from Proposition 5.2.3.15 and Example 5.3.3.14.

We conclude this section by showing that the weighted nerve can be characterized by a universal mapping property.

036R Notation 5.3.3.23. Let \(\mathcal{C}\) be a category and suppose we are given a morphism of simplicial sets \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\). For every object \(C \in \mathcal{C}\), let \(\mathscr{G}_{\mathcal{E}}(C)\) denote the fiber product \(\mathrm{N}_{\bullet}(\mathcal{C} / C) \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathcal{E}\). The construction \(C \mapsto \mathscr{G}_{\mathcal{E}}(C)\) then determines a functor \(\mathscr{G}_{\mathcal{E}}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\).

Suppose we are given an \(n\)-simplex \(\sigma\) of \(\mathcal{E}\). Then \(U(\sigma)\) is an \(n\)-simplex of the simplicial set \(\mathrm{N}_{\bullet}(\mathcal{C})\), which we can identify with a diagram
\[
C_{0} \xrightarrow{f_{1}} C_{1} \xrightarrow{f_{2}} C_{2} \rightarrow \cdots \xrightarrow{f_{n}} C_{n}
\]
in the category \(\mathcal{C}\). For \(0 \leq m \leq n\), we can view the diagram
\[
C_{0} \xrightarrow{f_{1}} C_{1} \xrightarrow{f_{2}} C_{2} \rightarrow \cdots \xrightarrow{f_{m}} C_{m} \xrightarrow{\text { id }} C_{m}
\]
as an \(m\)-simplex \(\bar{\tau}_{m}\) of the simplicial set \(\mathrm{N}_{\bullet}\left(\mathcal{C}_{/ C_{m}}\right)\). The pair \(\left(\bar{\tau}_{m},\left.U(\sigma)\right|_{\Delta^{m}}\right)\) can then be viewed as an \(m\)-simplex \(\tau_{m}\) of \(\mathscr{G}_{\mathcal{E}}\left(C_{m}\right)\). Setting \(\tau=\left(\tau_{0}, \tau_{1}, \cdots, \tau_{n}\right)\), we observe that the pair \((U(\sigma), \tau)\) can be regarded as an \(n\)-simplex \(u_{\mathcal{E}}(\sigma)\) of the weighted nerve \(\mathrm{N}_{\bullet}^{\mathscr{G}_{\mathcal{E}}}(\mathcal{C})\). Allowing \(n\) to vary, the construction \(\sigma \mapsto u_{\mathcal{E}}(\sigma)\) determines a morphism of simplicial sets \(u_{\mathcal{E}}: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}^{\mathscr{G}}(\mathcal{C})\) for which the diagram

is commutative.
036 S Proposition 5.3.3.24. Let \(\mathcal{C}\) be a category, let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a morphism of simplicial sets, and let \(u_{\mathcal{E}}: \mathcal{E} \rightarrow \mathrm{N}_{\mathcal{E}}^{\mathscr{E}}(\mathcal{C})\) be the morphism of Notation 5.3.3.23. For every functor \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\), precomposition with \(u_{\mathcal{E}}\) induces a bijection
\[
T_{\mathcal{E}}: \operatorname{Hom}_{\text {Fun }\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)}\left(\mathscr{G}_{\mathcal{E}}, \mathscr{F}\right) \rightarrow \operatorname{Hom}_{\left(\operatorname{Set}_{\Delta}\right) / \mathrm{N}_{\bullet}(\mathcal{C})}\left(\mathcal{E}, \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\right) .
\]

036 T Corollary 5.3.3.25. Let \(\mathcal{C}\) be a category. Then the weighted nerve functor
\[
\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right) \rightarrow\left(\operatorname{Set}_{\Delta}\right) / \mathrm{N}_{\bullet}(\mathcal{C}) \quad \mathscr{F} \mapsto \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})
\]
has a left adjoint, given by the construction \(\mathcal{E} \mapsto \mathscr{G}_{\mathcal{E}}\) of Notation 5.3.3.23.

Proof of Proposition 5.3.3.24. The construction \(\mathcal{E} \mapsto T_{\mathcal{E}}\) carries colimits in the category \(\left(\operatorname{Set}_{\Delta}\right) / N_{\bullet}(\mathcal{C})\) to limits in the arrow category \(\operatorname{Fun}([1]\), Set). We can therefore assume without loss of generality that \(\mathcal{E}=\Delta^{n}\) is a standard simplex, so that the morphism \(U\) determines a diagram \(C_{0} \rightarrow C_{1} \rightarrow \cdots \rightarrow C_{n}\) in the category \(\mathcal{C}\). Unwinding the definitions, we see that the codomain of \(T_{\mathcal{E}}\) can be identified with the set of tuples \(\tau=\left(\tau_{0}, \tau_{1}, \cdots, \tau_{n}\right)\), where \(\tau_{i}: \Delta^{i} \rightarrow \mathscr{F}\left(C_{i}\right)\) are simplices for which the diagram

is commutative. Let us regard \(\tau\) as fixed; we wish to prove that there is a unique natural transformation \(\alpha: \mathscr{G}_{\mathcal{E}} \rightarrow \mathscr{F}\) satisfying \(T_{\mathcal{E}}(\alpha)=\tau\).

Let \(D\) be an object of \(\mathcal{C}\) and let \(m \geq 0\) be an integer. Then \(m\)-simplices of the simplicial set \(\mathscr{G}_{\mathcal{E}}(D)=\mathrm{N}_{\bullet}\left(\mathcal{C}_{/ D}\right) \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathcal{E}\) can be identified with pairs \((f, g)\), where \(g:[m] \rightarrow[n]\) is a nondecreasing function and \(f: C_{g(m)} \rightarrow D\) is a morphism in the category \(\mathcal{C}\). Let \(\alpha_{D}(f, g)\) denote the \(m\)-simplex of \(\mathscr{F}(D)\) given by the composition
\[
\Delta^{m} \xrightarrow{g} \Delta^{g(m)} \xrightarrow{\tau_{g(m)}} \mathscr{F}\left(C_{g(m)}\right) \xrightarrow{\mathscr{F}(f)} \mathscr{F}(D) .
\]

The construction \((f, g) \mapsto \alpha_{D}(f, g)\) determines a morphism of simplicial sets \(\alpha_{D}: \mathscr{G}_{\mathcal{E}}(D) \rightarrow\) \(\mathscr{F}(D)\). The assignment \(D \mapsto \alpha_{D}\) determines a natural transformation of functors \(\alpha: \mathscr{G}_{\mathcal{E}} \rightarrow \mathscr{F}\) satisfying \(T_{\mathcal{E}}(\alpha)=\tau\). This proves existence.

We now prove uniqueness. Suppose we are given another natural transformation \(\alpha^{\prime}\) : \(\mathscr{G}_{\mathcal{E}} \rightarrow \mathscr{F}\) satisfying \(T_{\mathcal{E}}\left(\alpha^{\prime}\right)=\tau\); we wish to show that \(\alpha=\alpha^{\prime}\). Fix an object \(D \in \mathcal{C}\) and an \(m\)-simplex of the simplicial set \(\mathscr{G}_{\mathcal{E}}(D)\), which we identify with a pair \((f, g)\) as above. We wish to verify that \(\alpha_{D}(f, g)\) and \(\alpha_{D}^{\prime}(f, g)\) coincide (as \(m\)-simplices of the simplicial set \(\mathscr{F}(D))\). Set \(n^{\prime}=g(m)\), so that the function \(g\) factors as a composition \([m] \xrightarrow{g}\left[n^{\prime}\right] \xrightarrow{\iota}[n]\), where \(\iota:\left[n^{\prime}\right] \hookrightarrow[n]\) is the inclusion map. Since \(\alpha_{D}\) and \(\alpha_{D}^{\prime}\) are morphisms of simplicial sets, it will suffice to prove that \(\alpha_{D}(f, \iota)\) and \(\alpha_{D}^{\prime}(f, \iota)\) coincide (as \(n^{\prime}\)-simplices of the simplicial set \(\mathscr{F}(D)\) ). Since both \(\alpha_{D}\) and \(\alpha_{D}^{\prime}\) are natural in \(D\), we may assume without loss of generality that \(D=C_{n^{\prime}}\) and that \(f\) is the identity morphism. In this case, the identities \(T_{\mathcal{E}}(\alpha)=\tau=T_{\mathcal{E}}\left(\alpha^{\prime}\right)\) give \(\alpha_{D}(f, \iota)=\tau_{n^{\prime}}=\alpha_{D}^{\prime}(f, \iota)\).

Variant 5.3.3.26. Let \(\mathcal{C}\) be a category, and let us regard \(\operatorname{Fun}\left(\mathcal{C}, \operatorname{Set}_{\Delta}\right)\) as equipped with the simplicial enrichment described in Example 2.4.2.2. For every morphism of simplicial sets \(\mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) and every functor \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\), precomposition with the morphism
\(u_{\mathcal{E}}: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}^{\mathscr{G}_{\mathcal{E}}}(\mathcal{C})\) of Notation 5.3.3.23 induces an isomorphism of simplicial sets
\[
\operatorname{Hom}_{\text {Fun }^{\left(\mathcal{C}, \text { Set }_{\Delta}\right)}}\left(\mathscr{G}_{\mathcal{E}}, \mathscr{F}\right) \bullet \rightarrow \operatorname{Fun}_{/ \mathrm{N}_{\bullet}(\mathcal{C})}\left(\mathcal{E}, \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\right) .
\]

To see that this map is bijective on \(m\)-simplices, we can replace \(\mathcal{E}\) by the product \(\Delta^{m} \times \mathcal{E}\) to reduce to the case \(m=0\), in which case it follows from Proposition 5.3.3.24.

\subsection*{5.3.4 Scaffolds of Cocartesian Fibrations}

036 V Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow\) QCat be a (strictly commutative) diagram of \(\infty\)-categories indexed by \(\mathcal{C}\). Our goal in this section is to show that the diagram \(\mathscr{F}\) can be recovered, up to equivalence, from the weighted nerve \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) of Definition 5.3.3.1. More precisely, we will show that there exists a levelwise categorical equivalence from \(\mathscr{F}\) to the strict transport representation \(\operatorname{sTr}_{\mathrm{N} \mathscr{F}^{\mathscr{*}}(\mathcal{C}) / \mathcal{C}}\) of Construction 5.3.1.5 (Corollary 5.3.4.19).

We begin with some general remarks. Let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\overline{\mathcal{C}})\) be any cocartesian fibration of simplicial sets and let \(\operatorname{wTr}_{\mathcal{E} / \mathcal{C}}: \mathcal{C} \rightarrow\) QCat be the weak transport representation of \(U\) (Construction 5.3.1.1). Every levelwise categorical equivalence \(\alpha: \mathscr{F} \rightarrow \operatorname{sTr}_{\mathcal{E} / \mathcal{C}}\) can be viewed as a natural transformation from \(\mathscr{F}\) to the weak transport representation \(\mathrm{wTr} \mathrm{E}_{\mathcal{E}} \mathcal{C}\), which we can identify (using Corollary 5.3.2.23) with a morphism from the homotopy colimit \(\xrightarrow{\text { holim }}(\mathscr{F})\) into \(\mathcal{E}\). Our first goal is to give an explicit characterization of the collection of morphisms \(\lambda: \operatorname{holim}(\mathscr{F}) \rightarrow \mathcal{E}\) which arise in this way, which we will refer to as scaffolds of the cocartesian fibration \(U\) (Definition 5.3.4.2 and Remark 5.3.4.10).

036W Definition 5.3.4.1. Let \(\mathcal{C}\) be a category, let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets indexed by \(\mathcal{C}\), and let \(e\) be an edge of the homotopy colimit holim \((\mathscr{F})\). Let us identify \(e\) with a pair \((f, \bar{e})\), where \(f: C \rightarrow D\) is a morphism in the category \(\mathcal{C}\) and \(\bar{e}\) is an edge of the simplicial set \(\mathscr{F}(C)\). We will say that the edge \(e=(f, \bar{e})\) is horizontal if \(\bar{e}\) is a degenerate edge of \(\mathscr{F}(C)\).

0255 Definition 5.3.4.2. Let \(\mathcal{C}\) be a category, let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a cocartesian fibration of \(\infty\)-categories, and let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets. We will say that a morphism of simplicial sets \(\lambda: \operatorname{holim}(\mathscr{F}) \rightarrow \mathcal{E}\) is a scaffold if it satisfies the following conditions:
(0) The diagram of simplicial sets

is commutative (where the left vertical map is the projection map of Construction 5.3.2.1.
(1) The morphism \(\lambda\) carries horizontal edges of \(\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F})\) to \(U\)-cocartesian morphisms of \(\mathcal{E}\).
(2) For every object \(C \in \mathcal{C}\), the induced map
\[
\mathscr{F}(C) \simeq\{C\} \times_{\mathrm{N}_{\mathbf{0}}(\mathcal{C})} \xrightarrow[\longrightarrow]{\operatorname{holim}}(\mathscr{F}) \xrightarrow{\lambda}\{C\} \times_{\mathrm{N} \cdot(\mathcal{C})} \mathcal{E}
\]
is a categorical equivalence of simplicial sets.
Example 5.3.4.3. Let \(n\) be a nonnegative integer and let \(\mathcal{E}\) denote the nerve of the partially 036 X ordered set \(Q=\{(i, j) \in[n] \times[n]: j \leq i\}\). Then there is a cocartesian fibration of \(\infty\) categories \(U: \mathcal{E} \rightarrow \Delta^{n}\), given on vertices by the formula \(U(i, j)=i\). Let \(\mathscr{F}:[n] \rightarrow \operatorname{Set}_{\Delta}\) denote the functor given by \(\mathscr{F}(i)=\Delta^{i}\), so that vertices of the homotopy colimit can be identified with elements of \(Q\). There is a unique morphism of simplicial sets \(\lambda: \operatorname{holim}(\mathscr{F}) \rightarrow \mathcal{E}\) which is the identity at the level of vertices, which is a scaffold of the cocartesian fibration \(U\). Moreover, \(\lambda\) is a monomorphism, and an \(n\)-simplex \(\left(i_{0}, j_{0}\right) \leq\left(i_{1}, j_{1}\right) \leq \cdots \leq\left(i_{n}, j_{n}\right)\) belongs to the image of \(\lambda\) if and only if \(j_{n} \leq i_{0}\). The case \(n=3\) is depicted in the following diagram, where the image of \(\lambda\) is indicated with solid arrows:

Example 5.3.4.4. Let \(\mathcal{E}\) be an \(\infty\)-category equipped with a cocartesian fibration \(U: \mathcal{E} \rightarrow \Delta^{1} 0256\) having fibers \(\mathcal{E}_{0}=\{0\} \times_{\Delta^{1}} \mathcal{E}\) and \(\mathcal{E}_{1}=\{1\} \times_{\Delta^{1}} \mathcal{E}\). Choose a functor \(F: \mathcal{E}_{0} \rightarrow \mathcal{E}_{1}\) and a morphism \(h: \Delta^{1} \times \mathcal{E}_{0} \rightarrow \mathcal{E}\) which witnesses \(F\) as given by covariant transport along the nondegenerate edge of \(\Delta^{1}\), in the sense of Definition 5.2.2.4. Then \(F\) can be identified with a diagram \(\mathscr{F}:[1] \rightarrow\) QCat, and the map
\[
\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F})=\left(\Delta^{1} \times \mathcal{E}_{0}\right) \coprod_{\left(\{1\} \times \mathcal{E}_{0}\right)} \mathcal{E}_{1} \xrightarrow{(h, \mathrm{id})} \mathcal{E}
\]
is a scaffold.

036 Y Remark 5.3.4.5 (Isomorphism Invariance). In the situation of Definition 5.3.4.2, suppose that we are given a pair of morphisms \(\lambda, \lambda^{\prime}: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathcal{E}\) which are isomorphic when viewed as objects of the \(\infty\)-category Fun \(/ \mathrm{N}_{\bullet}(\mathcal{C})(\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}), \mathcal{E})\). Then \(\lambda\) is a scaffold if and only if \(\lambda^{\prime}\) is a scaffold (see Corollary 5.1.2.5 and Remark 4.5.1.15.
\(036 Z\) Remark 5.3.4.6 (Change of \(\mathcal{E}\) ). Suppose we are given a commutative diagram

where the vertical maps are cocartesian fibrations and \(T\) is an equivalence of cocartesian fibrations over \(\mathrm{N}_{\bullet}(\mathcal{C})\). Then a morphism \(\lambda: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathcal{E}\) is a scaffold of the cocartesian fibration \(U\) if and only if \(T \circ \lambda\) is a scaffold of the cocartesian fibration \(U^{\prime}\).

We now describe two important examples of scaffolds, both of which can be regarded as generalizations of Example 5.3.4.3.

026D Construction 5.3.4.7 (The Universal Scaffold). Let \(\mathcal{C}\) be a category, let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a cocartesian fibration of \(\infty\)-categories, and let \(s \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) denote the strict transport representation of \(U\) (Construction 5.3.1.5). For each \(n \geq 0\), we can identify \(n\)-simplices of the homotopy colimit \(\underset{\longrightarrow}{\text { holim }}\left(\operatorname{sTr}_{\mathcal{E}} / \mathcal{C}\right)\) with pairs \((\sigma, \tau)\), where \(\sigma\) is an \(n\)-simplex of \(\mathrm{N}_{\bullet}(\mathcal{C})\) (given by a diagram \(C_{0} \rightarrow C_{1} \rightarrow \cdots \rightarrow C_{n}\) in the category \(\mathcal{C}\) ) and \(\tau\) is an \(n\)-simplex of the \(\infty\)-category \(\operatorname{sir}_{\mathcal{E} / \mathcal{C}}\left(C_{0}\right)=\operatorname{Fun} / \underset{/ \mathrm{N}_{\bullet}(\mathcal{C})}{\mathrm{CCar}}\left(\mathrm{N}_{\bullet}\left(\mathcal{C}_{C_{0}} /\right), \mathcal{E}\right)\), which we identify with a morphism of simplicial sets \(\Delta^{n} \times \mathrm{N}_{\bullet}\left(\mathcal{C}_{C_{0}} /\right) \rightarrow \mathcal{E}\). Let us identify the diagram \(C_{0} \xrightarrow{\text { id }} C_{0} \rightarrow C_{1} \rightarrow \cdots \rightarrow C_{n}\) with an \(n\)-simplex \(\tilde{\sigma}\) of the simplicial set \(\mathrm{N}_{\bullet}\left(\mathcal{C}_{C_{0}} /\right)\), and let \(\lambda_{u}(\sigma, \tau)\) denote the \(n\)-simplex of \(\mathcal{E}\) given by the composite map
\[
\Delta^{n} \xrightarrow{(\mathrm{id}, \widetilde{\sigma})} \Delta^{n} \times \mathrm{N}_{\bullet}\left(\mathcal{C}_{C_{0} /}\right) \xrightarrow{\tau} \mathcal{E}
\]

The construction \((\sigma, \tau) \mapsto \lambda_{u}(\sigma, \tau)\) determines a morphism of simplicial sets
\[
\lambda_{u}: \operatorname{holim}\left(\operatorname{sir}_{\mathcal{E} / \mathcal{C}}\right) \rightarrow \mathcal{E},
\]
which we will refer to as the universal scaffold of the cocartesian fibration \(U\).
0370 Proposition 5.3.4.8. Let \(\mathcal{C}\) be a category and let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a cocartesian fibration of \(\infty\)-categories. Then the morphism \(\lambda_{u}: \operatorname{holim}\left(\operatorname{sTr}_{\mathcal{E}} / \mathcal{C}\right) \rightarrow \mathcal{E}\) of Construction 5.3.4.7 is a scaffold, in the sense of Definition 5.3.4.2.

Proof. It is clear that the composition \(U \circ \lambda_{u}\) coincides with the projection map holim \((\mathscr{F}) \rightarrow\) \(\mathrm{N}_{\bullet}(\mathcal{C})\). Let \(e\) be a horizontal edge of the homotopy colimit holim \(\left(\mathrm{sTr}_{\mathcal{E} / \mathcal{C}}\right)\), determined by a morphism \(\bar{e}: C \rightarrow D\) in the category \(\mathcal{C}\) together with a degenerate edge \(\mathrm{id}_{T}\) of the simplicial set \(\operatorname{sir}_{\mathcal{E} / \mathcal{C}}(C)\). Identifying \(T\) with an object of the \(\infty\)-category Fun/ \({ }_{\left(\mathrm{N}_{\bullet}(\mathcal{C})\right.}^{\mathrm{Cart}}\left(\mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right), \mathcal{E}\right)\), we see that \(\lambda_{u}(e)\) coincides with the morphism \(T(\bar{e})\) and is therefore a \(U\)-cocartesian morphism of \(\mathcal{E}\). To complete the proof, we observe that for every object \(C \in \mathcal{C}\), the induced map
\[
\operatorname{sTr}_{\mathcal{E} / \mathcal{C}}(C) \simeq\{C\} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \xrightarrow{\operatorname{holim}}\left(\mathrm{sTr}_{\mathcal{E} / \mathcal{C}}\right) \xrightarrow{\lambda}\{C\} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathcal{E}
\]
agrees with the map ev \(C: \underset{/ \mathrm{N}_{\bullet}(\mathcal{C})}{\mathrm{CCart}}\left(\mathrm{N}_{\bullet}\left(\mathcal{C}_{C /}\right), \mathcal{E}\right) \rightarrow \mathcal{E}_{C}\) given by evaluation on the initial object \(\mathrm{id}_{C} \in \mathcal{C}_{C /}\), and is therefore a trivial Kan fibration of simplicial sets (Proposition 5.3.1.7.

Corollary 5.3.4.9. Let \(\mathcal{C}\) be a category and let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a cocartesian fibration of \(\infty\)-categories. Then there exists a diagram \(\mathscr{F}: \mathcal{C} \rightarrow \mathrm{QCat}\) and a scaffold \(\lambda: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathcal{E}\).

Remark 5.3.4.10 (Universality). Let \(\mathcal{C}\) be a category, let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a cocartesian
0372 fibration of \(\infty\)-categories, and let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets. Applying Corollary 5.3 .2 .23 we obtain a bijection from the set of morphisms \(\lambda: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathcal{E}\) in the category \(\left(\operatorname{Set}_{\Delta}\right)_{/ N_{\bullet}(\mathcal{C})}\) to the set of natural transformations \(\alpha: \mathscr{F} \rightarrow \operatorname{wTr}_{\mathcal{E} / \mathcal{C}}\). Unwinding the definitions, we see that \(\alpha\) factors through the subfunctor \(\operatorname{sTr}_{\mathcal{E} / \mathcal{C}} \subseteq \mathrm{w} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) if and only if \(\lambda\) satisfies condition (1) of Definition 5.3.4.2. If this condition is satisfied, then \(\alpha: \mathscr{F} \rightarrow \operatorname{Tr}_{\mathcal{E}} / \mathcal{C}\) is a levelwise categorical equivalence if and only if \(\lambda\) satisfies condition (2) of Definition 5.3.4.2. We therefore obtain a bijection
\(\left\{\right.\) Levelwise categorical equivalences \(\left.\alpha: \mathscr{F} \rightarrow \operatorname{sir}_{\mathcal{E}} / \mathcal{C}\right\}\)

Concretely, this bijection carries a levelwise categorical equivalence \(\alpha: \mathscr{F} \rightarrow \operatorname{Sr}_{\mathcal{E}} / \mathcal{C}\) to the composite map
\[
\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \xrightarrow{\alpha} \underset{\longrightarrow}{\operatorname{holim}}\left(\operatorname{sTr}_{\mathcal{E}} / \mathcal{C}\right) \xrightarrow{\lambda_{u}} \mathcal{E},
\]
where \(\lambda_{u}\) is the universal scaffold of Construction 5.3.4.7.
Construction 5.3.4.11 (The Taut Scaffold). Let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial 0373 sets. By definition, an \(n\)-simplex of the homotopy colimit \(\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F})\) is a pair \((\sigma, \tau)\), where \(\sigma\)
is an \(n\)-simplex of \(\mathrm{N}_{\bullet}(\mathcal{C})\) (given by a diagram \(C_{0} \rightarrow \cdots \rightarrow C_{n}\) in the category \(\mathcal{C}\) ) and \(\tau\) is an \(n\)-simplex of the simplicial set \(\mathscr{F}\left(C_{0}\right)\). For \(0 \leq i \leq n\), let \(\tau_{i}\) denote the composite map
\[
\Delta^{i} \hookrightarrow \Delta^{n} \xrightarrow{\tau} \mathscr{F}\left(C_{0}\right) \rightarrow \mathscr{F}\left(C_{i}\right) .
\]

We then have a commutative diagram of simplicial sets

Consequently, we can view the pair ( \(\sigma,\left\{\tau_{i}\right\}_{0 \leq i \leq n}\) ) as an \(n\)-simplex of the weighted nerve \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\). The construction \((\sigma, \tau) \mapsto\left(\sigma,\left\{\tau_{i}\right\}_{0 \leq i \leq n}\right)\) determines a morphism of simplicial sets \(\lambda_{t}: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\). In the special case where \(\mathscr{F}: \mathcal{C} \rightarrow\) QCat is a diagram of \(\infty\) categories, we will refer to \(\lambda_{t}\) as the taut scaffold of the cocartesian fibration \(\mathrm{N}_{\bullet}^{\mathscr{Y}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\).

0374 Remark 5.3.4.12. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a functor. Then the diagram of simplicial sets

commutes, where \(\lambda_{t}\) is the morphism of Construction 5.3.4.11 and the vertical morphism are the projection maps of Construction 5.3.2.1 and Definition 5.3.3.1.

0375 Example 5.3.4.13. Let \(X\) be a simplicial set, which we identify with a diagram \(\mathscr{F}:[0] \rightarrow\) \(\operatorname{Set}_{\Delta}\). Then the homotopy colimit holim \((\mathscr{F})\) and the weighted nerve \(\mathrm{N}_{\bullet}^{\mathscr{F}}([0])\) can both be identified with \(X\) (see Examples \(\overrightarrow{5.3 .2 .2}\) and \(\boxed{5.3 .3 .2}\) ). Under these identifications, the taut scaffold \(\lambda_{t}: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{F}}([0])\) of Construction 5.3 .4 .11 corresponds to the identity map \(\operatorname{id}_{X}\).

0376 Remark 5.3.4.14 (Functoriality). Let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets and let \(\lambda_{t}: \operatorname{holim}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) be the morphism of Construction 5.3.4.11. If \(T: \mathcal{C}^{\prime} \rightarrow \mathcal{C}\) is any functor between categories, then \(\lambda\) induces a morphism
\[
\lambda_{t}^{\prime}: \mathrm{N}_{\bullet}\left(\mathcal{C}^{\prime}\right) \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \xrightarrow{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}\left(\mathcal{C}^{\prime}\right) \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) .
\]

Setting \(\mathscr{F}^{\prime}=\mathscr{F} \circ T\), we can use Remarks 5.3.2.3 and 5.3.3.7 to identify \(\lambda_{t}^{\prime}\) with a morphism from the homotopy colimit \(\underset{\longrightarrow}{\operatorname{holim}}\left(\mathscr{F}^{\prime}\right)\) to the weighted nerve \(\mathrm{N}_{\bullet}^{\mathscr{F}^{\prime}}\left(\mathcal{C}^{\prime}\right)\). This morphism coincides with the map obtained by applying Construction 5.3.4.11 to the diagram \(\mathscr{F}^{\prime}\).

Example 5.3.4.15 (Comparison of Fibers). Let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets and let \(\lambda_{t}: \operatorname{holim}(\mathscr{F}) \rightarrow \mathrm{N}_{\mathscr{\mathscr { F }}}^{\mathscr{F}}(\mathcal{C})\) be the morphism of Construction 5.3.4.11. Combining Example 5.3 .4 .13 with Remark 5.3.4.14 , we see that for every object \(C \in \mathcal{C}\), the induced map of fibers
\[
\{C\} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow\{C\} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})
\]
is an isomorphism of simplicial sets (under the identifications provided by Remark 5.3.2.3 and Example 5.3.3.8, it corresponds to the identity morphism id : \(\mathscr{F}(C) \rightarrow \mathscr{F}(C))\).

Example 5.3.4.16. Let \(f: X \rightarrow Y\) be a morphism of simplicial sets, which we identify with a diagram \(\mathscr{F}:[1] \rightarrow \operatorname{Set}_{\Delta}\). Then the homotopy colimit \(\operatorname{holim}(\mathscr{F})\) can be identified with the mapping cylinder \(\left(\Delta^{1} \times X\right) \amalg_{(\{1\} \times X)} Y\) (Example \(\sqrt{5.3 .2 .13)}\), and the weighted nerve \(\mathrm{N}_{\bullet}^{\mathscr{F}}([1])\) can be identified with the relative join \(X \star_{Y} Y\) (Example 5.3.3.13). Under these identifications, Construction 5.3.4.11 corresponds to a morphism of simplicial sets
\[
\lambda_{t}:\left(\Delta^{1} \times X\right) \coprod_{(\{1\} \times X)} Y \rightarrow X \star_{Y} Y .
\]

Unwinding the definitions, we see that this map classifies the commutative diagram

In particular, the morphism \(\lambda_{t}\) is an isomorphism if and only if 5.16) is a pushout square of simplicial sets.

Proposition 5.3.4.17. Let \(\mathscr{F}: \mathcal{C} \rightarrow\) QCat be a diagram of \(\infty\)-categories indexed by a 0379 category \(\mathcal{C}\). Then the morphism \(\lambda_{t}: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) of Construction 5.3.4.11 is a scaffold of the cocartesian fibration \(U: \mathrm{N}_{\bullet}^{\mathscr{*}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\).

Proof. Condition (0) of Definition 5.3.4.2 follows from Remark 5.3.4.12, condition (2) from Example 5.3.4.15, and condition (1) from the characterization of \(U\)-cocartesian morphisms supplied by Corollary 5.3.3.16.

Corollary 5.3.4.18. Let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets. Then there exists a 037 A cocartesian fibration of \(\infty\)-categories \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) and a scaffold \(\lambda: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathcal{E}\).

Proof. Using Proposition 4.1.3.2, we can choose a diagram of \(\infty\)-categories \(\mathscr{F}^{\prime}: \mathcal{C} \rightarrow\) QCat and a levelwise categorical equivalence \(\alpha: \mathscr{F} \rightarrow \mathscr{F}^{\prime}\). We can then take \(\lambda\) to be the composition \(\operatorname{holim}(\mathscr{F}) \xrightarrow{\alpha} \underset{\longrightarrow}{\operatorname{holim}}\left(\mathscr{F}^{\prime}\right) \xrightarrow{\lambda_{t}} \mathrm{~N}_{\bullet}^{\mathscr{F}^{\prime}}(\mathcal{C})\), where \(\lambda_{t}\) is the taut scaffold of Proposition 5.3.4.17

037B Corollary 5.3.4.19. Let \(\mathcal{C}\) be a category, let \(\mathscr{F}: \mathcal{C} \rightarrow\) QCat be a diagram of \(\infty\)-categories indexed by \(\mathcal{C}\), and let \(U: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be the cocartesian fibration of Corollary 5.3.3.16. Then there exists a levelwise categorical equivalence from \(\mathscr{F}\) to the strict transport representation \(\left.\mathrm{sTr}_{\mathrm{N}}^{\boldsymbol{*}} \boldsymbol{( \mathcal { C }}\right) / \mathcal{C}\).

Proof. Combine Proposition 5.3.4.17 with Remark 5.3.4.10 (for a more precise statement, see Construction 7.5.3.3.

In certain cases, one can improve on Example 5.3.4.15.

037 C Proposition 5.3.4.20. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a functor. Suppose that, for every morphism \(u: C \rightarrow D\) in the category \(\mathcal{C}\), the image \(\mathscr{F}(u): \mathscr{F}(C) \rightarrow \mathscr{F}(D)\) is a left covering map (Definition 4.2.3.8). Then the morphism \(\lambda_{t}: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) of Construction 5.3.4.11 is an isomorphism.

Proof. Let \(\left(\sigma,\left\{\tau_{i}\right\}_{0 \leq i \leq n}\right)\) be an \(n\)-simplex of the weighted nerve \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\). We identify \(\sigma\) with a diagram \(C_{0} \rightarrow \cdots \rightarrow C_{n}\) in the category \(\mathcal{C}\), and each \(\tau_{i}\) with an \(i\)-simplex of the simplicial set \(\mathscr{F}\left(C_{i}\right)\). We wish to show that there is a unique \(n\)-simplex \(\tau\) of \(\mathscr{F}\left(C_{0}\right)\) satisfying \(\lambda_{t}(\sigma, \tau)=\left(\sigma,\left\{\tau_{i}\right\}_{0 \leq i \leq n}\right)\). Note that, for this condition to be satisfied, the simplex \(\tau\) must be a solution to the lifting problem

Since the inclusion \(\{0\} \hookrightarrow \Delta^{n}\) is left anodyne (Example 4.3.7.11), our assumption that the right vertical map is a left covering guarantees that this lifting problem has a unique solution \(\tau: \Delta^{n} \rightarrow \mathscr{F}\left(C_{0}\right)\) (Corollary 4.2.4.6). This proves uniqueness. To prove existence, write \(\lambda_{t}(\sigma, \tau)=\left(\sigma,\left\{\tau_{i}^{\prime}\right\}_{0 \leq i \leq n}\right)\). We wish to prove that \(\tau_{i}=\tau_{i}^{\prime}\) for \(0 \leq i \leq n\). For this, we observe
that both \(\tau_{i}\) and \(\tau_{i}^{\prime}\) can be viewed as solutions to a common lifting problem

Since the inclusion \(\{0\} \hookrightarrow \Delta^{i}\) is left anodyne (Example 4.3.7.11) and the right vertical map is a left covering, the solution to this lifting problem is uniquely determined (Corollary 4.2.4.6.

Example 5.3.4.21 (Set-Valued Functors). Let \(\mathscr{F}: \mathcal{C} \rightarrow\) Set be a diagram of sets, and let 037D us abuse notation by identifying \(\mathscr{F}\) with a diagram of discrete simplicial sets. Then the taut scaffold \(\lambda_{t}: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) is an isomorphism. It follows that \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) can be identified with the nerve of the category of elements \(\int_{\mathcal{C}} \mathscr{F}\) (see Example 5.3.2.5).

Corollary 5.3.4.22. Let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a functor which carries each morphism of \(\mathcal{C}\) to 037 E an isomorphism of simplicial sets. Then the morphism \(\lambda_{t}: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) of Remark 5.3.4.12 is an isomorphism.

Corollary 5.3.4.23. Let \(\mathcal{C}\) be a groupoid and let \(\mathscr{F}: \mathcal{C} \rightarrow\) Kan be a diagram of Kan 037 F complexes. Then the homotopy colimit holim \((\mathscr{F})\) is a Kan complex.

Proof. Using Corollaries 5.3 .4 .22 and 5.3.3.19 we see that the map \(U: \operatorname{holim}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is a left fibration. Since \(N_{\bullet}(\mathcal{C})\) is a Kan complex (Proposition 1.3.5.2), it follows that \(U\) is a Kan fibration (Corollary 4.4.3.8), so that \(\operatorname{holim}(\mathscr{F})\) is also a Kan complex (Remark 3.1.1.11).

Example 5.3.4.24 (Homotopy Quotients). Let \(G\) be a group and let \(B G\) denote the 037G associated groupoid (consisting of a single object with automorphism group \(G\) ). Let \(X\) be a simplicial set equipped with an action of \(G\), which we identify with a functor \(\mathscr{F}: B G \rightarrow \operatorname{Set}_{\Delta}\). Applying Corollary 5.3.4.22, we obtain an isomorphism of simplicial sets \(X_{\mathrm{h} G} \xrightarrow{\sim} \mathrm{~N}_{\bullet}^{\mathscr{F}}(B G)\), where \(X_{\mathrm{h} G}\) is the homotopy quotient of \(X\) by the action of \(G\) (Example 5.3.2.15). If \(X\) is a Kan complex, then Corollary 5.3.4.23 guarantees that \(X_{\mathrm{h} G}\) is also a Kan complex.

\subsection*{5.3.5 Application: Classification of Cocartesian Fibrations}

Let \(\mathcal{C}\) be a category. In this section, we apply the results of \(\$ 5.3 .4\) to classify cocartesian 037H fibrations \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) up to equivalence. First, we need to introduce a bit of terminology.

037J Definition 5.3.5.1. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}_{0}, \mathscr{F}_{1}: \mathcal{C} \rightarrow\) QCat be diagrams of \(\infty\)-categories indexed by \(\mathcal{C}\). We will say that \(\mathscr{F}_{0}\) and \(\mathscr{F}_{1}\) are levelwise equivalent if there exists another diagram \(\mathscr{F}: \mathcal{C} \rightarrow\) QCat equipped with levelwise categorical equivalences \(\mathscr{F}_{0} \rightarrow \mathscr{F} \leftarrow \mathscr{F}_{1}\) (see Definition 4.5.6.1).
037 K Proposition 5.3.5.2. Let \(\mathcal{C}\) be a category and suppose we are given a pair of functors \(\mathscr{F}_{0}, \mathscr{F}_{1} \rightarrow\) QCat. Then \(\mathscr{F}_{0}\) is levelwise equivalent to \(\mathscr{F}_{1}\) (in the sense of Definition 5.3.5.1) if and only if the cocartesian fibrations \(U_{0}: \mathrm{N}_{\bullet}^{\mathscr{F}_{0}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) and \(U_{1}: \mathrm{N}_{\bullet}^{\mathscr{\mathscr { F } _ { 1 }}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) are equivalent (in the sense of Definition 5.1.7.1).
037 L Corollary 5.3.5.3. For every category \(\mathcal{C}\), levelwise equivalence determines an equivalence relation on the set of functors from \(\mathcal{C}\) to QCat.

037 M Exercise 5.3.5.4. Give a direct proof of Corollary 5.3.5.3 (which does not use the characterization of Proposition 5.3.5.2.

Proof of Proposition 5.3.5.2. Assume first that the functors \(\mathscr{F}_{0}, \mathscr{F}_{1}: \mathcal{C} \rightarrow\) QCat are levelwise equivalent. Then there exists a functor \(\mathscr{F}: \mathcal{C} \rightarrow\) QCat together with levelwise categorical equivalences \(\mathscr{F}_{0} \rightarrow \mathscr{F} \leftarrow \mathscr{F}_{1}\). Applying Corollary 5.3.3.20, we see that the induced maps \(\mathrm{N}_{\bullet}^{\mathscr{F}_{0}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \leftarrow \mathrm{N}_{\bullet}^{\mathscr{F}_{1}}(\mathcal{C})\) are equivalences of cocartesian fibrations over \(\mathrm{N}_{\bullet}(\mathcal{C})\).

We now prove the converse. Suppose that there exists a functor \(T: \mathrm{N}_{\bullet}^{\mathscr{\mathscr { F } _ { 0 }}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{\mathscr { H }}_{1}}(\mathcal{C})\) which is an equivalence of cocartesian fibrations over \(\mathrm{N}_{\bullet}(\mathcal{C})\). Let \(\lambda_{0}: \operatorname{holim}\left(\mathscr{F}_{0}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{F}_{0}}(\mathcal{C})\) and \(\lambda_{1}: \underset{\longrightarrow}{\operatorname{holim}}\left(\mathscr{F}_{1}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{F}_{1}}(\mathcal{C})\) be the taut scaffolds of Construction 5.3.4.11. Then \(T \circ \lambda_{0}\) is a scaffold of the cocartesian fibration \(U_{1}\) (Remark 5.3.4.6). Applying Remark 5.3.4.10, we obtain levelwise categorical equivalences \(\mathscr{F}_{0} \rightarrow \mathrm{sTr}_{\mathrm{N}_{\bullet}^{\mathscr{F}_{1}}(\mathcal{C}) / \mathcal{C}} \leftarrow \mathscr{F}_{1}\).

037N Warning 5.3.5.5. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}_{0}, \mathscr{F}_{1}: \mathcal{C} \rightarrow\) QCat be diagrams. The assumption that \(\mathscr{F}_{0}\) is levelwise equivalent to \(\mathscr{F}_{1}\) (in the sense of Definition 5.3.5.1) does not guarantee the existence of a levelwise categorical equivalence directly from \(\mathscr{F}_{0}\) to \(\mathscr{F}_{1}\) (or in the opposite direction).
037 P Theorem 5.3.5.6. Let \(\mathcal{C}\) be a category. Then the weighted nerve functor \(\mathscr{F} \mapsto \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) induces a bijection
\{Diagrams \(\mathcal{C} \rightarrow\) QCat \}/Levelwise Equivalence
\{Cocartesian Fibrations \(\stackrel{\mathcal{E}}{ } \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) \}/Equivalence.

The inverse bijection carries (the equivalence class of) a cocartesian fibration \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) to (the equivalence class of) the strict transport representation \(\operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\).

We will deduce Theorem 5.3.5.6 from the following result, which we prove at the end of this section:

Theorem 5.3.5.7. Let \(\mathcal{C}\) be a category, let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a functor, and suppose we are 037 Q given a commutative diagram of simplicial sets

where \(\mathcal{E}\) is an \(\infty\)-category. The following conditions are equivalent:
(1) The functor \(U\) is a cocartesian fibration and \(\lambda\) is a scaffold.
(2) The morphism \(\lambda\) is a categorical equivalence of simplicial sets.

Corollary 5.3.5.8. Let \(\mathcal{C}\) be a category, let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a cocartesian fibration of 037 R \(\infty\)-categories, and let \(\operatorname{sr}_{\mathcal{E} / \mathcal{C}}\) denote the strict transport representation of Construction 5.3.1.5. Then the universal scaffold \(\lambda_{u}: \operatorname{holim}\left(\operatorname{sTr}_{\mathcal{E}} / \mathcal{C}\right) \rightarrow \mathcal{E}\) of Construction 5.3.4.7 is a categorical equivalence of simplicial sets.

Proof. Combine Theorem 5.3.5.7 with Proposition 5.3.4.8.
Corollary 5.3.5.9. Let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets. Then the morphism 037 S \(\lambda_{t}: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) of Construction 5.3.4.11 is a categorical equivalence of simplicial sets.

Proof. Using Proposition 4.1.3.2, we can choose a diagram of \(\infty\)-categories \(\mathscr{F}^{\prime}: \mathcal{C} \rightarrow\) QCat and a levelwise categorical equivalence \(\alpha: \mathscr{F} \rightarrow \mathscr{F}^{\prime}\). We then have a commutative diagram of simplicial sets

where the horizontal maps are given by Construction 5.3.4.11 and the vertical maps are induced by the natural transformation \(\alpha\). Since \(\alpha\) is a levelwise categorical equivalence, Variant 5.3.2.19 and Corollary 5.3.3.20 guarantee that the vertical maps are categorical
equivalences of simplicial sets. Consequently, to show that \(\lambda_{t}\) is a categorical equivalence, it will suffice to show that \(\lambda_{t}^{\prime}\) is a categorical equivalence. This is a special case of Theorem 5.3.5.7, since \(\lambda_{t}^{\prime}\) is a scaffold of the cocartesian fibration \(\mathrm{N}_{\bullet}^{\mathscr{F}^{\prime}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) (Proposition 5.3.4.17).

037 T Example 5.3.5.10. In the special case \(\mathcal{C}=[1]\), Theorem 5.3.5.7 is a restatement of Theorem 5.2.4.1 and Corollary 5.3.5.9 is a restatement of Proposition 5.2.4.5.

Proof of Theorem 5.3.5.6. Let \(\mathcal{C}\) be a category. It follows from Proposition 5.3.5.2 that the construction \(\mathscr{F} \mapsto \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) determines an injective function

Moreover, the construction \(\left(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\right) \mapsto \operatorname{sTr}_{\mathcal{E} / \mathcal{C}}\) carries equivalences of cocartesian fibrations over \(\mathrm{N}_{\bullet}(\mathcal{C})\) to levelwise categorical equivalences, and therefore induces a function

in the opposite direction. We will show that \(\Phi \circ \Psi\) is equal to the identity; it will then follow that \(\Phi\) is a bijection and that \(\Psi=\Phi^{-1}\) is the inverse bijection.

Fix a cocartesian fibration \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\), let \(\mathscr{F}=\mathrm{sTr}_{\mathcal{E} / \mathcal{C}}\) denote its strict transport representation, and let \(U^{\prime}: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be the projection map. We wish to show that \(U\) and \(U^{\prime}\) are equivalent as cocartesian fibrations over \(\mathrm{N}_{\bullet}(\mathcal{C})\). Let \(\lambda_{u}: \operatorname{holim}(\mathscr{F}) \rightarrow \mathcal{E}\) denote the universal scaffold (Construction 5.3.4.7) and let \(\lambda_{t}: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) denote the taut scaffold (Construction 5.3.4.11). Then \(\lambda_{t}\) is a categorical equivalence of simplicial sets (Corollary 5.3.5.9). Applying Corollary 4.5.2.34 we see that precomposition with \(\lambda_{t}\) induces an equivalence of \(\infty\)-categories
\[
\text { Fun }_{/ \mathrm{N}_{\bullet}(\mathcal{C})}\left(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}), \mathcal{E}\right) \rightarrow \text { Fun }_{/ \mathrm{N}_{\bullet}(\mathcal{C})}\left(\operatorname{holim}_{\longrightarrow}^{(\mathscr{F})}, \mathcal{E}\right) .
\]

In particular, there exists a morphism \(T: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathcal{E}\) such that \(U \circ T=U^{\prime}\) and \(T \circ \lambda_{t}\) is isomorphic to \(\lambda_{u}\) (as an object of the \(\infty\)-category Fun/ \(\left.\mathrm{N}_{\bullet}(\mathcal{C})(\underset{\longrightarrow}{(\operatorname{holim}}(\mathscr{F}), \mathcal{E})\right)\). Since \(\lambda_{u}\) is a
categorical equivalence of simplicial sets (Corollary 5.3.5.8), it follows that \(T \circ \lambda_{t}\) is also a categorical equivalence of simplicial sets (Corollary 4.5.3.9). Applying the two-out-of-three property, we see that \(T\) is an equivalence of \(\infty\)-categories (Remark 4.5.3.5) and therefore an equivalence of cocartesian fibrations over \(\mathrm{N}_{\bullet}(\mathcal{C})\) (Proposition 5.1.7.5).

Proof of Theorem 5.3.5.7. We first show that (1) implies (2). Assume that \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is a cocartesian fibration of simplicial sets and let \(\lambda: \operatorname{holim}(\mathscr{F}) \rightarrow \mathcal{E}\) be a scaffold of \(U\); we wish to show that \(\lambda\) is a categorical equivalence of simplicial sets. By virtue of Corollary 4.5.7.3 it will suffice to show that for every \(n\)-simplex \(\sigma: \Delta^{n} \rightarrow \mathrm{~N}_{\bullet}(\mathcal{C})\), the induced map
\[
\Delta^{n} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \xrightarrow{\operatorname{holim}}(\mathscr{F}) \rightarrow \Delta^{n} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathcal{E}
\]
is a categorical equivalence of simplicial sets. We may therefore assume without loss of generality that the category \(\mathcal{C}\) is a linearly ordered set of the form \([n]=\{0<1<\cdots<n\}\) for some \(n \geq 0\).

We proceed by induction on \(n\). If \(n=0\), the result is clear. Let us therefore assume that \(n>0\). Let \(S=\mathrm{N}_{\bullet}(\{1<\cdots<n\})\) be the 0 th face of the simplex \(\Delta^{n}\) and set \(\mathcal{E}_{+}=S \times_{\Delta^{n}} \mathcal{E}\). Let \(\mathscr{F}+\) denote the restriction of \(\mathscr{F}\) to the subcategory \(\{1<\cdots<n\} \subset[n]\), so that our inductive hypothesis guarantees that \(\lambda\) restricts to a categorical equivalence \(\lambda_{+}: \underset{\longrightarrow}{\operatorname{holim}}\left(\mathscr{F}_{+}\right) \rightarrow \mathcal{E}_{+}\). Note that Remark 5.3 .2 .12 supplies an isomorphism of simplicial sets
\[
\left(\Delta^{n} \times \mathscr{F}(0)\right) \coprod_{(S \times \mathscr{F}(0))} \underset{\longrightarrow}{\operatorname{holim}}\left(\mathscr{F}_{+}\right) \rightarrow \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) .
\]

Let \(V: \Delta^{n} \rightarrow \Delta^{1}\) be the morphism given on vertices by the formula \(V(i)= \begin{cases}0 & \text { if } i=0 \\ 1 & \text { if } i>0 .\end{cases}\) Then \(V\) is a cocartesian fibration of simplicial sets, and the edge \(\mathrm{N}_{\bullet}(\{0<1\}) \subseteq \Delta^{n}\) is \(V\)-cocartesian. It follows that, for every vertex \(x\) of the simplicial set \(\mathscr{F}(0)\), the composite map
\[
\Delta^{1} \times\{x\} \hookrightarrow \Delta^{n} \times \mathscr{F}(0) \rightarrow \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \xrightarrow{\lambda} \mathcal{E}
\]
is a \((V \circ U)\)-cocartesian edge of \(\mathcal{E}\). Applying Theorem 5.2.4.1 to the cocartesian fibration \(V \circ U\), we deduce that the composition
\[
\begin{aligned}
\left(\Delta^{1} \times \mathscr{F}(0)\right) \coprod_{(\{1\} \times \mathscr{F}(0))} \operatorname{holim}_{\longrightarrow}\left(\mathscr{F}_{+}\right) & \xrightarrow{\iota}\left(\Delta^{n} \times \mathscr{F}(0)\right) \coprod_{(S \times \mathscr{F}(0))} \xrightarrow[\longrightarrow]{\operatorname{holim}\left(\mathscr{F}_{+}\right)} \\
& \simeq \operatorname{holim}(\mathscr{F}) \\
& \xrightarrow{\lambda} \mathcal{E} .
\end{aligned}
\]
is a categorical equivalence of simplicial sets. Consequently, to show that \(\lambda\) is a categorical equivalence of simplicial sets, it will suffice to show that \(\iota\) is inner anodyne. By construction, \(\iota\) is a pushout of the inclusion map
\[
\left(\Delta^{1} \coprod_{\{1\}} S\right) \times \mathscr{F}(0) \rightarrow \Delta^{n} \times \mathscr{F}(0)
\]

By virtue of Lemma 1.5 .7 .5 , it will suffice to show that the inclusion map \(\Delta^{1} \amalg_{\{1\}} S \hookrightarrow \Delta^{n}\) is inner anodyne. This is a special case of Example 4.3.6.5, since the inclusion \(\{1\} \hookrightarrow S\) is left anodyne (Lemma 4.3.7.8).

We now show that (2) implies (1). Let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a functor of \(\infty\)-categories, and suppose that \(\lambda: \operatorname{holim}(\mathscr{F}) \rightarrow \mathcal{E}\) is a categorical equivalence of simplicial sets such that \(U \circ \lambda\) is equal to the projection map \(\operatorname{holim}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\). We first claim that \(U\) is an isofibration of \(\infty\)-categories. Since \(\mathcal{E}\) is an \(\infty\)-category, the morphism \(U\) is an inner fibration (Proposition 4.1.1.10). It will therefore suffice to show that, for each object \(\widetilde{C} \in \mathcal{E}\) having image \(C=U(\widetilde{C}) \in \mathcal{C}\) and every isomorphism \(e: C \rightarrow D\) of \(\mathcal{C}\), there exists an isomorphism \(\widetilde{e}: \widetilde{C} \rightarrow \widetilde{D}\) in \(\mathcal{E}\) satisfying \(U(\widetilde{e})=e\). Since \(\lambda\) is a categorical equivalence, we can choose a vertex \(v\) of \(\operatorname{holim}(\mathscr{F})\) and an isomorphism \(\widetilde{f}: \widetilde{C} \rightarrow \lambda(v)\) in \(\mathcal{E}\). Let us identify \(v\) with a pair \(\left(C^{\prime}, X\right)\), where \(C^{\prime}\) is an object of \(\mathcal{C}\) and \(X\) is a vertex of the simplicial set \(\mathscr{F}\left(C^{\prime}\right)\). Then \(f=U(\tilde{f})\) is an isomorphism from \(C\) to \(C^{\prime}\) in the category \(\mathcal{C}\). Replacing \(v\) by the pair \(\left(C, \mathscr{F}\left(f^{-1}\right)(X)\right)\), we can reduce to the case where \(C^{\prime}=C\) and \(f=\operatorname{id}_{C}\) so that \(\tilde{f}\) is an isomorphism in the \(\infty\)-category \(\mathcal{E}_{C}\). In this case, we can take \(\widetilde{e}\) to be any composition of \(\tilde{f}\) with the morphism \(\lambda\left(e, \operatorname{id}_{X}\right): \lambda(C, X) \rightarrow \lambda(D, \mathscr{F}(e)(X))\) of \(\mathcal{E}\). This completes the proof that \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is an isofibration.

Using Corollary 5.3.4.18, we can choose a cocartesian fibration \(U^{\prime}: \mathcal{E}^{\prime} \rightarrow \mathrm{N}_{\mathbf{\bullet}}(\mathcal{C})\) and a scaffold \(\lambda^{\prime}: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathcal{E}^{\prime}\). Then \(U^{\prime}\) is an isofibration, so composition with \(\lambda\) induces a categorical equivalence Fun \(/ \mathrm{N}_{\bullet}(\mathcal{C})\left(\mathcal{E}, \mathcal{E}^{\prime}\right) \rightarrow \operatorname{Fun}_{/ \mathrm{N}_{\bullet}(\mathcal{C})}\left(\operatorname{holim}_{\longrightarrow}(\mathscr{F}), \mathcal{E}^{\prime}\right)\) (Corollary 4.5.2.34). It follows that there exists a functor \(F: \mathcal{E} \rightarrow \mathcal{E}^{\prime}\) satisfying \(U^{\prime} \circ F=U\) such that \(F \circ \lambda\) is isomorphic to \(\lambda^{\prime}\) as an object of the \(\infty\)-category Fun/ \(\mathrm{N}_{\bullet}(\mathcal{C})\left(\operatorname{holim}_{\longrightarrow}(\mathscr{F}), \mathcal{E}^{\prime}\right)\). Since \(\lambda^{\prime}\) is a categorical equivalence of simplicial sets, the morphism \(F \circ \lambda\) is also a categorical equivalence of simplicial sets (Corollary 4.5.3.9). Applying the two-out-of-three property (Remark 4.5 .3 .5 , we deduce that \(F\) is an equivalence of \(\infty\)-categories. It follows that \(U\) is also a cocartesian fibration (Corollary 5.1.6.2) and that \(\lambda\) is a scaffold of \(U\) (Remark 5.3.4.6).

We close this section by recording another consequence of Theorem 5.3.5.7.
037 U Corollary 5.3.5.11. Let \(\mathcal{C}\) be a category, let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a cocartesian fibration of \(\infty\)-categories, and let \(U^{\prime}: \mathcal{E}^{\prime} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be an isofibration of \(\infty\)-categories. Then the composite map
\[
\begin{aligned}
\operatorname{Fun}_{/ \mathrm{N}_{\bullet}(\mathcal{C})}\left(\mathcal{E}, \mathcal{E}^{\prime}\right) & \xrightarrow{\theta} \operatorname{Hom}_{{\operatorname{Fun}\left(\mathcal{C}, \mathrm{Set}_{\Delta}\right)}\left(\mathrm{wTr}_{\mathcal{E} / \mathcal{C}}, \mathrm{wTr}_{\mathcal{E}^{\prime} / \mathcal{C}}\right) \bullet} \\
& \rightarrow \operatorname{Hom}_{\operatorname{Fun}\left(\mathcal{C}, \mathrm{Set}_{\Delta}\right)}\left(\operatorname{sTr}_{\mathcal{E}} / \mathcal{C}, \operatorname{wTr}_{\mathcal{E}^{\prime} / \mathcal{C}}\right) \bullet
\end{aligned}
\]
is an equivalence of \(\infty\)-categories.
Proof. Using Corollary 5.3.2.23, we can identify \(\theta\) with the functor
\[
\text { Fun }_{/ \mathrm{N}_{\bullet}(\mathcal{C})}\left(\mathcal{E}, \mathcal{E}^{\prime}\right) \rightarrow \text { Fun }_{/ \mathrm{N}_{\bullet}(\mathcal{C})}\left(\operatorname{holim}_{\longrightarrow}\left(\mathrm{sTr}_{\mathcal{E} / \mathcal{C}}\right), \mathcal{E}^{\prime}\right)
\]
given by precomposition with the universal scaffold \(\lambda_{u}\). The desired result now follows by combining Corollaries 5.3.5.8 and 4.5.2.34.

Corollary 5.3.5.12. Let \(\mathcal{C}\) be a category and let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) and \(U^{\prime}: \mathcal{E}^{\prime} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be 037v cocartesian fibrations of \(\infty\)-categories, having strict transport representations \(s \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) and \(\mathrm{sTr}_{\mathcal{E}^{\prime} / \mathcal{C}}\), respectively. Then the tautological map
\[
\underset{\operatorname{Fun} / \mathrm{N}_{\bullet}(\mathcal{C})}{\mathrm{CCar}}\left(\mathcal{E}, \mathcal{E}^{\prime}\right) \rightarrow \operatorname{Hom}_{\mathrm{Fun}\left(\mathcal{C}, \text { Set }_{\Delta}\right)}\left(\operatorname{sTr}_{\mathcal{E} / \mathcal{C}}, \operatorname{sTr}_{\mathcal{E}^{\prime} / \mathcal{C}}\right) \bullet
\]
is an equivalence of \(\infty\)-categories.
Proof. By virtue of Remark 5.3.4.10, we have a pullback diagram of \(\infty\)-categories

where the vertical maps are inclusions of replete full subcategories (and are therefore isofibrations; see Example 4.4.1.12). Since the bottom horizontal map is an equivalence of \(\infty\)-categories (Corollary 5.3.5.11), it follows that the upper horizontal map is also an equivalence of \(\infty\)-categories (Corollary 4.5.2.29).

\subsection*{5.3.6 Application: Relative Exponentials}

Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be a cocartesian fibration of simplicial sets. Applying Construction 037W 5.2 .5 .2 , we obtain a homotopy transport representation
\[
\mathrm{hTr}_{\mathcal{C} / \mathcal{B}}: \mathrm{h} \mathrm{\mathcal{B}} \rightarrow \mathrm{hQCat} \quad B \mapsto \mathcal{C}_{B} .
\]

Let \(\mathcal{D}\) be an \(\infty\)-category. In this section, we will show that the composite functor
\[
\mathrm{h} \mathcal{B}^{\mathrm{op}} \xrightarrow{\mathrm{hTr}}{ }_{\mathcal{C} / \mathcal{B}}^{\mathrm{op}} \mathrm{hQCat}^{\mathrm{op}} \xrightarrow{\mathrm{Fun}(-, \mathcal{D})} \mathrm{hQCat}
\]
can be realized as the homotopy transport representation of a cartesian fibration \(\mathcal{C}^{\prime} \rightarrow\) \(\mathcal{B}\). Moreover, we can take \(\mathcal{C}^{\prime}\) to be the relative exponential \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\) introduced in Construction 4.5.9.1 (Corollary 5.3.6.10). Our starting point is the following:

Proposition 5.3.6.1. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a functor of \(\infty\)-categories which is either a cartesian 025 H fibration or a cocartesian fibration. Then \(U\) is exponentiable (in the sense of Definition
4.5.9.10). That is, if we are given any diagram of simplicial sets

where both squares are pullbacks and \(\bar{F}\) is a categorical equivalence, then \(F\) is also a categorical equivalence.

025J Remark 5.3.6.2. In the statement of Proposition 5.3.6.1, the hypothesis that \(\mathcal{C}\) is an \(\infty\)-category is not necessary: see Corollary 5.6.7.6.

Our proof of Proposition 5.3.6.1 will require some preliminaries.
025A Lemma 5.3.6.3. Let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets and suppose we are given morphisms of simplicial sets \(A \xrightarrow{f} B \xrightarrow{g} \mathrm{~N}_{\bullet}(\mathcal{C})\), where \(f\) is inner anodyne. Then the induced map
\[
\theta_{g}: A \times_{\mathrm{N}_{\mathbf{0}}(\mathcal{C})} \xrightarrow[\longrightarrow]{\operatorname{holim}}(\mathscr{F}) \rightarrow B \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \xrightarrow{\operatorname{holim}}(\mathscr{F})
\]
is inner anodyne.
Proof. Let \(S\) be the collection of all morphisms of simplicial sets \(f: A \rightarrow B\) having the property that, for every morphism \(g: B \rightarrow \mathrm{~N}_{\bullet}(\mathcal{C})\), the map \(\theta_{g}\) is inner anodyne. It follows immediately from the definitions that \(S\) is weakly saturated (in the sense of Definition 1.5.4.12. Consequently, to show that every inner anodyne morphism belongs to \(S\), it will suffice to prove that \(S\) contained every inner horn inclusion \(f: \Lambda_{i}^{n} \hookrightarrow \Delta^{n}, 0<i<n\). Using Remark 5.3.2.3, we can reduce to the case where \(\mathcal{C}=[n]\) and \(g: \Delta^{n} \rightarrow \mathrm{~N}_{\bullet}(\mathcal{C})\) is the identity map. In this case, Remark 5.3.2.14 shows that \(\theta_{g}\) is a pushout of the inclusion map \(\Lambda_{i}^{n} \times \mathscr{F}(0) \hookrightarrow \Delta^{n} \times \mathscr{F}(0)\), which is inner anodyne by virtue of Lemma 1.5.7.5.
037 X Lemma 5.3.6.4. Let \(\mathscr{F}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\) be a diagram of simplicial sets, let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a cocartesian fibration of \(\infty\)-categories, and let \(\lambda: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathcal{E}\) be a scaffold. Then, for every morphism of simplicial sets \(S \rightarrow \mathrm{~N}_{\bullet}(\mathcal{C})\), the induced map
\[
\lambda_{S}: S \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \xrightarrow{\operatorname{holim}}(\mathscr{F}) \rightarrow S \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathcal{E}
\]
is a categorical equivalence of simplicial sets.
Proof. By virtue of Corollary 4.5.7.3, we may assume without loss of generality that \(S=\Delta^{n}\) is a standard simplex. Replacing \(\mathcal{C}\) by the category \([n]=\{0<1<\cdots<n\}\), we are reduced to proving that \(\lambda\) is a categorical equivalence, which follows from Theorem 5.3.5.7.

Lemma 5.3.6.5. Suppose we are given a pullback diagram of simplicial sets

where \(\bar{F}\) is inner anodyne. If \(U\) is either a cartesian fibration or a cocartesian fibration, then \(F\) is a categorical equivalence of simplicial sets.

Proof. We will give the proof under the assumption that \(U\) is a cocartesian fibration; the proof when \(U\) is a cartesian fibration is similar. Let \(S\) be the collection of all monomorphisms of simplicial sets \(f: A \hookrightarrow B\) with the following property: for every morphism of simplicial sets \(B \rightarrow \mathcal{C}\), the induced map \(A \times_{\mathcal{C}} \mathcal{E} \hookrightarrow B \times_{\mathcal{C}} \mathcal{E}\) is a categorical equivalence. To complete the proof, it will suffice to show that the morphism \(\bar{F}: \mathcal{C}^{\prime} \hookrightarrow \mathcal{C}\) belongs to \(S\). In fact, we claim that every inner anodyne morphism of simplicial sets belongs to \(S\). Using Remark 4.5.3.6, Remark 4.5.3.5, Corollary 4.5.7.2, and Remark 4.5.4.13, we see that \(S\) is weakly saturated (see Definition 1.5.4.12). It will therefore suffice to show that \(S\) contains every inner horn inclusion \(\Lambda_{i}^{n} \hookrightarrow \Delta^{n}, 0<i<n\). In particular, we are reduced to proving Lemma 5.3.6.5 in the special case where \(\mathcal{C}=\mathrm{N}_{\bullet}\left(\mathcal{C}_{0}\right)\) is the nerve of a category \(\mathcal{C}_{0}\). Applying Corollary 5.3.4.9, we deduce that there exists a diagram of \(\infty\)-categories \(\mathscr{G}: \mathcal{C}_{0} \rightarrow\) QCat and a scaffold \(\lambda: \operatorname{holim}(\mathscr{G}) \rightarrow \mathcal{E}\). We then have a commutative diagram of simplicial sets

where the vertical maps are categorical equivalences (Lemma 5.3.6.4). Consequently, to show that \(F\) is a categorical equivalence, it will suffice to show that \(\widetilde{F}\) is a categorical equivalence, which follows from Lemma 5.3.6.3.

Proof of Proposition 5.3.6.1. Without loss of generality we may assume that \(U: \mathcal{E} \rightarrow \mathcal{C}\) is a cocartesian fibration of \(\infty\)-categories. Suppose we are given a commutative diagram of
simplicial sets

where both squares are pullbacks and \(\bar{F}\) is a categorical equivalence. We wish to show that \(F\) is also a categorical equivalence. By virtue of Proposition 4.1.3.2, the morphism \(\bar{G}\) factors as a composition \(\mathcal{C}^{\prime} \xrightarrow{\bar{G}^{\prime}} \mathcal{B} \xrightarrow{\bar{G}^{\prime \prime}} \mathcal{C}\), where \(\bar{G}^{\prime}\) is inner anodyne and \(\bar{G}^{\prime \prime}\) is an inner fibration. Note that the projection map \(V: \mathcal{B} \times \mathcal{C} \mathcal{E} \rightarrow \mathcal{B}\) is a cocartesian fibration of \(\infty\)-categories. We may therefore replace \(\mathcal{C}\) by \(\mathcal{B}\) and thereby reduce to the special case where \(\bar{G}\) is inner anodyne. In this case, the morphism \(G: \mathcal{E}^{\prime} \rightarrow \mathcal{E}\) is a categorical equivalence of simplicial sets (Lemma 5.3.6.5). Consequently, to show that \(F\) is a categorical equivalence of simplicial sets, it will suffice to show that the composite map \((G \circ F): \mathcal{E}^{\prime \prime} \rightarrow \mathcal{E}\) is a categorical equivalence of simplicial sets (Remark 4.5.3.5).

Since \(\bar{F}\) is a categorical equivalence and \(\bar{G}\) is inner anodyne, it follows that the composite \(\operatorname{map} \bar{G} \circ \bar{F}: \mathcal{C}^{\prime \prime} \rightarrow \mathcal{C}\) is also a categorical equivalence. Applying Proposition 4.1.3.2, we can factor \(\bar{G} \circ \bar{F}\) as a composition \(\mathcal{C}^{\prime \prime} \xrightarrow{\bar{F}_{0}} \mathcal{C}_{0}^{\prime} \xrightarrow{\bar{G}_{0}} \mathcal{C}\), where \(\bar{F}_{0}\) is inner anodyne and \(\bar{G}_{0}\) is an inner fibration. Since \(\mathcal{C}\) is an \(\infty\)-category, it follows that \(\mathcal{C}_{0}^{\prime}\) is also an \(\infty\)-category (Remark 4.1.1.9. Set \(\overline{\mathcal{E}}_{0}^{\prime}=\mathcal{C}_{0}^{\prime} \times_{\mathcal{C}} \mathcal{E}\), so that we have a commutative diagram

satisfying \(G \circ F=G_{0} \circ F_{0}\). Since \(U\) is an isofibration (Proposition 5.1.4.8) and \(\bar{G}_{0}\) is an equivalence of \(\infty\)-categories, it follows that \(G_{0}\) is an equivalence \(\infty\)-categories (Corollary 4.5.2.29. Applying Lemma 5.3.6.5 to the square on the left, we see that \(F_{0}\) is a categorical equivalence of simplicial sets. Invoking Remark 4.5.3.5, we deduce that \(G \circ F=G_{0} \circ F_{0}\) is also a categorical equivalence, as desired.

We now formulate the main result of this section. In what follows, we assume that the reader is familiar with the relative exponential construction introduced in \(\$ 4.5 .9\)

0470 Proposition 5.3.6.6. Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be a cocartesian fibration of simplicial sets and let \(V: \mathcal{D} \rightarrow \mathcal{E}\) be a cartesian fibration of simplicial sets. Then postcomposition with \(V\) induces
a cartesian fibration of simplicial sets
\[
V^{\prime}: \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D}) \rightarrow \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{E})
\]

Moreover, an edge e of \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\) is \(V^{\prime}\)-cocartesian if and only if satisfies the following condition:
(*) Write \(e=(\bar{e}, f)\), where \(\bar{e}\) is an edge of \(\mathcal{B}\) and \(f: \Delta^{1} \times_{\mathcal{B}} \mathcal{C} \rightarrow \mathcal{D}\) is a morphism of simplicial sets. Let \(U_{\bar{e}}: \Delta^{1} \times_{\mathcal{B}} \mathcal{C} \rightarrow \Delta^{1}\) be given by projection onto the first factor. Then \(f\) carries \(U_{\bar{e}}\)-cocartesian morphisms of \(\Delta^{1} \times_{\mathcal{B}} \mathcal{C}\) to \(V\)-cartesian morphisms of \(\mathcal{D}\).

Remark 5.3.6.7. For a more general version of Proposition 5.3.6.6 (which looses the 0471 requirement that \(U\) is a cocartesian fibration), see Corollary 7.3.7.6 (and Example 7.3.7.8).

Before giving the proof of Proposition 5.3.6.6, let us note some of its consequences.
Corollary 5.3.6.8. Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be a cocartesian fibration of simplicial sets and let \(\mathcal{D}\) be 0472 an \(\infty\)-category. Then:
(1) The projection map \(\pi: \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D}) \rightarrow \mathcal{B}\) is a cartesian fibration of simplicial sets.
(2) Let \(e\) be an edge of the simplicial set \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\), corresponding to a pair \((\bar{e}, f)\), where \(\bar{e}\) is an edge of the simplicial set \(\mathcal{B}\) and \(f: \Delta^{1} \times{ }_{\mathcal{B}} \mathcal{C} \rightarrow \mathcal{D}\) is a functor of \(\infty\)-categories. Let \(U_{\bar{e}}: \Delta^{1} \times_{\mathcal{B}} \mathcal{C} \rightarrow \Delta^{1}\) be given by projection onto the first factor. Then e is \(\pi\)-cartesian if and only if the functor \(f\) carries \(U_{\bar{e}}\)-cocartesian morphisms to isomorphisms in the \(\infty\)-category \(\mathcal{D}\).

Proof. Apply Proposition 5.3.6.6 in the special case \(\mathcal{E}=\Delta^{0}\) (and use Example 5.1.1.4.
In the situation of Corollary 5.3.6.8, contravariant transport for the cartesian fibration \(\pi\) has a simple explicit description.

Proposition 5.3.6.9. Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be a cocartesian fibration of simplicial sets, let 0473 \(f: B \rightarrow B^{\prime}\) be an edge of \(\mathcal{B}\), and let \(f_{!}: \mathcal{C}_{B} \rightarrow \mathcal{C}_{B^{\prime}}\) be given by covariant transport along \(f\) for the cocartesian fibration \(U\) (see Definition 5.2.2.4). For every \(\infty\)-category \(\mathcal{D}\), the functor
\[
\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})_{B^{\prime}} \simeq \operatorname{Fun}\left(\mathcal{C}_{B^{\prime}}, \mathcal{D}\right) \xrightarrow{\circ f_{1}} \operatorname{Fun}\left(\mathcal{C}_{B}, \mathcal{D}\right) \simeq \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})_{B}
\]
is given by contravariant transport along \(f\) (for the cartesian fibration \(\pi: \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D}) \rightarrow \mathcal{B})\).
Proof. Replacing \(\mathcal{C}\) by the fiber product \(\Delta^{1} \times_{\mathcal{B}} \mathcal{C}\), we can assume without loss of generality that \(\mathcal{B}=\Delta^{1}\) and \(f\) is the nondegenerate edge of \(\mathcal{B}\). By virtue of Corollary 5.2.4.4 we can choose a functor \(R: \mathcal{C} \rightarrow \mathcal{C}_{B^{\prime}}\) such that \(\left.R\right|_{\mathcal{C}_{B}}=f_{!},\left.R\right|_{\mathcal{C}_{B^{\prime}}}=\mathrm{id}\), and \(R\) carries \(U\)-cocartesian
morphisms of \(\mathcal{C}\) to isomorphisms in \(\mathcal{C}_{B^{\prime}}\). Precomposition with functor \((U, R): \mathcal{C} \rightarrow \Delta^{1} \times \mathcal{C}_{B^{\prime}}\) then determines a functor
\[
H: \Delta^{1} \times \operatorname{Fun}\left(\mathcal{C}_{B^{\prime}}, \mathcal{D}\right) \simeq \operatorname{Fun}\left(\left(\Delta^{1} \times \mathcal{C}_{B^{\prime}}\right) / \mathcal{B}, \mathcal{D}\right) \rightarrow \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})
\]

Unwinding the definitions, we see that \(\left.H\right|_{\{0\} \times \operatorname{Fun}\left(\mathcal{C}_{B^{\prime}}, \mathcal{D}\right)}\) is the functor given by precomposition with \(f_{!}\), and that \(\left.H\right|_{\{1\} \times \operatorname{Fun}\left(\mathcal{C}_{B^{\prime}}, \mathcal{D}\right)}\) is the identity functor from \(\operatorname{Fun}\left(\mathcal{C}_{B^{\prime}}, \mathcal{D}\right)\) to itself. It will therefore suffice to show that, for each object \(F \in \operatorname{Fun}\left(\mathcal{C}_{B^{\prime}}, \mathcal{D}\right)\), the restriction \(\left.H\right|_{\Delta^{1} \times\{F\}}\) is a \(\pi\)-cartesian morphism of the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\). By virtue of Corollary 5.3.6.8, this is equivalent to the assertion that the composite functor \(\mathcal{C} \xrightarrow{R} \mathcal{C}_{B^{\prime}} \xrightarrow{F} \mathcal{D}\) carries \(U\)-cocartesian morphisms of \(\mathcal{C}\) to isomorphisms in \(\mathcal{D}\). This follows from our assumption on \(R\), since the functor \(F\) carries isomorphisms of \(\mathcal{C}_{B^{\prime}}\) to isomorphisms of \(\mathcal{D}\).

0474 Corollary 5.3.6.10. Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be a cocartesian fibration of simplicial sets and let
\[
\mathrm{h} \operatorname{Tr}_{\mathcal{C} / \mathcal{B}}: \mathrm{hB} \rightarrow \mathrm{hQCat}
\]
be the homotopy transport representation for \(U\) (Construction 5.2.5.2). Then, for any \(\infty\)-category \(\mathcal{D}\), the composition
\[
\mathrm{h} \mathcal{B}^{\mathrm{op}} \xrightarrow{\mathrm{hTr}_{\mathcal{C} / \mathcal{B}}^{\mathrm{op}}} \mathrm{hQCat}^{\mathrm{op}} \xrightarrow{\operatorname{Fun}(-, \mathcal{D})} \mathrm{hQCat}
\]
is the homotopy transport representation for the cartesian fibration \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D}) \rightarrow \mathcal{B}\) of Corollary 5.3.6.8.

We will carry out the proof of Proposition 5.3.6.6 in several steps.
02UA Lemma 5.3.6.11. Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be a cocartesian fibration of simplicial sets, let \(V: \mathcal{D} \rightarrow \mathcal{E}\) be an isofibration of simplicial sets, and let e be an edge of the simplicial set \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\) which satisfies condition (*) of Proposition 5.3.6.6. Then e is \(V^{\prime}\)-cartesian, where \(V^{\prime}\) : \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D}) \rightarrow \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{E})\) is given by postcomposition with \(V\).

Proof. Let \(n \geq 2\) and suppose we are given a lifting problem

where \(\sigma_{0}\) carries the final edge \(\mathrm{N}_{\bullet}(\{n-1<n\}) \subseteq \Lambda_{n}^{n}\) to \(e\); we wish to show that this lifting problem admits a solution. Replacing \(U\) with the projection map \(\Delta^{n} \times_{\mathcal{B}} \mathcal{C} \rightarrow \Delta^{n}\), we can
assume without loss of generality that \(\mathcal{B}=\Delta^{n}\) is a standard simplex, so that \(\bar{\sigma}\) corresponds to a morphism of simplicial sets \(\bar{F}: \mathcal{C} \rightarrow \mathcal{E}\). Invoking the universal property of the simplicial sets \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\) and \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{E})\) (Proposition 4.5.9.5), we can rewrite (5.17) as a lifting problem

Note that since the edge \(e\) satisfies condition \((*)\), the morphism \(F_{0}\) satisfies the following condition:
\(\left(*^{\prime}\right)\) If \(u\) is a \(U\)-cocartesian edge of \(\mathcal{C}\) lying over the final edge \(\mathrm{N}_{\bullet}(\{n-1<n\}) \subseteq \Delta^{n}\), then \(F_{0}(u)\) is a \(V\)-cartesian edge of \(\mathcal{D}\).

Using Corollary 5.3.4.9, we can choose a diagram of \(\infty\)-categories \(\mathscr{F}:[n] \rightarrow\) QCat and a scaffold \(\lambda: \underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F}) \rightarrow \mathcal{C}\). Set \(\mathcal{C}^{\prime}=\underset{\longrightarrow}{\operatorname{holim}}(\mathscr{F})\) and \(\mathcal{C}_{0}^{\prime}=\Lambda_{n}^{n} \times \Delta^{n} \mathcal{C}^{\prime}\), so that \(\lambda\) restricts to a map \(\lambda_{0}: \mathcal{C}_{0}^{\prime} \rightarrow \mathcal{C}_{0}\). We then have a commutative diagram of \(\infty\)-categories

Since \(V\) is an isofibration (Proposition 5.1.4.8), the vertical maps in this diagram are isofibrations (Proposition 4.5.5.14). Since \(\lambda\) and \(\lambda_{0}\) are categorical equivalences of simplicial sets (Lemma 5.3.6.4), the horizontal maps are equivalences of \(\infty\)-categories. Applying Corollary 4.5.2.32, we deduce that the upper horizontal map in the diagram 5.19 restricts to an equivalence from each fiber of the left vertical map to the corresponding fiber of the right vertical map. Consequently, we can replace (5.18) with the lifting problem

Using Remark 5.3.2.12, we obtain a pushout square

Let us identify \(F_{0} \circ \lambda_{0} \circ G_{0}\) with a morphism of simplicial sets \(\tau_{0}: \Lambda_{n}^{n} \rightarrow \operatorname{Fun}(\mathscr{F}(0), \mathcal{D})\), and \(\bar{F} \circ \lambda \circ G\) with an \(n\)-simplex \(\bar{\tau}\) of \(\operatorname{Fun}(\mathscr{F}(0), \mathcal{E})\), so that we can rewrite 5.20 again as a lifting problem

To show that this lifting problem admits a solution, it will suffice to show that \(\tau_{0}\) carries the final edge \(\mathrm{N}_{\bullet}(\{n-1<n\})\) of \(\Lambda_{n}^{n}\) to a \(V^{\prime \prime}\)-cocartesian edge of the simplicial set Fun \((\mathscr{F}(0), \mathcal{E})\). Since \(\lambda\) is a scaffold, this follows by combining ( \(*^{\prime}\) ) with the criterion of Theorem 5.2.1.1.

02UF Lemma 5.3.6.12. Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be a cocartesian fibration of simplicial sets, let \(V: \mathcal{D} \rightarrow \mathcal{E}\) be a cartesian fibration of simplicial sets, and let \(V^{\prime}: \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D}) \rightarrow \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{E})\) be the morphism given by postcomposition with \(V\). Suppose we are given a vertex \(Y\) of the simplicial set \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\) having image \(\bar{Y}=V^{\prime}(Y)\), and an edge \(\bar{e}: \bar{X} \rightarrow \bar{Y}\) of the simplicial set \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{E})\). Then we can write \(\bar{e}=V^{\prime}(e)\) for some edge \(e: X \rightarrow Y\) of \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\) which satisfies condition ( \(*\) ) of Proposition 5.3.6.6.
Proof. As in the proof of Lemma 5.3.6.11, we may assume without loss of generality that \(\mathcal{B}=\Delta^{1}\), so that \(\mathcal{C}\) is an \(\infty\)-category and \(\bar{e}\) corresponds to a morphism \(T: \mathcal{C} \rightarrow \mathcal{E}\). Replacing \(\mathcal{D}\) by the fiber product \(\mathcal{C} \times_{\mathcal{E}} \mathcal{D}\), we can further reduce to the case where \(\mathcal{C}=\mathcal{E}\) and \(T\) is the identity functor (so that \(V: \mathcal{D} \rightarrow \mathcal{C}\) is a cartesian fibration of \(\infty\)-categories). Let \(\mathcal{C}(0)\) and \(\mathcal{C}(1)\) denote the fibers of \(\mathcal{C}\) over the the vertices \(0,1 \in \Delta^{1}\), so that we can identify \(Y\) with a functor \(\mathcal{C}(1) \rightarrow \mathcal{D}\) such that \(V \circ Y\) is the inclusion map \(\mathcal{C}(1) \hookrightarrow \mathcal{C}\). Applying Proposition 5.2 .2 .8 , we can choose a functor \(F: \mathcal{C}(0) \rightarrow \mathcal{C}(1)\) and a diagram

which exhibits \(F=\left.H\right|_{\{1\} \times \mathcal{C}(0)}\) as given by covariant transport along the nondegenerate edge of \(\mathcal{B}=\Delta^{1}\). Since \(V\) is a cartesian fibration, Proposition 5.2.1.3 guarantees that the lifting problem

admits a solution with the property that, for every object \(C\) of the \(\infty\)-category \(\mathcal{C}(0)\), the restriction \(\left.G\right|_{\Delta^{1} \times\{C\}}\) is a \(V\)-cartesian morphism of \(\mathcal{D}\).

Let \(\mathcal{C}^{\prime}=\left(\Delta^{1} \times \mathcal{C}(0)\right) \amalg_{(\{1\} \times \mathcal{C}(0))} \mathcal{C}(1)\) denote the mapping cylinder of the functor \(F\). Amalgamating \(H\) with the inclusion map \(\mathcal{C}(1) \hookrightarrow \mathcal{C}\), we obtain a morphism of simplicial sets \(\bar{H}: \mathcal{C}^{\prime} \rightarrow \mathcal{C}\) which is a categorical equivalence by virtue of Corollary 5.2.4.2. Amalgamating \(G\) with \(Y\), we obtain a diagram \(\bar{G}: \mathcal{C}^{\prime} \rightarrow \mathcal{D}\) satisfying \(V \circ \bar{G}=\bar{H}\). We have a commutative diagram of simplicial sets

where the horizontal maps are equivalences of \(\infty\)-categories. Since \(V\) is an isofibration, the vertical maps in this diagram are isofibrations (Proposition 4.5.5.14). Applying Corollary 4.5.2.32, we deduce that the upper horizontal map in the diagram (5.19) restricts to an equivalence of the fibers of the vertical maps over the object \(Y \in \operatorname{Fun}_{/ \mathcal{C}}(\mathcal{C}(1), \mathcal{D})\). It follows that there there exists a functor \(E: \mathcal{C} \rightarrow \mathcal{D}\) such that \(V \circ E=\operatorname{id}_{\mathcal{C}},\left.E\right|_{\mathcal{C}(1)}=Y\), and \(E \circ \bar{H}\) is isomorphic to \(\bar{G}\) as an object of the \(\infty\)-category Fun \(_{/ \mathcal{C}}\left(\mathcal{C}^{\prime}, \mathcal{D}\right)\). By construction, we can identify \(E\) with an edge \(e: X \rightarrow Y\) of \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\) satisfying \(V^{\prime}(e)=\bar{e}\). To complete the proof, it will suffice to show that \(e\) satisfies condition (*) of Proposition 5.3.6.6. Let \(f: C \rightarrow C^{\prime}\) be a \(U\)-cocartesian morphism of \(\mathcal{C}\); we wish to show that \(E(f)\) is a \(V\)-cartesian morphism of \(\mathcal{D}\). Without loss of generality, we may assume that \(U(f)\) is the nondegenerate edge of \(\mathcal{B}=\Delta^{1}\) (otherwise, \(f\) is an isomorphism and there is nothing to prove). By virtue of Remark 5.1.3.8, we can assume without loss of generality that \(f: C \rightarrow F(C)\) is the \(U\)-cocartesian morphism given by the restriction \(\left.H\right|_{\Delta^{1} \times\{C\}}\). In this case, \(E(f)\) is isomorphic (as an object of the \(\infty\)-category \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{D}\right)\) ) to the \(V\)-cartesian morphism \(\left.G\right|_{\Delta^{1} \times\{C\}}\), and is therefore also \(V\)-cartesian (Corollary 5.1.2.5).

Proof of Proposition 5.3.6.6. Let \(U: \mathcal{C} \rightarrow \mathcal{B}\) be a cocartesian fibration of simplicial sets, let \(V: \mathcal{D} \rightarrow \mathcal{E}\) be a cartesian fibration of simplicial sets, and let \(V^{\prime}: \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D}) \rightarrow\) \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{E})\) be given by postcomposition with \(V\). We first claim that \(V^{\prime}\) is an inner fibration. To prove this, we may assume without loss of generality that \(\mathcal{B}\) is a standard simplex, so that \(U: \mathcal{C} \rightarrow \mathcal{B}\) is a cocartesian fibration of \(\infty\)-categories. Proposition 5.3.6.1 then guarantees that \(U\) is exponentiable, so that \(V^{\prime}\) is an isofibration (Proposition 4.5.9.17) and therefore an inner fibration by virtue of Remark 4.5.5.7.

Let us say that an edge of \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\) is special if it satisfies condition \((*)\) appearing in the statement of Proposition 5.3.6.6. Lemma 5.3.6.11 guarantees that every special edge of \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\) is \(V^{\prime}\)-cartesian. Moreover, if \(Y\) is a vertex of \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\) and \(\bar{e}: \bar{X} \rightarrow V^{\prime}(Y)\) is an edge of \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{E})\), then Lemma 5.3.6.12 guarantees that there exists a special edge \(e: X \rightarrow Y\) of \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\) satisfying \(V^{\prime}(e)=\bar{e}\). It follows that \(V^{\prime}\) is a cartesian fibration of simplicial sets.

To complete the proof of Proposition 5.3.6.6, we must show that every \(V^{\prime}\)-cartesian edge \(e: X \rightarrow Y\) of \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\) is special. Without loss of generality we may assume that \(\mathcal{B}=\Delta^{1}\) and that \(e\) lies over the nondegenerate edge of \(\mathcal{B}\), so that \(e\) corresponds to a functor of \(\infty\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\). Replacing \(\mathcal{D}\) by the fiber product \(\mathcal{C} \times{ }_{\mathcal{E}} \mathcal{D}\), we can assume that \(\mathcal{E}=\mathcal{C}\) and that \(V \circ F: \mathcal{C} \rightarrow \mathcal{E}\) is the identity functor, so that \(V\) is a cartesian fibration of \(\infty\)-categories. Using Lemma 5.3.6.12, we can choose a special edge \(e^{\prime}: X^{\prime} \rightarrow Y\) of \(\operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\) satisfying \(V^{\prime}\left(e^{\prime}\right)=V^{\prime}(e)\), corresponding to another functor \(F^{\prime}: \mathcal{C} \rightarrow \mathcal{D}\) satisfying \(V \circ F^{\prime}=\operatorname{id}_{\mathcal{C}}\). Since \(e^{\prime}\) is also \(V^{\prime}\)-cartesian, it is isomorphic to \(e\) as an object of the \(\infty\)-category \(\operatorname{Fun}_{\mathcal{B}}\left(\Delta^{1}, \operatorname{Fun}(\mathcal{C} / \mathcal{B}, \mathcal{D})\right)\). It follows that \(F\) and \(F^{\prime}\) are isomorphic as objects of the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\). If \(u\) is a \(U\)-cocartesian edge of \(\mathcal{C}\), then \(F(u)\) is isomorphic to the \(V\)-cartesian morphism \(E^{\prime}(u)\) (as an object of the \(\infty\)-category \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{D}\right)\) ), and is therefore also \(V\)-cartesian (Corollary 5.1.2.5).

\subsection*{5.3.7 Application: Path Fibrations}

Recall that every morphism of Kan complexes \(f: X \rightarrow Y\) admits a canonical factorization
\[
X \xrightarrow{\delta} P(f) \xrightarrow{\pi} Y,
\]
where \(\delta\) is a homotopy equivalence and \(\pi\) is the path fibration
\[
P(f)=X \times_{\operatorname{Fun}(\{0\}, Y)} \operatorname{Fun}\left(\Delta^{1}, Y\right) \rightarrow \operatorname{Fun}(\{1\}, Y) \simeq Y
\]
of Example 3.1.7.10. Note that the simplicial set \(P(f)=X \tilde{x}_{Y} Y\) is an example of an oriented fiber product (Definition 4.6.4.1), which is defined for any morphism of simplicial sets \(f: X \rightarrow Y\). Beware that if \(X\) and \(Y\) are not Kan complexes, then \(\delta\) need not be a homotopy equivalence and \(\pi\) need not be a Kan fibration. However, if \(X=\mathcal{C}\) and \(Y=\mathcal{D}\) are \(\infty\)-categories, then we have the following weaker statements:
(a) The functor \(\delta: \mathcal{C} \rightarrow \mathcal{C} \tilde{\times}_{\mathcal{D}} \mathcal{D}\) is fully faithful, and its essential image is the homotopy fiber product \(\mathcal{C} \times{ }_{\mathcal{D}}^{\mathrm{h}} \mathcal{D}\) of Construction 4.5.2.1 (Corollary 4.5.2.22).
(b) The functor \(\pi: \mathcal{C} \tilde{\times}_{\mathcal{D}} \mathcal{D} \rightarrow \mathcal{D}\) is a cocartesian fibration of \(\infty\)-categories (Corollary 5.3.7.3).

Moreover, the oriented fiber product \(\mathcal{C} \tilde{\times}_{\mathcal{D}} \mathcal{D}\) can be characterized by a universal mapping property: roughly speaking, the diagonal map \(\delta\) exhibits the cocartesian fibration \(\pi\) as freely generated by the functor \(f\) (Theorem 5.3.7.6).

Our starting point is the following observation:
Lemma 5.3.7.1. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of simplicial sets, let \(e\) be an edge of 0475 \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)\), and let
\[
V: \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)=\mathcal{C} \tilde{x}_{\mathcal{C}} \mathcal{C} \rightarrow \mathcal{C} \tilde{\times}_{\mathcal{D}} \mathcal{C}
\]
denote the morphism induced by \(U\). Let \(\mathrm{ev}_{0}, \mathrm{ev}_{1}: \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right) \rightarrow \mathcal{C}\) be the evaluation maps. If \(\operatorname{ev}_{0}(e)\) is \(U\)-cocartesian, then \(e\) is \(V\)-cocartesian. If \(\operatorname{ev}_{1}(e)\) is \(U\)-cartesian, then \(e\) is \(V\)-cartesian.

Proof. Assume that \(\mathrm{ev}_{0}(e)\) is \(U\)-cocartesian; we will show that \(e\) is \(V\)-cocartesian (the second assertion follows by a similar argument). Let \(n \geq 2\); we wish to show that every lifting problem

admits a solution, provided that the composite map
\[
\Delta^{1} \simeq \mathrm{~N}_{\bullet}(\{0<1\}) \hookrightarrow \Lambda_{0}^{n} \xrightarrow{\tau_{0}} \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)
\]
coincides with \(e\). Let \(X(0)\) denote the simplicial subset of \(\Delta^{1} \times \Delta^{n}\) given by the union of \(\partial \Delta^{1} \times \Delta^{n}\) with \(\Delta^{1} \times \Lambda_{0}^{n}\). Unwinding the definitions, we can rewrite 5.21 as a lifting problem

Choose a filtration
\[
X(0) \subset X(1) \subset X(2) \subset \cdots \subset X(t)=\Delta^{1} \times \Delta^{n}
\]
satisfying the requirements of Lemma 4.4.4.7. We will complete the proof by showing that, for each \(s \leq t\), the morphism \(\tau_{0}\) admits an extension \(\tau_{s}: X(s) \rightarrow \mathcal{C}\) satisfying \(U \circ \tau_{s}=\left.\bar{\tau}\right|_{X(s)}\). The proof proceeds by induction on \(s\), the case \(s=0\) being vacuous. Let us therefore assume that \(0<s \leq t\) and that \(\tau_{0}\) has already been extended to a morphism of simplicial sets \(\tau_{s-1}: X(s-1) \rightarrow \mathcal{C}\). By construction, we have a pushout diagram of simplicial sets

for some \(q \geq 2\) and \(0 \leq p<q\). Consequently, to prove the existence of \(\tau_{s}\), it will suffice to show that \(\tau_{s-1} \circ \varphi_{0}\) can be extended to a \(q\)-simplex of \(\mathcal{C}\) lying over the simplex \(\bar{\tau} \circ \varphi: \Delta^{q} \rightarrow \mathcal{D}\). For \(p \neq 0\), the existence of this extension follows from our assumption that \(U\) is an inner fibration. To handle the case \(p=0\), we observe that the morphism \(\varphi\) carries the initial edge of \(\Delta^{q}\) to the edge \((0,0) \rightarrow(0,1)\) of \(\Delta^{1} \times \Delta^{n}\), so that \(\tau_{s-1} \circ \varphi_{0}\) carries the initial edge of \(\Delta^{q}\) to the edge \(\operatorname{ev}_{0}(e)\) of \(\mathcal{C}\), which is \(U\)-cocartesian by assumption.

0477 Proposition 5.3.7.2. Suppose we are given a commutative diagram of simplicial sets

where \(U_{0}, U_{1}\), and \(U\) are cocartesian fibrations, and \(F_{0}\) carries \(U_{0}\)-cocartesian edges of \(\mathcal{C}_{0}\) to \(U\)-cocartesian edges of \(\mathcal{C}\). Then the induced map
\[
V: \mathcal{C}_{0} \tilde{x}_{\mathcal{C}} \mathcal{C}_{1} \rightarrow \mathcal{D}_{0} \tilde{x}_{\mathcal{D}} \mathcal{D}_{1}
\]
is a cocartesian fibration of simplicial sets. Moreover, an edge e of \(\mathcal{C}_{0} \tilde{x}_{\mathcal{C}} \mathcal{C}_{1}\) is \(V\)-cocartesian if and only if it satisfies the following condition:
\((*)\) Let \(e_{0}\) and \(e_{1}\) denote the images of \(e\) in \(\mathcal{C}_{0}\) and \(\mathcal{C}_{1}\), respectively. Then \(e_{0}\) is \(U_{0}\)-cocartesian and \(e_{1}\) is \(U_{1}\)-cocartesian.

Proof. Let us say that an edge \(e\) of \(\mathcal{C}_{0} \tilde{x}_{\mathcal{C}} \mathcal{C}_{1}\) is special if it satisfies condition (*). We first show that if \(e\) is a special edge of \(\mathcal{C}_{0} \tilde{x}_{\mathcal{C}} \mathcal{C}_{1}\), then \(e\) is \(V\)-cocartesian. Let \(e_{0}\) and \(e_{1}\) denote the images of \(e\) in \(\mathcal{C}_{0}\) and \(\mathcal{C}_{1}\), respectively. Note that \(V\) factors as a composition
\[
\mathcal{C}_{0} \tilde{x}_{\mathcal{C}} \mathcal{C}_{1} \xrightarrow{V^{\prime}} \mathcal{C}_{0} \tilde{x}_{\mathcal{D}} \mathcal{C}_{1} \xrightarrow{V^{\prime \prime}} \mathcal{D}_{0} \tilde{x}_{\mathcal{D}} \mathcal{D}_{1} .
\]

Here \(V^{\prime}\) is a pullback of the projection map \(\bar{V}^{\prime}: \operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)=\mathcal{C} \tilde{x}_{\mathcal{C}} \mathcal{C} \rightarrow \mathcal{C} \tilde{x}_{\mathcal{D}} \mathcal{C}\). Since \(F\left(e_{0}\right)\) is \(U\)-cocartesian, Lemma 5.3.7.1 implies that \(e\) is \(V^{\prime}\)-cocartesian. Moreover, \(V^{\prime \prime}\) is a pullback of the product map \(\left(U_{0} \times U_{1}\right): \mathcal{C}_{0} \times \mathcal{C}_{1} \rightarrow \mathcal{D}_{0} \times \mathcal{D}_{1}\). By assumption, \(e_{0}\) is \(U_{0}\)-cocartesian and \(e_{1}\) is \(U_{1}\)-cocartesian. It follows that \(V^{\prime}(e)\) is \(V^{\prime \prime}\)-cocartesian, so that \(e\) is \(V\)-cocartesian by virtue of Remark 5.1.1.6.

Since \(U_{0}, U_{1}\), and \(U\) are inner fibrations, the morphisms \(\bar{V}^{\prime}\) and \(\left(U_{0} \times U_{1}\right)\) are also inner fibrations (see Proposition 4.1.4.1). It follows that \(V^{\prime}\) and \(V^{\prime \prime}\) are inner fibrations (Remark 4.1.1.5), so that \(V\) is an inner fibration (Remark 4.1.1.8). To show that \(V\) is a cocartesian fibration, it will suffice to show that if \(C\) is an object of \(\mathcal{C}_{0} \tilde{x}_{\mathcal{C}} \mathcal{C}_{1}\) and \(\bar{e}: V(C) \rightarrow \bar{C}^{\prime}\) is an edge of \(\mathcal{D}_{0} \tilde{x}_{\mathcal{D}} \mathcal{D}_{1}\), then there exists a special edge \(e: C \rightarrow C^{\prime}\) satisfying \(V(e)=\bar{e}\). Let us identify \(C\) with a triple \(\left(C_{0}, C_{1}, u\right)\) where \(C_{0}\) is a vertex of \(\mathcal{C}_{0}, C_{1}\) is a vertex of \(\mathcal{C}_{1}\), and \(u: F_{0}\left(C_{0}\right) \rightarrow F_{1}\left(C_{1}\right)\) is an edge of \(\mathcal{C}\). Similarly, we can identify \(\bar{C}^{\prime}\) with a triple ( \(\bar{C}_{0}^{\prime}, \bar{C}_{1}^{\prime}, \bar{u}^{\prime}\) ) where \(\bar{C}_{0}\) is a vertex of \(\mathcal{D}_{0}, \bar{C}_{1}^{\prime}\) is a vertex of \(\mathcal{D}_{1}\), and \(\bar{u}^{\prime}: G_{0}\left(\bar{C}_{0}^{\prime}\right) \rightarrow G_{1}\left(\bar{C}_{1}^{\prime}\right)\) is an edge of \(\mathcal{D}\). The edge \(\bar{e}\) has images \(\bar{e}_{0}: U_{0}\left(C_{0}\right) \rightarrow \bar{C}_{0}^{\prime}\) an \(\bar{e}_{1}: U_{1}\left(C_{1}\right) \rightarrow \bar{C}_{1}^{\prime}\) in \(\mathcal{D}_{0}\) and \(\mathcal{D}_{1}\)-respectively. Since \(U_{0}\) is a cocartesian fibration, we can lift \(\bar{e}_{0}\) to a \(U_{0}\)-cocartesian edge \(e_{0}: C_{0} \rightarrow C_{0}^{\prime}\) of \(\mathcal{C}_{0}\). Similarly, we can lift \(\bar{e}_{1}\) to a \(U_{1}\)-cocartesian edge \(e_{1}: C_{1} \rightarrow C_{1}^{\prime}\) of \(\mathcal{C}_{1}\). The edge \(\bar{e}\) also determines a map \(\Delta^{1} \times \Delta^{1} \rightarrow \mathcal{D}\), which we depict informally in the diagram

Using our assumption that \(U\) is an inner fibration, we can lift the upper right triangle to a 2-simplex \(\sigma\) :

of the simplicial set \(\mathcal{C}\). Using the fact that \(F_{0}\left(e_{0}\right)\) is \(U\)-cocartesian, we can lift the lower triangle to a 2 -simplex \(\tau\)

of \(\mathcal{C}\). Setting \(C^{\prime}=\left(C_{0}^{\prime}, C_{1}^{\prime}, w\right) \in \mathcal{C}_{0} \tilde{x}_{\mathcal{C}} \mathcal{C}_{1}\), we observe that the tuple \(\left(e_{0}, e_{1}, \sigma, \tau\right)\) determines a special edge \(e: C \rightarrow C^{\prime}\) satisfying \(V(e)=\bar{e}\).

We now complete the proof by showing that every \(V\)-cocartesian edge \(f: C \rightarrow C^{\prime \prime}\) in \(\mathcal{C}_{0} \tilde{x}_{\mathcal{C}} \mathcal{C}_{1}\) is special. Using the preceding argument, we can choose a special edge \(e: C \rightarrow C^{\prime}\)
satisfying \(V(e)=V(f)\). Set \(\bar{C}^{\prime}=V\left(C^{\prime}\right)=V\left(C^{\prime \prime}\right)\). Applying Remark 5.1.3.8, we deduce that there is a 2 -simplex \(\rho\) :

of the simplicial set \(\mathcal{C}_{0} \tilde{x}_{\mathcal{C}} \mathcal{C}_{1}\), where \(s\) is an isomorphism in the \(\infty\)-category \(V^{-1}\left(\left\{\bar{C}^{\prime}\right\}\right)\). Applying Example 5.1.3.6, we deduce that the images of \(s\) in \(\mathcal{C}_{0}\) is \(U_{0}\)-cocartesian, and the image of \(s\) in \(\mathcal{C}_{1}\) is \(U_{1}\)-cocartesian. Since the collections of \(U_{0}\)-cocartesian and \(U_{1}\)-cocartesian edges are closed under composition (Corollary 5.1.2.4), we conclude that \(f\) is also special.

0478 Corollary 5.3.7.3. Let \(F_{0}: \mathcal{C}_{0} \rightarrow \mathcal{C}\) and \(F_{1}: \mathcal{C}_{1} \rightarrow \mathcal{C}\) be morphisms of simplicial sets and let
\[
\mathcal{C}_{0} \stackrel{\pi}{\leftarrow} \mathcal{C}_{0} \tilde{x}_{\mathcal{C}} \mathcal{C}_{1} \xrightarrow{\pi^{\prime}} \mathcal{C}_{1}
\]
denote the projection maps. Then:
(1) If \(\mathcal{C}_{0}\) and \(\mathcal{C}\) are \(\infty\)-categories, then \(\pi^{\prime}\) is a cocartesian fibration of simplicial sets. Moreover, an edge e of \(\mathcal{C}_{0} \tilde{x}_{\mathcal{C}} \mathcal{C}_{1}\) is \(\pi^{\prime}\)-cocartesian if and only if \(\pi(e)\) is an isomorphism in the \(\infty\)-category \(\mathcal{C}_{0}\).
(2) If \(\mathcal{C}_{1}\) and \(\mathcal{C}\) are \(\infty\)-categories, then the evaluation map \(\pi: \mathcal{C}_{0} \tilde{x}_{\mathcal{C}} \mathcal{C}_{1}\) is a cartesian fibration of simplicial sets. Moreover, an edge e of \(\mathcal{C}_{0} \tilde{x}_{\mathcal{C}} \mathcal{C}_{1}\) is \(\pi\)-cartesian if and only if \(\pi^{\prime}(e)\) is an isomorphism in the \(\infty\)-category \(\mathcal{C}_{1}\).

Proof. Assertion (1) follows by applying Proposition 5.3.7.2 in the special case \(\mathcal{D}_{0}=\mathcal{D}=\Delta^{0}\) and \(\mathcal{D}_{1}=\mathcal{C}_{1}\). Assertion (2) follows by a similar argument.

010 U Example 5.3.7.4. Let \(\mathcal{C}\) be an \(\infty\)-category. Applying Corollary 5.3.7.3 in the case where both \(F\) and \(G\) are the identity functor id : \(\mathcal{C} \rightarrow \mathcal{C}\), we deduce that the evaluation functor
\[
\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right) \rightarrow \operatorname{Fun}(\{0\}, \mathcal{C}) \simeq \mathcal{C}
\]
is a cartesian fibration of \(\infty\)-categories, and the evaluation functor
\[
\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right) \rightarrow \operatorname{Fun}(\{1\}, \mathcal{C}) \simeq \mathcal{C}
\]
is a cocartesian fibration of \(\infty\)-categories.
02VW Corollary 5.3.7.5. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(K\) be a simplicial set. Then:
(1) The restriction map \(U: \operatorname{Fun}\left(K^{\triangleleft}, \mathcal{C}\right) \rightarrow \operatorname{Fun}(K, \mathcal{C})\) is a cocartesian fibration. Moreover, a morphism \(e\) of \(\operatorname{Fun}\left(K^{\triangleleft}, \mathcal{C}\right)\) is \(U\)-cocartesian if and only if carries the cone point \(\mathbf{0} \in K^{\triangleleft}\) to an isomorphism in \(\mathcal{C}\).
(2) The restriction map \(V: \operatorname{Fun}\left(K^{\triangleright}, \mathcal{C}\right) \rightarrow \operatorname{Fun}(K, \mathcal{C})\) is a cartesian fibration. Moreover, a morphism \(e\) of \(\operatorname{Fun}\left(K^{\triangleright}, \mathcal{C}\right)\) is \(U\)-cartesian if and only if carries the cone point \(\mathbf{1} \in K^{\triangleright}\) to an isomorphism in \(\mathcal{C}\).

Proof. We will prove (1); the proof of (2) is similar. Let \(\Delta^{0} \diamond K\) denote the blunt join of Notation 4.5.8.3, and let \(c: \Delta^{0} \diamond K \rightarrow \Delta^{0} \star K=K^{\triangleleft}\) be the categorical equivalence of Theorem 4.5.8.8. We have a commutative diagram of \(\infty\)-categories

where the horizontal map is an equivalence of \(\infty\)-categories (Proposition 4.5.3.8) and the vertical maps are isofibrations (Corollary 4.4.5.3). Unwinding the definitions, we can identify \(\operatorname{Fun}\left(\Delta^{0} \diamond K, \mathcal{C}\right)\) with the oriented fiber product \(\mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})} \operatorname{Fun}(K, \mathcal{C})\). Under this identification, the functor \(U^{\prime}\) is given by projection onto the second factor, and is therefore a cocartesian fibration (Corollaryt 5.3.7.3. Applying Corollary 5.1.6.2, we deduce that \(U\) is also a cocartesian fibration. Moreover, a morphism \(e\) of \(\operatorname{Fun}\left(K^{\triangleleft}, \mathcal{C}\right)\) is \(U\)-cocartesian if and only if its image in \(\operatorname{Fun}\left(\Delta^{0} \diamond K, \mathcal{C}\right)\) is \(U^{\prime}\)-cocartesian (Proposition 5.1.6.6). Using the criterion of Corollary 5.3.7.3 we see that this is equivalent to the requirement that \(e\) carries the cone point \(\mathbf{0} \in K^{\triangleleft}\) to an isomorphism in \(\mathcal{C}\).

Theorem 5.3.7.6. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, let \(\pi: \mathcal{C} \tilde{\times}_{\mathcal{D}} \mathcal{D} \rightarrow \mathcal{D}\) be given by projection onto the second factor, let \(\delta: \mathcal{C} \hookrightarrow \mathcal{C} \tilde{\times}_{\mathcal{D}} \mathcal{D}\) be the diagonal map. For every cocartesian fibration \(U: \mathcal{E} \rightarrow \mathcal{D}\), precomposition with \(\delta\) induces a trivial Kan fibration of \(\infty\)-categories
\[
\text { Fun }_{/ \mathcal{D}}^{\text {CCart }}\left(\mathcal{C} \tilde{\times}_{\mathcal{D}} \mathcal{D}, \mathcal{E}\right) \rightarrow \text { Fun }_{\mathcal{D}}(\mathcal{C}, \mathcal{E}) .
\]

Our proof of Theorem 5.3.7.6 will make use of an auxiliary construction.
Notation 5.3.7.7 (Cocartesian Direct Images). Let \(U: \mathcal{D} \rightarrow \mathcal{C}\) be a morphism of simplicial 02UH sets \(\operatorname{id}_{\mathcal{D}}: \mathcal{D} \rightarrow \mathcal{D}\) determines a section of the projection map \(\pi: \operatorname{Fun}(\mathcal{D} / \mathcal{C}, \mathcal{D}) \rightarrow \mathcal{C}\). For every morphism of simplicial sets \(V: \mathcal{E} \rightarrow \mathcal{D}\), we let \(\operatorname{Res}_{\mathcal{D} / \mathcal{C}}(\mathcal{E})\) denote the fiber product \(\mathcal{C} \times_{\operatorname{Fun}(\mathcal{D} / \mathcal{C}, \mathcal{D})} \operatorname{Fun}(\mathcal{D} / \mathcal{C}, \mathcal{E})\). Unwinding the definitions, we see that vertices of \(\operatorname{Res}_{\mathcal{D} / \mathcal{C}}(\mathcal{E})\) can be identified with pairs \((C, F)\), where \(C\) is a vertex of \(\mathcal{C}\) and
\[
F: \mathcal{D}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{D} \rightarrow\{C\} \times_{\mathcal{C}} \mathcal{E}=\mathcal{E}_{C}
\]
is a section of the map \(\left.V\right|_{\mathcal{E}_{C}}: \mathcal{E}_{C} \rightarrow \mathcal{D}_{C}\). If \(V\) is a cocartesian fibration, we let \(\operatorname{Res}_{\mathcal{D} / \mathcal{C}}^{\text {CCart }}(\mathcal{E})\) denote the full simplicial subset of \(\operatorname{Res}_{\mathcal{D} / \mathcal{C}}(\mathcal{E})\) spanned by those vertices \((C, F)\) where \(F\)
carries each edge of \(\mathcal{D}_{C}\) to \(V_{C}\)-cocartesian edge of \(\mathcal{E}_{C}\). We will refer to \(\operatorname{Res}_{\mathcal{D} / \mathcal{C}}^{\text {CCart }}(\mathcal{E})\) as the cocartesian direct image of \(\mathcal{E}\) along \(U\).

02UJ Remark 5.3.7.8. Let \(U: \mathcal{D} \rightarrow \mathcal{C}\) be a morphism of simplicial sets and let \(V: \mathcal{E} \rightarrow \mathcal{D}\) be a cocartesian fibration of simplicial sets. Then the projection map \(\pi: \operatorname{Res}_{\mathcal{D} / \mathcal{C}}(\mathcal{E}) \rightarrow \mathcal{C}\) restricts to a projection map \(\pi^{\text {CCart }}: \operatorname{Res}_{\mathcal{D} / \mathcal{C}}^{\text {CCart }}(\mathcal{E}) \rightarrow \mathcal{C}\). Moreover, for each vertex \(C \in \mathcal{C}\), the canonical isomorphism \(\{C\} \times_{\mathcal{C}} \operatorname{Res}_{\mathcal{D} / \mathcal{C}}(\mathcal{E}) \simeq \operatorname{Fun} / \mathcal{D}_{C}\left(\mathcal{D}_{C}, \mathcal{E}_{C}\right)\) restricts to an isomorphism of full subcategories \(\{C\} \times_{\mathcal{C}} \operatorname{Res}_{\mathcal{D} / \mathcal{C}}^{\text {CCart }}(\mathcal{E}) \simeq \operatorname{Fun} / \mathcal{D}_{C}{ }^{\text {Cart }}\left(\mathcal{D}_{C}, \mathcal{E}_{C}\right)\).

02UK Proposition 5.3.7.9. Let \(V: \mathcal{E} \rightarrow \mathcal{D}\) be a cocartesian fibration of simplicial sets, let \(U: \mathcal{D} \rightarrow \mathcal{C}\) be a cartesian fibration of simplicial sets. Then:
(1) The projection map \(\pi: \operatorname{Res}_{\mathcal{D} / \mathcal{C}}(\mathcal{E}) \rightarrow \mathcal{C}\) is a cocartesian fibration of simplicial sets.
(2) Let \(e: X \rightarrow Y\) be a \(\pi\)-cocartesian edge of the simplicial set \(\operatorname{Res}_{\mathcal{D} / \mathcal{C}}(\mathcal{E})\). If \(X\) belongs to the simplicial subset \(\operatorname{Res}_{\mathcal{D} / \mathcal{C}}^{\mathrm{CCart}}(\mathcal{E})\), then \(Y\) also belongs to the simplicial subset \(\operatorname{Res}_{\mathcal{D} / \mathcal{C}}^{\mathrm{CCart}}(\mathcal{E})\).
(3) The morphism \(\pi\) restricts to a cocartesian fibration \(\pi^{\mathrm{CCart}}: \operatorname{Res}_{\mathcal{D} / \mathcal{C}}^{\mathrm{CCart}}(\mathcal{E}) \rightarrow \mathcal{C}\).
(4) An edge of the simplicial set \(\operatorname{Res}_{\mathcal{D} / \mathcal{C}}^{\mathrm{CCart}}(\mathcal{E})\) is \(\pi^{\mathrm{CCart}}\)-cocartesian if and only if it is \(\pi\) cocartesian.

Proof. Assertion (1) follows from Proposition 5.3.6.6 (after passing to opposite simplicial sets). To prove (2), we may assume without loss of generality that \(\mathcal{C}=\Delta^{1}\) and \(\pi(e)\) is the nondegenerate edge of \(\mathcal{C}\). In this case, the simplicial sets \(\mathcal{D}\) and \(\mathcal{E}\) are \(\infty\)-categories, and we can identify the edge \(e\) with a morphism of simplicial sets \(E: \mathcal{D} \rightarrow \mathcal{E}\) satisfying \(V \circ E=\operatorname{id}_{\mathcal{D}}\). Let \(u: D \rightarrow D^{\prime}\) be a morphism in the \(\infty\)-category \(\mathcal{D}_{1}=\{1\} \times_{\mathcal{C}} \mathcal{D}\); we wish to show that \(E(u)\) is a \(V\)-cocartesian morphism of \(\mathcal{E}\). To prove this, let \(G: \mathcal{D}_{1} \rightarrow \mathcal{D}_{0}=\{0\} \times_{\mathcal{C}} \mathcal{D}\) be given by contravariant transport along the nondegenerate edge of \(\mathcal{C}\), so that we have a commutative diagram

in the \(\infty\)-category where the horizontal maps are \(U\)-cartesian. Our assumption that \(e\) is \(\pi\)-cocartesian guarantees that the functor \(E\) carries \(U\)-cartesian morphisms of \(\mathcal{D}\) to \(V\)-cocartesian morphisms of \(\mathcal{E}\) (Proposition 5.3.6.6). We therefore obtain a commutative
diagram

where the horizontal maps are \(V\)-cocartesian. By virtue of Corollary 5.1.2.4, it will suffice to show that the morphism \((E \circ G)(u)\) is \(V\)-cocartesian, which follows from our assumption that \(X\) belongs to \(\operatorname{Res}_{\mathcal{D} / \mathcal{C}}^{\text {CCart }}(\mathcal{E})\). This completes the proof of (2); assertions (3) and (4) then follow by applying Proposition 5.1.4.16.

In the situation of Proposition 5.3.7.9. the cocartesian direct image \(\operatorname{Res}_{\mathcal{D} / \mathcal{C}}^{\mathrm{CCart}}(\mathcal{E})\) can be characterized by a universal property:

Proposition 5.3.7.10. Let \(V: \mathcal{E} \rightarrow \mathcal{D}\) be a cocartesian fibration of simplicial sets and let 02UL \(U: \mathcal{D} \rightarrow \mathcal{C}\) be a cartesian fibration of simplicial sets. For every cocartesian fibration of simplicial sets \(W: \mathcal{C}^{\prime} \rightarrow \mathcal{C}\), the canonical isomorphism
\[
\operatorname{Fun}_{/ \mathcal{C}}\left(\mathcal{C}^{\prime}, \operatorname{Res}_{\mathcal{D} / \mathcal{C}}(\mathcal{E})\right) \xrightarrow{\sim} \operatorname{Fun}_{/ \mathcal{D}}\left(\mathcal{C}^{\prime} \times_{\mathcal{C}} \mathcal{D}, \mathcal{E}\right)
\]
restricts to an isomorphism of full simplicial subsets
\[
\operatorname{Fun}_{/ \mathcal{C}}^{\mathrm{CCart}}\left(\mathcal{C}^{\prime}, \operatorname{Res}_{\mathcal{D} / \mathcal{C}}^{\mathrm{CCart}}(\mathcal{E})\right) \xrightarrow{\sim} \operatorname{Fun}_{/ \mathcal{D}}^{\mathrm{CCart}}\left(\mathcal{C}^{\prime} \times_{\mathcal{C}} \mathcal{D}, \mathcal{E}\right)
\]

Proof. Let \(\pi: \operatorname{Res}_{\mathcal{D} / \mathcal{C}}(\mathcal{E}) \rightarrow \mathcal{C}\) denote the projection map and let \(f: \mathcal{C}^{\prime} \rightarrow \operatorname{Res}_{\mathcal{D} / \mathcal{C}}(\mathcal{E})\) be a morphism satisfying \(\pi \circ f=W\), corresponding to a morphism of simplicial sets \(F: \mathcal{C}^{\prime} \times_{\mathcal{C}} \mathcal{D} \rightarrow \mathcal{E}\) for which \(V \circ F\) is given by projection to the second factor. Note that we can regard \(F\) as a vertex of the simplicial subset \(\operatorname{Fun} / \mathcal{D}\) Cart \(\left(\mathcal{C}^{\prime} \times \mathcal{C} \mathcal{D}, \mathcal{E}\right)\) if and only if it satisfies the following condition:
(a) For every edge ( \(e^{\prime}, e\) ) of the fiber product \(\mathcal{C}^{\prime} \times_{\mathcal{C}} \mathcal{D}\) for which \(e^{\prime}\) is a \(W\)-cocartesian edge of \(\mathcal{C}^{\prime}\), the image \(F\left(e^{\prime}, e\right)\) is a \(V\)-cocartesian edge of \(\mathcal{E}\).

We wish to show that \((a)\) is equivalent to the following pair of conditions:
(b) The morphism \(f\) factors through the full simplicial subset \(\operatorname{Res}_{\mathcal{D} / \mathcal{C}}^{\mathrm{CCart}}(\mathcal{E}) \subseteq \operatorname{Res}_{\mathcal{D} / \mathcal{C}}(\mathcal{E})\). In other words, for every edge \(\left(e^{\prime}, e\right)\) of the fiber product \(\mathcal{C}^{\prime} \times_{\mathcal{C}} \mathcal{D}\) for which \(e^{\prime}\) is a degenerate edge of \(\mathcal{C}^{\prime}\), the image \(F\left(e^{\prime}, e\right)\) is a \(V\)-cocartesian edge of \(\mathcal{E}\).
(c) For every \(W\)-cocartesian edge \(e^{\prime}\) of \(\mathcal{C}^{\prime}\), the image \(f\left(e^{\prime}\right)\) is a \(\left.\pi\right|_{\operatorname{Res}_{\mathcal{D}}^{\text {Cart }}(\mathcal{E})}\)-cocartesian edge of \(\operatorname{Res}_{\mathcal{D} / \mathcal{C}}^{\mathrm{CCart}}(\mathcal{E})\). By virtue of Propositions 5.3.7.9 and 5.3.6.6, this is equivalent to the assertion that for every edge ( \(e^{\prime}, e\) ) of the fiber product \(\mathcal{C}^{\prime} \times_{\mathcal{C}} \mathcal{D}\) where \(e^{\prime}\) is \(W\)-cocartesian and \(e\) is \(U\)-cartesian, the image \(F\left(e^{\prime}, e\right)\) is a \(V\)-cocartesian edge of \(\mathcal{E}\).

The implications \((a) \Rightarrow(b)\) and \((a) \Rightarrow(c)\) are clear. For the converse, suppose that \((b)\) and (c) are satisfied; we wish to prove (a). Let \(\left(e^{\prime}, e\right):\left(X^{\prime}, X\right) \rightarrow\left(Z^{\prime}, Z\right)\) be an edge of the fiber product \(\mathcal{C}^{\prime} \times_{\mathcal{C}} \mathcal{D}\), where \(e^{\prime}: X^{\prime} \rightarrow Z^{\prime}\) is \(W\)-cocartesian. Let \(\bar{e}=U(e)=W\left(e^{\prime}\right)\) denote the corresponding edge of \(\mathcal{C}\). Since \(U\) is a cartesian fibration, there exists a \(U\)-cartesian morphism \(f: Y \rightarrow Z\) satisfying \(U(f)=\bar{e}\). Let \(\bar{\sigma}\) denote the left-degenerate 2-simplex \(s_{0}^{1}(\bar{e})\). Since \(f\) is \(U\)-cartesian, we can lift \(\bar{\sigma}\) to a 2-simplex of \(\mathcal{D}\) as indicated in the diagram

Writing \(\sigma^{\prime}\) for the left-degenerate 2-simplex \(s_{0}^{1}\left(e^{\prime}\right)\) of \(\mathcal{C}^{\prime}\), we obtain a 2 -simplex \(\tau=F\left(\sigma^{\prime}, \sigma\right)\) of \(\mathcal{E}\). It follows from assumption \((b)\) that the restriction \(\left.\tau\right|_{\mathrm{N} \cdot(\{0<1\})}\) is a \(V\)-cocartesian edge of \(\mathcal{E}\), and from assumption \((c)\) that the restriction \(\left.\tau\right|_{\mathrm{N}_{\bullet}(\{1<2\})}\) is a \(V\)-cocartesian edge of \(\mathcal{E}\). Applying Proposition 5.1.4.12, we conclude that \(F\left(e^{\prime}, e\right)=\left.\tau\right|_{\mathrm{N} \cdot(\{0<2\})}\) is also a \(V\)-cocartesian edge of \(\mathcal{E}\).

Proof of Theorem 5.3.7.6. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, let \(U: \mathcal{E} \rightarrow \mathcal{D}\) be a cocartesian fibration of \(\infty\)-categories, and let \(\delta: \mathcal{C} \hookrightarrow \mathcal{C} \tilde{x}_{\mathcal{D}} \mathcal{D}\) be the diagonal embedding. Since \(U\) is an isofibration (Proposition 5.1.4.8, the restriction map \(\bar{\theta}: \operatorname{Fun}_{/ \mathcal{D}}\left(\mathcal{C} \tilde{\times}_{\mathcal{D}} \mathcal{D}, \mathcal{E}\right) \rightarrow\) \(\operatorname{Fun}_{/ \mathcal{D}}(\mathcal{C}, \mathcal{E})\) is also an isofibration (Corollary 4.5.5.16. Because Fun \(\mathcal{D}_{\mathcal{D}}^{\text {CGart }}\left(\mathcal{C} \tilde{\times}_{\mathcal{D}} \mathcal{D}, \mathcal{E}\right)\) is a replete full subcategory of \(\operatorname{Fun}_{/ \mathcal{D}}\left(\mathcal{C} \tilde{\times}_{\mathcal{D}} \mathcal{D}, \mathcal{E}\right)\), it follows that \(\bar{\theta}\) restricts to an isofibration \(\theta: \operatorname{Fun}_{\mathcal{D}}^{\text {CCart }}\left(\mathcal{C} \tilde{x}_{\mathcal{D}} \mathcal{D}, \mathcal{E}\right) \rightarrow \operatorname{Fun}_{/ \mathcal{D}}(\mathcal{C}, \mathcal{E})\). To prove Theorem 5.3.7.6, we will show that \(\theta\) is an equivalence of \(\infty\)-categories (it is then automatically a trivial Kan fibration of simplicial sets: see Proposition 4.5.5.20).

Note that the functor \(U: \mathcal{E} \rightarrow \mathcal{D}\) induces cocartesian fibrations \(U^{\prime}: \mathcal{C} \tilde{\times}_{\mathcal{D}} \mathcal{E} \rightarrow \mathcal{C} \tilde{\times}_{\mathcal{D}} \mathcal{D}\) and \(U^{\prime \prime}: \mathcal{C} \times_{\mathcal{D}} \mathcal{E} \rightarrow \mathcal{C}\). Let \(\pi^{\prime}: \mathcal{C} \tilde{\times}_{\mathcal{D}} \mathcal{D} \rightarrow \mathcal{C}\) be given by projection onto the first factor, so that \(\pi^{\prime}\) is a cartesian fibration (Corollary 5.3.7.3). Let \(\mathcal{M}\) denote the cocartesian direct image \(\operatorname{Res}_{\mathcal{C}}^{\text {CCart }}{ }_{\mathcal{D}}\left(\mathcal{C} \mathcal{C}\left(\mathcal{C} \tilde{\times}_{\mathcal{D}} \mathcal{E}\right)\right.\) and let \(T: \mathcal{M} \rightarrow \mathcal{C}\) be the projection map. Precomposition with the diagonal embedding \(\delta: \mathcal{C} \hookrightarrow \mathcal{C} \tilde{\times}_{\mathcal{D}} \mathcal{D}\) induces a restriction functor
\[
\delta^{*}: \mathcal{M} \rightarrow \operatorname{Res}_{\mathcal{C} / \mathcal{C}}\left(\mathcal{C} \times_{\mathcal{D}} \mathcal{E}\right)=\mathcal{C} \times_{\mathcal{D}} \mathcal{E}
\]
which fits into a commutative diagram

It follows from Proposition 5.3.7.9 that \(T\) is a cocartesian fibration and that \(\delta^{*}\) carries \(T\)-cocartesian morphisms of \(\mathcal{M}\) to \(U^{\prime \prime}\)-cocartesian morphisms of \(\mathcal{C} \times_{\mathcal{D}} \mathcal{E}\). Using Proposition 5.3.7.10, we can identify \(\theta\) with the map
\[
\text { Fun }_{/ \mathcal{C}}(\mathcal{C}, \mathcal{M}) \rightarrow \operatorname{Fun}_{/ \mathcal{C}}\left(\mathcal{C}, \mathcal{C} \times_{\mathcal{D}}, \mathcal{E}\right) \simeq \operatorname{Fun}_{/ \mathcal{D}}(\mathcal{C}, \mathcal{E})
\]
given by postcomposition with \(\delta^{*}\). Consequently, to show that \(\theta\) is an equivalence of \(\infty\) categories, it will suffice to show that \(\delta^{*}\) is an equivalence of cocartesian fibrations over \(\mathcal{C}\). By virtue of Proposition 5.1.7.14, this can be checked fiberwise: that is, it suffices to show that for each object \(C \in \mathcal{C}\), the induced map of fibers
\[
\delta_{C}^{*}:\{C\} \times_{\mathcal{C}} \mathcal{M} \simeq \operatorname{Fun} / \mathcal{D} \text { Cart }\left(\{C\} \tilde{\times}_{\mathcal{D}} \mathcal{D}, \mathcal{E}\right) \rightarrow\{C\} \times_{\mathcal{D}} \mathcal{E}
\]
is an equivalence of \(\infty\)-categories. This is a special case of Corollary 5.3.1.22, since \(\delta(C)\) is an initial object of the \(\infty\)-category \(\{C\} \tilde{\times}_{\mathcal{D}} \mathcal{D}\) (Proposition 4.6.7.22).

\section*{\(5.4 \quad(\infty, 2)\)-Categories}

In \(\S 1.4\), we defined an \(\infty\)-category to be a simplicial set \(\mathcal{C}\) which satisfies the weak Kan extension condition: for \(0<i<n\), every morphism of simplicial sets \(\Lambda_{i}^{n} \hookrightarrow \mathcal{C}\) can be extended to an \(n\)-simplex of \(\mathcal{C}\) (Definition 1.4.0.1). Beware that this terminology is potentially confusing, because the theory of \(\infty\)-categories does not generalize the classical theory of 2-categories. For every 2-category \(\mathcal{E}\), the Duskin nerve \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{E})\) is a simplicial set which determines \(\mathcal{E}\) up to isomorphism (Theorem 2.3.4.1). However, the simplicial set \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{E})\) is an \(\infty\)-category if and only if \(\mathcal{E}\) is a (2,1)-category: that is, every 2 -morphism in \(\mathcal{E}\) is invertible (Theorem 2.3.2.1). Consequently, one can view the notions of 2-category and \(\infty\)-category as mutually incomparable extensions of the notion of \((2,1)\)-category. Our goal in this section is to show that these extensions admit a common generalization: a class of simplicial sets which we will refer to as \((\infty, 2)\)-categories.

Our starting point is the notion of a thin 2-simplex, which was introduced in \$2.3.2. Recall that if \(\mathcal{C}\) is a simplicial set, then a 2-simplex \(\sigma\) of \(\mathcal{C}\) is thin if every morphism of simplicial sets \(\tau_{0}: \Lambda_{i}^{n} \rightarrow \mathcal{C}\) can be extended to an \(n\)-simplex of \(\mathcal{C}\), provided that \(0<i<n\), \(n \geq 3\), and the 2 -simplex \(\left.\tau_{0}\right|_{N_{\bullet}(\{i-1<i<i+1\})}\) is equal to \(\sigma\) (Definition 2.3.2.3). By virtue of Example 2.3.2.4, \(\mathcal{C}\) is an \(\infty\)-category if and only if it satisfies the following pair of conditions:
(1) Every morphism of simplicial sets \(\Lambda_{1}^{2} \rightarrow \mathcal{C}\) can be extended to a 2 -simplex of \(\mathcal{C}\).
(2) Every 2 -simplex of \(\mathcal{C}\) is thin.

We will obtain the notion of \((\infty, 2)\)-category by weakening (2) to the requirement that degenerate 2 -simplices of \(\mathcal{C}\) are thin, but strengthening (1) to require that every map \(\Lambda_{1}^{2} \rightarrow \mathcal{C}\)
can be extended to a thin 2-simplex of \(\mathcal{C}\). We will also add additional axioms that guarantee the ability to fill outer horns of \(\mathcal{C}\) in certain special circumstances (see Definition 5.4.1.1).

Every \(\infty\)-category is an ( \(\infty, 2\) )-category (Proposition 5.4.1.2, and every 2-category can be regarded as an \((\infty, 2)\)-category by passing to its Duskin nerve (Proposition 5.4.1.5). The situation is summarized in the following diagram

where none of the inclusions is reversible.
Let \(\mathcal{C}\) be a simplicial set containing a pair of objects \(X\) and \(Y\), and let \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) and \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) denote the pinched morphism spaces of Construction 4.6.5.1. If \(\mathcal{C}\) is an \(\infty\)-category, then the simplicial sets \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) and \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) are Kan complexes (Proposition 4.6.5.5). In \(\$ 5.4 .3\), we prove an analogous result: if \(\mathcal{C}\) is an \((\infty, 2)\)-category, then the simplicial sets \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) and \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) are \(\infty\)-categories (Corollary 5.4.3.5). Recall that \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) is defined as the fiber over \(Y\) of the projection map \(q: \mathcal{C}_{X /} \rightarrow \mathcal{C}\), and \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) is defined as the fiber over \(X\) of the projection map \(q^{\prime}: \mathcal{C}_{/ Y} \rightarrow \mathcal{C}\). When \(\mathcal{C}\) is an \(\infty\)-category, the morphism \(q\) is a left fibration of simplicial sets and the morphism \(q^{\prime}\) is a right fibration of simplicial sets (Corollary 4.3.6.11). Beware that, in the case where \(\mathcal{C}\) is an \((\infty, 2)\)-category, the morphisms \(q\) and \(q^{\prime}\) are generally not inner fibrations. Nevertheless, we will deduce that the fibers of \(q\) and \(q^{\prime}\) are \(\infty\)-categories by showing that \(q\) and \(q^{\prime}\) are interior fibrations (Definition 5.4.2.1), a class of morphisms which we introduce and study in 5.4.2 From this we deduce also that the simplicial sets \(\mathcal{C}_{X /}\) and \(\mathcal{C}_{/ Y}\) are \((\infty, 2)\)-categories; moreover, an analogous result holds more generally for the slice and coslice constructions associated to any diagram \(f: K \rightarrow \mathcal{C}\) (Corollary 5.4.3.4).

Suppose that we are given a 2 -simplex \(\sigma\) of a \(\operatorname{simplicial}\) set \(\mathcal{C}\), whose 1 -skeleton we indicate in the diagram

Writing \(q: \mathcal{C}_{X /} \rightarrow \mathcal{C}\) for the projection map, we can identify \(\sigma\) with an edge \(\widetilde{g}\) of the simplicial set \(\mathcal{C}_{X /}\) satisfying \(q(\widetilde{g})=g\). It follows immediately from the definition that if the 2 -simplex \(\sigma\) is thin, then the edge \(\widetilde{g}\) is \(q\)-cocartesian (in the sense of Definition 5.1.1.1); in particular, it is locally \(q\)-cocartesian. In \(\$ 5.4 .4\) we prove that if \(\mathcal{C}\) is an \((\infty, 2)\)-category, then the converse holds: every locally \(q\)-cocartesian edge of \(\mathcal{C}_{X /}\) is thin when viewed as a 2 -simplex of \(\mathcal{C}\) (Theorem 5.4.4.1). Roughly speaking, one can think of \(\widetilde{g}\) as encoding the datum of a morphism \(\gamma\) from \(g \circ f\) to \(h\) in the \(\infty\)-category \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Z)\); Theorem 5.4.4.1 confirms the heuristic that \(\gamma\) is an isomorphism if and only if \(\sigma\) is thin (in the case where \(\mathcal{C}\) is the Duskin nerve of a 2-category, this is also the content of Theorem 2.3.2.5).

Let \(\mathcal{C}\) be an \((\infty, 2)\)-category. We define the pith of \(\mathcal{C}\) to be the simplicial subset \(\operatorname{Pith}(\mathcal{C}) \subseteq \mathcal{C}\) consisting of those simplices \(\Delta^{m} \rightarrow \mathcal{C}\) which carry each 2-simplex of \(\Delta^{m}\) to a thin 2 -simplex of \(\mathcal{C}\) (Construction 5.4.5.1). In \(\S 5.4 .5\), we show that \(\operatorname{Pith}(\mathcal{C})\) is an \(\infty\)-category (Proposition 5.4.5.6 whose pinched morphism spaces \(\left.\operatorname{Hom}_{\text {Pith }}^{\mathrm{L}} \mathrm{C}\right)(X, Y)\) and \(\operatorname{Hom}_{\operatorname{Pith}(\mathcal{C})}^{\mathrm{R}}(X, Y)\) can be identified with the cores of the \(\infty\)-categories \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) and \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\), respectively (Proposition 5.4.5.13). Roughly speaking, one can think of the \(\infty\)-category \(\operatorname{Pith}(\mathcal{C})\) as obtained from the \((\infty, 2)\)-category by "discarding" its noninvertible 2 -morphisms. In particular, when \(\mathcal{C}\) is the Duskin nerve of a 2 -category \(\mathcal{E}\), we can identify \(\operatorname{Pith}(\mathcal{C})\) with the Duskin nerve of the \((2,1)\)-category \(\operatorname{Pith}(\mathcal{E})\) introduced in Construction 2.2.8.9 (Example 5.4.5.4).

Let \(\mathcal{C}\) and \(\mathcal{D}\) be \((\infty, 2)\)-categories. We define a functor from \(\mathcal{C}\) to \(\mathcal{D}\) to be a morphism of simplicial sets \(F: \mathcal{C} \rightarrow \mathcal{D}\) which carries thin 2-simplices of \(\mathcal{C}\) to thin 2-simplices of \(\mathcal{D}\) (Definition 5.4.7.1). This definition can be somewhat cumbersome to work with in practice, because it requires us to check a condition for every thin 2 -simplex of \(\mathcal{C}\). In \(\$ 5.4 .7\), we show that this is unnecessary: to verify that a morphism of simplicial sets \(F: \mathcal{C} \rightarrow \mathcal{D}\) is a functor, it suffices to show that every morphism \(\sigma_{0}: \Lambda_{1}^{2} \rightarrow \mathcal{C}\) can be extended to a thin 2 -simplex \(\sigma\) of \(\mathcal{C}\) for which \(F(\sigma)\) is a thin 2 -simplex of \(\mathcal{D}\) (Proposition 5.4.7.9. Here we can think of \(\sigma_{0}\) as given by a pair of morphisms \(X \xrightarrow{f} Y \xrightarrow{g} Z\), and the thinness assumption on \(F(\sigma)\) corresponds heuristically to the requirement that \(F\) "preserves" the composition of \(f\) and \(g\) (up to isomorphism). Our proof will make use of a certain closure property enjoyed by the thin 2-simplices of an ( \(\infty, 2\)-category which we refer to as the four-out-of-five property, which we formulate and study in \(\$ 5.4 .6\) (see Definition 5.4.6.8 and Proposition 5.4.6.11).

Recall that a 2 -category \(\mathcal{E}\) is strict if its unit and associativity constraints are identity morphisms (Example 2.2.1.4); in this case, we can view \(\mathcal{E}\) as an ordinary category which is enriched over Cat (see Definition 2.2.0.1). This notion has a counterpart in the setting of \((\infty, 2)\)-categories. Let \(\operatorname{Set}_{\Delta}\) denote the ordinary category of simplicial sets, and let QCat denote the full subcategory of Set \({ }_{\Delta}\) whose objects are \(\infty\)-categories. Let \(\mathcal{E}\) be a QCat-enriched category: that is, a simplicial category with the property that, for every pair of objects \(X, Y \in \mathcal{C}\), the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) • is an \(\infty\)-category. In \(\$ 5.4 .8\), we
show that the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{E})\) is an \((\infty, 2)\)-category (Theorem 5.4.8.1). The construction \(\mathcal{E} \mapsto \mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{E})\) can be regarded as a generalization of the inclusion from strict 2-categories into general 2-categories (recall that if \(\mathcal{E}\) is a strict 2-category, then its Duskin nerve can be identified with the homotopy coherent nerve of the associated simplicial category; see Example 2.4.3.11). Beware that not every \((\infty, 2)\)-category \(\mathcal{C}\) is isomorphic to the homotopy coherent nerve of a QCat-enriched category. Nevertheless, we will later prove a coherence theorem which guarantees that \(\mathcal{C}\) is equivalent to the homotopy coherent nerve of a QCat-enriched category: see Theorem [?].

01W5 Remark 5.4.0.1. The ideas presented in this section are closely related to the work of Verity, who has proposed a simplicial framework for studying higher categories with noninvertible morphisms at all levels. We refer the reader to [57], [58], and [56] for Verity's work, and to [24] for a discussion of its relationship to the theory of \((\infty, 2)\)-categories presented here.

\subsection*{5.4.1 Definitions}

01W6 We begin by introducing some terminology.
01 W9 Definition 5.4.1.1. Let \(\mathcal{C}\) be a simplicial set. We will say that \(\mathcal{C}\) is an \((\infty, 2)\)-category if it satisfies the following axioms:
(1) Every morphism of simplicial sets \(\Lambda_{1}^{2} \rightarrow \mathcal{C}\) can be extended to a thin 2-simplex of \(\mathcal{C}\).
(2) Every degenerate 2-simplex of \(\mathcal{C}\) is thin.
(3) Let \(n \geq 3\) and let \(\sigma_{0}: \Lambda_{0}^{n} \rightarrow \mathcal{C}\) be a morphism of simplicial sets with the property that the 2-simplex \(\left.\sigma_{0}\right|_{\mathrm{N}_{\bullet}(\{0<1<n\})}\) is left-degenerate (see Example 1.1.2.8) Then \(\sigma_{0}\) can be extended to an \(n\)-simplex of \(\mathcal{C}\).
(4) Let \(n \geq 3\) and let \(\sigma_{0}: \Lambda_{n}^{n} \rightarrow \mathcal{C}\) be a morphism of simplicial sets with the property that the 2 -simplex \(\left.\sigma_{0}\right|_{\mathrm{N}^{\prime}}(\{0<n-1<n\})\) is right-degenerate. Then \(\sigma_{0}\) can be extended to an \(n\)-simplex of \(\mathcal{C}\).

01WA Proposition 5.4.1.2. Let \(\mathcal{C}\) be an \(\infty\)-category. Then \(\mathcal{C}\) is an ( \(\infty, 2\) )-category.
Proof. Our assumption that \(\mathcal{C}\) is an \(\infty\)-category guarantees that every 2 -simplex of \(\mathcal{C}\) is thin (Example 2.3.2.4). Consequently, condition (2) of Definition 5.4.1.1 is automatic, and condition (1) follows immediately from the definition. Conditions (3) and (4) follow from Theorem 4.4.2.6 (since every degenerate edge of \(\mathcal{C}\) is an isomorphism).

01 WB Remark 5.4.1.3. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category. We will refer to vertices of \(\mathcal{C}\) as objects, and to the edges of \(\mathcal{C}\) as morphisms. If \(f\) is an edge of \(\mathcal{C}\) satisfying \(d_{1}^{1}(f)=X\) and \(d_{0}^{1}(f)=Y\), then we say that \(f\) is a morphism from \(X\) to \(Y\) and write \(f: X \rightarrow Y\).

Suppose we are given morphisms \(f: X \rightarrow Y, g: Y \rightarrow Z\), and \(h: X \rightarrow Z\) of \(\mathcal{C}\). We will say that a 2-simplex \(\sigma\) witnesses \(h\) as a composition of \(f\) and \(g\) if it is thin and satisfies \(d_{0}^{2}(\sigma)=g, d_{1}^{2}(\sigma)=h\), and \(d_{2}^{2}(\sigma)=f\), as indicated in the diagram

Note that:
- When \(\mathcal{C}\) is an \(\infty\)-category, this recovers the terminology of Definition 1.4.4.1 (since the 2 -simplex \(\sigma\) is automatically thin).
- If \(\mathcal{C}\) is the Duskin nerve of a 2 -category \(\mathcal{E}\), the 2 -simplex \(\sigma\) can be identified with a 2-morphism \(\gamma: g \circ f \Rightarrow h\) of \(\mathcal{E}\), which is invertible if and only if \(\sigma\) is thin. In other words, \(\sigma\) witnesses \(h\) as a composition of \(f\) and \(g\) if and only if it encodes the datum of an isomorphism \(g \circ f \stackrel{\sim}{\Longrightarrow} h\) in the category \(\underline{\operatorname{Hom}}_{\mathcal{E}}(X, Z)\).
- Axiom (1) of Definition 5.4.1.1 asserts that the composition of 1-morphisms in \(\mathcal{C}\) is defined (albeit not uniquely). More precisely, it asserts that for every pair of morphisms \(f: X \rightarrow Y\) and \(g: Y \rightarrow Z\), there exists a morphism \(h: X \rightarrow Z\) and a 2 -simplex which witnesses \(h\) as a composition of \(f\) and \(g\).
Remark 5.4.1.4. Let \(\mathcal{C}\) be a simplicial set. Then \(\mathcal{C}\) is an ( \(\infty, 2\)-category if and only if the 01 WC opposite simplicial set \(\mathcal{C}^{\mathrm{op}}\) is an \((\infty, 2)\)-category.
Proposition 5.4.1.5. Let \(\mathcal{C}\) be a 2-category. Then the Duskin nerve \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{C})\) is an \((\infty, 2)-01 \mathrm{WD}\) category.

Proof. Condition (1) of Definition 5.4.1.1 follows immediately from Theorem 2.3.2.5, and condition (2) from Corollary 2.3.2.7. We will verify (4); the proof of (3) is similar. Suppose we are given an integer \(n \geq 3\) and a map \(\sigma_{0}: \Lambda_{n}^{n} \rightarrow \mathrm{~N}_{\bullet}^{\mathrm{D}}(\mathcal{C})\). for which the restriction \(\left.\sigma_{0}\right|_{\mathrm{N}_{\bullet}(\{0<n-1<n\})}\) is right-degenerate. We wish to show that \(\sigma_{0}\) can be extended to an \(n\)-simplex of \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{C})\). We now consider three cases:
- Suppose that \(n=3\). Then \(\sigma_{0}\) can be identified with a collection of objects \(\left\{X_{i}\right\}_{0 \leq i \leq 3}\), 1-morphisms \(\left\{f_{j i}: X_{i} \rightarrow X_{j}\right\}_{0 \leq i<j \leq 3}\), and 2-morphisms
\[
\mu_{321}: f_{32} \circ f_{21} \Rightarrow f_{31} \quad \mu_{320}: f_{32} \circ f_{20} \Rightarrow f_{30} \quad \mu_{310}: f_{31} \circ f_{10} \Rightarrow f_{30}
\]
in the 2 -category \(\mathcal{C}\). The assumption that \(\left.\sigma_{0}\right|_{\mathrm{N}_{\bullet}(\{0<n-1<n\})}\) is right-degenerate guarantees that \(X_{2}=X_{3}\), that \(f_{20}=f_{30}\), that the 1-morphism \(f_{32}\) is the identity id \(X_{X_{2}}\), and
that \(\mu_{320}\) is the left unit constraint \(\lambda_{f_{20}}\). To extend \(\sigma_{0}\) to a 3 -simplex of \(\mathrm{N}_{\bullet}^{\mathrm{D}}\), we must show that there exists a 2 -morphism \(\mu_{210}: f_{21} \circ f_{10} \Rightarrow f_{20}\) for which the diagram

is commutative, where \(\alpha=\alpha_{f_{32}, f_{21}, f_{10}}\) is the associativity constraint for the composition of 1 -morphisms in \(\mathcal{C}\) (Proposition 2.3.1.9). This commutativity can be rewritten as an equation
\[
\mu_{320}\left(\operatorname{id}_{f_{32}} \circ \mu_{210}\right)=\mu_{310}\left(\mu_{321} \circ \operatorname{id}_{f_{10}}\right) \alpha
\]

This equation has a unique solution, because \(\mu_{320}\) is invertible and horizontal composition with \(\operatorname{id}_{f_{32}}\) induces an equivalence of categories \(\underline{\operatorname{Hom}}_{\mathcal{C}}\left(X_{0}, X_{2}\right) \rightarrow \underline{\operatorname{Hom}}_{\mathcal{C}}\left(X_{0}, X_{3}\right)\).
- Suppose that \(n=4\). The restriction of \(\sigma_{0}\) to the 2 -skeleton of \(\Delta^{4}\) can be identified with a collection of objects \(\left\{X_{i}\right\}_{0 \leq i \leq 4}\), 1-morphisms \(\left\{f_{j i}: X_{i} \rightarrow X_{j}\right\}_{0 \leq i<j \leq 4}\), and 2-morphisms \(\left\{\mu_{k j i}: f_{k j} \circ f_{j i} \Rightarrow f_{k i}\right\}_{0 \leq i<j<k \leq 4}\) in the 2-category \(\mathcal{C}\). The assumption that \(\left.\sigma_{0}\right|_{\mathrm{N}}(\{0<n-1<n\})\) is right-degenerate guarantees that \(X_{3}=X_{4}\), that \(f_{30}=f_{40}\), that the 1-morphism \(f_{43}\) is the identity \(\mathrm{id}_{X_{3}}\), and that \(\mu_{430}\) is the left unit constraint
\(\lambda_{f_{30}}\). Consider the diagram

in the category \(\underline{\operatorname{Hom}}_{\mathcal{C}}\left(X_{0}, X_{4}\right)\), where the unlabeled 2-morphisms are given by the associativity constraints. Note that the 4 -cycles in this diagram commute by functoriality, and the central 5 -cycle commutes by the pentagon identity of \(\mathcal{C}\). Our assumption that \(\sigma_{0}\) is defined on the horn \(\Lambda_{4}^{4}\) guarantees that pentagonal cycles on the right and bottom of the diagram are commutative and that the outer cycle commutes. Since the 2-morphism \(\mu_{430}\) is invertible, a diagram chase shows that the pentagonal cycle on the left of the diagram also commutes. Since \(f_{43}\) is an identity 1-morphism, horizontal composition with \(f_{43}\) is isomorphic to the identity (via the left unit constraint of Construction 2.2.1.11) and is therefore faithful. It follows that the diagram (5.22) is commutative, so that \(\sigma_{0}\) extends (uniquely) to a 4 -simplex of \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{C})\).
- If \(n \geq 5\), then the horn \(\Lambda_{n}^{n}\) contains the 3 -skeleton of \(\Delta^{n}\). In this case, the morphism \(\sigma_{0}: \Lambda_{n}^{n} \rightarrow \mathrm{~N}_{\bullet}^{\mathrm{D}}(\mathcal{C})\) extends uniquely to an \(n\)-simplex of \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{C})\) by virtue of Corollary 2.3.1.10

\subsection*{5.4.2 Interior Fibrations}

Recall that a morphism of simplicial sets \(q: \mathcal{C} \rightarrow \mathcal{D}\) is an inner fibration if it is weakly right orthogonal to the horn inclusion \(\Lambda_{i}^{n} \hookrightarrow \Delta^{n}\) for every pair of integers \(0<i<n\). In the setting of \((\infty, 2)\)-categories, it will be convenient to consider a variant of this condition.

01WG Definition 5.4.2.1. Let \(\mathcal{D}\) be an \((\infty, 2)\)-category and let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets. We will say that \(q\) is an interior fibration if it satisfies the following conditions:
- Every lifting problem

admits a solution, provided that \(0<i<n\) and the restriction \(\left.\bar{\sigma}\right|_{\mathrm{N}_{\bullet}(\{i-1<i<i+1\})}\) is a thin 2-simplex of \(\mathcal{D}\).
- For every vertex \(X \in \mathcal{C}\), the degenerate edge \(\operatorname{id}_{X}\) is \(q\)-cartesian and \(q\)-cocartesian.

01 WH Example 5.4.2.2. Let \(\mathcal{D}\) be an \(\infty\)-category and let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets. The following conditions are equivalent:
(1) The morphism \(q\) is an interior fibration (in the sense of Definition 5.4.2.1.
(2) The morphism \(q\) is an inner fibration (in the sense of Definition 4.1.1.1).

The implication \((1) \Rightarrow(2)\) follows from the observation that every 2 -simplex of \(\mathcal{D}\) is thin, and the implication \((2) \Rightarrow(1)\) follows from Corollary 5.1.1.9. In particular, if either of these conditions is satisfied, then \(\mathcal{C}\) is an \(\infty\)-category.

01 WJ Remark 5.4.2.3. Let \(\mathcal{D}\) be an \((\infty, 2)\)-category and let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets. Then \(q\) is an interior fibration if and only if the opposite morphism \(q^{\text {op }}: \mathcal{C}^{\text {op }} \rightarrow \mathcal{D}^{\mathrm{op}}\) is an interior fibration.

01WK Remark 5.4.2.4. Suppose we are given a pullback diagram of simplicial sets

Assume that \(\mathcal{D}\) and \(\mathcal{D}^{\prime}\) are \((\infty, 2)\)-categories and that the morphism \(F\) carries thin 2-simplices of \(\mathcal{D}^{\prime}\) to thin 2 -simplices of \(\mathcal{D}\) (that is, that \(F\) is a functor of \((\infty, 2)\)-categories; see Definition 5.4.7.1). If \(q\) is an interior fibration, then \(q^{\prime}\) is an interior fibration.

Remark 5.4.2.5. Let \(\mathcal{D}\) be an ( \(\infty, 2\) )-category and let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be an interior fibration. 01WL Then, for every object \(X \in \mathcal{D}\), the fiber \(\mathcal{C}_{X}=\{X\} \times_{\mathcal{D}} \mathcal{C}\) is an \(\infty\)-category (this follows by combining Example 5.4.2.2 with Remark 5.4.2.4.

Our goal in this section is to show that, if \(\mathcal{D}\) is an \((\infty, 2)\)-category and \(q: \mathcal{C} \rightarrow \mathcal{D}\) is an interior fibration of simplicial sets, then \(\mathcal{C}\) is also an ( \(\infty, 2\) )-category (Proposition 5.4.2.8). To prove this, we must exhibit a sufficiently large collection of thin 2 -simplices of \(\mathcal{C}\).
Lemma 5.4.2.6. Let \(\mathcal{D}\) be an \((\infty, 2)\)-category, let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be an interior fibration of 01 WM simplicial sets, and let \(\sigma\) be a 2-simplex of \(\mathcal{C}\). If \(q(\sigma)\) is a thin 2 -simplex of \(\mathcal{D}\), then \(\sigma\) is a thin 2 -simplex of \(\mathcal{C}\).

Proof. Suppose we are given a morphism of simplicial sets \(\tau_{0}: \Lambda_{i}^{n} \rightarrow \mathcal{C}\), where \(n \geq 3\), \(0<i<n\), and \(\tau_{0}\) carries \(\mathrm{N}_{\bullet}(\{i-1<i<i+1\})\) to the 2 -simplex \(\sigma\). We wish to show that \(\tau_{0}\) can be extended to an \(n\)-simplex \(\tau\) of \(\mathcal{C}\). Let \(\bar{\tau}_{0}: \Lambda_{i}^{n} \rightarrow \mathcal{D}\) be the composition \(q \circ \tau_{0}\). Since \(q(\sigma)\) is a thin 2 -simplex of \(\mathcal{D}\), we can extend \(\bar{\tau}_{0}\) to an \(n\)-simplex \(\bar{\tau}: \Delta^{n} \rightarrow \mathcal{D}\). To complete the proof, it suffices to find a solution to the lifting problem

which exists by virtue of our assumption that \(q\) is an interior fibration.
Remark 5.4.2.7. In the situation of Lemma 5.4.2.6, we will see later that the converse 01WN assertion is also true: if \(\sigma\) is a thin 2 -simplex of \(\mathcal{C}\), then \(q(\sigma)\) is a thin 2-simplex of \(\mathcal{D}\) (Proposition 5.4.7.10).
Proposition 5.4.2.8. Let \(\mathcal{D}\) be an \((\infty, 2)\)-category and let \(q: \mathcal{C} \rightarrow \mathcal{D}\) be an interior fibration 01WP of simplicial sets. Then \(\mathcal{C}\) is also an \((\infty, 2)\)-category.
Proof. We must verify that the simplicial set \(\mathcal{C}\) satisfies each of the axioms of Definition 5.4.1.1
(1) Let \(f: X \rightarrow Y\) and \(g: Y \rightarrow Z\) be edges of the simplicial set \(\mathcal{C}\); we wish to show that there exists a thin 2-simplex \(\Delta^{2} \rightarrow \mathcal{C}\) satisfying \(d_{2}^{2}(\sigma)=f\) and \(d_{0}^{2}(\sigma)=g\), as indicated in the diagram

We first invoke our assumption that \(\mathcal{D}\) is an \((\infty, 2)\)-category to choose a thin 2-simplex \(\bar{\sigma}\) of \(\mathcal{D}\) satisfying \(d_{2}^{2}(\bar{\sigma})=q(f)\) and \(d_{0}^{2}(\bar{\sigma})=q(g)\). Since \(\bar{\sigma}\) is thin, our assumption that \(q\) is an interior fibration guarantees that the lifting problem

admits a solution. It follows from Lemma 5.4 .2 .6 that \(\sigma\) is a thin 2 -simplex of \(\mathcal{C}\).
(2) Let \(\sigma\) be a degenerate 2 -simplex of \(\mathcal{C}\). Then \(q(\sigma)\) is a degenerate 2 -simplex of \(\mathcal{D}\). Since \(\mathcal{D}\) is an \((\infty, 2)\)-category \(q(\sigma)\) is a thin 2 -simplex of \(\mathcal{D}\). Applying Lemma 5.4.2.6, we conclude that \(\sigma\) is a thin 2-simplex of \(\mathcal{C}\).
(3) Let \(n \geq 3\) and let \(\tau_{0}: \Lambda_{0}^{n} \rightarrow \mathcal{C}\) be a morphism of simplicial sets with the property that the 2-simplex \(\left.\tau_{0}\right|_{\mathrm{N}}\) ( \(\left.\{0<1<n\}\right)\) is left-degenerate; we wish to show that \(\tau_{0}\) can be extended to an \(n\)-simplex \(\tau\) of \(\mathcal{C}\). Let \(\bar{\tau}_{0}: \Lambda_{0}^{n} \rightarrow \mathcal{D}\) denote the composition \(q \circ \tau_{0}\). Since \(\mathcal{D}\) is an \((\infty, 2)\)-category, we can extend \(\bar{\tau}_{0}\) to an \(n\)-simplex \(\bar{\tau}: \Delta^{n} \rightarrow \mathcal{D}\). To complete the proof, it will suffice to show that the lifting problem

admits a solution. We conclude by observing that the edge \(\left.\tau_{0}\right|_{\mathrm{N}_{\bullet}(\{0<1\})}\) is degenerate and is therefore \(q\)-cocartesian by virtue of our assumption that \(q\) is an interior fibration.
(4) Let \(n \geq 3\) and let \(\tau_{0}: \Lambda_{n}^{n} \rightarrow \mathcal{C}\) be a morphism of simplicial sets with the property that the 2 -simplex \(\left.\tau_{0}\right|_{N_{\bullet}(\{0<n-1<n\})}\) is right-degenerate; we wish to show that \(\tau_{0}\) can be extended to an \(n\)-simplex \(\tau\) of \(\mathcal{C}\). This follows by the argument given above, applied to the opposite interior fibration \(q^{\mathrm{op}}: \mathcal{C}^{\mathrm{op}} \rightarrow \mathcal{D}^{\mathrm{op}}\).

01WQ Proposition 5.4.2.9. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be interior fibrations of \((\infty, 2)\) categories. Then the composition \((G \circ F): \mathcal{C} \rightarrow \mathcal{E}\) is also an interior fibration.

Proof. Suppose we are given an integer \(n \geq 2\) and a lifting problem

We wish to show that this lifting problem admits a solution if one of the following conditions is satisfied:
(a) The integer \(i\) is equal to 0 and \(\left.\sigma_{0}\right|_{\mathrm{N}_{\bullet}(\{0<1\})}\) is a degenerate edge of \(\mathcal{C}\).
(b) The integer \(i\) satisfies \(0<i<n\) and the restriction \(\left.\bar{\sigma}\right|_{\mathrm{N} \cdot(\{i-1<i<i+1\})}\) is a thin 2-simplex of \(\mathcal{E}\).
(c) The integer \(i\) is equal to \(n\) and \(\left.\sigma_{0}\right|_{\mathrm{N}_{\bullet}(\{n-1<n\})}\) is a degenerate edge of \(\mathcal{C}\).

Since \(G\) is an interior fibration, any of these hypotheses guarantee the existence of a solution to the associated lifting problem

It will therefore suffice to construct a solution to the lifting problem

In cases \((a)\) and \((c)\), our assumption that \(F\) is an interior fibration immediately guarantees the existence of \(\sigma\). In case (b), it suffices to verify that the restriction \(\left.\tau\right|_{\mathrm{N}_{\bullet}(\{i-1<i<i+1\})}\) is a thin 2 -simplex of \(\mathcal{D}\), which follows from Lemma 5.4.2.6.

Proposition 5.4.2.10. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an interior fibration between \((\infty, 2)\)-categories, 01WR and let \(X\) and \(Y\) be objects of \(\mathcal{C}\). Then:
(1) The induced map of left-pinched morphism spaces \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}^{\mathrm{L}}(F(X), F(Y))\) is a right fibration of simplicial sets.
(2) The induced map of right-pinched morphism spaces \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}^{\mathrm{R}}(F(X), F(Y))\) is a left fibration of simplicial sets.

Proof. We will prove (2); assertion (1) follows from a similar argument. We wish to show that, for every pair of integers \(0 \leq i<n\), every lifting problem

admits a solution. Unwinding the definitions, we can rewrite 5.23) as a lifting problem

where the restriction \(\left.\tau_{0}\right|_{\mathrm{N}_{\bullet}(\{0<1<\cdots<n\})}\) is the constant map taking the value \(X\). If \(i=0\), then this lifting problem admits a solution because the edge \(\left.\tau_{0}\right|_{\mathrm{N}_{\mathbf{0}}(\{0<1\})}\) is degenerate (and therefore \(F\)-cocartesian, by virtue of our assumption that \(F\) is an interior fibration). If \(0<i<n\), the solution exists by virtue of the fact that \(F\) is an interior fibration and \(\left.\bar{\tau}\right|_{\mathrm{N}_{\bullet}(\{i-1<i<i+1\})}\) is a degenerate 2 -simplex of \(\mathcal{D}\) (and therefore thin).

\subsection*{5.4.3 Slices of ( \(\infty, 2\) )-Categories}

01WT The slice and coslice constructions of \(\$ 4.3\) provide many examples of interior fibrations of ( \(\infty, 2\) )-categories.

01WU Proposition 5.4.3.1. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category and let \(f: K \rightarrow \mathcal{C}\) be a morphism of simplicial sets. Then the projection maps
\[
\mathcal{C}_{f /} \rightarrow \mathcal{C} \quad \mathcal{C}_{/ f} \rightarrow \mathcal{C}
\]
are interior fibrations.

Warning 5.4.3.2. In the situation of Proposition 5.4.3.1. the projection maps
\[
\mathcal{C}_{f /} \rightarrow \mathcal{C} \quad \mathcal{C}_{/ f} \rightarrow \mathcal{C}
\]
are generally not inner fibrations of simplicial sets.
Remark 5.4.3.3. Let \(\mathcal{C}\) be a simplicial set. Then axioms (3) and (4) of Definition 5.4.1.1 01WW can be stated as follows:
(3') Let \(X\) be any vertex of \(\mathcal{C}\) and let \(q: \mathcal{C}_{/ X} \rightarrow \mathcal{C}\) be the projection map. Then every degenerate edge of \(\mathcal{C}_{/ X}\) is \(q\)-cocartesian.
(4') Let \(X\) be any vertex of \(\mathcal{C}\) and let \(q^{\prime}: \mathcal{C}_{X /} \rightarrow \mathcal{C}\) be the projection map. Then every degenerate edge of \(\mathcal{C}_{X /}\) is \(q^{\prime}\)-cartesian.

Note that \(\left(3^{\prime}\right)\) and \(\left(4^{\prime}\right)\) appear as special cases of the conclusion of Proposition 5.4.3.1.
Corollary 5.4.3.4. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category and let \(f: K \rightarrow \mathcal{C}\) be a morphism of 01 WX simplicial sets. Then the simplicial sets \(\mathcal{C}_{f /}\) and \(\mathcal{C}_{/ f}\) are \((\infty, 2)\)-categories.

Proof. Combine Proposition 5.4.3.1 with Proposition 5.4.2.8.
Corollary 5.4.3.5. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category. For every pair of objects \(X\) and \(Y\), 01WY the pinched morphism spaces \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) and \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) of Construction 4.6.5.1 are \(\infty\)-categories.

Proof. By definition, the left-pinched morphism space \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) is the fiber over \(Y\) of the projection map \(\pi: \mathcal{C}_{X /} \rightarrow \mathcal{C}\). Since \(\pi\) is an interior fibration (Proposition 5.4.3.1), each of its fibers is an \(\infty\)-category (Remark 5.4.2.5). A similar argument shows that \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) is an \(\infty\)-category.

Warning 5.4.3.6. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category containing objects \(X\) and \(Y\). Then the 01WZ simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) of Construction 4.6.1.1 is generally not an \(\infty\)-category (see Warning 8.1.8.1.

Remark 5.4.3.7. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category containing \(X\) and \(Y\). We will see later 01X0 that the \(\infty\)-category \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) is naturally equivalent to the opposite of the \(\infty\)-category \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) (Proposition [?]). When \(\mathcal{C}\) is the Duskin nerve of a 2-category, we can do better: the \(\infty\)-category \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)\) is isomorphic to the opposite of \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\); see Example 4.6.5.13

We will deduce Proposition 5.4.3.1 from the following more precise result:

01 X 1 Proposition 5.4.3.8. Let \(f: K \rightarrow \mathcal{C}\) be a morphism of simplicial sets and let \(f_{0}: K_{0} \rightarrow \mathcal{C}\) be the restriction of \(f\) to a simplicial subset \(K_{0} \subseteq K\). Then every lifting problem

admits a solution provided that \(m \geq 2\) and one of the following additional conditions is satisfied:
(a) The simplicial set \(\mathcal{C}\) is an \((\infty, 2)\)-category, \(i=0\), and the composition
\[
\Delta^{1} \simeq \mathrm{~N}_{\bullet}(\{0<1\}) \subseteq \Lambda_{i}^{m} \xrightarrow{\sigma_{0}} \mathcal{C}_{/ f}
\]
is a degenerate edge of \(\mathcal{C}_{/ f}\).
(b) The integer \(i\) satisfies \(0<i<m\) and the composite map
\[
\Delta^{2} \simeq \mathrm{~N}_{\bullet}(\{i-1<i<i+1\}) \subseteq \Delta^{m} \xrightarrow{\frac{\bar{\sigma}}{\rightarrow}} \mathcal{C}_{/ f_{0}} \rightarrow \mathcal{C}
\]
is a thin 2-simplex of \(\mathcal{C}\).
(c) The integer \(i\) is equal to \(m\) and, for every vertex \(x \in K\), the composite map
\[
\Delta^{2} \simeq \mathrm{~N}_{\bullet}(\{m-1<m\}) \star\{x\} \hookrightarrow \Lambda_{i}^{m} \star K \xrightarrow{\sigma} \mathcal{C}
\]
is a thin 2-simplex of \(\mathcal{C}\).
Proof. Unwinding the definitions, we can identify the diagram (5.24) with a morphism of simplicial sets
\[
\bar{f}:\left(\Lambda_{i}^{m} \star K\right) \coprod_{\left(\Lambda_{i}^{m} \star K_{0}\right)}\left(\Delta^{m} \star K_{0}\right) \rightarrow \mathcal{C},
\]
and we wish to show that \(\bar{f}\) can be extended to a morphism \(\Delta^{m} \star K \rightarrow \mathcal{C}\). Let \(P\) be the collection of all pairs \((L, g)\), where \(L\) is a simplicial subset of \(K\) containing \(K_{0}\) and \(g: \Delta^{m} \star L \rightarrow \mathcal{C}\) is a morphism satisfying
\[
\left.g\right|_{\Delta^{m} \star K_{0}}=\left.\left.\bar{f}\right|_{\Delta^{m} \star K_{0}} \quad g\right|_{\Lambda_{i}^{m} \star L}=\left.\bar{f}\right|_{\Lambda_{i}^{m} \star L} .
\]

We regard \(P\) as a partially ordered set, with \((L, g) \leq\left(L^{\prime}, g^{\prime}\right)\) if \(L\) is contained in \(L^{\prime}\) and \(g=\left.g^{\prime}\right|_{\Delta^{m} \star L}\). The partially ordered set \(P\) satisfies the hypotheses of Zorn's lemma and therefore admits a maximal element \(\left(L_{\max }, g_{\max }\right)\). We will complete the proof by showing
that \(L_{\max }=K\) (so that \(g_{\max }\) is the desired extension of \(\bar{f}\) ). Suppose otherwise. Then there is some nondegenerate simplex \(\rho: \Delta^{n} \rightarrow K\) which is not contained in \(L_{\max }\). Choosing \(\rho\) so that \(n\) is as small as possible, we may assume without loss of generality that \(\rho\) carries the boundary \(\partial \Delta^{n}\) into \(L_{\max }\). Let \(L^{\prime} \subseteq K\) be the simplicial subset given by the union of \(L_{\max }\) together with the image of \(\rho\), so that \(\rho\) determines a pushout diagram

We will show that \(g_{\text {max }}\) can be extended to a morphism of simplicial sets \(g^{\prime}: \Delta^{m} \star L^{\prime} \rightarrow \mathcal{C}\) satisfying \(\left.g^{\prime}\right|_{\Lambda_{i}^{m} \star L^{\prime}}=\left.\bar{f}\right|_{\Lambda_{i}^{m} \star L^{\prime}}\); thereby contradicting the maximality of ( \(L_{\max }, g_{\max }\) ) and completing the proof of Proposition 5.4.3.8. Note that the composite maps
\[
\begin{gathered}
\Lambda_{i}^{m} \star \Delta^{n} \xrightarrow{\mathrm{id} \star \rho} \Lambda_{i}^{m} \star K \xrightarrow{\text { 岢 }} \mathcal{C} \\
\Delta^{m} \star \partial \Delta^{n} \xrightarrow{\mathrm{id} \star \rho} \Delta^{m} \star L_{\max } \xrightarrow{g_{\max }} \mathcal{C}
\end{gathered}
\]
can be amalgamated to a morphism of simplicial sets
\[
\tau_{0}:\left(\Lambda_{i}^{m} \star \Delta^{n}\right) \coprod_{\left(\Lambda_{i}^{m} \star \partial \Delta^{n}\right)}\left(\Delta^{m} \star \partial \Delta^{n}\right) \rightarrow \mathcal{C},
\]
whose source can be identified with the horn \(\Lambda_{i}^{m+1+n} \subseteq \Delta^{m+1+n}\) (Lemma 4.3.6.15). We wish to show that \(\tau_{0}\) can be extended to a map
\[
\tau: \Delta^{m} \star \Delta^{n} \simeq \Delta^{m+1+n} \rightarrow \mathcal{C} .
\]

If \(0<i \leq m\), the desired extension exists because the composite map
\[
\Delta^{2} \simeq \mathrm{~N}_{\bullet}(\{i-1<i<i+1\}) \subseteq \Lambda_{i}^{m+1+n} \xrightarrow{\tau_{0}} \mathcal{C}
\]
is a thin 2-simplex of \(\mathcal{C}\) (by virtue of assumption (b) when \(i<m\) or \((c)\) in the case \(i=m\) ). If \(i=0\), then the desired extension exists because assumption (a) guarantees that \(\mathcal{C}\) is an \((\infty, 2)\)-category and the 2 -simplex
\[
\Delta^{2} \simeq \mathrm{~N}_{\bullet}(\{0<1<m+1+n\}) \subseteq \Lambda_{i}^{m+1+n} \xrightarrow{\tau_{0}} \mathcal{C}
\]
is left-degenerate.

Proof of Proposition 5.4.3.1. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category and let \(f: K \rightarrow \mathcal{C}\) be a morphism of simplicial sets. We will show that the projection \(\operatorname{map} q: \mathcal{C}_{/ f} \rightarrow \mathcal{C}\) is an interior fibration; the analogous assertion for the coslice simplicial set \(\mathcal{C}_{f /}\) follows by a similar argument. Let \(m \geq 2\) and suppose that we are given a lifting problem

We wish to show that a solution exists under any of the following additional assumptions:
(a) The integer \(i\) is equal to zero and the restriction \(\left.\sigma_{0}\right|_{\mathrm{N}_{\bullet}(\{0<1\})}\) is a degenerate edge of \(\mathcal{C}_{/ f}\).
(b) The integer \(i\) satisfies \(0<i<m\) and the composite map
\[
\Delta^{2} \simeq \mathrm{~N}_{\bullet}(\{i-1<i<i+1\}) \subseteq \Delta^{m} \xrightarrow{\bar{\sigma}} \mathcal{C}_{/ f_{0}} \rightarrow \mathcal{C}
\]
is a thin 2 -simplex of \(\mathcal{C}\).
(c) The integer \(i\) is equal to \(m\) and the restriction \(\left.\sigma_{0}\right|_{\mathrm{N}}(\{m-1<m\})\) is a degenerate edge of \(\mathcal{C}_{/ f}\).

In cases \((a)\) and \((b)\), this follows immediately from Proposition 5.4.3.8. In case ( \(c\) ), we observe that for every vertex \(x \in K\), the composite map
\[
\Delta^{2} \simeq \mathrm{~N}_{\bullet}(\{m-1<m\}) \star\{x\} \hookrightarrow \Lambda_{i}^{m} \star K \xrightarrow{\sigma_{0}} \mathcal{C}
\]
is a left-degenerate 2 -simplex of \(\mathcal{C}\). Since \(\mathcal{C}\) is an ( \(\infty, 2\) )-category, this degenerate 2 -simplex is thin, so that existence of the desired extension again follows from Proposition 5.4.3.8.

In the situation of Proposition 5.4.3.1, the interior fibration \(\mathcal{C}_{/ f} \rightarrow \mathcal{C}\) behaves like a cartesian fibration (with the caveat that it need not be an inner fibration).

01 X 3 Proposition 5.4.3.9. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category, let \(f: K \rightarrow \mathcal{C}\) be a morphism of simplicial sets, and let \(q: \mathcal{C}_{/ f} \rightarrow \mathcal{C}\) be the projection map. Let \(Y\) be an object of the \((\infty, 2)\)-category \(\mathcal{C}_{/ f}\), and let \(\bar{u}: \bar{X} \rightarrow q(Y)\) be a morphism in the \((\infty, 2)\)-category \(\mathcal{C}\). Then \(\bar{u}\) can be lifted to a morphism \(u: X \rightarrow Y\) of \(\mathcal{C}_{/ f}\) with the following property:
(*) For every vertex \(z \in K\), the image of \(u\) in \(\mathcal{C}_{/ f(z)}\) is a thin 2-simplex of \(\mathcal{C}\).

Remark 5.4.3.10. In the situation of Proposition 5.4.3.9. condition (*) guarantees that 01X4 \(u\) is a \(q\)-cartesian morphism of \(\mathcal{C}_{/ f}\) (this follows immediately from Proposition 5.4.3.8). In \(\$ 5.4 .4\), we will prove the converse: every \(q\)-cartesian morphism of \(\mathcal{C}_{/ f}\) satisfies condition (*) (Corollary 5.4.4.2).

Proposition 5.4.3.9 is a special case of the following more general assertion:
Proposition 5.4.3.11. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category, let \(f: K \rightarrow \mathcal{C}\) be a morphism of 01 x 5 simplicial sets, and let \(f_{0}: K_{0} \rightarrow \mathcal{C}\) be the restriction of \(f\) to a simplicial subset \(K_{0} \subseteq K\). Let \(q: \mathcal{C}_{/ f} \rightarrow \mathcal{C}_{/ f_{0}}\) denote the projection map, and suppose we are given a lifting problem

01X6
with the following property:
( \(*_{0}\) ) For every vertex \(x \in K_{0}\), the composition
\[
\Delta^{2} \simeq \Delta^{1} \star\{x\} \hookrightarrow \Delta^{1} \star K_{0} \xrightarrow{\bar{\sigma}} \mathcal{C}
\]
is a thin 2-simplex of \(\mathcal{C}\).
Then there exists an edge \(\sigma: \Delta^{1} \rightarrow \mathcal{C}_{/ f}\) which solves the lifting problem problem (5.25) and which satisfies the following stronger version of ( \(*_{0}\) ):
(*) For every vertex \(x \in K\), the composition
\[
\Delta^{2} \simeq \Delta^{1} \star\{x\} \hookrightarrow \Delta^{1} \star K \xrightarrow{\sigma} \mathcal{C}
\]
is a thin 2-simplex of \(\mathcal{C}\).
Proof. Arguing as in the proof of Proposition 5.4.3.8, we can reduce to the case where \(K=\Delta^{n}\) is a standard simplex and \(K_{0}=\partial \Delta^{n}\) is its boundary. In this case, the lifting problem (5.25) determines a morphism of simplicial sets
\[
\tau_{0}:\left(\{1\} \star \Delta^{n}\right) \coprod_{\left(\{1\} \star \partial \Delta^{n}\right)}\left(\Delta^{1} \star \partial \Delta^{n}\right) \rightarrow \mathcal{C}
\]
whose source can be identified with the horn \(\Lambda_{1}^{n+2} \subseteq \Delta^{n+2}\) (Lemma 4.3.6.15), and we wish to extend \(\tau\) to an \((n+2)\)-simplex of \(\mathcal{C}\). If \(n>0\), then the desired extension exists because \(\tau_{0}\) carries \(\mathrm{N}_{\bullet}(\{0<1<2\})\) to a thin 2-simplex of \(\mathcal{C}\) (by virtue of assumption \(\left.\left(*_{0}\right)\right)\). If \(n=0\), then our assumption that \(\mathcal{C}\) is an \((\infty, 2)\)-category allows us to extend \(\tau_{0}\) to a thin 2 -simplex of \(\mathcal{C}\).

\subsection*{5.4.4 The Local Thinness Criterion}
\(01 \mathrm{X7}\) Let \(\mathcal{C}\) be an \((\infty, 2)\)-category and let \(\sigma\) be a 2 -simplex of \(\mathcal{C}\), whose restriction to the 1 -skeleton of \(\Delta^{2}\) we indicate in the diagram

Roughly speaking, we can think of \(\sigma\) as encoding a 2-morphism \(\gamma: v \circ u \Rightarrow w\), and we can think of the condition that \(\sigma\) is thin as corresponding to the requirement that \(\gamma\) is invertible. In the case where \(\mathcal{C}\) is the Duskin nerve of a 2-category, this is the content of Theorem 2.3.2.5. For a general \((\infty, 2)\)-category, we can formulate this heuristic more precisely as follows:

01 X 8 Theorem 5.4.4.1 (Local Thinness Criterion). Let \(\mathcal{C}\) be an ( \(\infty, 2\)-category and let \(\sigma\) be a 2-simplex of \(\mathcal{C}\), which we represent by the diagram

The following conditions are equivalent:
(1) The 2-simplex \(\sigma\) is thin.
(2) Let \(q: \mathcal{C}_{/ Z} \rightarrow \mathcal{C}\) denote the projection map. Then \(\sigma\) is \(q\)-cartesian when viewed as an edge of the simplicial set \(\mathcal{C}_{/ Z}\).
(3) The 2-simplex \(\sigma\) is locally \(q\)-cartesian when viewed as an edge of the simplicial set \(\mathcal{C}_{/ Z}\).
(4) Let \(q^{\prime}: \mathcal{C}_{X /} \rightarrow \mathcal{C}\) denote the projection map. Then \(\sigma\) is \(q^{\prime}\)-cocartesian when viewed as an edge of the simplicial set \(\mathcal{C}_{X /}\).
(5) The 2-simplex \(\sigma\) is locally \(q^{\prime}\)-cocartesian when viewed as an edge of the simplicial set \(\mathcal{C}_{X /}\).

Proof. We will prove that \((1) \Leftrightarrow(2) \Leftrightarrow(3)\); the proof that \((1) \Leftrightarrow(4) \Leftrightarrow(5)\) follows by applying the same argument to the opposite \((\infty, 2)\)-category \(\mathcal{C}^{\text {op }}\). The implication \((1) \Rightarrow(2)\) follows from Proposition 5.4.3.8, and the implication \((2) \Rightarrow(3)\) is immediate (see Remark 5.1.3.3). For each integer \(n \geq 3\), consider the following weaker version of condition (1):
\(\left(1_{n}\right)\) For every integer \(0<i<n\) and every morphism of simplicial sets \(\mu_{0}: \Lambda_{i}^{n} \rightarrow \mathcal{C}\) for which the composition
\[
\Delta^{2} \simeq \mathrm{~N}_{\bullet}(\{i-1<i<i+1\}) \hookrightarrow \Lambda_{i}^{n} \xrightarrow{\mu_{0}} \mathcal{C}
\]
is equal to \(\sigma\), there exists a map \(\mu: \Delta^{n} \rightarrow \mathcal{C}\) extending \(\mu_{0}\).
Note that \(\sigma\) satisfies condition (1) if and only if it satisfies condition ( \(1_{n}\) ) for each \(n \geq 3\). We will complete the proof by showing that \((3) \Rightarrow\left(1_{n}\right)\), using a fairly elaborate induction on \(n\).

Assume that \(\sigma\) is locally \(q\)-cartesian when viewed as a morphism in the \((\infty, 2)\)-category \(\mathcal{C}_{/ Z}\). Since \(\mathcal{C}\) is an ( \(\infty, 2\) )-category, we can choose a thin 2-simplex \(\sigma^{\prime}\) satisfying \(d_{0}^{2}\left(\sigma^{\prime}\right)=d_{0}^{2}(\sigma)\) and \(d_{2}^{2}\left(\sigma^{\prime}\right)=d_{2}^{2}(\sigma)\), which we represent as a diagram

The implication \((1) \Rightarrow(3)\) shows that \(\sigma^{\prime}\) is also locally \(q\)-cartesian when viewed as an edge of the simplicial set \(\mathcal{C}_{/ Z}\). Let us regard the edge \(u\) as a morphism of simplicial sets \(\Delta^{1} \rightarrow \mathcal{C}\), and let \(\mathcal{E}\) denote the fiber product \(\Delta^{1} \times_{\mathcal{C}} \mathcal{C}_{/ Z}\). Since \(q\) is an interior fibration, it follows from Remark 5.4.2.4 and Example 5.4.2.2 that the projection map \(\pi: \mathcal{E} \rightarrow \Delta^{1}\) is an inner fibration. Moreover, we can identify \(\sigma\) and \(\sigma^{\prime}\) with \(\pi\)-cartesian edges of \(\mathcal{E}\) having nondegenerate images under \(\pi\). Applying Remark 5.1.3.8, we see that there exists a 2 -simplex of \(\mathcal{E}\) which exhibits \(\sigma^{\prime}\) as a composition of \(\sigma\) with an isomorphism in \(\mathcal{E}\). The image of this 2 -simplex under the projection map \(\mathcal{E} \rightarrow \mathcal{C}_{/ Z}\) can be identified with a 3 -simplex \(\rho\) of \(\mathcal{C}\) such that \(d_{0}^{3}(\rho)=\sigma\), \(d_{1}^{3}(\rho)=\sigma^{\prime}\), and \(d_{3}^{3}(\rho)=s_{0}^{1}(u)\) is left-degenerate; the restriction of \(\rho\) to the 1 -skeleton of \(\Delta^{3}\) we can represent by the diagram

By construction, the remaining face \(\sigma^{\prime \prime}=d_{2}^{3}(\rho)\) is an isomorphism when viewed as a morphism in the \(\infty\)-category \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Z)=\{X\} \times_{\mathcal{C}} \mathcal{C}_{/ Z}\), and is therefore locally \(q\)-cartesian (Example 5.1.3.6. In particular, our inductive hypothesis guarantees that the simplex \(\sigma^{\prime \prime}\) satisfies condition \(\left(1_{m}\right)\) for \(3 \leq m<n\).

Fix a morphism of simplicial sets \(\mu_{0}: \Lambda_{i}^{n} \rightarrow \mathcal{C}\) as in condition \(\left(1_{n}\right)\); we wish to show that \(\mu_{0}\) can be extended to an \(n\)-simplex \(\mu\) of \(\mathcal{C}\). Let \(\delta_{n+1}^{i-1}: \Delta^{n} \hookrightarrow \Delta^{n+1}\) denote the inclusion of the \((i-1)\) st face, given on vertices by the formula
\[
\delta_{n+1}^{i-1}(j)= \begin{cases}j & \text { if } j<i-1 \\ j+1 & \text { if } j \geq i-1\end{cases}
\]

We will construct an ( \(n+1\) )-simplex \(\nu: \Delta^{n+1} \rightarrow \mathcal{C}\) which satisfies the following conditions:
(a) The composite map
\[
\Lambda_{i}^{n} \hookrightarrow \Delta^{n} \xrightarrow{\delta_{n+1}^{i-1}} \Delta^{n+1} \xrightarrow{\nu} \mathcal{C}
\]
is equal to \(\mu_{0}\).
(b) The composite map
\[
\Delta^{3} \simeq \mathrm{~N}_{\bullet}(\{i-1<i<i+1<i+2\}) \hookrightarrow \Delta^{n+1} \xrightarrow{\nu} \mathcal{C}
\]
is equal to the 3 -simplex \(\rho\).
(c) For every integer \(0 \leq j<i-1\), the 2 -simplex
\[
\Delta^{2} \simeq \mathrm{~N}_{\bullet}(\{j<i-1<i\}) \hookrightarrow \Delta^{n+1} \xrightarrow{\nu} \mathcal{C}
\]
is right-degenerate (in particular, it is thin).
(d) For every integer \(i+2<j \leq n+1\), the 2 -simplex
\[
\Delta^{2} \simeq \mathrm{~N}_{\bullet}(\{i-1<i<j\}) \hookrightarrow \Delta^{n+1} \xrightarrow{\nu} \mathcal{C}
\]
is left-degenerate (in particular, it is thin).
Assuming that this construction is possible, we complete the proof by observing that \(\mu=\nu \circ \delta_{n+1}^{i-1}\) provides the desired extension of \(\mu_{0}\) (by virtue of assumption (a)).

The construction of the \((n+1)\)-simplex \(\nu\) will take place in several steps. We define simplicial subsets
\[
K_{0} \subsetneq K_{1} \subsetneq K_{2} \subsetneq K_{3} \subsetneq K_{4} \subsetneq \Delta^{n+1}
\]
and maps \(\nu_{j}: K_{j} \rightarrow \mathcal{C}\) as follows:
- Let \(K_{0} \subseteq \Delta^{n+1}\) be the image of the horn \(\Lambda_{i}^{n}\) under \(\delta_{n+1}^{i-1}\), so that \(\delta_{n+1}^{i-1}\) induces an isomorphism \(\Lambda_{i}^{n} \xrightarrow{\sim} K_{0}\). It follows that there is a unique morphism of simplicial sets \(\nu_{0}: K_{0} \rightarrow \mathcal{C}\) satisfying \(\mu_{0}=\left.\nu_{0} \circ \delta_{n+1}^{i-1}\right|_{\Lambda_{i}^{n}}\). By construction, the map \(\nu_{0}\) satisfies condition (a).
- Let \(K_{1} \subseteq \Delta^{n+1}\) be the union of \(K_{0}\) with the 3 -simplex \(\mathrm{N}_{\bullet}(\{i-1<i<i+1<i+2\})\). It follows from the identity \(d_{0}^{3}(\rho)=\sigma\) that \(\nu_{0}\) extends uniquely to a map \(\nu_{1}: K_{1} \rightarrow \mathcal{C}\) satisfying condition (b).
- Let \(K_{2}\) be the simplicial subset of \(\Delta^{n+1}\) obtained by removing those nondegenerate simplices which contain all of the vertices \(\{0<1<\cdots<i-2<i+2<i+3<\cdots<\) \(n+1\}\) and at least one of the vertices \(\{i-1, i\}\). We will prove below that \(\nu_{1}\) can be extended to a map \(\nu_{2}: K_{2} \rightarrow \mathcal{C}\) which satisfies conditions \((c)\) and \((d)\).
- Let \(\delta_{n+1}^{i}: \Delta^{n} \hookrightarrow \Delta^{n+1}\) denote the inclusion of the \(i\) th face, given on vertices by the formula
\[
\delta_{n+1}^{i}(j)= \begin{cases}j & \text { if } j<i \\ j+1 & \text { if } j \geq i\end{cases}
\]

Let \(K_{3}\) be the union of \(K_{2}\) with the image of \(\delta_{n+1}^{i}\). Note that \(\delta_{n+1}^{i}\) determines a pushout diagram of simplicial sets

Let \(\alpha_{0}\) denote the composite map \(\Lambda_{i}^{n} \xrightarrow{\delta_{n+1}^{i}} K_{2} \xrightarrow{\nu_{2}} \mathcal{C}\). Since \(\nu_{1}\) satisfies condition (b), \(\alpha_{0}\) carries \(\mathrm{N}_{\bullet}(\{i-1<i<i+1\})\) to the thin 2-simplex \(\sigma^{\prime}\) of \(\mathcal{C}\), and can therefore be extended to an \(n\)-simplex \(\alpha\) of \(\mathcal{C}\). It follows that \(\nu_{2}\) extends uniquely to a morphism of simplicial sets \(\nu_{3}: K_{3} \rightarrow \mathcal{C}\) satisfying \(\nu_{3} \circ \delta_{n+1}^{i}=\alpha\).
- Let \(K_{4}\) denote the horn \(\Lambda_{i-1}^{n+1} \subsetneq \Delta^{n}\). Note that \(K_{4}\) can be written as the union of \(K_{3}\) with the image of the face inclusion \(\delta_{n+1}^{i+1}: \Delta^{n} \hookrightarrow \Delta^{n+1}\), given on vertices by the formula
\[
\delta_{n+1}^{i+1}(j)= \begin{cases}j & \text { if } j \leq i \\ j+1 & \text { if } j>i\end{cases}
\]

Moreover, we have a pushout diagram

Let \(\beta_{0}\) denote the composite map
\[
\Lambda_{i-1}^{n} \xrightarrow{\delta_{n+1}^{i+1}} K_{3} \xrightarrow{\nu_{3}} \mathcal{C} .
\]

If \(i>1\), then condition \((c)\) guarantees that the restriction \(\left.\beta_{0}\right|_{\mathrm{N}_{\bullet}(\{i-2<i-1<i\})}\) is a rightdegenerate 2 -simplex of \(\mathcal{C}\). If \(i=1\), then condition (d) guarantees that the restriction \(\left.\beta_{0}\right|_{N_{\bullet}(\{0<1<n\})}\) is a left-degenerate 2-simplex of \(\mathcal{C}\). In either case, our assumption that \(\mathcal{C}\) is an \((\infty, 2)\)-category guarantees that \(\beta_{0}\) can be extended to an \(n\)-simplex \(\beta\) of \(\mathcal{C}\), so that \(\nu_{3}\) can be extended uniquely to a map \(\nu_{4}: K_{4} \rightarrow \mathcal{C}\) satisfying \(\nu_{4} \circ \delta_{n+1}^{i+1}=\beta\).
- If \(i>1\), then condition (c) guarantees that the map \(\nu_{4}: \Lambda_{i-1}^{n+1} \rightarrow \mathcal{C}\) carries \(\mathrm{N}_{\bullet}(\{i-2<\) \(i-1<i\}\) ) to a right-degenerate 2 -simplex of \(\mathcal{C}\). If \(i=1\), then condition (d) guarantees that \(\nu_{4}\) carries \(\mathrm{N}_{\bullet}(\{0<1<n+1\})\) to a left-degenerate 2 -simplex of \(\mathcal{C}\). In either case, our assumption that \(\mathcal{C}\) is an \((\infty, 2)\)-category guarantees that we can extend \(\nu_{4}\) to an \((n+1)\)-simplex \(\nu: \Delta^{n+1} \rightarrow \mathcal{C}\), thereby completing the proof of Theorem 5.4.4.1.

It remains to show that \(\nu_{1}\) admits an extension \(\nu_{2}: K_{2} \rightarrow \mathcal{C}\) which satisfies conditions (c) and (d). Let us say that a simplex \(\tau: \Delta^{m} \rightarrow K_{2}\) is free if it is nondegenerate, not contained in \(K_{1}\), and there exists an integer \(0 \leq j \leq m\) satisfying \(\tau(j)=i\). Note that in this case, we automatically have \(j>0\) and \(\tau(j-1)=i-1\) (otherwise, \(\tau\) would be contained in \(K_{1}\) ). Moreover, if \(\tau\) is any nondegenerate \(m\)-simplex of \(K_{2}\) which is not contained in \(K_{1}\), then \(\tau\) is either free or can be realized uniquely as a face of a free \((m+1)\)-simplex \(\tau^{\prime}: \Delta^{m+1} \rightarrow K_{2}\) (obtained by adjoining \(i\) to the image of \(\tau\) ).

Let \(\left\{\tau_{1}, \tau_{2}, \cdots, \tau_{t}\right\}\) be an enumeration of the collection of all free simplices of \(K_{2}\), chosen so \(\operatorname{dim}\left(\tau_{1}\right) \leq \operatorname{dim}\left(\tau_{2}\right) \leq \cdots \leq \operatorname{dim}\left(\tau_{t}\right)\). For \(0 \leq s \leq t\), let \(K_{2}(s)\) denote the union of \(K_{1}\) with the images of the maps \(\left\{\tau_{1}, \tau_{2}, \cdots, \tau_{s}\right\}\), so that we have inclusions of simplicial sets
\[
K_{1}=K_{2}(0) \subset K_{2}(1) \subset K_{2}(2) \subset \cdots \subset K_{2}(t)=K_{2}
\]

We will complete the proof by inductively constructing a compatible sequence of maps \(\nu_{2}(s): K_{2}(s) \rightarrow \mathcal{C}\) satisfying \(\nu_{2}(0)=\nu_{1}\) together with the following translation of conditions (c) and (d):
\(\left(*_{s}\right)\) If the simplex \(\tau_{s}\) has dimension 2, then the 2-simplex \(\nu_{2} \circ \tau_{s}\) of \(\mathcal{C}\) is left-degenerate if \(\tau_{s}(1)=i\) and right-degenerate if \(\tau_{s}(2)=i\).

Assume that \(s>0\) and that the map \(\nu_{2}(s-1)\) has already been constructed. Set \(\tau=\tau_{s}\) : \(\Delta^{m} \rightarrow K_{2}\), so that there is a unique integer \(1 \leq j \leq m\) satisfying \(\tau(j)=i\). Note that for \(0 \leq k \leq m\) with \(k \neq j\), the face \(d_{k}^{m}(\tau)\) is either free or belongs to \(K_{1}\); in either case, it belongs to \(K_{2}(s-1)\). Moreover, the face \(d_{j}^{m}(\tau)\) is neither free, nor contained in \(K_{1}\), nor
contained as a face of any other free \(m\)-simplex of \(K_{2}\). It follows that \(\tau\) determines a pushout diagram of simplicial sets

Let \(\xi_{0}: \Lambda_{j}^{m} \rightarrow \mathcal{C}\) denote the composite map \(\Lambda_{j}^{m} \xrightarrow{\tau} K_{2}(s-1) \xrightarrow{\nu_{2}(s-1)} \mathcal{C}\); we wish to show that \(\xi_{0}\) can be extended to an \(m\)-simplex of \(\mathcal{C}\). If \(m=2\), then there is a unique such extension which satisfies condition \(\left(*_{s}\right)\) (since, by construction, the morphism \(\nu_{1}\) carries \(\mathrm{N}_{\bullet}(\{i-1<i\})\) to the degenerate edge \(\operatorname{id}_{X}\) of \(\mathcal{C}\) ). We may therefore assume that \(m \geq 3\). We consider several cases:
- If \(j=m\), then it follows from assumption \(\left(*_{s^{\prime}}\right)\) for \(s^{\prime}<s\) that \(\xi_{0}\) carries \(\mathrm{N}_{\bullet}(\{0<\) \(m-1<m\}\) ) to a right-degenerate 2 -simplex of \(\mathcal{C}\), so the desired extension exists by virtue of our assumption that \(\mathcal{C}\) is an \((\infty, 2)\)-category.
- If \(j<m\) and \(\tau(j+1)=i+1\), then it follows from (b) that \(\xi_{0}\) carries \(\mathrm{N}_{\bullet}(\{j-1<\) \(j<j+1\}\) ) to the left-degenerate 2 -simplex \(d_{3}^{3}(\rho)\). Since \(\mathcal{C}\) is an ( \(\left.\infty, 2\right)\)-category, this 2 -simplex is thin so that \(\xi_{0}\) can be extended to an \(m\)-simplex of \(\mathcal{C}\).
- If \(j<m\) and \(\tau(j+1)>i+2\), then it follows from assumption \(\left(*_{s^{\prime}}\right)\) for \(s^{\prime}<s\) that \(\xi_{0}\) carries \(\mathrm{N}_{\bullet}(\{j-1<j<j+1\})\) to a left-degenerate 2 -simplex of \(\mathcal{C}\). Since \(\mathcal{C}\) is an \((\infty, 2)\)-category, this 2 -simplex is thin so that \(\xi_{0}\) can be extended to an \(m\)-simplex of \(\mathcal{C}\).
- If \(j<m\) and \(\tau(j+1)=i+2\), then it follows from (b) that \(\xi_{0}\) carries \(\mathrm{N}_{\bullet}(\{j-1<j<\) \(j+1\}\) ) to the 2 -simplex \(\sigma^{\prime \prime}\) of \(\mathcal{C}\). In this case, our assumption that \(\tau\) belongs to \(K_{2}\) guarantees that \(m<n\), so the existence of the desired extension follows the fact that \(\sigma^{\prime \prime}\) satisfies condition ( \(1_{m}\) ) (by virtue of our inductive hypothesis).

Theorem 5.4.4.1 immediately generalizes to other slice constructions:
Corollary 5.4.4.2. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category, let \(f: K \rightarrow \mathcal{C}\) be a morphism of simplicial 01X9 sets, and let \(q: \mathcal{C}_{/ f} \rightarrow \mathcal{C}\) denote the projection map. Let \(u: X \rightarrow Y\) be a morphism in the \((\infty, 2)\)-category \(\mathcal{C}_{/ f}\). The following conditions are equivalent:
(1) For every vertex \(z \in K\), the composite map
\[
\Delta^{2} \simeq \Delta^{1} \star\{z\} \hookrightarrow \Delta^{1} \star K \xrightarrow{u} \mathcal{C}
\]
is a thin 2-simplex of \(\mathcal{C}\).
(2) The morphism \(u\) is \(q\)-cartesian.
(3) The morphism \(u\) is locally \(q\)-cartesian.

Proof. The implication (1) \(\Rightarrow(2)\) follows from Proposition 5.4.3.8, and the implication \((2) \Rightarrow(3)\) is immediate (see Remark 5.1.3.3). We will show that (3) \(\Rightarrow\) (1). Fix a vertex \(z \in K\); we wish to show that the composite map
\[
\Delta^{2} \simeq \Delta^{1} \star\{z\} \hookrightarrow \Delta^{1} \star K \xrightarrow{u} \mathcal{C}
\]
is a thin 2 -simplex of \(\mathcal{C}\). Set \(Z=f(z) \in \mathcal{C}\), so that \(q\) factors as a composition
\[
\mathcal{C}_{/ f} \xrightarrow{q^{\prime}} \mathcal{C}_{/ Z} \xrightarrow{q^{\prime \prime}} \mathcal{C} .
\]

By virtue of Theorem 5.4.4.1, it will suffice to show that the \(q^{\prime}(u)\) is a locally \(q^{\prime \prime}\)-cartesian morphism of the \((\infty, 2)\)-category \(\mathcal{C}_{/ Z}\).

Set \(\bar{u}=q(u)\), which we regard as a morphism \(\bar{q}: \bar{X} \rightarrow \bar{Y}\) in the \((\infty, 2)\)-category \(\mathcal{C}\). By virtue of Proposition 5.4.3.9, we can lift \(\bar{u}\) to a morphism \(u^{\prime}: X^{\prime} \rightarrow Y\) in \(\mathcal{C}_{/ f}\) which satisfies condition (1) (and therefore also satisfies (3)). Regard \(\bar{u}\) as a 1 -simplex of \(\mathcal{C}\) and let \(\mathcal{E}\) denote the fiber product \(\Delta^{1} \times_{\mathcal{C}} \mathcal{C}_{/ f}\). Since \(q\) is an interior fibration (Proposition 5.4.3.1), the projection map \(\pi: \mathcal{E} \rightarrow \Delta^{1}\) is also an interior fibration (Remark 5.4.2.4) and therefore an inner fibration (Example 5.4.2.2). Let us abuse notation by identifying \(u\) and \(u^{\prime}\) with morphisms in the \(\infty\)-category \(\mathcal{E}\) lying over the unique nondegenerate edge of \(\Delta^{1}\). Assumption (3) then guarantees that \(u\) and \(u^{\prime}\) are \(\pi\)-cartesian. Invoking Remark 5.1.3.8, we deduce that there exists a 2 -simplex \(\rho: \Delta^{2} \rightarrow \mathcal{E}\), which we display as a diagram

where \(v\) is an isomorphism in the \(\infty\)-category \(\{0\} \times_{\Delta^{1}} \mathcal{E} \simeq\{\bar{X}\} \times_{\mathcal{C}} \mathcal{C}_{/ f}\). It follows that \(q^{\prime}(v)\) is an isomorphism in the \(\infty\)-category \(\{\bar{X}\} \times_{\mathcal{C}} \mathcal{C}_{/ Z}\). Since \(u^{\prime}\) satisfies condition (1), Theorem 5.4.4.1 guarantees that \(q^{\prime}\left(u^{\prime}\right)\) is locally \(q^{\prime \prime}\)-cartesian. Invoking Remark 5.1.3.8 again, we deduce that \(q^{\prime}(u)\) is locally \(q^{\prime \prime}\)-cartesian, as desired.

\subsection*{5.4.5 The Pith of an ( \(\infty, 2\) )-Category}

01 XA Let \(\mathcal{C}\) be a 2-category. Recall that the pith of \(\mathcal{C}\) is the subcategory \(\operatorname{Pith}(\mathcal{C}) \subseteq \mathcal{C}\) obtained by removing the non-invertible 2 -morphisms of \(\mathcal{C}\) (Construction 2.2.8.9). In this section, we generalize this definition to the setting of \((\infty, 2)\)-categories.

Construction 5.4.5.1. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category. We let \(\operatorname{Pith}(\mathcal{C}) \subseteq \mathcal{C}\) denote the 01xB simplicial subset consisting of those simplices \(\sigma: \Delta^{n} \rightarrow \mathcal{C}\) which carry every 2 -simplex of \(\Delta^{n}\) to a thin 2 -simplex of \(\mathcal{C}\). We will refer to \(\operatorname{Pith}(\mathcal{C})\) as the pith of \(\mathcal{C}\).

Remark 5.4.5.2. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category. Then every degenerate 2 -simplex of \(\mathcal{C}\) is 01XC thin. Consequently, to check that a simplex \(\sigma: \Delta^{n} \rightarrow \mathcal{C}\) belongs to the pith \(\operatorname{Pith}(\mathcal{C})\), it suffices to check that \(\sigma\) carries every nondegenerate 2 -simplex of \(\Delta^{n}\) to a thin 2 -simplex of \(\mathcal{C}\). In particular:
- Every object of \(\mathcal{C}\) belongs to \(\operatorname{Pith}(\mathcal{C})\).
- Every morphism of \(\mathcal{C}\) belongs to \(\operatorname{Pith}(\mathcal{C})\).
- A 2 -simplex \(\sigma\) of \(\mathcal{C}\) belongs to \(\operatorname{Pith}(\mathcal{C})\) if and only if it is thin.

Remark 5.4.5.3. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category. Then \(\operatorname{Pith}(\mathcal{C})\) is the largest simplicial subset
01XD of \(\mathcal{C}\) which does not contain any non-thin 2 -simplices of \(\mathcal{C}\).

Example 5.4.5.4. Let \(\mathcal{C}\) be a 2 -category and let \(\operatorname{Pith}(\mathcal{C})\) denote its pith (Construction 01XE 2.2.8.9). Then the inclusion \(\operatorname{Pith}(\mathcal{C}) \hookrightarrow \mathcal{C}\) induces an isomorphism of simplicial sets \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\operatorname{Pith}(\mathcal{C})) \simeq \operatorname{Pith}\left(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{C})\right)\). This is an immediate consequence of Theorem 2.3.2.5.

Example 5.4.5.5. Let \(\mathcal{C}\) be an \(\infty\)-category. Then \(\operatorname{Pith}(\mathcal{C})=\mathcal{C}\) (see Example 2.3.2.4. 01XF
Proposition 5.4.5.6. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category. Then \(\operatorname{Pith}(\mathcal{C})\) is an \(\infty\)-category.
Our proof of Proposition 5.4.5.6 will make use of a closure property of the collection of thin 2 -simplices of an \((\infty, 2)\)-category \(\mathcal{C}\).

Definition 5.4.5.7. Let \(\mathcal{C}\) be a simplicial set and let \(T\) be a collection of 2 -simplices of \(\mathcal{C}\). 01xH We will say that \(T\) has the inner exchange property if the following condition is satisfied:
(*) Let \(\sigma: \Delta^{3} \rightarrow \mathcal{C}\) be a 3 -simplex of \(\mathcal{C}\). For every triple of integers \(0 \leq i<j<k \leq 3\), let \(\sigma_{k j i}\) be the face of \(\sigma\) given by the restriction \(\left.\sigma\right|_{\mathrm{N} \cdot(\{i<j<k\})}\). Assume that the outer faces \(\sigma_{210}\) and \(\sigma_{321}\) belong to \(T\). Then \(\sigma_{310}\) belongs to \(T\) if and only if \(\sigma_{320}\) belongs to \(T\).

Remark 5.4.5.8. Let \(\mathcal{C}\) be a simplicial set, let \(T\) be a collection of 2-simplices of \(\mathcal{C}\), and let 01XJ \(T^{\mathrm{op}}\) denote the set \(T\), regarded as a collection of simplices of the opposite simplicial set \(\mathcal{C}^{\mathrm{op}}\). Then \(T\) has the inner exchange property if and only if \(T^{\mathrm{op}}\) has the inner exchange property.

Remark 5.4.5.9. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets and let \(T\) be a collection 01XK of 2 -simplices of \(\mathcal{D}\). If \(T\) has the inner exchange property, then the inverse image \(F^{-1}(T)\) has the inner exchange property.

01XL Proposition 5.4.5.10 (Inner Exchange). Let \(\mathcal{C}\) be an \((\infty, 2)\)-category. Then the collection of thin 2 -simplices of \(\mathcal{C}\) has the inner exchange property (Definition 5.4.5.7).

01XM Remark 5.4.5.11. To get a feeling for the content of Proposition 5.4.5.10, let us specialize to the case where \(\mathcal{C}=\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{D})\) is the Duskin nerve of a 2-category \(\mathcal{D}\). In this case, we can identify a 3 -simplex \(\sigma: \Delta^{3} \rightarrow \mathcal{C}\) with a collection of objects \(\left\{X_{i}\right\}_{0 \leq i \leq 3}\) of \(\mathcal{D}\), a collection of 1-morphisms \(\left\{f_{j i}: X_{i} \rightarrow X_{j}\right\}_{0 \leq i<j \leq 3}\), and a collection of 2-morphisms \(\left\{\mu_{k j i}: f_{k j} \circ f_{j i} \Rightarrow f_{k i}\right\}\) for which the diagram

is commutative, where \(\alpha=\alpha_{f_{32}, f_{21}, f_{10}}\) is the associativity constraint for the composition of 1 -morphisms in \(\mathcal{C}\) (Proposition 2.3.1.9. The assumption that the outer faces of \(\sigma\) are thin guarantees that the 2 -morphisms \(\mu_{321}\) and \(\mu_{210}\) are isomorphisms. In this case, Proposition 5.4.5.10 asserts that \(\mu_{320}\) is an isomorphism if and only if \(\mu_{310}\) is an isomorphism, which follows by inspection.

Proof of Proposition 5.4.5.10, Let \(\mathcal{C}\) be an \((\infty, 2)\)-category, let \(\sigma: \Delta^{3} \rightarrow \mathcal{C}\) be a 3 -simplex of \(\mathcal{C}\) and let \(C=\sigma(3) \in \mathcal{C}\) be the image of the final vertex. Let us regard the face \(\sigma_{210}=\left.\sigma\right|_{N_{\bullet}(\{0<1<2\})}\) as a morphism of simplicial sets from \(\Delta^{2}\) to \(\mathcal{C}\), and let \(\mathcal{E}\) denote the pullback \(\Delta^{2} \times_{\mathcal{C}} \mathcal{C}_{/ C}\). Note that the projection map \(\mathcal{C}_{/ C} \rightarrow \mathcal{C}\) is an interior fibration (Proposition 5.4.3.1). If \(\sigma_{210}\) is thin, then the projection map \(\pi: \mathcal{E} \rightarrow \Delta^{2}\) is also an interior fibration (Remark 5.4.2.4); since \(\Delta^{2}\) is an \(\infty\)-category, it is an inner fibration (Example 5.4.2.2. Unwinding the definitions, we can identify \(\sigma\) with a 2 -simplex of \(\mathcal{E}\) lying over the unique nondegenerate 2 -simplex of \(\Delta^{2}\), which we display as a diagram

If \(\sigma_{321}=\left.\sigma\right|_{\mathrm{N}_{\bullet}(\{1<2<3\})}\) is a thin 2-simplex of \(\mathcal{C}\), then the "easy direction" of Theorem 5.4.4.1 guarantees that \(g\) is \(\pi\)-cartesian. It follows that \(f\) is \(\pi\)-cartesian if and only if \(h\) is \(\pi\)-cartesian (Corollary 5.1.2.4). Equivalently, \(f\) is locally \(\pi\)-cartesian if and only if \(h\) is locally \(\pi\)-cartesian (see Remark 5.1.3.4. Applying the "hard direction" of Theorem 5.4.4.1, we conclude that the 2-simplex \(\sigma_{310}=\left.\sigma\right|_{\mathrm{N}_{\bullet}(\{0<1<3\})}\) is thin if and only if the 2-simplex \(\sigma_{320}=\left.\sigma\right|_{\mathrm{N}_{\bullet}}(\{0<2<3\})\) is thin.

Proof of Proposition 5.4.5.6. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category. Suppose we are given integers \(0<i<n\) and a morphism of simplicial sets \(\sigma_{0}: \Lambda_{i}^{n} \rightarrow \operatorname{Pith}(\mathcal{C})\); we wish to show that \(\sigma_{0}\) can be extended to an \(n\)-simplex \(\sigma: \Delta^{n} \rightarrow \operatorname{Pith}(\mathcal{C})\). If \(n=2\), then condition (1) of Definition 5.4.1.1 guarantees that we can extend \(\sigma_{0}\) to a thin 2 -simplex of \(\mathcal{C}\), which then belongs to \(\operatorname{Pith}(\mathcal{C})\) by virtue of Remark 5.4.5.2. We may therefore assume that \(n \geq 3\). In this case, we observe that the composite map
\[
\Delta^{2} \simeq \mathrm{~N}_{\bullet}(\{i-1<i<i+1\}) \hookrightarrow \Lambda_{i}^{n} \xrightarrow{\sigma_{0}} \operatorname{Pith}(\mathcal{C}) \rightarrow \mathcal{C}
\]
is a thin 2 -simplex of \(\mathcal{C}\), so that we can extend \(\sigma_{0}\) to an \(n\)-simplex \(\sigma: \Delta^{n} \rightarrow \mathcal{C}\). To complete the proof, it will suffice to show that \(\sigma\) carries each 2 -simplex of \(\Delta^{n}\) to a thin 2 -simplex of \(\mathcal{C}\). If \(n \geq 4\), this is automatic (since every 2 -simplex of \(\Delta^{n}\) is contained in the horn \(\Lambda_{i}^{n}\) ). In the case \(n=3\), it follows from our assumption that the collection of thin 2-simplices of \(\mathcal{C}\) has the inner exchange property (Proposition 5.4.5.10).

Definition 5.4.5.12. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category. We say that a morphism \(f: X \rightarrow Y\) of \(\mathcal{C}\) is an isomorphism if it is an isomorphism when viewed as a morphism in the \(\infty\)-category \(\operatorname{Pith}(\mathcal{C})\). We say that objects \(X, Y \in \mathcal{C}\) are isomorphic if there is an isomorphism from \(X\) to \(Y\) (that is, if \(X\) and \(Y\) are isomorphic when viewed as objects of the \(\infty\)-category \(\operatorname{Pith}(\mathcal{C})\) ).

Let \(\mathcal{C}\) be an \((\infty, 2)\)-category. Heuristically, one can think of the \(\infty\)-category \(\operatorname{Pith}(\mathcal{C})\) as obtained from \(\mathcal{C}\) by removing its noninvertible 2 -morphisms, just as the core \(\mathcal{E}^{\simeq}\) of an \(\infty\)-category \(\mathcal{E}\) is obtained by removing its noninvertible morphisms (see Construction 4.4.3.1). We now make this heuristic more precise (see Corollary 5.4.7.12 for a relative version):

Proposition 5.4.5.13. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category containing objects \(X\) and \(Y\). Then the 01 xN inclusion \(\operatorname{Pith}(\mathcal{C}) \hookrightarrow \mathcal{C}\) induces isomorphisms of simplicial sets
\[
\operatorname{Hom}_{\operatorname{Pith}(\mathcal{C})}^{\mathrm{L}}(X, Y) \simeq \operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y)^{\simeq} \quad \operatorname{Hom}_{\operatorname{Pith}(\mathcal{C})}^{\mathrm{R}}(X, Y) \simeq \operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)^{\simeq} .
\]

Proof. Let \(\sigma\) be an \(n\)-simplex of the simplicial set \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\), which we view as a morphism of simplicial sets \(\tau: \Delta^{n+1} \rightarrow \mathcal{C}\) whose restriction to the face \(\Delta^{n} \subseteq \Delta^{n+1}\) equal to the constant map \(\Delta^{n} \rightarrow\{X\} \hookrightarrow \mathcal{C}\). Then \(\sigma\) belongs to the simplicial subset \(\operatorname{Hom}_{\operatorname{Pith}(\mathcal{C})}^{\mathrm{R}}(X, Y) \subseteq\) \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) if and only if, for every 2-simplex \(\rho: \Delta^{2} \rightarrow \Delta^{n+1}\), the composition \(\tau \circ \rho\) is a
thin 2 -simplex of \(\mathcal{C}\). Note that this condition is automatically satisfied if \(\rho\) is degenerate, or takes values in the subset \(\Delta^{n} \subseteq \Delta^{n+1}\) (since every degenerate 2 -simplex of \(\mathcal{C}\) is thin). Consequently, it suffices to verify this condition in the case where \(\rho\) is the right cone of a map \(\rho_{0}: \Delta^{1} \rightarrow \Delta^{n}\). In this case, \(\tau \circ \rho\) is thin if and only if the edge \(\Delta^{1} \xrightarrow{\rho_{0}} \Delta^{n} \xrightarrow{\sigma} \operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) is an isomorphism in the \(\infty\)-category \(\operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y)\) (Theorem 5.4.4.1). Allowing \(\tau_{0}\) to vary, we obtain the identification \(\operatorname{Hom}_{\operatorname{Pith}(\mathcal{C})}^{\mathrm{R}}(X, Y) \simeq \operatorname{Hom}_{\mathcal{C}}^{\mathrm{R}}(X, Y) \simeq\); the proof of the analogous statement for left-pinched morphism spaces is similar.

01 XP Proposition 5.4.5.14. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category and let \(f: K \rightarrow \mathcal{C}\) be a morphism of simplicial sets. Then:
(1) The projection map \(\pi: \mathcal{C}_{/ f} \times \mathcal{C} \operatorname{Pith}(\mathcal{C}) \rightarrow \operatorname{Pith}(\mathcal{C})\) is a cartesian fibration of \(\infty\)-categories. Moreover, a morphism \(u\) of \(\mathcal{C}_{/ f} \times{ }_{\mathcal{C}} \operatorname{Pith}(\mathcal{C})\) is \(\pi\)-cartesian if and only if, for every vertex \(z \in K\), the composite map
\[
\Delta^{2} \simeq \Delta^{1} \star\{z\} \hookrightarrow \Delta^{1} \star K \xrightarrow{u} \mathcal{C}
\]
is a thin 2-simplex of \(\mathcal{C}\).
(2) The projection map \(\pi^{\prime}: \mathcal{C}_{f /} \times_{\mathcal{C}} \operatorname{Pith}(\mathcal{C}) \rightarrow \operatorname{Pith}(\mathcal{C})\) is a cocartesian fibration of \(\infty-\) categories. Moreover, a morphism \(v\) of \(\mathcal{C}_{f /} \times \mathcal{C} \operatorname{Pith}(\mathcal{C})\) is \(\pi^{\prime}\)-cocartesian if and only if, for every vertex \(x \in K\), the composite map
\[
\Delta^{2} \simeq\{x\} \star \Delta^{1} \hookrightarrow K \star \Delta^{1} \xrightarrow{v} \mathcal{C}
\]
is a thin 2-simplex of \(\mathcal{C}\).
Proof. We will prove (1); the proof of (2) is similar. It follows from Remark 5.4.2.4 that \(\pi\) is an interior fibration. Since \(\operatorname{Pith}(\mathcal{C})\) is an \(\infty\)-category (Proposition 5.4.5.6), it is an inner fibration of \(\infty\)-categories (Example 5.4.2.2). Let us say that a morphism \(u\) of \(\mathcal{C}_{/ f} \times \mathcal{C} \operatorname{Pith}(\mathcal{C})\) is special if, for every vertex \(z \in K\), the composite map
\[
\Delta^{2} \simeq \Delta^{1} \star\{z\} \hookrightarrow \Delta^{1} \star K \xrightarrow{u} \mathcal{C}
\]
is a thin 2 -simplex of \(\mathcal{C}\). Let \(\bar{\pi}: \mathcal{C}_{/ f} \rightarrow \mathcal{C}\) be the projection map. It follows from Corollary 5.4.4.2 that every special morphism of \(\mathcal{C}_{/ f} \times \mathcal{C} \operatorname{Pith}(\mathcal{C})\) is \(\bar{\pi}\)-cartesian when viewed as a morphism of \(\mathcal{C}_{/ f}\), and therefore also \(\pi\)-cartesian (Remark 5.1.1.11). Conversely, any \(\pi\) cartesian morphism of \(\mathcal{C}_{/ f} \times{ }_{\mathcal{C}} \operatorname{Pith}(\mathcal{C})\) is locally \(\bar{\pi}\)-cartesian when viewed as a morphism of \(\mathcal{C}_{/ f}\), and therefore special (again by Corollary 5.4.4.2. To complete the proof, it will suffice to show that if \(Y\) is an object of \(\mathcal{C} / f\), then any morphism \(\bar{u}: \bar{X} \rightarrow q(\bar{Y})\) in \(\operatorname{Pith}(\mathcal{C})\) can be lifted to a special morphism \(u: X \rightarrow Y\) of \(\mathcal{C}_{/ f} \times{ }_{\mathcal{C}} \operatorname{Pith}(\mathcal{C})\), which follows from Proposition 5.4.3.9.

\subsection*{5.4.6 The Four-out-of-Five Property}

Let \(\mathcal{C}\) be an \(\infty\)-category. Recall that the collection of isomorphisms in \(\mathcal{C}\) has the "two- 01 XQ out-of-three" property: if \(f: X \rightarrow Y\) and \(g: Y \rightarrow Z\) are composable morphisms of \(\mathcal{C}\) and any two of the morphisms \(f, g\), and \(g \circ f\) is an isomorphism, then so is the third (Remark 1.4.6.3). This can be regarded as a special case of a more general closure property.

Definition 5.4.6.1. Let \(\mathcal{C}\) be a simplicial set and let \(W\) be a collection of edges of \(\mathcal{C}\). We will say that \(W\) has the two-out-of-six property if it satisfies the following condition:
(*) Let \(\sigma\) be a 3 -simplex of \(\mathcal{C}\) and, for every pair of integers \(0 \leq i<j \leq 3\), let \(\sigma_{j i}\) denote the edge of \(\mathcal{C}\) given by \(\left.\sigma\right|_{\mathrm{N}_{\bullet}(\{i<j\})}\). If the edges \(\sigma_{20}\) and \(\sigma_{31}\) belong to \(W\), then the edges \(\sigma_{10}, \sigma_{21}, \sigma_{32}\), and \(\sigma_{30}\) also belong to \(W\).

Exercise 5.4.6.2. Let \(\mathcal{C}\) be a simplicial set and let \(W\) be a collection of edges of \(\mathcal{C}\) which has the two-out-of-six property. Show that \(W\) has the two-out-of-three property. That is, for any 2 -simplex \(\sigma\) of \(\mathcal{C}\), if any two of the faces \(d_{0}^{2}(\sigma), d_{1}^{2}(\sigma)\), and \(d_{2}^{2}(\sigma)\) belong to \(W\), then so does the third.

Remark 5.4.6.3. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(W\) be a collection of edges of \(\mathcal{C}\). We can informally summarize Definition 5.4.6.1 as follows: a collection of morphisms \(W\) of \(\mathcal{C}\) has the two-out-of-six property if, for every triple of composable morphisms \(f: A \rightarrow B, g: B \rightarrow C\), and \(h: C \rightarrow D\), if the compositions \(g \circ f\) and \(h \circ g\) belong to \(W\), then the morphisms \(f, g\), \(h\), and \(h \circ g \circ f\) belong to \(W\). Beware that this summary is somewhat imprecise, since the compositions \(g \circ f, h \circ g\), and \(h \circ g \circ f\) are a priori only well-defined up to homotopy.

Remark 5.4.6.4. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets and let \(W\) be a collection of edges of \(\mathcal{D}\). If \(W\) has the two-out-of-six property, then the inverse image \(F^{-1}(W)\) also has the two-out-of-six property.

Proposition 5.4.6.5 (Two-out-of-Six). Let \(\mathcal{C}\) be an \(\infty\)-category and let \(W\) be the collection 0051 of isomorphisms in \(\mathcal{C}\). Then \(W\) has the two-out-of-six property.

Proof. By definition, a morphism \(f\) of \(\mathcal{C}\) is an isomorphism if and only if its homotopy class \([f]\) is an isomorphism in the homotopy category hC (Definition 1.4.6.1). By virtue of Remark 5.4.6.4 we can replace \(\mathcal{C}\) by the nerve \(\mathrm{N}_{\bullet}(\mathrm{hC})\) and thereby reduce to the case where \(\mathcal{C}=\mathrm{N}_{\bullet}\left(\mathcal{C}^{\prime}\right)\) for some category \(\mathcal{C}^{\prime}\). Let \(\sigma\) be a 3 -simplex of \(\mathcal{C}\), corresponding to a triple of morphisms
\[
A \xrightarrow{f} B \xrightarrow{g} C \xrightarrow{h} D
\]
in \(\mathcal{C}^{\prime}\), and suppose that \(g \circ f\) and \(h \circ g\) are isomorphisms. Then \(g \circ f\) admits an inverse \(u: C \rightarrow A\). It follows that \(g \circ(f \circ u)=(g \circ f) \circ u=\mathrm{id}_{C}\), so that \(g\) admits a right inverse. A similar argument shows that \(g\) also admits a left inverse, and is therefore an isomorphism
(Remark 1.4.6.7). Applying the two-out-three property, we deduce that \(f\) and \(h\) are also isomorphisms. Since the collection of isomorphisms is closed under composition, it also follows that \(h \circ g \circ f\) is an isomorphism.

Proposition 5.4.6.5 admits a converse:
01 XV Proposition 5.4.6.6. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(W\) be a collection of morphisms of \(\mathcal{C}\) which has the two-out-of-six property. If \(W\) contains every identity morphism of \(\mathcal{C}\), then it contains every isomorphism of \(\mathcal{C}\).

In other words, the collection of isomorphisms in an \(\infty\)-category \(\mathcal{C}\) is the smallest collection of morphisms which contains all identity morphisms and has the two-out-of-six property.

01XW Warning 5.4.6.7. The analogue of Proposition 5.4.6.6 for the two-out-of-three property is false in general. For example, if \(\mathcal{C}\) is the nerve of a category, then the collection of identity morphisms of \(\mathcal{C}\) has the two-out-of-three property, but usually does not contain all the isomorphisms of \(\mathcal{C}\).

Proof of Proposition 5.4.6.6. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(f: X \rightarrow Y\) be an isomorphism in \(\mathcal{C}\). Then \(f\) admits a homotopy inverse \(g: Y \rightarrow X\). Let \(\sigma\) be a 2 -simplex of \(\mathcal{C}\) which witnesses \(\operatorname{id}_{X}\) as a composition \(f\) and \(g\), and let \(\sigma^{\prime}\) be a 2 -simplex of \(\mathcal{C}\) which witnesses \(\operatorname{id}_{Y}\) as a composition of \(g\) and \(f\). Then the triple \(\left(\sigma^{\prime}, s_{0}^{1}(f), \bullet, \sigma\right)\) can be regarded as a morphism of simplicial sets \(\tau_{0}: \Lambda_{2}^{3} \rightarrow \mathcal{C}\). Since \(\mathcal{C}\) is an \(\infty\)-category, we can extend \(\tau_{0}\) to a 3 -simplex \(\tau: \Delta^{3} \rightarrow \mathcal{C}\), whose restriction to the 1 -skeleton of \(\Delta^{3}\) is indicated in the diagram

It follows that if \(W\) is a collection of morphisms of \(\mathcal{C}\) which contains \(\mathrm{id}_{X}, \mathrm{id}_{Y}\), and has the two-out-of-six property, then \(W\) also contains the isomorphism \(f\).

Our goal in this section is to prove analogues of Propositions 5.4.6.5 and Proposition 5.4.6.6 in the setting of \((\infty, 2)\)-categories, where we replace the set \(W \subseteq \operatorname{Hom}_{\text {Set }_{\Delta}}\left(\Delta^{1}, \mathcal{C}\right)\) of isomorphisms with the set \(T \subseteq \operatorname{Hom}_{\text {Set }_{\Delta}}\left(\Delta^{2}, \mathcal{C}\right)\) of thin 2-simplices.

01XX Definition 5.4.6.8. Let \(\mathcal{C}\) be a simplicial set and let \(T\) be a collection of 2-simplices of \(\mathcal{C}\). We say that \(T\) has the four-out-of-five property if it satisfies the following condition:
(*) Let \(\sigma: \Delta^{4} \rightarrow \mathcal{C}\) be a 4 -simplex of \(\mathcal{C}\). For every triple of integers \(0 \leq i<j<k \leq 4\), let \(\sigma_{k j i}\) denote the 2-simplex of \(\mathcal{C}\) given by the restriction of \(\sigma\) to \(\mathrm{N}_{\bullet}(\{i<j<k\})\). If the 2 -simplices \(\sigma_{310}, \sigma_{420}, \sigma_{321}\), and \(\sigma_{432}\) belong to \(T\), then the 2-simplex \(\sigma_{430}\) also belongs to \(T\).

Warning 5.4.6.9. Definition 5.4.6.8 is not self-dual. Let \(T\) be a collection of 2-simplices of 01 XY \(\mathcal{C}\) which satisfies the four-out-of-five property and let \(T^{\mathrm{op}}\) denote the same set, regarded as a collection of 2 -simplices of the opposite simplicial set \(\mathcal{C}^{\text {op }}\). Then \(T^{\mathrm{op}}\) need not satisfy the four-out-of-five property.

Remark 5.4.6.10. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets and let \(T\) be a collection 01XZ of 2 -simplices of \(\mathcal{D}\). If \(T\) has the four-out-of-five-property, then the inverse image \(F^{-1}(T)\) also has the four-out-of-five property.

Proposition 5.4.6.11 (Four-out-of-Five). Let \(\mathcal{C}\) be an ( \(\infty, 2\) )-category and let \(T\) be the 01 YO collection of all thin 2-simplices of \(\mathcal{C}\). Then \(T\) has the four-out-of-five property.

Warning 5.4.6.12. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category and let \(\sigma: \Delta^{4} \rightarrow \mathcal{C}\) be a 4 -simplex of \(\mathcal{C}\). 01 Y 1 For \(0 \leq i<j<k \leq 4\), let \(\sigma_{k j i}\) denote the restriction \(\left.\sigma\right|_{\mathrm{N}_{\bullet}(\{i<j<k\})}\). Proposition 5.4.6.11. asserts that, if the 2-simplices \(\sigma_{310}, \sigma_{420}, \sigma_{321}\), and \(\sigma_{432}\) are thin, then \(\sigma_{430}\) is also thin. Beware that the remaining 2-simplices \(\sigma_{210}, \sigma_{410}, \sigma_{320}, \sigma_{421}\), and \(\sigma_{431}\) need not be thin.

Example 5.4.6.13. To get a feeling for the content of Proposition 5.4.6.11, let us consider 01Y2 the special case where \(\mathcal{C}=\mathrm{N}_{\bullet}^{\mathrm{D}}\left(\mathcal{C}^{\prime}\right)\) is the Duskin nerve of a strict 2-category \(\mathcal{C}^{\prime}\). Let \(\sigma\) be a 4 -simplex of \(\mathcal{C}\), which we identify with a collection of objects \(\left\{X_{i}\right\}_{0 \leq i \leq 4}\), 1-morphisms \(\left\{f_{j i}: X_{j} \rightarrow X_{i}\right\}_{0 \leq i<j \leq 4}\), and 2-morphisms \(\left\{\mu_{k j i}: f_{k j} \circ f_{j i} \Rightarrow f_{k i}\right\}_{0 \leq i<j<k \leq 4}\) of \(\mathcal{C}\) satisfying the condition described in Proposition 2.3.1.9. Proposition 5.4.6.11 asserts that if the 2-morphisms \(\mu_{310}, \mu_{420}, \mu_{321}\), and \(\mu_{432}\) are invertible, then the 2-morphism \(\mu_{430}\) is also
invertible. This follows by inspecting the cubical diagram

in the category \(\operatorname{Hom}_{\mathcal{C}^{\prime}}\left(X_{0}, X_{4}\right)\) and applying the two-out-of-six property to the chain of 2-morphisms
\[
f_{43} \circ f_{32} \circ f_{21} \circ f_{10} \xrightarrow{\mu_{210}} f_{43} \circ f_{32} \circ f_{20} \xrightarrow{\mu_{320}} f_{43} \circ f_{30} \xrightarrow{\mu_{430}} f_{40} .
\]

Proof of Proposition 5.4.6.11. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category and let \(\sigma: \Delta^{4} \rightarrow \mathcal{C}\) be a 4simplex. For every triple of integers \(0 \leq i<j<k \leq 4\), let \(\sigma_{k j i}\) denote the 2-simplex of \(\mathcal{C}\) given by the restriction of \(\sigma\) to \(\mathrm{N}_{\bullet}(\{i<j<k\})\). Assume that the 2 -simplices \(\sigma_{310}, \sigma_{420}\), \(\sigma_{321}\), and \(\sigma_{432}\) are thin. We wish to show that \(\sigma_{430}\) is also thin.

Set \(X=\sigma(0) \in \mathcal{C}\). Let \(\mathcal{E}\) denote the fiber product \(\mathcal{C}_{X /} \times_{\mathcal{C}} \operatorname{Pith}(\mathcal{C})\) and let \(\pi: \mathcal{E} \rightarrow \operatorname{Pith}(\mathcal{C})\) be the projection map, so that \(\pi\) is a cocartesian fibration of \(\infty\)-categories (Proposition 5.4.5.14). For \(1 \leq i \leq 4\), let \(\mathcal{E}_{i}\) denote the \(\infty\)-category \(\{\sigma(i)\} \times_{\text {Pith }(\mathcal{C})} \mathcal{E}\), so that the edge \(\left.\sigma\right|_{\mathrm{N}_{\bullet}(\{0<i\})}\) of \(\mathcal{C}\) can be identified with an object \(Y_{i} \in \mathcal{E}_{i}\). For \(1 \leq i<j \leq 4\), let us identify the 2-simplex \(\left.\sigma\right|_{\mathrm{N}_{\bullet}(\{0<i<j\})}\) with a morphism \(f_{j, i}: Y_{i} \rightarrow Y_{j}\) in \(\mathcal{E}\). By virtue of Proposition 5.4.5.14, it will suffice to show that the morphism \(f_{4,3}: Y_{3} \rightarrow Y_{4}\) is \(\pi\)-cocartesian.

For \(2 \leq i \leq 4\), let \(F_{i}: \mathcal{E}_{i-1} \rightarrow \mathcal{E}_{i}\) be given by covariant transport along the edge \(\left.\sigma\right|_{\mathrm{N} \cdot(\{i-1<i\})}\) of \(\operatorname{Pith}(\mathcal{C})\) (see Definition 5.2.2.4) so that we have a sequence of functors
\[
\mathcal{E}_{1} \xrightarrow{F_{2}} \mathcal{E}_{2} \xrightarrow{F_{3}} \mathcal{E}_{3} \xrightarrow{F_{4}} \mathcal{E}_{4} .
\]

Let \(H_{i}: \Delta^{1} \times \mathcal{E}_{i-1} \rightarrow \mathcal{E}\) be a functor which witnesses that \(F_{i}\) is given by covariant transport along \(\left.\sigma\right|_{\mathrm{N} \cdot(\{i-1<i\})}\), so that \(h_{i}=\left.H_{i}\right|_{\Delta^{1} \times\left\{Y_{i-1}\right\}}\) is a \(\pi\)-cocartesian morphism of \(\mathcal{E}\). It follows that the morphism \(f_{i, i-1}\) can be written as a composition
\[
Y_{i-1} \xrightarrow{h_{i}} F_{i}\left(Y_{i-1}\right) \xrightarrow{g_{i}} Y_{i},
\]
where \(g_{i}\) is a morphism in the \(\infty\)-category \(\mathcal{E}_{i}\). To complete the proof, it will suffice to show that the morphism \(g_{4}: F_{4}\left(Y_{3}\right) \rightarrow Y_{4}\) is an isomorphism in the \(\infty\)-category \(\mathcal{E}_{4}\) (see Remark 5.1.3.8.

Note that we have a chain of 1-morphisms
\[
\left(F_{4} \circ F_{3} \circ F_{2}\right)\left(Y_{1}\right) \xrightarrow{\left(F_{4} \circ F_{3}\right)\left(g_{2}\right)}\left(F_{4} \circ F_{3}\right)\left(Y_{2}\right) \xrightarrow{F_{4}\left(g_{3}\right)} F_{4}\left(Y_{3}\right) \xrightarrow{g_{4}} Y_{4}
\]
in the \(\infty\)-category \(\mathcal{E}_{4}\). Since the collection of isomorphisms in the homotopy category h \(\mathcal{E}_{4}\) satisfies the two-out-of-six property, it will suffice to prove the following:
(a) The composition
\[
\left(F_{4} \circ F_{3} \circ F_{2}\right)\left(Y_{1}\right) \xrightarrow{\left[\left(F_{4} \circ F_{3}\right)\left(g_{2}\right)\right]}\left(F_{4} \circ F_{3}\right)\left(Y_{2}\right) \xrightarrow{\left[F_{4}\left(g_{3}\right)\right]} F_{4}\left(Y_{3}\right)
\]
is an isomorphism in the homotopy category \(\mathrm{h}_{4}\).
(b) The composition
\[
\left(F_{4} \circ F_{3}\right)\left(Y_{2}\right) \xrightarrow{\left[F_{4}\left(g_{3}\right)\right]} F_{4}\left(Y_{3}\right) \xrightarrow{\left[g_{4}\right]} Y_{4}
\]
is an isomorphism in the homotopy category \(h \mathcal{E}_{4}\).
We will deduce (a) from the following slightly stronger assertion:
( \(a^{\prime}\) ) The composition
\[
\left(F_{3} \circ F_{2}\right)\left(Y_{1}\right) \xrightarrow{\left[F_{3}\left(g_{2}\right)\right]} F_{3}\left(Y_{2}\right) \xrightarrow{\left[g_{3}\right]} Y_{3}
\]
is an isomorphism in the homotopy category \(\mathrm{h} \mathcal{E}_{3}\).
To prove ( \(a^{\prime}\) ), we first note that the 2 -simplex \(\sigma_{321}\) is thin, and can therefore be regarded as a 2 -simplex of \(\operatorname{Pith}(\mathcal{C})\). Let \(\mathcal{E}^{\prime}\) denote the fiber product \(\mathrm{N}_{\bullet}(\{1<2<3\}) \times_{\operatorname{Pith}(\mathcal{C})} \mathcal{E}\), and let \(\pi^{\prime}: \mathcal{E}^{\prime} \rightarrow \mathrm{N}_{\bullet}(\{1<2<3\})\) be the projection map. In the homotopy category \(h \mathcal{E}^{\prime}\), we have a commutative diagram

where the upper horizontal composition is the homotopy class of a \(\pi^{\prime}\)-cocartesian morphism (Corollary 5.1.2.4). It follows that the vertical composition on the right is an isomorphism if and only if the diagonal composition is also the homotopy class of a \(\pi^{\prime}\)-cocartesian morphism (Remark 5.1 .3 .8 ). We now observe that the 3 -simplex \(\left.\sigma\right|_{\mathrm{N}_{\mathbf{\bullet}}}(\{0<1<2<3\})\) witnesses the identity \(\left[f_{3,2}\right] \circ\left[f_{2,1}\right]=\left[f_{3,1}\right]\) in the homotopy category \(\mathrm{h} \mathcal{E}^{\prime}\). It will therefore suffice to show that \(f_{3,1}\) is a \(\pi^{\prime}\)-cocartesian morphism of the \(\infty\)-category \(\mathcal{E}^{\prime}\), which follows from Proposition 5.4.5.14 and our assumption that \(\sigma_{310}\) is thin. This completes the proof of \((a)\). The proof of (b) follows by the same argument, using the thinness of the 2-simplices \(\sigma_{432}\) and \(\sigma_{420}\) in place of \(\sigma_{321}\) and \(\sigma_{310}\).

We now prove a partial converse to Proposition 5.4.6.11, which can be regarded as an \((\infty, 2)\)-categorical analogue of Proposition 5.4.6.6.
\(01 \mathrm{Y3}\) Proposition 5.4.6.14. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category and let \(T\) be a collection of 2-simplices of \(\mathcal{C}\). Assume that:
(1) Every degenerate 2-simplex of \(\mathcal{C}\) belongs to \(T\).
(2) For every pair of morphisms \(f: X \rightarrow Y\) and \(g: Y \rightarrow Z\) in \(\mathcal{C}\), there exists a thin 2-simplex \(\sigma\) of \(\mathcal{C}\) which belongs to \(T\) and satisfies \(d_{2}^{2}(\sigma)=f\) and \(d_{0}^{2}(\sigma)=g\), as indicated in the diagram

(3) The collection \(T\) has the inner exchange property (Definition 5.4.5.7).
(4) The collection \(T\) has the four-out-of-five property (Definition 5.4.6.8).

Then every thin 2-simplex of \(\mathcal{C}\) belongs to \(T\).
Proof. Let \(\sigma\) be a thin 2-simplex of \(\mathcal{C}\), whose 1 -skeleton we represent by the diagram

Applying assumption (2), we can choose a thin 2-simplex \(\sigma^{\prime}\) of \(\mathcal{C}\) which belongs to \(T\) whose restriction to the 1 -skeleton of \(\Delta^{2}\) is represented by the diagram

The edge \(g\) determines a morphism of simplicial sets \(\Delta^{1} \rightarrow \mathcal{C}\). Let \(\mathcal{E}\) denote the fiber product \(\Delta^{1} \times_{\mathcal{C}} \mathcal{C}_{X /}\). Since the projection map \(\mathcal{C}_{X /} \rightarrow \mathcal{C}\) is an interior fibration (Proposition 5.4.3.1, it follows from Remark 5.4.2.4 and Example 5.4.2.2 that the projection map \(\pi: \mathcal{E} \rightarrow \Delta^{1}\) is an inner fibration; in particular, \(\mathcal{E}\) is an \(\infty\)-category. Moreover, we can identify the edges \(f, h\), and \(h^{\prime}\) of \(\mathcal{C}\) with objects \(\widetilde{Y}, \widetilde{Z}\), and \(\widetilde{Z}^{\prime}\) of \(\mathcal{E}\), and the 2-simplices \(\sigma\) and \(\sigma^{\prime}\) with morphisms \(\widetilde{h}: \widetilde{Y} \rightarrow \widetilde{Z}\) and \(\widetilde{h}^{\prime}: \widetilde{Y} \rightarrow \widetilde{Z}^{\prime}\). Since \(\sigma\) and \(\sigma^{\prime}\) are both thin, the morphisms \(\widetilde{h}\) and \(\widetilde{h}^{\prime}\) are both \(\pi\)-cocartesian (Theorem 5.4.4.1). It follows that \(\widetilde{h}\) and \(\widetilde{h}^{\prime}\) are isomorphic when viewed as objects of the \(\infty\)-category \(\mathcal{E}_{\widetilde{Y} /}\) (see Remark 5.1.3.8). We can therefore choose a 2-simplex \(\rho\) of \(\mathcal{E}_{\widetilde{Y} /}\) whose 1 -skeleton is given by the diagram

which we can identify with a 4 -simplex \(\tau: \Delta^{4} \rightarrow \mathcal{C}\). For \(0 \leq i<j<k \leq 4\), let \(\tau_{k j i}\) denote the 2 -simplex of \(\mathcal{C}\) given by \(\left.\tau\right|_{\mathrm{N}_{\bullet}(\{i<j<k\})}\). By construction, the 2 -simplex \(\tau_{310}\) is equal to \(\sigma^{\prime}\), and therefore belongs to \(T\). Moreover, the 2 -simplices \(\tau_{420}, \tau_{321}, \tau_{431}\), and \(\tau_{432}\) are right-degenerate, and therefore belong to \(T\) by virtue of assumption (1). Since \(T\) has the four-out-of-five-property, it follows that \(\tau_{430}\) belongs to \(T\). Applying the inner exchange property to the 3 -simplex \(\left.\tau\right|_{\mathrm{N}_{\bullet}(\{0<1<3<4\})}\), we deduce that the 2 -simplex \(\sigma=\tau_{410}\) also belongs to \(T\), as desired.

\subsection*{5.4.7 Functors of \((\infty, 2)\)-Categories}

Let \(\mathcal{C}\) and \(\mathcal{D}\) be \(\infty\)-categories. Recall that a functor from \(\mathcal{C}\) to \(\mathcal{D}\) is a morphism of simplicial sets \(F: \mathcal{C} \rightarrow \mathcal{D}\) (Definition 1.5.0.1). In this case, it is automatic that \(F\) carries isomorphisms in \(\mathcal{C}\) to isomorphisms in \(\mathcal{D}\) (Remark 1.5.1.6). Beware that the ( \(\infty, 2\) )-categorical analogue of this statement is false: if \(\mathcal{C}\) and \(\mathcal{D}\) are ( \(\infty, 2\) )-categories, then a morphism of
simplicial sets \(F: \mathcal{C} \rightarrow \mathcal{D}\) will generally not carry thin 2-simplices of \(\mathcal{C}\) to thin 2-simplices of \(\mathcal{D}\). This motivates the following:
01 Y 5 Definition 5.4.7.1. Let \(\mathcal{C}\) and \(\mathcal{D}\) be \((\infty, 2)\)-categories. A functor from \(\mathcal{C}\) to \(\mathcal{D}\) is a morphism of simplicial sets \(F: \mathcal{C} \rightarrow \mathcal{D}\) which carries thin 2 -simplices of \(\mathcal{C}\) to thin 2-simplices of \(\mathcal{D}\).

01 Y 6 Example 5.4.7.2. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category and let \(\mathcal{D}\) be an \(\infty\)-category. Then every 2 -simplex of \(\mathcal{D}\) is thin, so every morphism of simplicial sets \(F: \mathcal{C} \rightarrow \mathcal{D}\) is a functor. In particular, when \(\mathcal{C}\) and \(\mathcal{D}\) are \(\infty\)-categories, Definition 5.4.7.1 reduces to Definition 1.5.0.1.

01 Y 7 Example 5.4.7.3. Let \(\mathcal{C}\) and \(\mathcal{D}\) be 2-categories. By virtue of Theorem 2.3.4.1 and Corollary 2.3.4.5, passage to the Duskin nerve induces a bijection

01Y8 Remark 5.4.7.4 (Functoriality). Let \(\mathcal{C}\) and \(\mathcal{D}\) be \((\infty, 2)\)-categories, and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets. Then \(F\) is a functor (Definition 5.4.7.1) if and only it carries \(\operatorname{Pith}(\mathcal{C})\) into \(\operatorname{Pith}(\mathcal{D})\). If this condition is satisfied, then \(\operatorname{Pith}(F)=\left.F\right|_{\operatorname{Pith}(\mathcal{C})}\) can be regarded as a functor from the \(\infty\)-category \(\operatorname{Pith}(\mathcal{C})\) to the \(\infty\)-category \(\operatorname{Pith}(\mathcal{D})\).

047S Remark 5.4.7.5. Let \(\mathcal{C}\) and \(\mathcal{D}\) be \((\infty, 2)\)-categories and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets. If \(F\) is a functor of \((\infty, 2)\)-categories and \(u: X \rightarrow Y\) is an isomorphism in the \((\infty, 2)\)-category \(\mathcal{C}\), then \(F(u): F(X) \rightarrow F(Y)\) is an isomorphism in the \((\infty, 2)\) category \(\mathcal{D}\) (see Definition 5.4.5.12). This follows by applying Remark 1.5.1.6 to the functor \(\operatorname{Pith}(F): \operatorname{Pith}(\mathcal{C}) \rightarrow \operatorname{Pith}(\mathcal{D})\) of Remark 5.4.7.4. Beware that, if \(F\) is not assumed to be a functor, then \(F(u)\) need not be an isomorphism.

01 Y9 Remark 5.4.7.6. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(\mathcal{D}\) be an \((\infty, 2)\)-category. Then every functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) takes values in the pith \(\operatorname{Pith}(\mathcal{D}) \subseteq \mathcal{D}\). Consequently, the inclusion \(\operatorname{Pith}(\mathcal{D}) \hookrightarrow \mathcal{D}\) induces a bijection
\(\{\) Functors of \(\infty\)-categories from \(\mathcal{C}\) to \(\operatorname{Pith}(\mathcal{D})\}\)
\(\{\) Functors of \((\infty, 2)\)-categories from \(\mathcal{C}\) to \(\mathcal{D}\}\).
Note that this property (together with Proposition 5.4.5.6) characterize the simplicial set \(\operatorname{Pith}(\mathcal{D})\) up to unique isomorphism.

Remark 5.4.7.7. The existence of morphisms between ( \(\infty, 2\) )-categories which do not 01YA preserve thin 2 -simplices should be viewed as a feature of our formalism, rather than a bug. Recall that, if \(\mathcal{C}\) and \(\mathcal{D}\) are 2-categories, then Theorem 2.3.4.1 supplies a bijection
\(\{\) Strictly unitary lax functors \(\mathcal{C} \rightarrow \mathcal{D}\}\)

\(\left\{\right.\) Morphisms of simplicial sets \(\left.\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{D})\right\}\).
Consequently, we can think of general morphisms of simplicial sets as providing a generalization of the notion of (strictly) unitary lax functors to the setting of \((\infty, 2)\)-categories.

Warning 5.4.7.8. For every pair of simplicial sets \(\mathcal{C}\) and \(\mathcal{D}\), we let \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\) denote the
01 YB simplicial set introduced in Construction 1.5.3.1. When working with \((\infty, 2)\)-categories, this notation is potentially confusing. By construction, vertices of the simplicial set Fun \((\mathcal{C}, \mathcal{D})\) can be identified with morphisms of simplicial sets \(F: \mathcal{C} \rightarrow \mathcal{D}\). If \(\mathcal{C}\) and \(\mathcal{D}\) are \((\infty, 2)\)-categories, then such morphisms need not carry thin 2 -simplices of \(\mathcal{C}\) to thin 2 -simplices of \(\mathcal{D}\), and therefore need not correspond to functors from \(\mathcal{C}\) to \(\mathcal{D}\) in the sense of Definition 5.4.7.1. We will return to this point in §[?].

The following criterion is often useful for checking that a morphism of \((\infty, 2)\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\) is a functor:

Proposition 5.4.7.9. Let \(\mathcal{C}\) and \(\mathcal{D}\) be \((\infty, 2)\)-categories and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism 01 YC of simplicial sets. The following conditions are equivalent:
(1) The morphism \(F\) is a functor: that is, it carries thin 2 -simplices of \(\mathcal{C}\) to thin 2 -simplices of \(\mathcal{D}\).
(2) For every pair of morphisms \(f: X \rightarrow Y\) and \(g: Y \rightarrow Z\) of \(\mathcal{C}\), there exists a thin 2-simplex \(\sigma\) of \(\mathcal{C}\) with \(d_{0}^{2}(\sigma)=g\) and \(d_{2}^{2}(\sigma)=f\), as indicated in the diagram

such that \(F(\sigma)\) is a thin 2-simplex of \(\mathcal{D}\).

Proof. The implication (1) \(\Rightarrow(2)\) is immediate. To prove the converse, let \(T\) be the collection of all 2-simplices of \(\mathcal{C}\) for which \(F(\sigma)\) is a thin 2-simplex of \(\mathcal{D}\). Since the collection of thin 2 -simplices of \(\mathcal{D}\) has the four-out-of-five property (Proposition 5.4.6.11), it follows that \(T\) also has the four-out-of-five property (Remark 5.4.6.10). Since the collection of thin 2-simplices of \(\mathcal{D}\) has the inner exchange property (Proposition 5.4.5.10), \(T\) has the inner exchange property (Remark 5.4.5.9). Since \(\mathcal{D}\) is an \((\infty, 2)\)-category, every degenerate 2 -simplex of \(\mathcal{D}\) is thin, so every degenerate 2 -simplex of \(\mathcal{C}\) belongs to \(T\). If condition (2) is satisfied, then Proposition 5.4.6.14 guarantees that every thin 2 -simplex of \(\mathcal{C}\) belongs to \(T\), so that \(F\) is a functor.

01YD Proposition 5.4.7.10. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an interior fibration of \((\infty, 2)\)-categories (Definition 5.4.2.1). Then:
(1) The morphism \(F\) is a functor of \((\infty, 2)\)-categories: that is, it carries thin 2-simplices of \(\mathcal{C}\) to thin 2-simplices of \(\mathcal{D}\), and therefore induces a functor \(\operatorname{Pith}(F): \operatorname{Pith}(\mathcal{C}) \rightarrow \operatorname{Pith}(\mathcal{D})\).
(2) The diagram of simplicial sets

is a pullback square.
(3) The functor \(\operatorname{Pith}(F): \operatorname{Pith}(\mathcal{C}) \rightarrow \operatorname{Pith}(\mathcal{D})\) is an inner fibration of \(\infty\)-categories.

Proof. We will prove assertion (1) by showing that \(F\) satisfies the criterion of Proposition 5.4.7.9. Let \(f: X \rightarrow Y\) and \(g: Y \rightarrow Z\) be morphisms of \(\mathcal{C}\). Since \(\mathcal{D}\) is an \((\infty, 2)\)-category, we can choose a thin 2-simplex \(\bar{\sigma}\) of \(\mathcal{D}\) satisfying \(d_{0}^{2}(\bar{\sigma})=F(g)\) and \(d_{2}^{2}(\bar{\sigma})=F(f)\), which we depict as a diagram

Since \(F\) is an interior fibration, the lifting problem

admits a solution. Then \(\sigma\) is a thin 2-simplex of \(\mathcal{C}\) (Lemma 5.4.2.6) for which the image \(\bar{\sigma}=F(\sigma)\) is a thin 2-simplex of \(\mathcal{D}\).

We now prove (2). Let \(\tau\) be an \(m\)-simplex of the simplicial set \(\mathcal{C}\), and suppose that \(F(\tau)\) belongs to the pith \(\operatorname{Pith}(\mathcal{D})\). We wish to show that \(\tau\) belongs to \(\operatorname{Pith}(\mathcal{C})\) : that is, that it carries each 2-simplex of \(\Delta^{m}\) to a thin 2-simplex of \(\mathcal{C}\). This follows immediately from Lemma 5.4.2.6. since the composite map
\[
\Delta^{2} \rightarrow \Delta^{m} \xrightarrow{\tau} \mathcal{C} \xrightarrow{F} \mathcal{D}
\]
is a thin 2 -simplex of \(\mathcal{D}\).
Combining (2) with Remark 5.4.2.4 we conclude that the functor \(\operatorname{Pith}(F): \operatorname{Pith}(\mathcal{C}) \rightarrow\) \(\operatorname{Pith}(\mathcal{D})\) is an interior fibration. Since \(\operatorname{Pith}(\mathcal{D})\) is an \(\infty\)-category (Proposition 5.4.5.6), it follows that \(\operatorname{Pith}(F)\) is an inner fibration (Example 5.4.2.2).

Corollary 5.4.7.11. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category, let \(f: K \rightarrow \mathcal{C}\) be a morphism of simplicial 01 YE sets, and let
\[
q^{\prime}: \mathcal{C}_{f /} \rightarrow \mathcal{C} \quad q: \mathcal{C}_{/ f} \rightarrow \mathcal{C}
\]
be the projection maps. Then:
(1) The functor \(\operatorname{Pith}(q): \operatorname{Pith}\left(\mathcal{C}_{/ f}\right) \rightarrow \operatorname{Pith}(\mathcal{C})\) is a cartesian fibration of \(\infty\)-categories. Moreover, a morphism \(u\) of \(\operatorname{Pith}\left(\mathcal{C}_{/ f}\right)\) is \(\operatorname{Pith}(q)\)-cartesian if and only if, for every vertex \(z \in K\), the composite map
\[
\Delta^{2} \simeq \Delta^{1} \star\{z\} \hookrightarrow \Delta^{1} \star K \xrightarrow{u} \mathcal{C}
\]
is a thin 2-simplex of \(\mathcal{C}\).
(2) The functor \(\operatorname{Pith}\left(q^{\prime}\right): \operatorname{Pith}\left(\mathcal{C}_{f /}\right) \rightarrow \operatorname{Pith}(\mathcal{C})\) is a cocartesian fibration of \(\infty\)-categories. Moreover, a morphism \(v\) of \(\operatorname{Pith}\left(\mathcal{C}_{f /}\right)\) is \(\operatorname{Pith}\left(q^{\prime}\right)\)-cocartesian if and only if, for every vertex \(x \in K\), the composite map
\[
\Delta^{2} \simeq\{x\} \star \Delta^{1} \hookrightarrow K \star \Delta^{1} \xrightarrow{v} \mathcal{C}
\]
is a thin 2-simplex of \(\mathcal{C}\).

Proof. Combine Propositions 5.4.7.10 and 5.4.5.14
Specializing Corollary 5.4.7.11 to the case \(K=\Delta^{0}\), we obtain the following:
01 YF Corollary 5.4.7.12. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category and let \(Z\) be an object of \(\mathcal{C}\). Then:
(1) The projection map \(\pi: \mathcal{C}_{/ Z} \rightarrow \mathcal{C}\) induces a cartesian fibration of \(\infty\)-categories \(\operatorname{Pith}(\pi)\) : \(\operatorname{Pith}\left(\mathcal{C}_{/ Z}\right) \rightarrow \operatorname{Pith}(\mathcal{C})\).
(2) A morphism \(u\) of \(\operatorname{Pith}\left(\mathcal{C}_{/ Z}\right)\) is \(\operatorname{Pith}(\pi)\)-cartesian if and only if it corresponds to a thin 2 -simplex of \(\mathcal{C}\) (in this case, it is also \(\pi\)-cartesian when viewed as a morphism of \(\mathcal{C}_{/ Z}\) ).
(3) The inclusion \(\operatorname{Pith}(\mathcal{C}) \hookrightarrow \mathcal{C}\) induces an isomorphism from \(\operatorname{Pith}(\mathcal{C})_{/ Z}\) to the (non-full) subcategory of \(\operatorname{Pith}\left(\mathcal{C}_{/ Z}\right)\) spanned by the \(\pi\)-cartesian morphisms.

Proof. Assertions (1) and (2) follow from Corollary 5.4.7.11, and assertion (3) is an immediate consequence of (2).

01 YG Remark 5.4.7.13. Recall that every cartesian fibration of simplicial sets \(\pi: \mathcal{E} \rightarrow \mathcal{D}\) has an underlying right fibration \(\pi^{\prime}: \mathcal{E}^{\prime} \rightarrow \mathcal{D}\), given by restricting \(\pi\) to the simplicial subset \(\mathcal{E}^{\prime} \subseteq \mathcal{E}\) spanned by those simplices \(\sigma: \Delta^{n} \rightarrow \mathcal{E}\) which carry each edge of \(\Delta^{n}\) to \(\pi\)-cartesian edge of \(\mathcal{E}\). Corollary 5.4.7.12 asserts that, when \(\pi\) is the cartesian fibration \(\operatorname{Pith}\left(\mathcal{C}_{/ Z}\right) \rightarrow \operatorname{Pith}(\mathcal{C})\) associated to a choice of object \(Z\) of an \((\infty, 2)\)-category \(\mathcal{C}\), then \(\pi^{\prime}\) can be identified with the right fibration \(\operatorname{Pith}(\mathcal{C})_{/ Z} \rightarrow \operatorname{Pith}(\mathcal{C})\) supplied by Corollary 4.3.6.11 compare with Proposition 5.4.5.13,

We can also use Proposition 5.4.7.10 to deduce a relative version of Proposition 5.4.3.1.
01 YH Corollary 5.4.7.14. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category, let \(f: K \rightarrow \mathcal{C}\) be a morphism of simplicial sets, and let \(f_{0}=\left.f\right|_{K_{0}}\) denote the restriction of \(f\) to a simplicial subset \(K_{0} \subseteq K\). Then the projection maps
\[
\mathcal{C}_{f /} \rightarrow \mathcal{C}_{f_{0} /} \quad \mathcal{C}_{/ f} \rightarrow \mathcal{C}_{/ f_{0}}
\]
are interior fibrations of \((\infty, 2)\)-categories.
01 YJ Warning 5.4.7.15. In the situation of Corollary 5.4.7.14, the induced map \(\operatorname{Pith}\left(\mathcal{C}_{/ f}\right) \rightarrow\) \(\operatorname{Pith}\left(\mathcal{C}_{/ f_{0}}\right)\) is generally not a cartesian fibration, and the induced map \(\operatorname{Pith}\left(\mathcal{C}_{f /}\right) \rightarrow \operatorname{Pith}\left(\mathcal{C}_{f_{0} /}\right)\) is generally not a cocartesian fibration.

Proof of Corollary 5.4.7.14. We will show that the map of slice simplicial sets \(q: \mathcal{C}_{/ f} \rightarrow \mathcal{C}_{/ f_{0}}\) is an interior fibration; the analogous statement for coslice simplicial sets follows by a similar
argument. We first observe that \(\mathcal{C}_{/ f_{0}}\) is an ( \(\infty, 2\) )-category (Corollary 5.4.3.4). Suppose we are given an integer \(n \geq 2\) and a lifting problem

We wish to show that this lifting problem admits a solution provided that one of the following conditions is satisfied:
(a) The integer \(i\) is equal to 0 and \(\left.\sigma_{0}\right|_{\mathrm{N}_{\bullet}(\{0<1\})}\) is a degenerate edge of \(\mathcal{C}_{/ f}\).
(b) The integer \(i\) satisfies \(0<i<n\) and the restriction \(\left.\bar{\sigma}\right|_{\mathrm{N}} \cdot(\{i-1<i<i+1\})\) is a thin 2-simplex of \(\mathcal{C}_{/ f_{0}}\).
(c) The integer \(i\) is equal to \(n\) and \(\left.\sigma_{0}\right|_{N_{\bullet}(\{n-1<n\})}\) is a degenerate edge of \(\mathcal{C}_{/ f}\).

In cases \((a)\) and \((c)\), this follows immediately from Proposition 5.4.3.8 In case \((b)\), it suffices (by virtue of Proposition 5.4.3.8) to verify that the composite map
\[
\Delta^{2} \simeq \mathrm{~N}_{\bullet}(\{i-1<i<i+1\}) \subseteq \Delta^{n} \xrightarrow{\bar{\sigma}} \mathcal{C}_{/ f_{0}} \rightarrow \mathcal{C}
\]
is a thin 2 -simplex of \(\mathcal{C}\). This follows from our hypothesis, since the projection map \(\mathcal{C}_{/ f_{0}} \rightarrow \mathcal{C}\) preserves thin 2-simplices (Proposition 5.4.7.10).

\subsection*{5.4.8 Strict \((\infty, 2)\)-Categories}

Let \(\mathcal{C}\) be a simplicial category. If \(\mathcal{C}\) is locally Kan, then Theorem 2.4.5.1 guarantees 01YK that the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\) is an \(\infty\)-category. Our goal in this section is to establish an ( \(\infty, 2\) )-categorical variant of this result:

Theorem 5.4.8.1. Let \(\mathcal{C}\) be a simplicial category. Suppose that, for every pair of objects 01 YL \(X\) and \(Y\), the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\). is an \(\infty\)-category. Then the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\) is an \((\infty, 2)\)-category.

We will deduce Theorem 5.4.8.1 from the following thinness criterion for 2-simplices of the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\).

Proposition 5.4.8.2. Let \(\mathcal{C}\) be a simplicial category. Suppose that, for every pair of objects 01 YM \(X\) and \(Y\), the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\). is an \(\infty\)-category. Let \(\sigma\) be a 2-simplex of the
homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\), which we identify with a (not necessarily commutative) diagram

in \(\mathcal{C}\) together with an edge \(\mu: g \circ f \rightarrow h\) in the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Z)\). If \(\mu\) is an isomorphism, then \(\sigma\) is thin.

Proof. Suppose we are given integers \(n \geq 3,0<i<n\), and a morphism of simplicial sets \(\tau_{0}: \Lambda_{i}^{n} \rightarrow \mathrm{~N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) for which the restriction \(\left.\tau_{0}\right|_{\mathrm{N}}(\{i-1<i<i+1\})\) is the 2 -simplex \(\sigma\). We wish to show that \(\tau_{0}\) can be extended to an \(n\)-simplex of \(\mathcal{C}\). Let Path \([n]\) • be the simplicial category described in Notation 2.4.3.1, and let us identify Path \(\left[\Lambda_{i}^{n}\right] \bullet\) with the simplicial subcategory of Path \([n]\) • described in Proposition 2.4.5.8. Then \(\tau_{0}\) can be identified with a simplicial functor \(F_{0}: \operatorname{Path}\left[\Lambda_{i}^{n}\right] \bullet \rightarrow \mathcal{C}\), and we wish to show that \(\tau_{0}\) can be extended to a simplicial functor \(F: \operatorname{Path}[n] \bullet \rightarrow \mathcal{C}\).

For \(0 \leq j \leq n\), let \(C_{j}\) denote the object of \(\mathcal{C}\) given by \(F_{0}(j)\). For \(1 \leq j \leq n\), let \(u_{j}: C_{j-1} \rightarrow C_{j}\) be the morphism in \(\mathcal{C}\) obtained by applying \(F_{0}\) to the unique vertex of \(\operatorname{Hom}_{\operatorname{Path}\left[\Lambda_{i}^{n}\right]}(j-1, j)\), so that we have a chain of composable morphisms
\[
C_{0} \xrightarrow{u_{1}} C_{1} \xrightarrow{u_{2}} \cdots \xrightarrow{u_{n}} C_{n}
\]
in the simplicial category \(\mathcal{C}\). Let \(\square^{n-1}\) denote the simplicial cube of dimension \((n-1)\) and let \(\Pi_{i}^{n-1} \subseteq \square^{n-1}\) denote the hollow cube of Notation 2.4.5.5. so that Remark 2.4.5.4 and Proposition 2.4.5.8 supply isomorphisms
\[
\operatorname{Hom}_{\operatorname{Path}[n]}(0, n) \bullet \simeq \square^{n-1} \quad \operatorname{Hom}_{\operatorname{Path}\left[\Lambda_{i}^{n}\right]}(0, n) \bullet \simeq \Pi_{i}^{n-1} .
\]

Let \(\lambda_{0}\) denote the composite map
\[
\Pi_{i}^{n-1} \simeq \operatorname{Hom}_{\operatorname{Path}\left[\Lambda_{i}^{n}\right]}(0, n) \bullet \xrightarrow{F_{0}} \operatorname{Hom}_{\mathcal{C}}\left(C_{0}, C_{n}\right) \bullet .
\]

By virtue of Corollary 2.4.5.10 it will suffice to show that \(\lambda_{0}\) can be extended to a morphism of simplicial sets \(\lambda: \square^{n-1} \rightarrow \operatorname{Hom}_{\mathcal{C}}\left(C_{0}, C_{n}\right)\) 。

Let \(I\) denote the set \(\{1,2, \ldots, i-1, i+1, \cdots, n-1\}\), so that we can identify \(\square^{n-1}\) with the product \(\Delta^{1} \times \square^{I}\). Under this identification, \(\Pi_{i}^{n-1}\) corresponds to the pushout
\[
\left(\Delta^{1} \times \partial \square^{I}\right) \coprod_{\left(\{0\} \times \partial \square^{I}\right)}\left(\{0\} \times \square^{I}\right)
\]

Let \(v \in \square^{I}\) be the initial vertex (corresponding to the empty subset of \(I\) ), and let \(e\) be the edge of \(\operatorname{Hom}_{\mathcal{C}}\left(C_{0}, C_{n}\right)\) • given by the composite map
\[
\Delta^{1} \times\{v\} \hookrightarrow \Delta^{1} \times \partial \square^{I} \hookrightarrow \Pi_{i}^{n-1} \xrightarrow{\lambda_{0}} \operatorname{Hom}_{\mathcal{C}}\left(C_{0}, C_{n}\right) .
\]

Unwinding the definitions, we see that \(e\) is the image of \(\mu\) under the morphism of simplicial sets
\[
\operatorname{Hom}_{\mathcal{C}}\left(C_{i-1}, C_{i+1}\right) \bullet \rightarrow \operatorname{Hom}_{\mathcal{C}}\left(C_{0}, C_{n}\right) \bullet \quad \rho \mapsto u_{n} \circ u_{n-1} \circ \cdots u_{i+2} \circ \rho \circ u_{i-1} \circ \cdots \circ u_{1},
\]
and is therefore an isomorphism in the \(\infty\)-category \(\operatorname{Hom}_{\mathcal{C}}\left(C_{0}, C_{n}\right)\). Note that every simplex of \(\square^{I}\) which is not contained in the boundary \(\partial \square^{I}\) has initial vertex \(v\). The existence of the desired extension \(\lambda\) now follows from Proposition 4.4.5.8.

Example 5.4.8.3. Let \(\mathcal{C}\) be a simplicial category. Suppose that, for every pair of objects \(X\)
01YN and \(Y\), the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{\bullet}\) is an \(\infty\)-category. Then the inclusion \(\mathrm{N}_{\bullet}(\mathcal{C}) \hookrightarrow \mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\) of Remark 2.4.3.8 carries every 2-simplex of the ordinary nerve \(\mathrm{N}_{\bullet}(\mathcal{C})\) to a thin 2-simplex of the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\).

To verify the outer horn-filling conditions which appear in Definition 5.4.1.1, we will need a variant of Proposition 2.4.5.8.

Proposition 5.4.8.4. Let \(n \geq 2\) be an integer and let \(F: \operatorname{Path}\left[\Lambda_{n}^{n}\right] \bullet \rightarrow \operatorname{Path}\left[\Delta^{n}\right]\). be the 01YP simplicial functor induced by the horn inclusion \(\Lambda_{n}^{n} \hookrightarrow \Delta^{n}\). Then:
(a) The functor \(F\) is bijective on objects; in particular, we can identify the objects of \(\operatorname{Path}\left[\Lambda_{n}^{n}\right]\) • with elements of the set \([n]=\{0<1<\cdots<n\}\).
(b) For \((0, n-1) \neq(i, j) \neq(0, n)\), the functor \(F\) induces an isomorphism of simplicial sets
\[
\operatorname{Hom}_{\operatorname{Path}\left[\Lambda_{n}^{n}\right]}(i, j)_{\bullet} \simeq \operatorname{Hom}_{\operatorname{Path}\left[\Delta^{n}\right]}(i, j)_{\bullet} .
\]
(c) The functor \(F\) induces a monomorphism of simplicial sets
\[
\operatorname{Hom}_{\text {Path }\left[\Lambda_{n}^{n}\right]}(0, n-1) \bullet \hookrightarrow \operatorname{Hom}_{\text {Path }\left[\Delta^{n}\right]}(0, n-1)_{\bullet},
\]
whose image can be identified with the boundary
\[
\partial \square^{n-2} \subseteq \square^{n-2} \simeq \operatorname{Hom}_{\text {Path }\left[\Delta^{n}\right]}(0, n-1) .
\]
introduced in Notation 2.4.5.5.
(d) The functor \(F\) induces a monomorphism of simplicial sets
\[
\operatorname{Hom}_{\operatorname{Path}\left[\Lambda_{n}^{n}\right]}(0, n) \bullet \hookrightarrow \operatorname{Hom}_{\operatorname{Path}\left[\Delta^{n}\right]}(0, n)_{\bullet},
\]
whose image can be identified with the hollow cube
\[
\sqcup_{n-1}^{n-1} \subseteq \square^{n-1} \simeq \operatorname{Hom}_{\operatorname{Path}\left[\Delta^{n}\right]}(0, n)
\]
introduced in Notation 2.4.5.5.
Proof. Assertion (a) is immediate from Theorem 2.4.4.10. To prove the remaining assertions, fix an integer \(m \geq 0\). Using Lemma 2.4.4.16, we see that Path \(\left[\Delta^{n}\right]_{m}\) can be identified with the path category Path \([G]\) of a directed graph \(G\) which can be described concretely as follows:
- The vertices of \(G\) are the elements of the set \([n]=\{0<1<\cdots<n\}\).
- For \(0 \leq i<j \leq n\), an edge of \(G\) with source \(j\) and target \(k\) is a chain of subsets
\[
\{i, i+1, \ldots, j-1, j\} \supseteq I_{0} \supseteq \cdots \supseteq I_{m}=\{i, j\}
\]

Using Theorem 2.4.4.10, we see that Path \(\left[\Lambda_{n}^{n}\right]_{m}\) can be identified with the path category of the directed subgraph \(G^{\prime} \subseteq G\) having the same vertices, where an edge \(\vec{I}=\left(I_{0} \supseteq \cdots \supseteq I_{m}\right)\) of \(G\) belongs to \(G^{\prime}\) if and only if the subset \(I_{0} \subseteq[n]\) corresponds to a simplex of \(\Delta^{n}\) which belongs to the horn \(\Lambda_{n}^{n}\) : that is, if and only if \([n-1] \nsubseteq I_{0}\). We now argue as follows:
- For \((0, n-1) \neq(i, j) \neq(0, n)\), every path from \(i\) to \(j\) in the graph \(G\) is also a path in the graph \(G^{\prime}\). This proves (b).
- Let \(\tau\) be a morphism from 0 to \(n-1\) in the category \(\operatorname{Path}[n]_{m}\), which we identify with a chain of subsets
\[
[n-1] \supseteq I_{0} \supseteq I_{1} \supseteq \cdots \supseteq I_{m} \supseteq\{0, n-1\} .
\]

Then \(\tau\) belongs to \(\operatorname{Path}\left[\Lambda_{n}^{n}\right]_{m}\) if and only if \(I_{0} \neq[n-1]\) or \(I_{m} \neq\{0, n-1\}\) : that is, if and only if \(\tau\) corresponds to an \(m\)-simplex of the cube \(\partial \square^{n-2} \subseteq \square^{n-2}\). This proves (c).
- Let \(\tau\) be a morphism from 0 to \(n\) in the category \(\operatorname{Path}[n]_{m}\), which we identify with a chain of subsets
\[
[n] \supseteq I_{0} \supseteq I_{1} \supseteq \cdots \supseteq I_{m} \supseteq\{0, n\}
\]

Then \(\tau\) belongs to \(\operatorname{Path}\left[\Lambda_{n}^{n}\right]_{m}\) if and only if \(I_{0} \neq[n]\) or \(\{0, n\} \neq I_{m} \neq\{0, n-1, n\}\) : that is, if and only if \(\tau\) corresponds to an \(m\)-simplex of the hollow cube \(\sqcup_{n-1}^{n-1} \subseteq \square^{n-1}\). This proves (d).

Corollary 5.4.8.5. Let \(\mathcal{C}\) be a simplicial category, let \(n \geq 2\) be an integer, and let \(\sigma_{0}: 01 \mathrm{YQ}\) \(\Lambda_{n}^{n} \rightarrow \mathrm{~N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) be a morphism of simplicial sets, which we identify with a simplicial functor \(F: \operatorname{Path}\left[\Lambda_{n}^{n}\right] \bullet \rightarrow \mathcal{C}\) inducing a map of simplicial sets
\[
\lambda_{0}: \sqcup_{n-1}^{n-1} \simeq \operatorname{Hom}_{\text {Path }\left[\Lambda_{n}^{n}\right]}(0, n) \bullet \rightarrow \operatorname{Hom}_{\mathcal{C}}(F(0), F(n)) \bullet
\]

Suppose that \(F\) carries the edge \(\mathrm{N}_{\bullet}(\{n-1<n\}) \subseteq \Lambda_{n}^{n}\) to an isomorphism in \(\mathcal{C}\). Then the restriction map

is bijective.
Proof. By virtue of Corollary 2.4.6.13, we can identify \(\theta\) with a pullback of the restriction map

It will therefore suffice to show that \(\theta^{\prime}\) is bijective. Let us identify \(\Delta^{n-1}\) with a simplicial subset of \(\Delta^{n}\) (via the map which is the identity on vertices), so that the boundary \(\partial \Delta^{n-1}\) is contained in the horn \(\Lambda_{n}^{n}\). Let \(\tau_{0}\) denote the restriction of \(\sigma_{0}\) to \(\partial \Delta^{n-1}\), let \(\mu_{0}\) denote the \(\lambda_{0}\) to the simplicial subset \(\partial \square^{n-2} \times\{0\} \subseteq \sqcup_{n-1}^{n-1}\). Note that \(\mu_{0}\) can be written as a composition
\[
\partial \square^{n-2} \simeq \operatorname{Hom}_{\operatorname{Path}\left[\partial \Delta^{n-1}\right]}(0, n-1) \bullet \xrightarrow{\nu_{0}} \operatorname{Hom}_{\mathcal{C}}(F(0), F(n-1)) \bullet \xrightarrow{e \bullet} \operatorname{Hom}_{\mathcal{C}}(F(0), F(n)) \bullet,
\]
where \(\nu_{0}\) is determined by \(\tau_{0}\). Using the identifications
\[
\partial \Delta^{n} \simeq \Delta^{n-1} \coprod_{\partial \Delta^{n-1}} \Lambda_{n}^{n} \quad \partial \square^{n-1} \simeq\left(\square^{n-2} \times\{0\}\right) \coprod_{\left(\partial \square^{n-2} \times\{0\}\right)} \sqcup_{n-1}^{n-1},
\]
we can identify \(\theta^{\prime}\) with composition

Here the first map is bijective by virtue of Corollary 2.4.6.13, and the second by virtue of our assumption that \(e\) is an isomorphism in the simplicial category \(\mathcal{C}\).

Proof of Theorem 5.4.8.1. Let \(\mathcal{C}\) be a simplicial category with the property that, for every pair of objects \(X, Y \in \mathcal{C}\), the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\). is an \(\infty\)-category. Using Example 5.4.8.3, we immediately deduce that every degenerate 2 -simplex of the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) is thin, and that every morphism \(\Lambda_{1}^{2} \rightarrow \mathrm{~N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) can be extended to a thin 2 -simplex of \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\). We will complete the proof that \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) is an \((\infty, 2)\)-category by showing that, if \(n \geq 3\) and \(\sigma_{0}: \Lambda_{n}^{n} \rightarrow \mathrm{~N}_{\bullet}^{\text {hc }}(\mathcal{C})\) is a morphism of simplicial sets for which the 2-simplex \(\left.\sigma_{0}\right|_{\mathrm{N}_{\bullet}(\{0<n-1<n\})}\) is right-degenerate, then \(\sigma_{0}\) can be extended to an \(n\)-simplex \(\sigma\) of \(\mathcal{C}\) (the dual assertion regarding extension of maps \(\Lambda_{0}^{n} \rightarrow \mathrm{~N}_{\bullet}^{\text {hc }}(\mathcal{C})\) follows by the same argument, applied to the opposite simplicial category \(\mathcal{C}^{\mathrm{op}}\) ). Let us identify \(\sigma_{0}\) with a simplicial functor \(F: \operatorname{Path}\left[\Lambda_{n}^{n}\right] \bullet \mathcal{C}\), carrying each element \(i \in[n]\) to an object \(C_{i} \in \mathcal{C}\).

Let \(\square^{n-1}\) denote the simplicial cube of dimension \((n-1)\) and let \(\sqcup_{n-1}^{n-1} \subseteq \square^{n-1}\) denote the hollow cube of Notation 2.4.5.5, so that Remark 2.4.5.4 and Proposition 5.4.8.4 supply isomorphisms
\[
\operatorname{Hom}_{\text {Path }[n]}(0, n) \bullet \simeq \square^{n-1} \quad \operatorname{Hom}_{\operatorname{Path}\left[\Lambda_{n}^{n}\right]}(0, n) \simeq \sqcap_{n-1}^{n-1}
\]

Let \(\lambda_{0}\) denote the composite map
\[
\sqcup_{n-1}^{n-1} \simeq \operatorname{Hom}_{\text {Path }\left[\Lambda_{n}^{n}\right]}(0, n) \bullet \xrightarrow{F} \operatorname{Hom}_{\mathcal{C}}\left(C_{0}, C_{n}\right) .
\]

Note that our degeneracy assumption on \(\left.\sigma_{0}\right|_{\mathrm{N}_{\bullet}(\{0<n-1<n\})}\) guarantees that the functor \(F\) induces an isomorphism \(C_{n-1} \simeq C_{n}\) in the category \(\mathcal{C}\). By virtue of Corollary 5.4.8.5, it will suffice to show that \(\lambda_{0}\) can be extended to a morphism of simplicial sets \(\lambda: \square^{n-1} \rightarrow\) \(\left.\operatorname{Hom}_{\mathcal{C}} C_{0}, C_{n}\right)\).

Let us identify \(\sqcup_{n-1}^{n-1}\) with the pushout
\[
\left(\partial \square^{n-2} \times \Delta^{1}\right) \coprod_{\left(\partial \square^{n-2} \times\{1\}\right)}\left(\square^{n-2} \times\{1\}\right) .
\]

Let \(v\) be the final vertex of the cube \(\partial \square^{n-2}\) (corresponding to the set \(\{1,2, \ldots, n-2\}\), regarded as a subset of itself). Our assumption that the 2 -simplex \(\left.\sigma_{0}\right|_{\mathrm{N}_{\bullet}(\{0<n-1<n\})}\) is right-degenerate guarantees that the composite map
\[
\{v\} \times \Delta^{1} \hookrightarrow \sqcup_{n-1}^{n-1} \xrightarrow{\lambda_{0}} \operatorname{Hom}_{\mathcal{C}}\left(C_{0}, C_{n}\right)_{\bullet} .
\]
is a degenerate edge of the \(\infty\)-category \(\operatorname{Hom}_{\mathcal{C}}\left(C_{0}, C_{n}\right)_{\bullet}\); in particular, it is an isomorphism of \(\operatorname{Hom}_{\mathcal{C}}\left(C_{0}, C_{n}\right)\). Note that every simplex of \(\square^{n-2}\) which is not contained in the boundary \(\partial \square^{n-2}\) has final vertex \(v\). The existence of the desired extension \(\lambda\) now follows by applying Proposition 4.4.5.8

Proposition 5.4.8.6 (Functoriality). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of simplicial categories. 01 YR Assume that:
- For every pair of objects \(C, C^{\prime} \in \mathcal{C}\), the simplicial set \(\operatorname{Hom}_{\mathcal{C}}\left(C, C^{\prime}\right)\). is an \(\infty\)-category.
- For every pair of objects \(D, D^{\prime} \in \mathcal{D}\), the simplicial set \(\operatorname{Hom}_{\mathcal{D}}\left(D, D^{\prime}\right)\). is an \(\infty\)-category. Then the induced map \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(F): \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{D})\) is a functor of \((\infty, 2)\)-categories: that is, it carries thin 2-simplices of \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) to thin 2-simplices of \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{D})\).

Proof. It follows from Theorem 5.4.8.1 that the simplicial sets \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) and \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{D})\) are \((\infty, 2)\)-categories. We will show that the morphism \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(F)\) is a functor by verifying the criterion of Proposition 5.4.7.9. Let \(f: X \rightarrow Y\) and \(g: Y \rightarrow Z\) be morphisms in the category \(\mathcal{C}\) (or, equivalently, in the \((\infty, 2)\)-category \(\left.\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\right)\). Then \(f\) and \(g\) determine a 2 -simplex of the nerve \(\mathrm{N}_{\bullet}(\mathcal{C})\), which we identify with 2 -simplex \(\sigma\) of the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) (see Remark 2.4.3.8. By virtue of Example 5.4.8.3, \(\sigma\) is a thin 2-simplex of \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) and its image \(\mathrm{N}_{\bullet}^{\text {hc }}(F)(\sigma)\) is a thin 2 -simplex of \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{D})\).

We are now equipped to establish the converse of Proposition 5.4.8.2.
Proposition 5.4.8.7. Let \(\mathcal{C}\) be a simplicial category. Suppose that, for every pair of objects 01 YS \(X\) and \(Y\), the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\). is an \(\infty\)-category. Let \(\sigma\) be a 2-simplex of the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\), which we identify with a (not necessarily commutative) diagram

in \(\mathcal{C}\) together with an edge \(\mu: g \circ f \rightarrow h\) in the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Z)\). Then \(\sigma\) is thin if and only if \(\mu\) is an isomorphism in the \(\infty\)-category \(\operatorname{Hom}_{\mathcal{C}}(X, Z)\).

Proof. It follows from Proposition 5.4.8.2 that if \(\mu\) is an isomorphism, then \(\sigma\) is thin. Conversely, assume that \(\sigma\) is thin; we wish to show that \(\mu\) is an isomorphism. Define a strict 2-category \(\mathcal{E}\) as follows:
- The objects of \(\mathcal{E}\) are the objects of \(\mathcal{C}\).
- For every pair of objects \(A, B \in \mathcal{C}\), we define \(\underline{\operatorname{Hom}}_{\mathcal{E}}(A, B)\) to be the homotopy category of the \(\infty\)-category \(\operatorname{Hom}_{\mathcal{C}}(A, B)\).
- For every triple of objects \(A, B, C \in \mathcal{C}\), we define the composition law
\[
\circ: \underline{\operatorname{Hom}}_{\mathcal{E}}(B, C) \times \underline{\operatorname{Hom}}_{\mathcal{E}}(A, B) \rightarrow \underline{\operatorname{Hom}}_{\mathcal{E}}(A, C)
\]
to be the functor of homotopy categories induced by the composition law
\[
\operatorname{Hom}_{\mathcal{C}}(B, C)_{\bullet} \times \operatorname{Hom}_{\mathcal{C}}(A, B)_{\bullet} \rightarrow \operatorname{Hom}_{\mathcal{C}}(A, C)
\]
of the simplicial category \(\mathcal{C}\).
Let \(\mathcal{D}\) denote the simplicial category obtained by applying the construction of Example 2.4.2.8 to the strict 2 -category \(\mathcal{E}\) : the simplicial category \(\mathcal{D}\) has the same objects as \(\mathcal{C}\), with simplicial morphism spaces given by
\[
\operatorname{Hom}_{\mathcal{D}}(A, B)_{\bullet}=\mathrm{N}_{\bullet}\left(\operatorname{Hom}_{\mathcal{E}}(A, B)\right)=\mathrm{N}_{\bullet}\left(\operatorname{hHom}_{\mathcal{C}}(A, B)_{\bullet}\right)
\]

There is an evident functor of simplicial categories \(F: \mathcal{C} \rightarrow \mathcal{D}\), which is the identity on objects and which induces the unit map \(\operatorname{Hom}_{\mathcal{C}}(A, B)_{\bullet} \rightarrow \mathrm{N}_{\bullet}\left(\operatorname{hHom}_{\mathcal{C}}(A, B)_{\bullet}\right)\) on simplicial morphism spaces. Invoking Proposition 5.4.8.6, we see that the induced map \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(F)\) carries \(\sigma\) to a thin 2 -simplex of the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{D})\), which we can identify with the Duskin nerve \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{E})\) of the 2-category \(\mathcal{E}\) (Example 2.4.3.11). Using the description of the thin simplices of \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathcal{E})\) supplied by Theorem 2.3.2.5. we conclude that the homotopy class [ \(\mu\) ] is an isomorphism in the category \(\underline{\operatorname{Hom}}_{\mathcal{E}}(X, Z)=\operatorname{hHom}_{\mathcal{C}}(X, Z)_{\text {. }}\), so that \(\mu\) is an isomorphism in the \(\infty\)-category \(\operatorname{Hom}_{\mathcal{C}}(X, Z)\).

01 YT Corollary 5.4.8.8. Let \(\mathcal{C}\) be a simplicial category having the property that, for every pair of objects \(X, Y \in \mathcal{C}\), the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\). is an \(\infty\)-category. Let \(\mathcal{C}^{\prime}\) denote the simplicial subcategory of \(\mathcal{C}\) having the same objects, with morphism simplicial sets given by \(\operatorname{Hom}_{\mathcal{C}^{\prime}}(X, Y) \bullet=\operatorname{Hom}_{\mathcal{C}}(X, Y) \simeq\). Then the inclusion of simplicial categories \(\mathcal{C}^{\prime} \hookrightarrow \mathcal{C}\) induces an isomorphism of \(\infty\)-categories \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}^{\prime}\right) \simeq \operatorname{Pith}\left(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\right)\).

Proof. Let \(\sigma\) be an \(n\)-simplex of the homotopy coherent nerve \(\mathrm{N}_{\bullet}(\mathcal{C})\), which we identify with a simplicial functor \(F: \operatorname{Path}[n] \bullet \rightarrow \mathcal{C}\) carrying each \(i \in[n]\) to an object \(C_{i} \in \mathcal{C}\). If \(T \subseteq[n]\) is a nonempty subset having smallest element \(i\) and largest element \(k\), let us write \(F(T)\) for the corresponding vertex of the simplicial set \(\operatorname{Hom}_{\mathcal{C}}\left(C_{i}, C_{k}\right)_{\text {e }}\). If \(S \subseteq T\) is a subset containing \(i\) and \(k\), let us write \(F(S \subseteq T): F(T) \rightarrow F(S)\) for the corresponding edge of the simplicial set \(\operatorname{Hom}_{\mathcal{C}}\left(C_{i}, C_{k}\right)_{\bullet}\). Let us abuse notation by identifying \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}^{\prime}\right)\) with a simplicial subset of \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\). Unwinding the definitions, we see that \(\sigma\) is contained in \(\mathrm{N}_{\bullet}^{\text {hc }}\left(\mathcal{C}^{\prime}\right)\) if and only if the following condition is satisfied:
(1) For every inclusion \(S \subseteq T\) of nonempty subsets of [ \(n\) ] having the same smallest element \(i\) and largest element \(k\), the edge \(F(S \subseteq T): F(T) \rightarrow F(S)\) is an isomorphism in the \(\infty\)-category \(\operatorname{Hom}_{\mathcal{C}}\left(C_{i}, C_{k}\right)\).
Using the thinness criterion of Proposition 5.4.8.7, we see that \(\sigma\) belongs to the pith \(\operatorname{Pith}\left(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\right)\) if and only if the following a priori weaker condition is satisfied:
(2) For every triple of elements \(0 \leq i \leq j \leq k \leq n\), the edge
\[
F(\{i, k\} \subseteq\{i, j, k\}): F(\{i, j, k\}) \rightarrow F(\{i, k\})
\]
is an isomorphism in the \(\infty\)-category \(\left.\operatorname{Hom}_{\mathcal{C}}\left(C_{i}, C_{k}\right)_{\bullet}\right)\).
To complete the proof, it will suffice to show that \((2) \Rightarrow(1)\). Assume that (2) is satisfied, and suppose that we are given nonempty subsets \(S \subseteq T\) of \([n]\) having the same smallest element \(i\) and largest element \(k\). We wish to show that \(F(S \subseteq T)\) is an isomorphism in the \(\infty\)-category \(\operatorname{Hom}_{\mathcal{C}}\left(C_{i}, C_{k}\right)_{\text {e }}\). Since the collection of isomorphisms contains all identity morphisms and is closed under composition (Remark 1.4.6.3), we may assume without loss of generality that the difference \(T \backslash S\) contains exactly one element \(j\). Set \(S_{-}=\{s \in S: s<j\}\) and \(S_{+}=\{s \in S: s>j\}\). Let \(i^{\prime}\) be the largest element of \(S_{-}\), and let \(k^{\prime}\) denote the smallest element of \(S_{+}\). Unwinding the definitions, we see that the edge \(F(S \subseteq T)\) is the image of \(F\left(\left\{i^{\prime}, k^{\prime}\right\} \subseteq\left\{i^{\prime}, j, k^{\prime}\right\}\right)\) under the functor
\[
\operatorname{Hom}_{\mathcal{C}}\left(C_{i^{\prime}}, C_{k^{\prime}}\right) \bullet \xrightarrow{F\left(S_{+}\right) \bullet \bullet \bullet F\left(S_{-}\right)} \operatorname{Hom}_{\mathcal{C}}\left(C_{i}, C_{k}\right) \bullet,
\]
and is therefore an isomorphism by virtue of assumption (2).

\subsection*{5.4.9 Comparison of Homotopy Transport Representations}

Let \(\mathcal{C}\) be a locally Kan simplicial category containing an object \(X\). Since the ho- 02RX motopy coherent nerve \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\) is an \(\infty\)-category (Theorem 2.4.5.1), the projection map \(U: \mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})_{X /} \rightarrow \mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\) is a left fibration (Proposition 4.3.6.1). Let \(\operatorname{hrr}_{\mathrm{N}_{\bullet}(\mathcal{C})_{X /} / \mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})}\) : \(h N_{\bullet}^{\text {hc }}(\mathcal{C}) \rightarrow\) hKan denote the homotopy transport representation of \(U\). Combining Example 5.2.8.13 with Corollary 4.6.9.20 we obtain the following concrete description of the functor \(\mathrm{h} \operatorname{Tr}_{\mathrm{Nb}_{\boldsymbol{e}}(\mathcal{C})_{X /} / \mathrm{N}_{\boldsymbol{\bullet}}(\mathcal{C})}:\)

02RY Proposition 5.4.9.1. Let \(\mathcal{C}\) be locally Kan simplicial category containing an object \(X\), and let \(\Phi: \mathrm{hC} \xrightarrow{\sim} \mathrm{hN}{ }_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) be the isomorphism of Proposition 2.4.6.9. Then the diagram of functors

commutes up to isomorphism.
Our goal in this section is to formulate and prove a stronger version of Proposition 5.4.9.1, which differs in three respects:
- We drop the assumption that the simplicial category \(\mathcal{C}\) is locally Kan, and assume instead that the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(Y, Z)\). is an \(\infty\)-category for every pair of objects \(Y, Z \in \mathcal{C}\). In this case, the nerve \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\) need not be an \(\infty\)-category, so the projection map \(U: \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /} \rightarrow \mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\) need not be a left fibration. However, Theorem 5.4.8.1 guarantees that \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\) is an \((\infty, 2)\)-category, so that \(U\) restricts to a cocartesian fibration of \(\infty\)-categories \(\operatorname{Pith}(U): \operatorname{Pith}\left(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})_{X /}\right) \rightarrow \operatorname{Pith}\left(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\right)\) (Corollary 5.4.7.11). Note that Proposition 2.4.6.9 and Corollary 5.4.8.8 supply an isomorphism of homotopy categories \(\Phi: \mathrm{hC}^{\prime} \xrightarrow{\sim} \mathrm{hPith}\left(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\right)\), where \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) is the locally Kan simplicial subcategory with morphism spaces given by \(\operatorname{Hom}_{\mathcal{C}^{\prime}}(Y, Z) \bullet=\operatorname{Hom}_{\mathcal{C}}(Y, Z) \simeq\).
- Proposition 5.4.9.1 asserts that a certain diagram commutes up to isomorphism. However, it is possible to be more precise. For every pair of objects \(X, Y \in \mathcal{C}\), Theorem 4.6 .8 .9 supplies an equivalence of \(\infty\)-categories
\[
\theta_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})}^{\mathrm{L}}(X, Y)=\operatorname{hTr}_{\operatorname{Pith}\left(\mathrm{Nh}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /}\right) / \operatorname{Pith}\left(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\right)}(Y),
\]
so that the homotopy class \(\left[\theta_{X, Y}\right]\) can be viewed as an isomorphism in the category hQCat. We will show that \(\left[\theta_{X, Y}\right]\) depends functorially on \(Y\), so that the construction \(Y \mapsto\left[\theta_{X, Y}\right]\) furnishes a natural isomorphism of functors
\[
\operatorname{Hom}_{\mathcal{C}}(X, \bullet) \bullet \rightarrow \operatorname{hTr}_{\operatorname{Pith}\left(\mathrm{Nb}_{\bullet}(\mathcal{C})_{X /}\right) / \operatorname{Pith}\left(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\right)} \circ \Phi
\]
- Since \(\operatorname{Pith}\left(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\right)\) is an \(\infty\)-category, we can regard the homotopy transport representation
\[
\mathrm{h} \operatorname{Tr}_{\operatorname{Pith}\left(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /}\right) / \operatorname{Pith}\left(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\right)}: \operatorname{hPith}\left(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\right) \rightarrow \mathrm{hQCat}
\]
as an hKan-enriched functor (Construction 5.2.8.9). Similarly, we can regard \(\Phi\) as an isomorphism of hKan-enriched categories (Corollary 4.6.9.20), and the construction
\(Y \mapsto \operatorname{Hom}_{\mathcal{C}}(X, Y)\) • determines an hKan-enriched functor from \(\mathrm{hC}{ }^{\prime}\) to hQCat. We will show that the natural isomorphism \(Y \mapsto\left[\theta_{Y}\right]\) is compatible with these hKanenrichments.

Our main result is the following:

Theorem 5.4.9.2. Let \(\mathcal{C}\) be a simplicial category having the property that, for every pair 02RZ of objects \(Y, Z \in \mathcal{C}\), the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(Y, Z)\). is an \(\infty\)-category. Let \(X\) be an object of \(\mathcal{C}\), let hTr denote the (enriched) homotopy transport representation associated to the cocartesian fibration \(\operatorname{Pith}(U): \operatorname{Pith}\left(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /}\right) \rightarrow \operatorname{Pith}\left(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\right)\), and let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be the locally Kan simplicial subcategory defined above. Then the diagram of hKan-enriched functors

commutes up to natural isomorphism, given explicitly by the map
\[
Y \mapsto\left(\left[\theta_{X, Y}\right]: \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet} \mathrm{c}(\mathcal{C})}^{\mathrm{L}}(X, Y)\right) .
\]
of Construction 4.6.8.3.

Proof. For every object \(Y \in \mathcal{C}\), the comparison functor
\[
\theta_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \rightarrow \operatorname{Hom}_{\mathrm{Nh}_{\bullet}(\mathcal{C})}^{\mathrm{L}}(X, Y)
\]
is an equivalence of \(\infty\)-categories (Theorem 4.6.8.9), so its homotopy class \(\left[\theta_{X, Y}\right]\) is an isomorphism when regarded as a morphism in the homotopy category hQCat. To complete the proof, it will suffice to show that the construction \(Y \mapsto\left[\theta_{X, Y}\right]\) determines a natural transformation of hKan-enriched functors. Let \(Y\) and \(Z\) be objects of \(\mathcal{C}\), so that the map \(\theta_{Y, Z}\) restricts to a homotopy equivalence of Kan complexes \(\theta_{\bar{Y}, Z}: \operatorname{Hom}_{\mathcal{C}^{\prime}}(Y, Z) \bullet \rightarrow\)
\(\operatorname{Hom}_{\mathrm{Nbc}\left(\mathcal{C}^{\prime}\right)}(Y, Z)\). We wish to show that the diagram of Kan complexes

commutes up to homotopy, where \(\rho\) is given by parametrized covariant transport for the cocartesian fibration \(\operatorname{Pith}(U): \operatorname{Pith}\left(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})_{X /}\right) \rightarrow \operatorname{Pith}\left(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\right) \simeq \mathrm{N}_{\bullet}^{\text {hc }}\left(\mathcal{C}^{\prime}\right)\).

We will show that there exists a functor of \(\infty\)-categories
\[
H: \Delta^{1} \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \times \operatorname{Hom}_{\mathcal{C}}(Y, Z)_{\bullet} \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /}
\]
satisfying the following requirements:
(a) The diagram of simplicial sets

commutes.
(b) The restriction \(H_{0}=\left.H\right|_{\{0\} \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \times \operatorname{Hom}_{\mathcal{C}}(Y, Z)}\). is given by the composition
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \times \operatorname{Hom}_{\mathcal{C}}(Y, Z) \bullet \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \xrightarrow{\theta_{X, Y}} \operatorname{Hom}_{\mathrm{Nb}_{\bullet}(\mathcal{C})}^{\mathrm{L}}(X, Y) .
\]
(c) The restriction \(H_{1}=\left.H\right|_{\{1\} \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \times \operatorname{Hom}_{\mathcal{C}}(Y, Z)}\). is given by the composition
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \times \operatorname{Hom}_{\mathcal{C}}(Y, Z) \bullet \xrightarrow{\circ} \operatorname{Hom}_{\mathcal{C}}(X, Z) \bullet \xrightarrow{\theta_{X, Z}} \operatorname{Hom}_{\mathrm{Nh}_{\bullet}(\mathcal{C})}^{\mathrm{L}}(X, Z) .
\]
(d) For every pair of morphisms \(f: X \rightarrow Y\) and \(g: Y \rightarrow Z\) in \(\mathcal{C}\), the composite map
\[
\Delta^{1} \times\{f\} \times\{g\} \hookrightarrow \Delta^{1} \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \times \operatorname{Hom}_{\mathcal{C}}(Y, Z) \bullet \xrightarrow{H} \mathrm{~N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /}
\]
is a \(U\)-cocartesian morphism of the \((\infty, 2)\)-category \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /}\) (that is, it corresponds to a thin 2 -simplex of \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})\); see Theorem 5.4.4.1.

Assume for the moment that there exists a morphism \(H\) satisfying these requirements. Note that the restriction \(\left.H\right|_{\{1\} \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \times \operatorname{Hom}_{\mathcal{C}^{\prime}}(Y, Z)}\) • can be identified with a map of Kan complexes
\[
\lambda: \operatorname{Hom}_{\mathcal{C}^{\prime}}(Y, Z)_{\bullet} \rightarrow \operatorname{Fun}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{\bullet}, \operatorname{Hom}_{\mathrm{N}_{\bullet}}^{\mathrm{L}}(X, Z)\right)^{\sim} .
\]

It follows from requirement \((c)\) that \(\lambda\) is given by clockwise composition around the diagram (5.26), and from requirements (a), (b), and (d) that \(\lambda\) is also given (up to homotopy) by counterclockwise composition around the diagram (5.26). It follows that the diagram (5.26) commutes up to homotopy, as desired.

It remains to construct the morphism \(H\). Fix an auxiliary symbol \(e\), let \(n \geq 0\), and let \(\sigma\) be an \(n\)-simplex of the simplicial set \(\Delta^{1} \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \times \operatorname{Hom}_{\mathcal{C}}(Y, Z)\). We will identify \(\sigma\) with a triple \(\left(\alpha, f_{\sigma}, g_{\sigma}\right)\), where \(\alpha:[n] \rightarrow[1]\) is a nondecreasing function, \(f_{\sigma}\) is an \(n\)-simplex of \(\operatorname{Hom}_{\mathcal{C}}(X, Y)_{\bullet}\), and \(F g_{\sigma}\) is an \(n\)-simplex of \(\operatorname{Hom}_{\mathcal{C}}(Y, Z)_{\text {. . Let } \operatorname{Path}[\{e\} \star[n]] \text { • denote the }}\) simplicial path category of the linearly ordered set \(\{e\} \star[n]=\{e<0<\cdots<n\}\) (see Notation 2.4.3.1). To the \(n\)-simplex \(\sigma\), we associate a simplicial functor \(h_{\sigma}: \operatorname{Path}[\{e\} \star[n]] \bullet \rightarrow \mathcal{C}\) as follows:
- On objects, the functor \(h_{\sigma}\) is given by the formula
\[
h_{\sigma}(i)= \begin{cases}X & \text { if } i=e \\ Y & \text { if } 0 \leq i \leq n \text { and } \alpha(i)=0 \\ Z & \text { if } 0 \leq i \leq n \text { and } \alpha(i)=1\end{cases}
\]
- Let \(i<j\) be elements of the linearly ordered set \(\{e\} \star[n]\), so that \(\operatorname{Hom}_{\text {Path }[\{e\} \star[n]]}(i, j)\) • can be identified with the nerve \(\mathrm{N}_{\bullet}(Q)\), where \(Q\) is the collection of all subsets \(K \subseteq\{e\} \star[n]\) having smallest element \(i\) and largest element \(j\) (and we regard \(Q\) as ordered by reverse inclusion). The simplicial functor \(h_{\sigma}\) is given on morphisms by a map of simplicial sets \(u_{i, j}: \mathrm{N}_{\bullet}(Q) \rightarrow \operatorname{Hom}_{\mathcal{C}}\left(h_{\sigma}(i), h_{\sigma}(j)\right)\). If \(0 \leq i<j \leq n\) with \(\alpha(i)=\alpha(j)\), we take \(u_{i, j}\) to be the constant map taking the value id \({ }_{Y}(\) if \(\alpha(i)=0)\) or \(\operatorname{id}_{Z}\) (if \(\alpha(i)=1\) ). The remaining cases can be described as follows:
( \(a^{\prime}\) ) If \(0 \leq i<j \leq n\) satisfy \(\alpha(i)=0\) and \(\alpha(j)=1\), then \(u_{i, j}\) is given by the composition
\[
\mathrm{N}_{\bullet}(Q) \xrightarrow{r_{+}} \Delta^{n} \xrightarrow{g_{\sigma}} \operatorname{Hom}_{\mathcal{C}}(Y, Z)_{\bullet}
\]
where \(r_{+}\)is given on vertices by the formula \(r_{+}(K)=\min \{k \in K: \alpha(k)=1\}\).
( \(b^{\prime}\) ) If \(i=e\) and \(\alpha(j)=0\), then \(u_{i, j}\) is given by the composition
\[
\mathrm{N}_{\bullet}(Q) \xrightarrow{r_{-}} \Delta^{n} \xrightarrow{f_{\sigma}} \operatorname{Hom}_{\mathcal{C}}(X, Y)_{\bullet},
\]
where \(r_{-}\)is given on vertices by the formula \(r_{-}(K)=\min \{k \in K: k>e\}\).
\(\left(c^{\prime}\right)\) If \(i=e\) and \(\alpha(j)=1\), then \(u_{i, j}\) is given by the composition
\[
\mathrm{N}_{\bullet}(Q) \xrightarrow{\left(r_{+}, r_{-}\right)} \Delta^{n} \times \Delta^{n} \xrightarrow{g_{\sigma} \times f_{\sigma}} \operatorname{Hom}_{\mathcal{C}}(Y, Z)_{\bullet} \times \operatorname{Hom}_{\mathcal{C}}(X, Y)_{\bullet} \xrightarrow{\circ} \operatorname{Hom}_{\mathcal{C}}(X, Z)_{\bullet},
\]
where \(r_{-}\)and \(r_{+}\)are defined as above.
Note that we can identify \(h_{\sigma}\) with a morphism of simplicial sets \(\{e\} \star \Delta^{n} \rightarrow \mathrm{~N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) carrying \(\{e\}\) to the vertex \(X\), which we can view as an \(n\)-simplex \(H(\sigma)\) of the \((\infty, 2)\)-category \(\mathrm{N}^{\mathrm{hc}}(\mathcal{C})_{X /}\). The construction \(\sigma \mapsto H(\sigma)\) determines a morphism of simplicial sets
\[
H: \Delta^{1} \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \times \operatorname{Hom}_{\mathcal{C}}(Y, Z)_{\bullet} \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /}
\]

Requirements \((a),(b)\), and \((c)\) follow immediately from \(\left(a^{\prime}\right),\left(b^{\prime}\right)\), and ( \(\left.c^{\prime}\right)\) (together with the definitions of the maps \(\theta_{Y, Z}, \theta_{X, Y}\), and \(\theta_{X, Z}\), respectively). Requirement (d) follows from the description of the thin 2 -simplices of \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) supplied by Proposition 5.4.8.7.

\subsection*{5.5 The \(\infty\)-Categories \(\mathcal{S}\) and \(\mathcal{Q C}\)}

Let Kan denote the category of Kan complexes and let hKan denote its homotopy category (Construction 3.1.5.10). There is an evident forgetful functor \(U: \mathrm{Kan} \rightarrow \mathrm{hKan}\), which carries each Kan complex \(X\) to itself and each morphism of Kan complexes \(f: X \rightarrow Y\) to its homotopy class \([f] \in \pi_{0}(\operatorname{Fun}(X, Y))\). Broadly speaking, homotopy theory is concerned with questions about Kan complexes which are invariant under homotopy equivalence. Since a morphism of Kan complexes \(f\) is a homotopy equivalence if and only if its homotopy class \([f]\) is an isomorphism, it is tempting to characterize homotopy theory as the study of the category hKan. Beware that this characterization is somewhat misleading: many questions belonging to the purview of homotopy theory cannot be formulated at the level of the homotopy category. For example, suppose we are given a commutative diagram of Kan complexes \(\sigma\) :

One can then ask if \(\sigma\) is a homotopy pullback square (Definition 3.4.1.1). Though the answer to this question depends only on the homotopy type of the diagram \(\sigma\) (Corollary 3.4.1.12), it does not depend only on the associated diagram \(U(\sigma)\) in the homotopy category hKan (see Example 3.4.1.13).

Roughly speaking, the problem is that passage from the category of Kan complexes Kan to its homotopy category hKan destroys too much information. To remedy the situation, it is convenient to consider a refinement of the homotopy category hKan. Note that Kan has the structure of a simplicial category (see Example 2.4.2.1. In \$5.5.1, we show that the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\text {hc }}\) (Kan) is an \(\infty\)-category (Proposition 5.5.1.2), which we will denote by \(\mathcal{S}\) and refer to as the \(\infty\)-category of spaces (Construction 5.5.1.1). After passing to nerves, the forgetful functor \(U: \operatorname{Kan} \rightarrow\) hKan factors as a composition
\[
\mathrm{N}_{\bullet}(\operatorname{Kan}) \xrightarrow{U^{\prime}} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathrm{Kan})=\mathcal{S} \xrightarrow{U^{\prime \prime}} \mathrm{N}_{\bullet}(\mathrm{hKan})
\]
with the following features:
- The functor \(U^{\prime}\) is a monomorphism of simplicial sets which is bijective on vertices and edges. In particular, we can identify objects of the \(\infty\)-category \(\mathcal{S}\) with Kan complexes, and morphisms in the \(\infty\)-category \(\mathcal{S}\) with morphisms of Kan complexes (Remark 5.5.1.3).
- The functor \(U^{\prime \prime}\) exhibits hKan as a homotopy category of the \(\infty\)-category \(\mathcal{S}\) (Remark 5.5.1.6. In particular, a map of Kan complexes \(f: X \rightarrow Y\) is a homotopy equivalence if and only if it is an isomorphism when regarded as a morphism of the \(\infty\)-category \(\mathcal{S}\) (Remark 5.5.1.4).

In \(\$ 5.5 .3\), we introduce a variant of the \(\infty\)-category \(\mathcal{S}\) whose objects are pointed Kan complexes \((X, x)\). Here there are (at least) two different ways we might proceed:
- Let \(\mathrm{Kan}_{*}\) denote the category of pointed Kan complexes (Definition 3.2.1.5). Note that \(\mathrm{Kan}_{*}\) can be identified with the coslice category \(\mathrm{Kan}_{\Delta^{0}}\), where we regard the standard simplex \(\Delta^{0}\) as an object of the category Kan. This identification determines a simplicial enrichment of the category \(\mathrm{Kan}_{*}\), and we can obtain an \(\infty\)-category \(\mathrm{N}_{\bullet}^{\text {hc }}\left(\mathrm{Kan}_{*}\right)\) by passing to the homotopy coherent nerve.
- If we regard \(\Delta^{0}\) as an object of the \(\infty\)-category \(\mathcal{S}\), then we can instead form the coslice \(\infty\)-category \(\mathcal{S}_{\Delta^{0}}\). We will denote this \(\infty\)-category by \(\mathcal{S}_{*}\) and refer to it as the \(\infty\)-category of pointed spaces (Construction 5.5.3.1).

Beware that the \(\infty\)-categories \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{Kan}_{*}\right)\) and \(\mathcal{S}_{*}\) are not isomorphic as simplicial sets. However, there is a natural comparison functor \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Kan}_{*}\right) \hookrightarrow \mathcal{S}_{*}\) which is an equivalence of \(\infty\)-categories (Proposition 5.5.3.8). This is a special case of a general assertion concerning
the compatibility of the homotopy coherent nerve with (co)slice constructions (Theorem 5.5.2.21, which we formulate and prove in \$5.5.2.

In \(\$ 5.5 .5\) we consider an enlargement of the \(\infty\)-category \(\mathcal{S}\). Let \(\operatorname{Set}_{\Delta}\) denote the category of simplicial sets and let \(\mathbf{Q C a t} \subseteq \operatorname{Set}_{\Delta}\) denote the full subcategory spanned by the \(\infty\) categories, which we again regard as a simplicial category (see Example 2.4.2.1). The homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathbf{Q C a t})\) is an ( \(\infty, 2\) )-category (Proposition 5.5.5.2), which we will denote by \(\mathcal{Q C}\) and refer to as the \((\infty, 2)\)-category of \(\infty\)-categories (Construction 5.5.5.1. For many applications, it is convenient to work instead with the underlying \(\infty\) category \(\mathcal{Q C}=\operatorname{Pith}(\mathcal{Q C})\), which we study in \(\$ 5.5 .4\) Both of these constructions have pointed analogues, which we introduce and compare in \(\$ 5.5 .6\).

01YW Warning 5.5.0.1. The constructions of this section depend on a choice of dichotomy between "small" and "large" mathematical objects, and we implicitly assume that the categories \(\operatorname{Set}_{\Delta} \supseteq\) QCat \(\supseteq\) Kan consist only of small simplicial sets. In particular, the objects of \(\mathcal{S}\) are small Kan complexes, and the objects of \(\mathcal{Q C}\) are small \(\infty\)-categories. By contrast, the \(\infty\)-categories \(\mathcal{S}\) and \(\mathcal{Q C}\) are not themselves small. In particular, one cannot regard \(\mathcal{Q C}\) as an object of itself, or the Kan complex \(\mathcal{S}^{\simeq}\) as an object of \(\mathcal{S}\).

\subsection*{5.5.1 The \(\infty\)-Category of Spaces}

01YX We begin by introducing a refinement of Construction 3.1.5.10.
\(00 T Z\) Construction 5.5.1.1 (The \(\infty\)-Category of Spaces). Let Kan denote the category of Kan complexes. We view Kan as a simplicial category, with simplicial morphism sets given by the construction
\[
\operatorname{Hom}_{\mathrm{Kan}}(X, Y) \bullet=\operatorname{Fun}(X, Y) .
\]

We let \(\mathcal{S}\) denote the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathrm{Kan})\) (Definition 2.4.3.5. We will refer to \(\mathcal{S}\) as the \(\infty\)-category of spaces.

01 YY Proposition 5.5.1.2. The simplicial set \(\mathcal{S}\) is an \(\infty\)-category.
Proof. By virtue of Theorem 2.4.5.1, it suffices to show that the simplicial category Kan is locally Kan: that is, for every pair of Kan complexes \(X\) and \(Y\), the simplicial set \(\operatorname{Fun}(X, Y)\) is also a Kan complex. This is a special case of Corollary 3.1.3.4.

01 YZ Remark 5.5.1.3. Let \(\mathrm{N}_{\bullet}(\mathrm{Kan})\) denote the nerve of the category of Kan complexes, where we view Kan as an ordinary category. There is an evident monomorphism of simplicial sets
\[
\iota: \mathrm{N}_{\bullet}(\operatorname{Kan}) \hookrightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\operatorname{Kan})=\mathcal{S}
\]
which is bijective on simplices of dimension \(\leq 1\) (Example 2.4.3.9). In other words:
- The objects of the \(\infty\)-category \(\mathcal{S}\) are Kan complexes.
- If \(X\) and \(Y\) are Kan complexes, then morphisms \(f: X \rightarrow Y\) in the \(\infty\)-category \(\mathcal{S}\) can be identified with morphisms of simplicial sets from \(X\) to \(Y\).

However, \(\iota\) is not bijective on simplices of dimension \(\geq 2\). For example, 2 -simplices of \(\mathcal{S}\) can be identified with diagrams of Kan complexes

which commute up to a specified homotopy \(\mu:(g \circ f) \rightarrow h\).
Remark 5.5.1.4. Let \(f: X \rightarrow Y\) be a morphism of Kan complexes. Then \(f\) is a homotopy equivalence (in the sense of Definition 3.1.6.1) if and only if it is an isomorphism when viewed as a morphism of the \(\infty\)-category \(\mathcal{S}\).
Remark 5.5.1.5. Let \(X\) and \(Y\) be Kan complexes. Then Remark 4.6.8.6 supplies a canonical homotopy equivalence of \(\operatorname{Kan}\) complexes \(\operatorname{Fun}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{S}}(X, Y)\). Beware that this homotopy equivalence is generally not an isomorphism.

Remark 5.5.1.6. Let \(X\) and \(Y\) be Kan complexes, and let \(f, g: X \rightarrow Y\) be morphisms.
0120

\(01 \mathrm{Z1}\)
 Then \(f\) and \(g\) are homotopic as morphisms of simplicial sets (that is, they belong to the same connected component of the Kan complex Fun \((X, Y)\) ) if and only if they are homotopic as morphisms in the \(\infty\)-category \(\mathcal{S}\) (Definition 1.4.3.1). Consequently, the category hKan of Construction 3.1.5.10 can be identified with the homotopy category of the \(\infty\)-category \(\mathcal{S}\) (this is a special case of Proposition 2.4.6.9). Moreover, this identification is compatible (via the homotopy equivalences of Remark 5.5.1.5) with the hKan-enrichments supplied by Remark 3.1.5.12 and Construction 4.6.9.13 (see Corollary 4.6.9.20).
Remark 5.5.1.7 (Comparison with Sets). For every set \(S\), let \(\underline{S}\) denote the associated constant simplicial set (Construction 1.1.5.2). The construction \(S \mapsto \underline{S}\) determines a fully faithful embedding from the category of sets to the category of Kan complexes. Passing to homotopy coherent nerves, we obtain a functor of \(\infty\)-categories \(\mathrm{N}_{\bullet}\) (Set) \(\rightarrow \mathcal{S}\). This functor is fully faithful: in fact, it is an isomorphism from \(\mathrm{N}_{\bullet}\) (Set) to the full subcategory of \(\mathcal{S}\) spanned by Kan complexes of the form \(\underline{S}\). We will generally abuse notation by identifying (the nerve of) the category Set with its image in \(\mathcal{S}\) : in particular, we will not distinguish between a set \(S\) and the associated constant simplicial set \(\underline{S}\), viewed as an object of \(\mathcal{S}\). We can summarize the situation informally by saying that the \(\infty\)-category \(\mathcal{S}\) is an enlargement of the ordinary category Set.
\(01 \mathrm{Z3}\) Remark 5.5.1.8 (Comparison with Groupoids). Let Cat denote the (strict) 2-category of small categories, let \(\mathbf{G p d} \subseteq\) Cat denote the full subcategory spanned by the groupoids, and let Gpd. denote the associated simplicial category (Example 2.4.2.8), which we can describe concretely as follows:
- The objects of the simplicial category Gpd. are small groupoids.
- If \(\mathcal{C}\) and \(\mathcal{D}\) are groupoids, then the simplicial set \(\operatorname{Hom}_{\operatorname{Gpd}}(\mathcal{C}, \mathcal{D})\) • is the nerve of the functor category \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\).

Note that if \(\mathcal{C}\) is a groupoid, then the nerve \(\mathrm{N}_{\mathbf{\bullet}}(\mathcal{C})\) is a Kan complex (Proposition 1.3.5.2). By virtue of Proposition 1.5.3.3, the construction \(\mathcal{C} \mapsto \mathrm{N}_{\bullet}(\mathcal{C})\) determines a fully faithful embedding of simplicial categories Gpd. \(\hookrightarrow\) Kan. Passing to homotopy coherent nerves and invoking Example 2.4.3.11, we obtain a functor of \(\infty\)-categories
\[
\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathbf{G p d}) \simeq \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathbf{G p d} \mathbf{p d}_{\bullet}\right) \hookrightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\operatorname{Kan})=\mathcal{S}
\]
where \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathbf{G p d})\) is the Duskin nerve of the 2-category Gpd (Construction 2.3.1.1. This functor restricts to an isomorphism of \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathbf{G p d})\) with the full subcategory of \(\mathcal{S}\) spanned by those Kan complexes of the form \(\mathrm{N}_{\bullet}(\mathcal{C})\), where \(\mathcal{C}\) is a small groupoid. We can informally summarize the situation informally by saying that the \(\infty\)-category \(\mathcal{S}\) is an enlargement of the 2-category of groupoids Gpd.

0124 Remark 5.5.1.9 (Comparison with Topological Spaces). Let Top denote the category of topological spaces and continuous functions, endowed with the simplicial enrichment described in Example 2.4.1.5. The geometric realization construction \(X \mapsto|X|\) determines a functor of simplicial categories \(|\bullet|: \operatorname{Kan} \rightarrow\) Top (see Construction 3.6.5.1). Moreover, if \(X\) and \(Y\) are Kan complexes, then Proposition 3.6.5.2 guarantees that the induced map
\[
\operatorname{Fun}(X, Y)=\operatorname{Hom}_{K a n}(X, Y) \bullet \rightarrow \operatorname{Hom}_{\mathrm{Top}}(|X|,|Y|) \bullet
\]
is a homotopy equivalence of Kan complexes. Applying Corollary 4.6.8.8, we deduce that the induced map
\[
\mathcal{S}=\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathrm{Kan}) \xrightarrow{|\bullet|} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathrm{Top})
\]
is a fully faithful functor of \(\infty\)-categories. The essential image of this functor is the full subcategory \(\mathcal{T}_{0} \subseteq \mathrm{~N}_{\bullet}^{\text {hc }}\) (Top) spanned by those topological spaces which have the homotopy type of a CW complex (Proposition 3.6.5.3). We therefore obtain an equivalence of \(\infty\) category \(\mathcal{S} \xrightarrow{|\bullet|} \mathcal{T}_{0}\) (Theorem 4.6.2.20), which has a homotopy inverse induced by the simplicial functor \(X \mapsto \operatorname{Sing}\) • \((X)\).

\subsection*{5.5.2 Digression: Slicing and the Homotopy Coherent Nerve}

Let \(\mathcal{C}\) be a category and let \(\mathrm{N}_{\bullet}(\mathcal{C})\) denote its nerve. For every object \(X \in \mathcal{C}\), Example \(01 \mathrm{Z5}\) 4.3.5.8 supplies canonical isomorphisms
\[
\mathrm{N}_{\bullet}\left(\mathcal{C}_{/ X}\right) \simeq \mathrm{N}_{\bullet}(\mathcal{C})_{/ X} \quad \mathrm{~N}_{\bullet}\left(\mathcal{C}_{X /}\right) \simeq \mathrm{N}_{\bullet}(\mathcal{C})_{X /}
\]

Our goal in this section is to establish a counterpart of this result in the case where \(\mathcal{C}\) is a (locally Kan) simplicial category. In this case, the slice and coslice categories \(\mathcal{C}_{/ X}\) and \(\mathcal{C}_{X /}\) inherit simplicial enrichments (Construction 5.5.2.1), and there are natural comparison maps
\[
\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}_{/ X}\right) \hookrightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{/ X} \quad \mathrm{~N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}_{X /}\right) \hookrightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /} .
\]

Beware that these maps are generally not isomorphisms at the level of simplicial sets (Warning 5.5.2.19). However, we will show that, under some mild assumptions, they are equivalences of \(\infty\)-categories (Theorem 5.5.2.21).

Construction 5.5.2.1 (Slices of Simplicial-Categories). Let \(\mathcal{C}\) be a simplicial category and \(01 \mathrm{Z6}\) let \(X\) be an object of \(\mathcal{C}\). We define a simplicial category \(\mathcal{C}_{/ X}\) as follows:
- The objects of \(\mathcal{C}_{/ X}\) are pairs \((C, f)\), where \(C\) is an object of \(\mathcal{C}\) and \(f: C \rightarrow X\) is a vertex of the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(C, X)\).
- Let \((C, f)\) and \((D, g)\) be objects of \(\mathcal{C}_{/ X}\). We let \(\operatorname{Hom}_{\mathcal{C}_{X X}}((C, f),(D, g))\). denote the simplicial set given by the fiber product
\[
\operatorname{Hom}_{\mathcal{C}}(C, D) \bullet \times_{\operatorname{Hom}_{\mathcal{C}}(C, X) \bullet}\{f\},
\]
which we regard as a simplicial subset of \(\operatorname{Hom}_{\mathcal{C}}(C, D)\). More precisely, we let \(\operatorname{Hom}_{\mathcal{C}_{/ X}}((C, f),(D, g)) \bullet\) denote the simplicial subset of \(\operatorname{Hom}_{\mathcal{C}}(C, D) \bullet\) consisting of those \(n\)-simplices \(\sigma\) for which the composite map is equal to the constant map \(\Delta^{n} \rightarrow\{f\}\).
- Let \((C, f),(D, g)\), and \((E, h)\) be objects of \(\mathcal{C}_{/ X}\). Then the composition law
\[
\circ: \operatorname{Hom}_{\mathcal{C}_{X /}}((D, g),(E, h)) \bullet \times \operatorname{Hom}_{\mathcal{C}_{/ X}}((C, f),(D, g)) \bullet \rightarrow \operatorname{Hom}_{\mathcal{C}_{/ X}}((C, f),(E, h))_{\bullet}
\]
for the simplicial category \(\mathcal{C}_{/ X}\) is given by the restriction of the composition law
\[
\circ: \operatorname{Hom}_{\mathcal{C}}(D, E) \bullet \times \operatorname{Hom}_{\mathcal{C}}(C, D) \bullet \rightarrow \operatorname{Hom}_{\mathcal{C}}(C, E) \bullet
\]
for the simplicial category \(\mathcal{C}\).
Exercise 5.5.2.2. Let \(\mathcal{C}\) be a simplicial category containing an object \(X\). Show that the 0177 simplicial categories \(\mathcal{C}_{/ X}\) and \(\mathcal{C}_{X /}\) of Construction 5.5.2.1 are well-defined (that is, the composition law of Construction 5.5.2.1 is unital and associative).
\(01 \mathrm{Z8}\) Variant 5.5.2.3 (Coslices of Simplicial-Categories). Let \(\mathcal{C}\) be a simplicial category and let \(X\) be an object of \(\mathcal{C}\). We define a simplicial category \(\mathcal{C}_{X /}\) as follows:
- The objects of \(\mathcal{C}_{X /}\) are pairs \((C, f)\), where \(C\) is an object of \(\mathcal{C}\) and \(f\) is a vertex of the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(X, C)\).
- Let \((C, f)\) and \((D, g)\) be objects of \(\mathcal{C}_{X /}\). We let \(\operatorname{Hom}_{\mathcal{C}_{X /}}((C, f),(D, g))\). denote the simplicial set given by the fiber product
\[
\operatorname{Hom}_{\mathcal{C}}(C, D) \bullet \times_{\operatorname{Hom}_{\mathcal{C}}(X, D)} \cdot\{g\},
\]
which we regard as a simplicial subset of \(\operatorname{Hom}_{\mathcal{C}}(C, D)\).
- Let \((C, f),(D, g)\), and \((E, h)\) be objects of \(\mathcal{C}_{X /}\). Then the composition law
\[
\circ: \operatorname{Hom}_{\mathcal{C}_{/ X}}((D, g),(E, h)) \bullet \times \operatorname{Hom}_{\mathcal{C}_{X /}}((C, f),(D, g)) \bullet \rightarrow \operatorname{Hom}_{\mathcal{C}_{X /}}((C, f),(E, h)) \bullet
\]
for the simplicial category \(\mathcal{C}_{X /}\) is given by the restriction of the composition law
\[
\circ: \operatorname{Hom}_{\mathcal{C}}(D, E) \bullet \times \operatorname{Hom}_{\mathcal{C}}(C, D) \bullet \rightarrow \operatorname{Hom}_{\mathcal{C}}(C, E) \bullet
\]
for the simplicial category \(\mathcal{C}\).
01 Z9 Remark 5.5.2.4. Let \(\mathcal{C}\) be a simplicial category containing an object \(X\), which we also regard as an object of the opposite simplicial category \(\mathcal{C}^{\mathrm{op}}\). Then there is a canonical isomorphism of simplicial categories \(\left(\mathcal{C}_{X /}\right)^{\mathrm{op}} \simeq\left(\mathcal{C}^{\mathrm{op}}\right)_{/ X}\).
01ZA Remark 5.5.2.5. For every simplicial category \(\mathcal{C}\), let \(\mathcal{C}^{\circ}\) denote the underlying ordinary category of \(\mathcal{C}\) (Example 2.4.1.4). If \(X\) is an object of \(\mathcal{C}\), then we have canonical isomorphisms
\[
\left(\mathcal{C}_{/ X}\right)^{\circ} \simeq\left(\mathcal{C}^{\circ}\right)_{/ X} \quad\left(\mathcal{C}_{X /}\right)^{\circ} \simeq\left(\mathcal{C}^{\circ}\right)_{X /}
\]
where the left hand sides are defined using the slice and coslice operations on simplicial categories (Construction 5.5.2.1 and Variant 5.5.2.3) and the right hand sides are defined using the slice and coslice operations on ordinary categories (Construction 4.3.1.1 and Variant 4.3.1.4. In other words, the slice and coslice constructions are compatible with the forgetful functor from simplicial categories to ordinary categories. We can summarize the situation more informally as follows: if \(\mathcal{C}\) is a category and \(X\) is an object of \(\mathcal{C}\), then any simplicial enrichment of \(\mathcal{C}\) determines a simplicial enrichment on the slice and coslice categories \(\mathcal{C}_{/ X}\) and \(\mathcal{C}_{X /}\).
01ZB Remark 5.5.2.6. Let \(\mathcal{C}\) be an ordinary category and let \(\underline{\mathcal{C}}\) denote the associated constant simplicial category (Example 2.4.2.4). Then the simplicial categories \(\underline{\mathcal{C}}_{/ X}\) and \(\underline{\mathcal{C}}_{X /}\) of Construction 5.5.2.1 and Variant 5.5.2.3 are also constant, associated to the ordinary categories \(\mathcal{C}_{/ X}\) and \(\mathcal{C}_{X /}\) of Construction 4.3.1.1 and Variant 4.3.1.4 respectively. In other words, the slice and coslice constructions are compatible with the operation of regarding an ordinary category as a (constant) simplicial category.

Warning 5.5.2.7. Let \(\mathcal{C}\) be a simplicial category and let hC denote the homotopy category 01 ZC of \(\mathcal{C}\) (Construction 2.4.6.1). For every object \(X \in \mathcal{C}\), there is a natural comparison map \(\mathrm{h}(\mathcal{C} / X) \rightarrow(\mathrm{hC})_{/ X}\), which carries an object \((C, f)\) of the slice simplicial category \(\mathcal{C}_{/ X}\) to the object \((C,[f])\) of the slice category \((\mathrm{hC})_{/ X}\), where \([f] \in \pi_{0}\left(\operatorname{Hom}_{\mathcal{C}}(C, X)_{\bullet}\right)\) denotes the homotopy class of \(f\). Beware that this functor is generally not an equivalence of categories (see Warning 3.2.1.11).

We now characterize the simplicial category \(\mathcal{C}_{/ X}\) of Construction 5.5.2.1 by a universal property.

Notation 5.5.2.8. Let \(\mathcal{C}\) be a simplicial category. We define a simplicial category \(\mathcal{C}{ }^{\triangleleft}\) as 01ZD follows:
- The set of objects \(\operatorname{Ob}\left(\mathcal{C}^{\triangleleft}\right)\) is the (disjoint) union \(\operatorname{Ob}(\mathcal{C}) \cup\left\{X_{0}\right\}\), where \(X_{0}\) is an auxiliary symbol.
- The simplicial morphism sets in \(\mathcal{C}^{\triangleleft}\) are given by
\[
\operatorname{Hom}_{\mathcal{C}^{\triangleleft}}(C, D) \bullet \begin{cases}\operatorname{Hom}_{\mathcal{C}}(C, D) \bullet & \text { if } C, D \in \mathrm{Ob}(\mathcal{C}) \\ \Delta^{0} & \text { if } C=X_{0} \\ \emptyset & \text { otherwise. }\end{cases}
\]
- For objects \(C, D, E \in \mathrm{Ob}\left(\mathcal{C}^{\triangleleft}\right)\), the composition law
\[
\circ: \operatorname{Hom}_{\mathcal{C}^{\triangleleft}}(D, E) \bullet \times \operatorname{Hom}_{\mathcal{C}^{\triangleleft}}(C, D) \bullet \rightarrow \operatorname{Hom}_{\mathcal{C}^{\triangleleft}}(C, E) \bullet
\]
is given by the composition law on \(\mathcal{C}\) in the case where \(C, D, E \in \mathrm{Ob}(\mathcal{C})\), and is otherwise uniquely determined (since either the left hand side is empty or the right hand side is \(\Delta^{0}\) ).

More informally, the simplicial category \(\mathcal{C}^{\triangleleft}\) is obtained from \(\mathcal{C}\) by adjoining a (new) initial object \(X_{0}\). We will refer to \(\mathcal{C}^{\triangleleft}\) as the left cone on \(\mathcal{C}\), and to the object \(X_{0} \in \mathcal{C}^{\triangleleft}\) as the cone point.

Variant 5.5.2.9. Let \(\mathcal{C}\) be a simplicial category. We define a simplicial category \(\mathcal{C}^{\triangleright}\) as 01 ZE follows:
- The set of objects \(\operatorname{Ob}\left(\mathcal{C}^{\triangleright}\right)\) is given by the (disjoint) union \(\operatorname{Ob}(\mathcal{C}) \cup\left\{Y_{0}\right\}\), where \(Y_{0}\) is an auxiliary symbol.
- The simplicial morphism sets in \(\mathcal{C}^{\triangleright}\) are given by
\[
\operatorname{Hom}_{\mathcal{C}^{\triangleright}}(C, D) \bullet \begin{cases}\operatorname{Hom}_{\mathcal{C}}(C, D) \bullet & \text { if } C, D \in \mathrm{Ob}(\mathcal{C}) \\ \Delta^{0} & \text { if } D=Y_{0} \\ \emptyset & \text { otherwise. }\end{cases}
\]
- For objects \(C, D, E \in \mathrm{Ob}\left(\mathcal{C}^{\triangleright}\right)\), the composition law
\[
\circ: \operatorname{Hom}_{\mathcal{C}^{\triangleright}}(D, E) \bullet \times \operatorname{Hom}_{\mathcal{C}^{\triangleright}}(C, D) \bullet \rightarrow \operatorname{Hom}_{\mathcal{C}^{\triangleright}}(C, E)_{\bullet}
\]
is given by the composition law on \(\mathcal{C}\) in the case where \(C, D, E \in \operatorname{Ob}(\mathcal{C})\), and is otherwise uniquely determined.

More informally, the simplicial category \(\mathcal{C}^{\triangleright}\) is obtained from \(\mathcal{C}\) by adjoining a (new) final object \(Y_{0}\). We will refer to \(\mathcal{C}^{\triangleright}\) as the right cone on \(\mathcal{C}\), and to the object \(Y_{0} \in \mathcal{C}^{\triangleright}\) as the cone point.

01ZF Remark 5.5.2.10. Let \(\mathcal{C}\) be a simplicial category. Then there is a canonical isomorphism of simplicial categories \(\left(\mathcal{C}^{\triangleleft}\right)^{\mathrm{op}} \simeq\left(\mathcal{C}^{\text {op }}\right)^{\triangleright}\).

01ZG Remark 5.5.2.11. For every simplicial category \(\mathcal{C}\), let \(\mathcal{C}^{\circ}\) denote the underlying ordinary category of \(\mathcal{C}\) (Example 2.4.1.4). Then we have canonical isomorphisms
\[
\left(\mathcal{C}^{\triangleleft}\right)^{\circ} \simeq\left(\mathcal{C}^{\circ}\right)^{\triangleleft} \quad\left(\mathcal{C}^{\triangleright}\right)^{\circ} \simeq\left(\mathcal{C}^{\circ}\right)^{\triangleright},
\]
where the left hand sides are defined using Notation 5.5.2.8 and Variant 5.5.2.9, and the right hand sides are defined in Example 4.3.2.5. In other words, the formation of cones is compatible with the forgetful functor from simplicial categories to ordinary categories.

01ZH Remark 5.5.2.12. Let \(\mathcal{C}\) be an ordinary category and let \(\mathcal{C}\) denote the associated constant simplicial category (Example 2.4.2.4). Then the simplicial categories \(\underline{\mathcal{C}}^{\triangleleft}\) and \(\underline{\mathcal{C}}^{\triangleright}\) of Notation 5.5 .2 .8 and Variant 5.5.2.9 are also constant, associated to the ordinary categories \(\mathcal{C}^{\triangleleft}\) and \(\mathcal{C}^{\triangleright}\) of Example 4.3.2.5. In other words, the formation of cones is compatible with the operation of regarding an ordinary category as a (constant) simplicial category.

01 ZJ Remark 5.5.2.13. For every simplicial category \(\mathcal{C}\), let hC denote its homotopy category. Then there are canonical isomorphisms of categories
\[
\mathrm{h}\left(\mathcal{C}^{\triangleleft}\right) \simeq(\mathrm{hC})^{\triangleleft} \quad \mathrm{h}\left(\mathcal{C}^{\triangleright}\right) \simeq(\mathrm{hC})^{\triangleright} .
\]

In other words, the formation of cones is compatible with the passage from a simplicial category to its homotopy category.

01 ZK Remark 5.5.2.14. For every simplicial category \(\mathcal{C}\), let \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) denote the homotopy coherent nerve of \(\mathcal{C}\). Then there are canonical isomorphisms of simplicial sets
\[
\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}^{\triangleleft}\right) \simeq \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})^{\triangleleft} \quad \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}^{\triangleright}\right) \simeq \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})^{\triangleright},
\]
which are uniquely determined by the requirements that they restrict to the identity on \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\) and preserve the cone points. In other words, the formation of cones is compatible with the homotopy coherent nerve.

Construction 5.5.2.15. Let \(\mathcal{C}\) be a simplicial category and let \(Y\) be an object of \(\mathcal{C}\). We 01ZL define a simplicial functor \(V:(\mathcal{C} / Y)^{\triangleright} \rightarrow \mathcal{C}\) as follows:
- The functor \(V\) carries each object \((C, f) \in \mathcal{C} / Y\) to the object \(C \in \mathcal{C}\), and carries the cone point \(Y_{0} \in\left(\mathcal{C}_{/ Y}\right)^{\triangleright}\) to the object \(Y \in \mathcal{C}\).
- If \((C, f)\) and \((D, g)\) are objects of \(\mathcal{C}_{/ Y}\), then the induced map of simplicial sets
\[
\operatorname{Hom}_{\left(\mathcal{C}_{/ Y}\right)^{\triangleright}}((C, f),(D, g)) \bullet \rightarrow \operatorname{Hom}_{\mathcal{C}}(V(C, f), V(D, g)) \bullet
\]
is equal to the inclusion map \(\operatorname{Hom}_{\mathcal{C}_{/ Y}}((C, f),(D, g))_{\bullet} \hookrightarrow \operatorname{Hom}_{\mathcal{C}}(C, D)\) •
- If \((C, f)\) is an object of \(\mathcal{C}_{/ Y}\), then the induced map
\[
\left.\Delta^{0}=\operatorname{Hom}_{(\mathcal{C} / Y)}\right)^{\triangleright}\left((C, f), Y_{0}\right) \bullet \rightarrow \operatorname{Hom}_{\mathcal{C}}\left(V(C, f), V\left(Y_{0}\right)\right)_{\bullet}=\operatorname{Hom}_{\mathcal{C}}(C, Y)
\]
is equal to the vertex \(f\).
We will refer to \(V\) as the right cone contraction functor. Similarly, to every object \(X \in \mathcal{C}\) we can associate a simplicial functor \(V^{\prime}:\left(\mathcal{C}_{X /}\right)^{\triangleleft} \rightarrow \mathcal{C}\) carrying the cone point of \(\left(\mathcal{C}_{X /}\right)^{\triangleleft}\) to the object \(X\), which we will refer to as the left cone contraction functor.

Proposition 5.5.2.16. Let \(\mathcal{C}\) and \(\mathcal{D}\) be simplicial categories. Let \(X_{0}\) and \(Y_{0}\) denote the 01 ZM cone points of \(\mathcal{D}^{\triangleleft}\) and \(\mathcal{D}^{\triangleright}\), respectively. Then:
- For every object \(Y \in \mathcal{C}\), postcomposition with the right cone contraction functor \(V:\left(\mathcal{C}_{/ Y}\right)^{\triangleright} \rightarrow \mathcal{C}\) of Construction 5.5.2.15 induces a bijection
\[
\left\{\text { Simplicial functors } F: \mathcal{D} \rightarrow \mathcal{C}_{/ Y}\right\}
\]

\(\left\{\right.\) Simplicial functors \(G: \mathcal{D}^{\triangleright} \rightarrow \mathcal{C}\) with \(\left.G\left(Y_{0}\right)=Y\right\}\)
- For every object \(X \in \mathcal{C}\), postcomposition with the left cone contraction functor \(V^{\prime}\) : \(\left(\mathcal{C}_{X /}\right)^{\triangleleft} \rightarrow \mathcal{C}\) of Construction 5.5.2.15 induces a bijection
\(\left\{\right.\) Simplicial functors \(\left.F: \mathcal{D} \rightarrow \mathcal{C}_{X /}\right\}\)

\(\left\{\right.\) Simplicial functors \(G: \mathcal{D}^{\triangleleft} \rightarrow \mathcal{C}\) with \(\left.G\left(X_{0}\right)=X\right\}\)

Proof. We will prove the first assertion; the proof of the second is similar. Fix a simplicial functor \(G: \mathcal{D}^{\triangleright} \rightarrow \mathcal{C}\) and set \(Y=G\left(Y_{0}\right)\). We wish to show that there is a unique simplicial functor \(F: \mathcal{D} \rightarrow \mathcal{C}_{/ Y}\) for which the composition
\[
\mathcal{D}^{\triangleright} \xrightarrow{F^{\triangleright}}\left(\mathcal{C}_{/ Y}\right)^{\triangleright} \xrightarrow{V} \mathcal{C}
\]
is equal to \(G\). For each object \(D \in \mathcal{D}\), the simplicial functor \(G\) induces a morphism of simplicial sets
\[
\Delta^{0}=\operatorname{Hom}_{\mathcal{D}^{\triangleright}}\left(D, Y_{0}\right) \bullet \xrightarrow{G} \operatorname{Hom}_{\mathcal{C}}\left(G(D), G\left(Y_{0}\right)\right) \bullet,
\]
which we can identify with a vertex \(f\) of the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(G(D), Y)\). The simplicial functor \(F\) is then given on objects by the formula \(F(D)=(G(D), f)\), and is determined on morphisms by the requirement that the composition
\[
\operatorname{Hom}_{\mathcal{D}}(D, E) \bullet \xrightarrow{F} \operatorname{Hom}_{\mathcal{C}_{/ Y}}(F(D), F(E)) \bullet \subseteq \operatorname{Hom}_{\mathcal{C}}(G(D), G(E)) \bullet
\]
coincides with the map of simplicial sets determined by the simplicial functor \(G\).
01 ZN Construction 5.5.2.17. Let \(\mathcal{C}\) be a simplicial category, let \(X\) be an object of \(\mathcal{C}\), and let \(V:\left(\mathcal{C}_{/ X}\right)^{\triangleright} \rightarrow \mathcal{C}\) be the right cone contraction functor of Construction 5.5.2.15. Passing to homotopy coherent nerves (and invoking Remark 5.5.2.14), we obtain a map
\[
\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}_{/ X}\right)^{\triangleright} \simeq \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\left(\mathcal{C}_{/ X}\right)^{\triangleright}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})
\]
carrying the cone point to the vertex \(X\), which we can further identify with a morphism of simplicial sets \(c: \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}_{/ X}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{/ X}\). We will refer to \(c\) as the slice comparison morphism. Similarly, the left cone contraction functor \(V^{\prime}:\left(\mathcal{C}_{X /}\right)^{\triangleleft} \rightarrow \mathcal{C}\) induces a morphism of simplicial sets \(c^{\prime}: \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}_{X /}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /}\), which we will refer to as the coslice comparison morphism.

01 ZP Example 5.5.2.18. Let \(\mathcal{C}\) be an ordinary category, which we identify with the associated constant simplicial category \(\mathcal{C}\) of Example 2.4.2.4. For every object \(X \in \mathcal{C}\), the slice and coslice comparison morphisms
\[
c: \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}_{/ X}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{/ X} \quad c^{\prime}: \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}_{X /}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /}
\]
of Construction 5.5.2.17 can be identified with the isomorphisms \(\mathrm{N}_{\bullet}\left(\mathcal{C}_{/ X}\right) \simeq \mathrm{N}_{\bullet}(\mathcal{C})_{/ X}\) and \(\mathrm{N}_{\bullet}\left(\mathcal{C}_{X^{\prime}}\right) \simeq \mathrm{N}_{\bullet}(\mathcal{C})_{X /}\) described in Example 4.3.5.8.

01ZQ Warning 5.5.2.19. Let \(\mathcal{C}\) be a simplicial category containing an object \(X\). Then the slice and coslice comparison morphisms
\[
c: \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}_{/ X}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{/ X} \quad c^{\prime}: \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}_{X /}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /}
\]
of Construction 5.5.2.17 are always bijective at the level of vertices (on the left side, vertices of either of the simplicial sets \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}_{/ X}\right)\) and \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{/ X}\) can be identified with pairs \((C, f)\), where \(C\) is an object of \(\mathcal{C}\) and \(f\) is a morphism from \(C\) to \(X\) ). Beware that \(c\) and \(c^{\prime}\) are generally not bijective on simplices of dimension \(\geq 1\). Unwinding the definitions, we see that edges of the simplicial set \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}_{/ X}\right)\) can be identified with diagrams

in the category \(\mathcal{C}\) which are strictly commutative, while edges of \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})_{/ X}\) can be identified with diagrams which commute up to a specified homotopy \(\mu: g \circ h \rightarrow f\) in \(\operatorname{Hom}_{\mathcal{C}}(C, X)_{\bullet}\).
Exercise 5.5.2.20. Let \(\mathcal{C}\) be a simplicial category and let \(X\) be an object of \(\mathcal{C}\). Show that 01ZR the slice and coslice comparison morphisms
\[
c: \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}_{/ X}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{/ X} \quad c^{\prime}: \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}_{X /}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /}
\]
are monomorphisms of simplicial sets.
We are now ready to state the main result of this section. For the sake of brevity, we will formulate the statement only for coslice categories (one can deduce a dual statement for slice categories by replacing \(\mathcal{C}\) by its opposite).
Theorem 5.5.2.21. Let \(\mathcal{C}\) be a locally Kan simplicial category and let \(X\) be an object of \(\mathcal{C} 01 \mathrm{ZS}\) with the following property:
(*) For every morphism \(f: X \rightarrow Y\) and every object \(Z \in \mathcal{C}\), the morphism of simplicial sets \(\operatorname{Hom}_{\mathcal{C}}(Y, Z) \bullet \xrightarrow{\circ f} \operatorname{Hom}_{\mathcal{C}}(X, Z)\) • is a Kan fibration.

Then the coslice comparison morphism \(c^{\prime}: \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}_{X /}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /}\) of Construction 5.5.2.17 is an equivalence of \(\infty\)-categories.

For many applications, hypothesis \((*)\) of Theorem 5.5.2.21 is too strong: it is often satisfied only for morphisms \(f: X \rightarrow Y\) which are sufficiently well-behaved. We therefore consider a somewhat more general situation:

Proposition 5.5.2.22. Let \(\mathcal{C}\) be a locally Kan simplicial category, let \(X\) be an object of \(\mathcal{C}, 01 \mathrm{ZT}\) and let \(\mathcal{E}\) be a full simplicial subcategory of \(\mathcal{C}_{X /}\) with the following property:
(*) For every pair of objects \((Y, f)\) and \((Z, g)\) of the simplicial category \(\mathcal{E} \subseteq \mathcal{C}_{X /}\), the morphism of simplicial sets \(\operatorname{Hom}_{\mathcal{C}}(Y, Z) \bullet \xrightarrow{\circ \circ} \operatorname{Hom}_{\mathcal{C}}(X, Z)\) • is a Kan fibration.

Then the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{E})\) is an \(\infty\)-category, and the coslice comparison morphism \(c^{\prime}: \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}_{X /}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /}\) of Construction 5.5.2.17 restricts to a fully faithful functor of \(\infty\)-categories \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{E}) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /}\).

Proof of Theorem 5.5.2.21 from Proposition 5.5.2.22. Let \(\mathcal{C}\) be a locally Kan simplicial category and let \(X\) be an object of \(\mathcal{C}\) which satisfies hypothesis ( \(*\) ) of Theorem 5.5.2.21. Applying Proposition 5.5 .2 .22 in the case \(\mathcal{E}=\mathcal{C}_{X /}\), we conclude that the coslice comparison morphism \(c^{\prime}: \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathcal{C}_{X /}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /}\) is fully faithful. Since \(c^{\prime}\) is bijective on vertices, it is also essentially surjective, and is therefore an equivalence of \(\infty\)-categories by virtue of Theorem 4.6.2.20.

Proof of Proposition 5.5.2.22. Let \(\mathcal{C}\) be a locally Kan simplicial category containing an object \(X\), and let \(\mathcal{E} \subseteq \mathcal{C}_{X /}\) be a full simplicial subcategory satisfying hypothesis (*) of Proposition 5.5.2.22 For every pair of objects \((Y, f),(Z, g) \in \mathcal{E}\), the simplicial set \(\operatorname{Hom}_{\mathcal{E}}((Y, f),(Z, g)) \bullet\) is the fiber of the Kan fibration
\[
\operatorname{Hom}_{\mathcal{C}}(Y, Z) \bullet \xrightarrow{\circ f} \operatorname{Hom}_{\mathcal{C}}(X, Z) \bullet
\]
over the vertex \(g\), and is therefore a Kan complex (Remark 3.1.1.9). Applying Theorem 2.4.5.1, we conclude that the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{E})\) is an \(\infty\)-category. We wish to show that, for every pair of objects \((Y, f),(Z, g) \in \mathcal{E}\) as above, the coslice comparison morphism \(c^{\prime}\) induces a homotopy equivalence of morphism spaces
\[
\operatorname{Hom}_{\mathrm{N}_{\mathbf{c}} \mathrm{C}(\mathcal{E})}((Y, f),(Z, g)) \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X} /}((Y, f),(Z, g)) .
\]

By virtue of Proposition 4.6.5.10, this is equivalent to the requirement that \(c^{\prime}\) induces a homotopy equivalence \(\rho: \operatorname{Hom}_{\mathrm{Nh}_{\boldsymbol{b}}(\mathcal{E})}^{\mathrm{L}}((Y, f),(Z, g)) \rightarrow \operatorname{Hom}_{\mathrm{N} \cdot(\mathcal{C})_{X} /}^{\mathrm{L}}((Y, f),(Z, g))\) of leftpinched morphism spaces.

Construction 4.6.8.3 supplies comparison maps
\[
\begin{gathered}
\bar{\theta}: \operatorname{Hom}_{\mathcal{E}}((Y, f),(Z, g)) \bullet \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{E})}^{\mathrm{L}}((Y, f),(Z, g)) \\
\theta_{Y, Z}: \operatorname{Hom}_{\mathcal{C}}(Y, Z) \bullet \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet} \mathrm{c}(\mathcal{C})}^{\mathrm{L}}(Y, Z) \quad \theta_{X, Z}: \operatorname{Hom}_{\mathcal{C}}(X, Z) \bullet \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet}(\mathcal{C})}^{\mathrm{L}}(X, Z),
\end{gathered}
\]
which are homotopy equivalences of Kan complexes by virtue of Theorem 4.6.8.5. Let us regard \(f: X \rightarrow Y\) as an edge of the simplicial set \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})\), and let \(Q\) denote the fiber \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})_{f /} \times_{\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})}\{Z\}\). Since the inclusion \(\{1\} \hookrightarrow \Delta^{1}\) is right anodyne, the restriction map \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})_{f /} \rightarrow \mathrm{N}_{\bullet}^{\text {hc }}(\mathcal{C})_{Y /}\) is a trivial Kan fibration (Proposition 4.3.6.12), and therefore restricts to a trivial Kan fibration
\[
\pi: Q \rightarrow \mathrm{~N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{Y /} \times_{\mathrm{N}_{\bullet}(\mathcal{C})}\{Z\}=\operatorname{Hom}_{\mathrm{N}_{\bullet} \mathrm{C}(\mathcal{C})}^{\mathrm{L}}(Y, Z) .
\]

In particular, \(Q\) is a Kan complex and \(\pi\) is a homotopy equivalence. Let \(\pi^{\prime}\) denote the restriction map
\[
Q \rightarrow \mathrm{~N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /} \times_{\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})}\{Z\}=\operatorname{Hom}_{\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})}^{\mathrm{L}}(X, Z) .
\]

Note that \(\pi^{\prime}\) is a pullback of the left fibration \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{f /} \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C})_{X /}\) (Corollary 4.3.6.11), and is therefore also a left fibration (Remark 4.2.1.8). Since the left-pinched morphism space \(\operatorname{Hom}_{\mathrm{N}_{\mathrm{C}}(\mathcal{C})}^{\mathrm{L}}(X, Z)\) is a Kan complex (Proposition 4.6.5.5), the morphism \(\pi^{\prime}\) is a Kan fibration (Corollary 4.4.3.8). We will construct an auxiliary map of Kan complexes \(\lambda\) : \(\operatorname{Hom}_{\mathcal{C}}(Y, Z) \bullet \rightarrow Q\) with the following properties:
(a) The composition \(\operatorname{Hom}_{\mathcal{C}}(Y, Z) \stackrel{\lambda}{\rightarrow} Q \xrightarrow{\pi} \operatorname{Hom}_{\mathrm{N}_{\bullet}(\mathcal{C})}^{\mathrm{L}}(Y, Z)\) is equal to \(\theta_{Y, Z}\).
(b) The cubical diagram of Kan complexes

is commutative.
Suppose that such a map has been constructed. It follows from (a) that \(\lambda\) is a homotopy equivalence. Moreover, the front and back faces of the diagram (5.27) are pullback squares of simplicial sets. Since the vertical maps
\[
\operatorname{Hom}_{\mathcal{C}}(Y, Z) \bullet \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Z)_{\bullet} \quad \pi^{\prime}: Q \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet}}^{\mathrm{Lhc}(\mathcal{C})}(X, Z)
\]
are Kan fibrations, these faces are also homotopy pullback squares (Example 3.4.1.3). Since \(\lambda, \theta_{X, Z}\), and the identity map id : \(\{g\} \rightarrow\{g\}\) are homotopy equivalences of Kan complexes, it follows from Corollary 3.4.1.12 that the map \(\rho \circ \bar{\theta}\) is also a homotopy equivalence of Kan complexes. Since \(\bar{\theta}\) is a homotopy equivalence, we conclude that \(\rho\) is a homotopy equivalence as desired.

We now complete the proof by constructing the morphism \(\lambda: \operatorname{Hom}_{\mathcal{C}}(Y, Z) \bullet \rightarrow Q\). Let \(\sigma\) be an \(n\)-simplex of the simplicial set \(\operatorname{Hom}_{\mathcal{C}}(Y, Z)\) •, so that \(\theta_{Y, Z}(\sigma)\) is an \(n\)-simplex of the left-pinched morphism space \(\operatorname{Hom}_{\mathrm{N}^{\mathrm{hc}}(\mathcal{C})}^{\mathrm{L})}(Y, Z)\) which we can identify with a simplicial functor \(F_{\sigma}: \operatorname{Path}[\{y\} \star[n]] \bullet \rightarrow \mathcal{C}\) such that \(F_{\sigma}(y)=Y\) and \(\left.F_{\sigma}\right|_{\operatorname{Path}[n]}\). is the constant
functor taking the value \(Z\) (see Construction 4.6.8.3). We extend \(F_{\sigma}\) to a simplicial functor \(F_{\sigma}^{+}: \operatorname{Path}[\{x\} \star\{y\} \star[n]] \bullet \rightarrow \mathcal{C}\) as follows:
- The functor \(F_{\sigma}^{+}\)carries \(x\) to the object \(X \in \mathcal{C}\).
- For every element \(i \in\{y\} \star[n]\), the induced map of simplicial sets
\[
\operatorname{Hom}_{\text {Path }[\{x\} \star\{y\} \star[n]]}(x, i) \bullet \rightarrow \operatorname{Hom}_{\mathcal{C}}\left(X, F_{\sigma}(i)\right) \bullet
\]
is given by the composition
\[
\begin{aligned}
& \operatorname{Hom}_{\text {Path }[\{x\} \star\{y\} \star[n]]}(x, i) \bullet \xrightarrow{u} \\
& \operatorname{Hom}_{\text {Path }[\{y\} \star[n]]}(y, i) \bullet \\
& \xrightarrow{F_{\sigma}} \operatorname{Hom}_{\mathcal{C}}\left(Y, F_{\sigma}(i)\right) \bullet \\
& \xrightarrow{\circ f} \\
& \operatorname{Hom}_{\mathcal{C}}\left(X, F_{\sigma}(i)\right) \bullet,
\end{aligned}
\]
where \(u\) is induced by the map of partially ordered sets \(\{x\} \star\{y\} \star[n] \rightarrow\{y\} \star[n]\) which is the identity on \(\{y\} \star[n]\) and carries \(x\) to \(y\).

Then \(F_{\sigma}^{+}\)determines a morphism of simplicial sets \(\{x\} \star\{y\} \star \Delta^{n} \rightarrow \mathrm{~N}_{\bullet}^{\text {hc }}(\mathcal{C})\) carrying \(\{x\} \star\{y\}\) to the edge \(f\) and \(\Delta^{n}\) to the vertex \(Z\), which we can identify with an \(n\)-simplex \(\lambda(\sigma)\) of the Kan complex \(Q\). The construction \(\sigma \mapsto \lambda(\sigma)\) depends functorially on \([n] \in \boldsymbol{\Delta}\), and therefore induces a morphism of simplicial sets \(\lambda: \operatorname{Hom}_{\mathcal{C}}(Y, Z) \bullet \rightarrow Q\) which is easily verified to satisfy conditions (a) and (b).

\subsection*{5.5.3 The \(\infty\)-Category of Pointed Spaces}

Construction 5.5.3.1 (The \(\infty\)-Category of Pointed Spaces). Let \(\mathcal{S}=\mathrm{N}_{\bullet}^{\mathrm{hc}}(\) Kan \()\) denote the \(\infty\)-category of spaces, and regard the Kan complex \(\Delta^{0}\) as an object of \(\mathcal{S}\). We let \(\mathcal{S}_{*}\) denote the coslice \(\infty\)-category \(\mathcal{S}_{\Delta^{0}}\). We will refer to \(\mathcal{S}_{*}\) as the \(\infty\)-category of pointed spaces.
01 ZX Proposition 5.5.3.2. The simplicial set \(\mathcal{S}_{*}\) is an \(\infty\)-category, and the projection map \(\mathcal{S}_{*} \rightarrow \mathcal{S}\) is a left fibration of \(\infty\)-categories.

Proof. By virtue of Proposition 5.5.1.2, the simplicial set \(\mathcal{S}\) is an \(\infty\)-category. It follows that for every object \(X \in \mathcal{S}\), the projection \(\operatorname{map} \mathcal{S}_{X /} \rightarrow \mathcal{S}\) is a left fibration (Corollary 4.3.6.11). Taking \(X=\Delta^{0}\), we conclude that the projection map \(\mathcal{S}_{*} \rightarrow \mathcal{S}\) is a left fibration, so that \(\mathcal{S}_{*}\) is an \(\infty\)-category (Remark 4.2.1.4).

01 ZY Example 5.5.3.3 (Objects of \(\mathcal{S}_{*}\) ). By definition, an object of the \(\infty\)-category \(\mathcal{S}_{*}\) is an edge \(e: \Delta^{0} \rightarrow X\) of the simplicial set \(\mathcal{S}=\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathrm{Kan})\) whose source is the Kan complex \(\Delta^{0}\). By virtue of Remark 5.5.1.3, this is the same data as a morphism \(e: \Delta^{0} \rightarrow X\) in the ordinary category of Kan complexes: that is, the data of a pointed Kan complex ( \(X, x\) ) (Definition 3.2.1.5.

Example 5.5.3.4 (Morphisms of \(\left.\mathcal{S}_{*}\right)\). Let \((X, x)\) and \((Y, y)\) be pointed Kan complexes, 01 ZZ regarded as objects of the \(\infty\)-category \(\mathcal{S}_{*}\). By definition, a morphism from \((X, x)\) to \((Y, y)\) in the \(\infty\)-category \(\mathcal{S}_{*}\) can be identified with a 2 -simplex \(\sigma\) of the simplicial set \(\mathcal{S}=\mathrm{N}_{\bullet}^{\text {hc }}\) (Kan), which we can identify with a diagram of simplicial sets

which commutes up to a specified homotopy \(h\). In other words, a morphism from ( \(X, x\) ) to \((Y, y)\) in the \(\infty\)-category \(\mathcal{S}_{*}\) can be identified with a pair \((f, h)\), where \(f: X \rightarrow Y\) is a morphism of Kan complexes and \(h: f(x) \rightarrow y\) is an edge of the simplicial set \(Y\).

Remark 5.5.3.5. Let \(X\) be a Kan complex, which we regard as an object of the \(\infty\)-category 02 S 1 \(\mathcal{S}\). Then Theorem 4.6.8.5 supplies a homotopy equivalence
\[
\theta_{X}: X=\operatorname{Hom}_{\text {Kan }}\left(\Delta^{0}, X\right)_{\bullet} \rightarrow \operatorname{Hom}_{\mathcal{S}}^{\mathrm{L}}\left(\Delta^{0}, X\right)=\{X\} \times_{\mathcal{S}} \mathcal{S}_{*} .
\]

Beware that \(\theta_{X}\) is generally not an isomorphism of simplicial sets.
Proposition 5.5.3.6. Let \(U: \mathcal{S}_{*} \rightarrow \mathcal{S}\) be the left fibration of Proposition 5.5.3.2, and let 02 S 2
\[
\mathrm{hTr}_{\mathcal{S}_{*} / \mathcal{S}}: \mathrm{h} \mathcal{S} \rightarrow \mathrm{hKan}
\]
be the enriched homotopy transport representation of Variant 5.2.8.11. Then \(\mathrm{h} \operatorname{Tr}_{\mathcal{S}_{*} / \mathcal{S}}\) is homotopy inverse (as an hKan-enriched functor) to the isomorphism \(\mathrm{hKan} \simeq \mathrm{h} \mathcal{S}\) of Remark 5.5.1.6. In particular, \(\mathrm{h}_{\mathcal{S}_{*} / \mathcal{S}}\) is an equivalence of hKan-enriched categories.

Proof. Apply Theorem 5.4.9.2 to the simplicial category Kan.
Remark 5.5.3.7. The statement of Proposition 5.5.3.6 can be made more precise: Theorem 02S3 5.4.9.2 supplies an explicit hKan-enriched isomorphism from the identity functor id \({ }_{h K a n}\) to the composition
\[
\mathrm{hKan} \xrightarrow{\sim} \mathrm{~h} \mathcal{S} \xrightarrow{\mathrm{~h} \operatorname{Tr}_{\mathcal{S}_{*} / \mathcal{S}}} \mathrm{hKan},
\]
which carries each Kan complex \(X\) to the homotopy equivalence \(\theta_{X}: X \rightarrow\{X\} \times \mathcal{S} \mathcal{S}_{*}=\) \(\mathrm{h} \operatorname{Tr}_{\mathcal{S}_{*} / \mathcal{S}}(X)\) of Remark 5.5.3.5.

Let \(\mathrm{Kan}_{*}\) denote the category of pointed Kan complexes (Definition 3.2.1.5). For every pair of pointed Kan complexes \((X, x)\) and \((Y, y)\), we let
\[
\operatorname{Hom}_{\text {Kan }_{*}}((X, x),(Y, y))_{\bullet}=\operatorname{Fun}(X, Y) \times_{\operatorname{Fun}(\{x\}, Y)}\{y\}
\]
5.5. THE \(\infty\)-CATEGORIES \(\mathcal{S}\) AND \(\mathcal{Q C}\)
be the simplicial set parametrizing pointed morphisms from \(X\) to \(Y\). If \((Z, z)\) is another pointed Kan complex, we have an evident composition law
\[
\circ: \operatorname{Hom}_{\text {Kan }_{*}}((Y, y),(Z, z)) \bullet \times \operatorname{Hom}_{\text {Kan }_{*}}((X, x),(Y, y)) \bullet \rightarrow \operatorname{Hom}_{\text {Kan }_{*}}((X, x),(Z, z)),
\]
which endows \(\mathrm{Kan}_{*}\) with the structure of a simplicial category. Note that this construction is a special case of Variant 5.5.2.3, since \(\mathrm{Kan}_{*}\) can be identified with the coslice category \(\operatorname{Kan}_{\Delta^{0} \%}\). Applying Construction 5.5.2.17, we obtain a coslice comparison functor
\[
\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Kan}_{*}\right)=\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Kan}_{\Delta^{0} /}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\operatorname{Kan})_{\Delta^{0} /}=\mathcal{S}_{*} .
\]

0200 Proposition 5.5.3.8. The coslice comparison functor \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Kan}_{*}\right) \rightarrow \mathcal{S}_{*}\) is an equivalence of \(\infty\)-categories.

Proof. Note that, for every pair of pointed Kan complexes \((X, x)\) and \((Y, y)\), the evaluation map \(\operatorname{Fun}(X, Y) \rightarrow \operatorname{Fun}(\{x\}, Y)\) is a Kan fibration (Corollary 3.1.3.3). Proposition 5.5.3.8 is therefore a special case of Theorem 5.5.2.21.

0201 Warning 5.5.3.9. The coslice comparison functor \(F: \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{Kan}_{*}\right) \rightarrow \mathcal{S}_{*}\) of Proposition 5.5 .3 .8 is bijective on vertices: objects of either \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{Kan}_{*}\right)\) and \(\mathcal{S}_{*}\) can be identified with pointed Kan complexes ( \(X, x\) ). However, it is not bijective on edges (and is therefore not an isomorphism of simplicial sets). If ( \(X, x)\) and \((Y, y)\) are pointed Kan complexes, then a morphism from \((X, x)\) to \((Y, y)\) in the \(\infty\)-category \(\mathcal{S}_{*}\) can be identified with a pair \((f, h)\), where \(f: X \rightarrow Y\) is a morphism of Kan complexes and \(h: f(x) \rightarrow y\) is an edge of the Kan complex \(Y\). The pair \((f, h)\) belongs to the image of \(F\) if and only if the edge \(h\) is degenerate (which guarantees in particular that \(f(x)=y\), so that \(f\) is a morphism of pointed Kan complexes).

0202 Corollary 5.5.3.10. The coslice comparison functor \(\Phi: \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Kan}_{*}\right) \rightarrow \mathcal{S}_{*}\) induces an isomorphism of homotopy categories \(\mathrm{h} \Phi: \mathrm{hKan}_{*} \xrightarrow{\sim} \mathrm{~h} \mathcal{S}_{*}\), where \(\mathrm{hKan}_{*}\) denotes the homotopy category of pointed Kan complexes (Construction 3.2.1.12).

Proof. It follows from Propositions 2.4.6.9 and 5.5.3.8 that the functor \(\mathrm{h} \Phi\) is an equivalence of categories. Since it is bijective on objects, it is an isomorphism of categories.

Note that the coslice comparison functor \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Kan}_{*}\right) \rightarrow \mathcal{S}_{*}\) is a monomorphism of simplicial sets (Exercise 5.5.2.20). Heuristically, we can think of \(\mathcal{S}_{*}\) as an enlargement of the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{Kan}_{*}\right)\) which is obtained by allowing morphisms between pointed Kan complexes which preserve base points only up to (specified) homotopy. By virtue of Proposition 5.5.3.8, this enlargement gives rise to an equivalent \(\infty\)-category. However, the \(\infty\)-category \(\mathcal{S}_{*}\) is in some respects more convenient to work with, because the forgetful functor \(\mathcal{S}_{*} \rightarrow \mathcal{S}\) is a left fibration of \(\infty\)-categories. The composite functor \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Kan}_{*}\right) \rightarrow \mathcal{S}_{*} \rightarrow \mathcal{S}\) does not share this property:

Warning 5.5.3.11. There is an evident simplicial functor from the category \(\mathrm{Kan}_{*}\) of pointed Kan complexes to the category Kan of Kan complexes, given on objects by the construction \((X, x) \mapsto X\). Passing to homotopy coherent nerves, we obtain a functor of \(\infty\)-categories \(U: \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Kan}_{*}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\) Kan \()=\mathcal{S}\). Beware that the functor \(U\) is not a left fibration of simplicial sets. For example, suppose we are given a 2 -simplex \(\sigma\) of \(\mathcal{S}\), corresponding to a diagram of Kan complexes

which commutes up to a homotopy \(\mu:(g \circ f) \rightarrow h\) (see Remark 5.5.1.3). Pick a vertex \(x \in X\) and set \(y=f(x)\) and \(z=h(x)\), so that we have morphisms of pointed Kan complexes \(f:(X, x) \rightarrow(Y, y)\) and \(h:(X, x) \rightarrow(Z, z)\). This data determines a lifting problem

which admits a solution if and only if \(\mu(x): g(y) \rightarrow z\) is a degenerate edge of the Kan complex \(Z\) (in which case \(g(y)=z\), so that \(g:(Y, y) \rightarrow(Z, z)\) is also a morphism of pointed Kan complexes).
Example 5.5.3.12 (Pointed Sets as Pointed Spaces). Let Set \({ }_{*}\) denote the category of pointed sets (see Example 4.2.3.3). Every pointed set \((X, x)\) can be regarded as a pointed Kan complex by identifying \(X\) with the corresponding constant simplicial set. This construction determines a fully faithful embedding \(\operatorname{Set}_{*} \hookrightarrow \mathrm{Kan}_{*}\). Composing with the equivalence of Proposition 5.5.3.8, we obtain a functor of \(\infty\)-categories
\[
\mathrm{N}_{\bullet}\left(\operatorname{Set}_{*}\right) \hookrightarrow \mathrm{N}_{\bullet}\left(\operatorname{Kan}_{*}\right) \hookrightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Kan}_{*}\right) \hookrightarrow \mathcal{S}_{*} .
\]

It follows from Remark 5.5.1.7 that this functor is fully faithful: in fact, it is an isomorphism from \(\mathrm{N}_{\bullet}\left(\mathrm{Set}_{*}\right)\) to the full subcategory of \(\mathcal{S}_{*}\) spanned by those pointed Kan complexes \((X, x)\) where the simplicial set \(X\) is constant.

For every group \(G\), let \(B . G\) denote its classifying simplicial set (Construction 1.3.2.5), which we regard as a Kan complex (Proposition 1.2.5.9) having a unique vertex. The
construction \(G \mapsto B_{\bullet} G\) determines a functor from the category Group of groups to the category \(\mathrm{Kan}_{*}\) of pointed Kan complexes. Passing to nerves, we obtain a functor of \(\infty\) categories
\[
\mathrm{N}_{\bullet}(\text { Group }) \rightarrow \mathrm{N}_{\bullet}\left(\operatorname{Kan}_{*}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Kan}_{*}\right) \rightarrow \mathcal{S}_{*} .
\]

0205 Proposition 5.5.3.13. The functor
\[
\mathrm{N}_{\bullet}(\text { Group }) \rightarrow \mathcal{S}_{*} \quad G \mapsto B_{\bullet} G
\]
is fully faithful.
Proof. By virtue of Proposition 5.5.3.8 and Corollary 4.6.8.8, it will suffice to show that the construction \(G \mapsto B \bullet G\) determines a weakly fully faithful functor from Group (regarded as a constant simplicial category) to the simplicial category \(\mathrm{Kan}_{*}\). In other words, we must show that for every pair of groups \(G\) and \(H\), the canonical map
\[
\theta:\{\text { Group homomorphisms from } G \text { to } H\} \rightarrow \operatorname{Hom}_{\text {Kan }_{*}}(B \bullet G, B \bullet H) \bullet
\]
is a homotopy equivalence of Kan complexes. In fact, we claim that \(\theta\) is an isomorphism of simplicial sets. Let \(B G\) denote the category having a single object \(X\) with automorphism group \(G\), and let \(B H\) denote the category having a single object \(Y\) with automorphism group \(H\). Proposition 1.5.3.3 then supplies an isomorphism
\[
\begin{aligned}
\operatorname{Hom}_{\mathrm{Kan}_{*}}\left(B \bullet G, B_{\bullet} H\right) \bullet & =\operatorname{Fun}\left(\mathrm{N}_{\bullet}(B G), \mathrm{N}_{\bullet}(B H)\right) \times_{\mathrm{N}_{\bullet}(B H)} \mathrm{N}_{\bullet}(\{Y\}) \\
& \simeq \mathrm{N}_{\bullet}(\operatorname{Fun}(B G, B H)) \times_{\mathrm{N}_{\bullet}(B H)} \mathrm{N}_{\bullet}(\{Y\}) \\
& \simeq \mathrm{N}_{\bullet}\left(\operatorname{Fun}(B G, B H) \times_{B H}\{Y\}\right) .
\end{aligned}
\]

Note that if \(F, F^{\prime}: B G \rightarrow B H\) are functors and \(\alpha: F \rightarrow F^{\prime}\) is a natural transformation with the property that \(\alpha_{X}: F(X) \rightarrow F^{\prime}(X)\) is the identity morphism id \({ }_{Y}\), then the functors \(F\) and \(F^{\prime}\) are equal and \(\alpha\) is the identity transformation (since \(X\) is the only object of the category \(B G)\). It follows that the fiber product category \(\operatorname{Fun}(B G, B H) \times_{B H}\{Y\}\) is discrete: that is, it has only identity morphisms. We conclude by observing that the set of objects of the category \(\operatorname{Fun}(B G, B H) \times_{B H}\{Y\}\) can be identified with the set of group homomorphisms from \(G\) to \(H\).

0206 Remark 5.5.3.14 (Comparison with Pointed Topological Spaces). Let Top \({ }_{*}\) denote the category whose objects are pointed topological spaces \((X, x)\) and whose morphisms \(f\) : \((X, x) \rightarrow(Y, y)\) are continuous functions \(f: X \rightarrow Y\) satisfying \(f(x)=y\). We regard Top \({ }_{*}\) as a simplicial category, where the \(n\)-simplices of \(\operatorname{Hom}_{\text {Top }_{*}}((X, x),(Y, y))\) • are continuous maps \(f:\left|\Delta^{n}\right| \times X \rightarrow Y\) satisfying \(f(t, x)=y\) for every point \(t \in\left|\Delta^{n}\right|\).

The construction \((X, x) \mapsto(|X|, x)\) determines a simplicial functor from the category \(\mathrm{Kan}_{*}\) of pointed Kan complexes to the category Top \({ }_{*}\) of pointed topological spaces. Moreover,
if \((X, x)\) and \((Y, y)\) are pointed Kan complexes, then we have a commutative diagram of Kan complexes

where the vertical maps are Kan fibrations given by evaluation at \(x\) and the horizontal maps are homotopy equivalences (Proposition 3.6.5.2). Passing to the fiber over the vertex \(y \in Y\), we deduce that the induced map
\[
\operatorname{Hom}_{\text {Kan }_{*}}((X, x),(Y, y)) \bullet \rightarrow \operatorname{Hom}_{\text {Top }_{*}}((|X|, x),(|Y|, y)) \bullet
\]
is also a homotopy equivalence of Kan complexes. Allowing \((X, x)\) and \((Y, y)\) to vary, we deduce that geometric realization \(|\bullet|: \operatorname{Kan}_{*} \rightarrow \mathrm{Top}_{*}\) is a weakly fully faithful functor of simplicial categories (Definition 4.6.8.7), and therefore induces a fully faithful functor of \(\infty\)-categories \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{Kan}_{*}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{Top}_{*}\right)\) (Corollary 4.6.8.8). Composing this functor with a homotopy inverse to the equivalence \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Kan}_{*}\right) \rightarrow \mathcal{S}_{*}\) of Proposition 5.5.3.8, we obtain a fully faithful functor \(\mathcal{S}_{*} \rightarrow \mathrm{~N}_{\bullet}^{\text {hc }}\left(\mathrm{Top}_{*}\right)\).

Exercise 5.5.3.15. Let \((X, x)\) be a pointed topological space. Show that \((X, x)\) belongs to 0207 the essential image of the functor \(\mathcal{S}_{*} \rightarrow \mathrm{~N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{Top}_{*}\right)\) if and only if the topological space \(X\) has the homotopy type of a CW complex and the inclusion map \(\{x\} \hookrightarrow X\) is a Hurewicz cofibration (that is, the union \((\{0\} \times X) \cup([0,1] \times\{x\})\) is a retract of the product space \([0,1] \times X)\).

\subsection*{5.5.4 The \(\infty\)-Category of \(\infty\)-Categories}

Let hQCat denote the homotopy category of (small) \(\infty\)-categories (Construction 4.5.1.1).
Recall that the objects of hQCat are (small) \(\infty\)-categories, and a morphism from \(\mathcal{C}\) to \(\mathcal{D}\) in hQCat is an isomorphism class of functors from \(\mathcal{C}\) to \(\mathcal{D}\). In this section, we show that hQCat can be realized as the homotopy category of an \(\infty\)-category \(\mathcal{Q C}\), which we will refer to as the \(\infty\)-category of \(\infty\)-categories. Proceeding as in \(\S 5.5 .1\), we will realize \(\mathcal{Q C}\) as the homotopy coherent nerve of a simplicial category.

Construction 5.5.4.1 (The \(\infty\)-Category of \(\infty\)-Categories). We define a simplicial category 0209 QCat as follows:
- The objects of QCat are (small) \(\infty\)-categories.
5.5. THE \(\infty\)-CATEGORIES \(\mathcal{S}\) AND \(\mathcal{Q C}\)
- If \(\mathcal{C}\) and \(\mathcal{D}\) are \(\infty\)-categories, then the simplicial set \(\operatorname{Hom}_{\mathrm{QCat}}(\mathcal{C}, \mathcal{D})\). is the core \(\operatorname{Fun}(\mathcal{C}, \mathcal{D}) \simeq\) of the functor \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\).
- If \(\mathcal{C}, \mathcal{D}\), and \(\mathcal{E}\) are \(\infty\)-categories, then the composition law
\[
\circ: \operatorname{Hom}_{Q \mathrm{Cat}}(\mathcal{D}, \mathcal{E}) \bullet \times \operatorname{Hom}_{Q \mathrm{Cat}}(\mathcal{C}, \mathcal{D}) \bullet \rightarrow \operatorname{Hom}_{Q \mathrm{Cat}}(\mathcal{C}, \mathcal{E}) \bullet
\]
is induced by the composition map \(\operatorname{Fun}(\mathcal{D}, \mathcal{E}) \times \operatorname{Fun}(\mathcal{C}, \mathcal{D}) \rightarrow \operatorname{Fun}(\mathcal{C}, \mathcal{E})\).
We let \(\mathcal{Q C}\) denote the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathrm{QCat})\). We will refer to \(\mathcal{Q C}\) as the \(\infty\)-category of \(\infty\)-categories.

020A Remark 5.5.4.2. Many authors use the term quasicategory for what we refer to as an \(\infty\)-category (see Remark 1.4.0.2); the notations of Construction 5.5.4.1 reflect this alternative terminology.

Proposition 5.5.4.3. The simplicial set \(\mathcal{Q C}\) is an \(\infty\)-category.
Proof. For every pair of \(\infty\)-categories \(\mathcal{C}\) and \(\mathcal{D}\), the core \(\operatorname{Fun}(\mathcal{C}, \mathcal{D}) \simeq\) is a Kan complex (Corollary 4.4.3.11). It follows that the simplicial category QCat of Construction 5.5.4.1 is locally Kan, so its homotopy coherent nerve \(\mathcal{Q C}=\mathrm{N}_{\bullet}^{\text {hc }}\) (QCat) is an \(\infty\)-category by virtue of Theorem 2.4.5.1.

020C Remark 5.5.4.4. The low-dimensional simplices of \(\mathcal{Q C}\) are simple to describe:
- An object of \(\mathcal{Q C}\) is a (small) \(\infty\)-category \(\mathcal{C}\).
- If \(\mathcal{C}\) and \(\mathcal{D}\) are objects of \(\mathcal{Q C}\), then a morphism from \(\mathcal{C}\) to \(\mathcal{D}\) in \(\mathcal{Q C}\) is a functor \(F: \mathcal{C} \rightarrow \mathcal{D}\).
- A 2-simplex of \(\mathcal{Q C}\) can be identified with a diagram

where \(\mathcal{C}, \mathcal{D}\), and \(\mathcal{E}\) are (small) \(\infty\)-categories, \(F, G\), and \(H\) are functors, and \(\mu: G \circ F \rightarrow\) \(H\) is an isomorphism in the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{E})\).

020 F Remark 5.5.4.5. Let \(\mathcal{C}\) and \(\mathcal{D}\) be \(\infty\)-categories. Then Remark 4.6.8.6 supplies a homotopy equivalence of Kan complexes \(\phi: \operatorname{Fun}(\mathcal{C}, \mathcal{D})^{\simeq} \rightarrow \operatorname{Hom}_{\mathcal{Q} \mathcal{C}}(\mathcal{C}, \mathcal{D})\). Beware that this homotopy equivalence is generally not an isomorphism.

Remark 5.5.4.6. Let hQCat denote the homotopy category of \(\infty\)-categories (Construction 4.5.1.1), which we view as an hKan-enriched category (see Remark 3.1.5.12). Applying Proposition 2.4.6.9 and Corollary 4.6.9.20, we obtain a canonical isomorphism of hKanenriched categories \(\Phi: \mathrm{hQCat} \xrightarrow{\sim} \mathrm{hQC}\), which is given on objects by the construction \(\Phi(\mathcal{C})=\mathcal{C}\) and on morphism spaces by the homotopy equivalences
\[
\operatorname{Hom}_{Q \mathrm{Cat}}(\mathcal{C}, \mathcal{D})_{\bullet}=\operatorname{Fun}(\mathcal{C}, \mathcal{D})^{\simeq} \rightarrow \operatorname{Hom}_{\mathcal{Q}}(\mathcal{C}, \mathcal{D})
\]
of Remark 5.5.4.5
Remark 5.5.4.7. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between \(\infty\)-categories. Then \(F\) is an equivalence of \(\infty\)-categories (in the sense of Definition 4.5.1.10) if and only if it is an isomorphism in the \(\infty\)-category \(\mathcal{Q C}\).

Remark 5.5.4.8 (Comparison with Kan Complexes). Every Kan complex is an \(\infty\)-category (Example 1.4.0.3). Moreover, if \(X\) and \(Y\) are Kan complexes, then the simplicial set Fun \((X, Y)\) is also a Kan complex (Corollary 3.1.3.4), and therefore coincides with its core \(\operatorname{Fun}(X, Y)^{\simeq}\). It follows that we can regard the simplicial category Kan of Construction 5.5.1.1 as a full simplicial subcategory of QCat. Passing to homotopy coherent nerves, we deduce that the \(\infty\)-category \(\mathcal{S}=\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathrm{Kan})\) is the full subcategory of \(\mathcal{Q C}=\mathrm{N}_{\bullet}^{\mathrm{hc}}(\) QCat \()\) spanned by the Kan complexes.
Remark 5.5.4.9 (Comparison with Categories). Let Cat denote the strict 2-category of
020E small categories (Example 2.2.0.4), let Pith (Cat) denote its pith (Construction 2.2.8.9), and let us abuse notation by identifying \(\operatorname{Pith}(\mathbf{C a t})\) with the simplicial category described in Example 2.4.2.8. Concretely, this simplicial category can be described as follows:
- The objects of Pith \((\mathbf{C a t})\) are small categories.
- If \(\mathcal{C}\) and \(\mathcal{D}\) are objects of \(\operatorname{Pith}(\mathbf{C a t})\), then the simplicial set \(\operatorname{Hom}_{\text {Pith }(\mathbf{C a t})}(\mathcal{C}, \mathcal{D})\) • is the nerve of the groupoid \(\operatorname{Fun}(\mathcal{C}, \mathcal{D}) \simeq\) whose objects are functors from \(\mathcal{C}\) to \(\mathcal{D}\) and whose morphisms are natural isomorphisms.

By virtue of Proposition 1.5.3.3, the construction \(\mathcal{C} \mapsto \mathrm{N}_{\bullet}(\mathcal{C})\) determines a fully faithful embedding of simplicial categories \(\operatorname{Pith}(\mathbf{C a t}) \hookrightarrow\) QCat. Passing to homotopy coherent nerves (and invoking Example 2.4.3.11), we obtain a functor of \(\infty\)-categories \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\operatorname{Pith}(\mathbf{C a t})) \rightarrow \mathcal{Q C}\). Unwinding the definitions, we see that this functor induces an isomorphism from the Duskin nerve \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\operatorname{Pith}(\mathbf{C a t}))\) to the full subcategory of \(\mathcal{Q C}\) spanned by those \(\infty\)-categories of the form \(\mathrm{N}_{\bullet}(\mathcal{C})\), where \(\mathcal{C}\) is an ordinary category.

Variant 5.5.4.10. Let \(\kappa\) be an uncountable cardinal. We let \(\mathcal{Q C}{ }^{<\kappa}\) denote the full subcate- 03UT gory of \(\mathcal{Q C}\) spanned by the \(\infty\)-categories which are \(\kappa\)-small. We will refer to \(\mathcal{Q C}{ }^{<\kappa}\) as the \(\infty\)-category of essentially \(\kappa\)-small \(\infty\)-categories.

03UU Remark 5.5.4.11 (Set-Theoretic Conventions). By definition, the objects of the \(\infty\)-category \(\mathcal{Q C}=\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathrm{QCat})\) are small \(\infty\)-categories. According to the convention of Remark 4.7.0.5, this means that we restrict our attention to essentially \(\lambda\)-small Kan complexes, where \(\lambda\) is some fixed uncountable strongly inaccessible cardinal. In this case, the definitions given in Variant 5.5.4.10 are appropriate only for uncountable cardinals \(\kappa<\lambda\). More generally, if \(\kappa\) is an arbitrary uncountable cardinal, we can define \(\mathcal{Q C}^{<\kappa}\) to be the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\right.\) QCat \(\left.^{<\kappa}\right)\), where QCat \({ }^{<\kappa}\) denotes the (simplicially enriched) category of \(\kappa\)-small \(\infty\)-categories. We then have three cases:
(a) If \(\kappa<\lambda\), then \(\mathcal{Q C}^{<\kappa}\) is a full subcategory of \(\mathcal{Q C}\).
(b) If \(\kappa=\lambda\), then \(\mathcal{Q C}^{<\kappa}\) coincides with \(\mathcal{Q C}\).
(c) If \(\kappa>\lambda\), then \(\mathcal{Q C}\) is a full subcategory of \(\mathcal{Q C}^{<\kappa}\).

To simplify the exposition, we will often implicitly assume that we are in case (a), as suggested in Variant 5.5.4.10. However, it will be convenient to also allow case (c) when working with \(\infty\)-categories which are not necessarily small (such as \(\mathcal{Q C}\) itself).

03UV Variant 5.5.4.12. Let \(\kappa\) be an uncountable cardinal. We let \(\mathcal{S}^{<\kappa}\) denote the full subcategory of \(\mathcal{S}\) spanned by the \(\kappa\)-small Kan complexes, which we also regard as a full subcategory of \(\mathcal{Q C}^{<\kappa}\). Similarly, we let \(\mathcal{S}_{*}^{<\kappa}\) denote the full subcategory of \(\mathcal{S}_{*}\) spanned by those pointed Kan complexes ( \(X, x\) ) where \(X\) is \(\kappa\)-small.

03UW Remark 5.5.4.13. Let \(\kappa\) and \(\lambda\) be regular cardinals and suppose that \(\kappa\) is less than or equal to the exponential cofinality \(\operatorname{ecf}(\lambda)\) (see Definition 4.7.3.16). Then the \(\infty\)-category \(\mathcal{Q C}{ }^{<\kappa}\) is locally \(\lambda\)-small. This follows by combining Remarks 5.5.4.5 and 4.7.5.10. It follows that the full subcategory \(\mathcal{S}^{<\kappa} \subseteq \mathcal{Q C}^{<\kappa}\) is also locally \(\lambda\)-small.

\subsection*{5.5.5 The \((\infty, 2)\)-Category of \(\infty\)-Categories}

020 J For some applications, it will be convenient to work with a variant of Construction 5.5.4.1, which retains information about non-invertible natural transformations of functors.

020K Construction 5.5.5.1 (The \((\infty, 2)\)-Category of \(\infty\)-Categories). Let \(\operatorname{Set}_{\Delta}\) denote the cate- \(^{\text {d }}\) gory of simplicial sets, endowed with the simplicial enrichment of Example 2.4.2.1. We let QCat denote the full simplicial subcategory of \(\operatorname{Set}_{\Delta}\) spanned by the (small) \(\infty\)-categories, which we can describe concretely as follows:
- The objects of QCat are (small) \(\infty\)-categories.
- If \(\mathcal{C}\) and \(\mathcal{D}\) are \(\infty\)-categories, then the simplicial set \(\operatorname{Hom}_{\mathbf{Q C a t}}(\mathcal{C}, \mathcal{D})\) • is the \(\infty\)-category of functors \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\).

We let \(\mathcal{Q C}\) denote the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathbf{Q C a t})\). We will refer to \(\mathcal{Q C}\) as the \((\infty, 2)\)-category of \(\infty\)-categories.

Proposition 5.5.5.2. The simplicial set \(\mathcal{Q C}\) is an ( \(\infty, 2\) )-category.
Proof. For every pair of \(\infty\)-categories \(\mathcal{C}\) and \(\mathcal{D}\), Theorem 1.5.3.7 guarantees that the simplicial set \(\operatorname{Hom}_{\mathbf{Q C a t}}(\mathcal{C}, \mathcal{D}) \bullet=\operatorname{Fun}(\mathcal{C}, \mathcal{D})\) is an \(\infty\)-category. The desired result is now a special case of Theorem 5.4.8.1.

Remark 5.5.5.3. The low-dimensional simplices of \(\mathcal{Q C}\) are simple to describe:
- An object of \(\mathcal{Q C}\) is a (small) \(\infty\)-category \(\mathcal{C}\).
- If \(\mathcal{C}\) and \(\mathcal{D}\) are objects of \(\mathcal{Q C}\), then a morphism from \(\mathcal{C}\) to \(\mathcal{D}\) in \(\mathcal{Q C}\) is a functor \(F: \mathcal{C} \rightarrow \mathcal{D}\).
- A 2-simplex \(\sigma\) of \(\mathcal{Q C}\) can be identified with a diagram

where \(\mathcal{C}, \mathcal{D}\), and \(\mathcal{E}\) are (small) \(\infty\)-categories, \(F, G\), and \(H\) are functors, and \(\mu: G \circ F \rightarrow\) \(H\) is a morphism in the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{E})\). Moreover, \(\sigma\) is thin if and only if \(\mu\) is an isomorphism of functors (Proposition 5.4.8.7).

Remark 5.5.5.4 (Comparison with \(\mathcal{Q C}\) ). Let QCat and QCat be the simplicial categories 020 N defined in Constructions 5.5.4.1 and 5.5.5.1, respectively. There is an evident comparison map QCat \(\hookrightarrow\) QCat which is the identity at the level of objects, and which is given on morphism spaces by the inclusion maps
\[
\operatorname{Hom}_{Q \mathrm{Cat}}(\mathcal{C}, \mathcal{D})_{\bullet}=\operatorname{Fun}(\mathcal{C}, \mathcal{D})^{\simeq} \hookrightarrow \operatorname{Fun}(\mathcal{C}, \mathcal{D})=\operatorname{Hom}_{\mathbf{Q C a t}}(\mathcal{C}, \mathcal{D}) .
\]

Passing to the homotopy coherent nerve, we obtain a functor of \((\infty, 2)\)-categories \(\mathcal{Q C} \hookrightarrow \mathcal{Q C}\) which restricts to an isomorphism of \(\infty\)-categories \(\mathcal{Q C} \simeq \operatorname{Pith}(\mathcal{Q C})\) (Corollary 5.4.8.8).

Remark 5.5.5.5. Let \(\mathcal{C}\) and \(\mathcal{D}\) be \(\infty\)-categories. Then Theorem 4.6.8.5 supplies an equivalence of \(\infty\)-categories \(\operatorname{Fun}(\mathcal{C}, \mathcal{D}) \rightarrow \operatorname{Hom}_{\mathcal{Q} \mathcal{C}}^{\mathrm{L}}(\mathcal{C}, \mathcal{D})\). Beware that this equivalence is generally not an isomorphism at the level of simplicial sets.

020Q Remark 5.5.5.6 (Comparison with Kan Complexes). Since every Kan complex is an \(\infty\) category (Example 1.4.0.3), we can identify the simplicial category Kan of Construction 5.5.1.1 with a full simplicial subcategory of QCat. Passing to homotopy coherent nerves, we can identify \(\infty\)-category of spaces \(\mathcal{S}=\mathrm{N}_{\bullet}^{\text {hc }}(\) Kan \()\) with the full subcategory of \(\mathcal{Q} \mathcal{C}=\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathbf{Q C a t})\) spanned by the Kan complexes.

020R Remark 5.5.5.7 (Comparison with Categories). Let Cat denote the strict 2-category of small categories (Example 2.2.0.4). By virtue of Proposition 1.5.3.3, the construction \(\mathcal{C} \mapsto \mathrm{N}_{\bullet}(\mathcal{C})\) induces an isomorphism from the Duskin nerve \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathbf{C a t})\) to the full subcategory of \(\mathcal{Q C}\) spanned by those \(\infty\)-categories of the form \(\mathrm{N}_{\bullet}(\mathcal{C})\), where \(\mathcal{C}\) is an ordinary category.

025K Remark 5.5.5.8 (Passage to the Homotopy Category). Let Cat. denote the simplicial category associated to the strict 2-category Cat (see Example 2.4.2.8). For every pair of \(\infty\)-categories \(\mathcal{C}\) and \(\mathcal{D}\), Corollary 1.5 .3 .5 supplies a comparison map
\[
\operatorname{Fun}(\mathcal{C}, \mathcal{D}) \rightarrow \operatorname{Fun}\left(\mathcal{C}, \mathrm{N}_{\bullet}(\mathrm{h} \mathrm{\mathcal{D}})\right) \simeq \mathrm{N}_{\bullet}(\operatorname{Fun}(\mathrm{h} \mathrm{\mathcal{C}}, \mathrm{~h} \mathcal{D}))
\]

This construction is compatible with composition, and therefore determines a functor of simplicial categories
\[
\text { QCat } \rightarrow \text { Cat. } \quad \mathcal{C} \mapsto \mathrm{hC} .
\]

Passing to homotopy coherent nerves (and invoking Example 2.4.3.11), we obtain a functor of \((\infty, 2)\)-categories
\[
\mathcal{Q C}=\mathrm{N}_{\bullet}^{\mathrm{hc}}(\text { QCat }) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\text { Cat }) \simeq \mathrm{N}_{\bullet}^{\mathrm{D}}(\text { Cat })
\]

Stated more informally, the construction \(\mathcal{C} \mapsto \mathrm{hC}\) determines a functor from the \((\infty, 2)\) category \(\mathcal{Q C}\) to the ordinary 2 -category Cat.

03UX Variant 5.5.5.9. Let \(\kappa\) be an uncountable cardinal. We let \(\mathcal{Q C}^{<\kappa}\) denote the full simplicial subset of \(\mathcal{Q C}\) spanned by those \(\infty\)-categories \(\mathcal{C}\) which are \(\kappa\)-small. Then \(\mathcal{Q C}^{<\kappa}\) is an \((\infty, 2)\) category, which we will refer to as the ( \(\infty, 2\) )-category of essentially \(\kappa\)-small \(\infty\)-categories.

\subsection*{5.5.6 \(\infty\)-Categories with a Distinguished Object}

In this section, we study pairs \((\mathcal{C}, C)\), where \(\mathcal{C}\) is a (small) \(\infty\)-category and \(C \in \mathcal{C}\) is a distinguished object. Our goal is to organize the collection of such pairs into an \(\infty\)-category. We consider several variants of this construction which are related by inclusion maps
\[
\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{QCat}_{*}\right) \hookrightarrow \mathcal{Q \mathcal { C } _ { * } \hookrightarrow \mathcal { Q C } \mathcal { O b j } \hookrightarrow \mathcal { Q C } _ { \mathrm { Obj } } ; ~}
\]
their interrelationships can be described informally as follows:
- Morphisms from \((\mathcal{C}, C)\) to \((\mathcal{D}, D)\) in the \(\infty\)-category \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{QCat}_{*}\right)\) are given by functors \(F: \mathcal{C} \rightarrow \mathcal{D}\) which satisfy \(F(C)=D\) (that is, \(F\) is strictly compatible with the choice of distinguished objects).
- Morphisms from \((\mathcal{C}, C)\) to ( \(\mathcal{D}, D\) ) in the \(\infty\)-category \(\mathcal{Q C} \mathcal{F}_{*}\) are given by pairs \((F, \alpha)\), where \(F: \mathcal{C} \rightarrow \mathcal{D}\) is a functor and \(\alpha: F(C) \rightarrow D\) is an isomorphism in the \(\infty\)-category \(\mathcal{D}\) (that is, \(F\) is compatible with the choice of distinguished objects up to isomorphism). The inclusion \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{QCat}_{*}\right) \hookrightarrow \mathcal{Q C}{ }_{*}\) is an equivalence of \(\infty\)-categories (Proposition 5.5.6.6.
- Morphisms from \((\mathcal{C}, C)\) to \((\mathcal{D}, D)\) in the \(\infty\)-category \(\mathcal{Q C}_{\text {Obj }}\) are given by pairs \((F, \alpha)\), where \(F: \mathcal{C} \rightarrow \mathcal{D}\) is a functor and \(\alpha: F(C) \rightarrow D\) is an morphism in the \(\infty\)-category \(\mathcal{D}\) which is not required to be an isomorphism; this \(\infty\)-category contains \(\mathcal{Q} \mathcal{C}_{*}\) as a (non-full) subcategory (Remark 5.5.6.16).
- The simplicial set \(\mathcal{Q C}_{\text {Obj }}\) is an \((\infty, 2)\)-category having the same objects and morphisms as \(\mathcal{Q C}_{\mathrm{Obj}}\), but which also contains information about non-invertible natural transformations between functors (see Example 5.5.6.17).

Construction 5.5.6.1. Let \(\mathcal{Q C}\) denote the \(\infty\)-category of \(\infty\)-categories (Construction 020T 5.5.4.1, and regard the Kan complex \(\Delta^{0}\) as an object of \(\mathcal{Q C}\). We let \(\mathcal{Q C}\), denote the coslice simplicial set \(\mathcal{Q C}_{\Delta^{0}}\).

Proposition 5.5.6.2. The simplicial set \(\mathcal{Q C}_{*}\) is an \(\infty\)-category, and the projection map 020 U \(\mathcal{Q C}_{*} \rightarrow \mathcal{Q C}\) is a left fibration of \(\infty\)-categories.

Proof. By virtue of Proposition 5.5.4.3, the simplicial set \(\mathcal{Q C}\) is an \(\infty\)-category. It follows that for every object \(\mathcal{C} \in \mathcal{Q C}\), the projection map \(\mathcal{Q C}_{\mathcal{C}} / \rightarrow \mathcal{Q C}\) is a left fibration (Corollary 4.3.6.11. Taking \(\mathcal{C}=\Delta^{0}\), we conclude that the projection map \(\mathcal{Q C}_{*} \rightarrow \mathcal{Q C}\) is a left fibration, so that \(\mathcal{Q C}_{*}\) is an \(\infty\)-category (Remark 4.2.1.4).

Example 5.5.6.3 (Objects and Morphisms of \(\mathcal{Q C}_{*}\) ). The low-dimensional simplices of the 020 V \(\infty\)-category \(\mathcal{Q C}_{*}\) are easy to describe:
- The objects of \(\mathcal{Q C}_{*}\) can be identified with pairs \((\mathcal{C}, C)\), where \(\mathcal{C}\) is a (small) \(\infty\)-category and \(C \in \mathcal{C}\) is an object (which we identify with the morphism \(\Delta^{0} \rightarrow \mathcal{C}\) taking the value \(C)\).
- Let \((\mathcal{C}, C)\) and \((\mathcal{D}, D)\) be objects of \(\mathcal{Q C}_{*}\). A morphism from \((\mathcal{C}, C)\) to \((\mathcal{D}, D)\) in the \(\infty\)-category \(\mathcal{Q C}_{*}\) can be identified with a pair \((F, \alpha)\), where \(F: \mathcal{C} \rightarrow \mathcal{D}\) is a functor of \(\infty\)-categories and \(\alpha: F(C) \rightarrow D\) is an isomorphism in the \(\infty\)-category \(\mathcal{D}\).

020W Warning 5.5.6.4. By analogy with Definition 3.2 .1 .5 , it would be natural to refer to the objects \((\mathcal{C}, C)\) of \(\mathcal{Q C}_{*}\) as pointed \(\infty\)-categories. We will avoid using this terminology, since it conflicts with another (related but distinct) notion of pointed \(\infty\)-category that we will consider later (Definition [?]).

020X Remark 5.5.6.5 (Comparison with Pointed Spaces). Let us regard the \(\infty\)-category of spaces \(\mathcal{S}\) as a full subcategory of the \(\infty\)-category \(\mathcal{Q C}\) (Remark 5.5.4.8). The inclusion \(\mathcal{S} \hookrightarrow \mathcal{Q C}\) determines a functor of coslice \(\infty\)-categories \(\mathcal{S}_{*} \rightarrow \mathcal{Q} \mathcal{C}_{*}\). This functor restricts to an isomorphism from \(\mathcal{S}_{*}\) with the full subcategory of \(\mathcal{Q} \mathcal{C}_{*}\) spanned by those pairs \((\mathcal{C}, C)\), where \(\mathcal{C}\) is a Kan complex.

Let QCat denote the ordinary category whose objects are (small) \(\infty\)-categories and whose morphisms are functors, and let \(\mathrm{QCat}_{*}\) denote the coslice category QCat \({ }_{\Delta^{0}} \%\). The simplicial enrichment of QCat (described in Construction 5.5.4.1) determines a simplicial enrichment of the coslice category QCat \({ }_{*}\) (see Variant 5.5.2.3), and Construction 5.5.2.17 yields a coslice comparison functor
\[
\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{QCat}_{*}\right)=\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{QCat}_{\Delta^{0} /}\right) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{QCat}_{\Delta^{0}}=\mathcal{Q} \mathcal{C}_{*} .\right.
\]

020 Y Proposition 5.5.6.6. The coslice comparison functor \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{QCat}_{*}\right) \rightarrow \mathcal{Q C}{ }_{*}\) is an equivalence of \(\infty\)-categories.

Proof. By virtue of Theorem 5.5.2.21, it will suffice to show that for every pair of objects \((\mathcal{C}, C),(\mathcal{D}, D) \in \mathcal{Q C}_{*}\), the restriction map
\[
\operatorname{Fun}(\mathcal{C}, \mathcal{D}) \simeq=\operatorname{Hom}_{\mathrm{QCat}}(\mathcal{C}, \mathcal{D}) \bullet \rightarrow \operatorname{Hom}_{\mathrm{QCat}}(\{C\}, \mathcal{D})=\operatorname{Fun}(\{C\}, \mathcal{D})^{\simeq}
\]
is a Kan fibration. This follows from Proposition 4.4.3.7, since the restriction functor \(\operatorname{Fun}(\mathcal{C}, \mathcal{D}) \rightarrow \operatorname{Fun}(\{C\}, \mathcal{D})\) is an isofibration of \(\infty\)-categories (Corollary 4.4.5.3).
\(020 Z\) Warning 5.5.6.7. The coslice comparison functor \(U: \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{QCat}_{*}\right) \rightarrow \mathcal{Q C}_{*}\) of Proposition 5.5.6.6 is bijective on vertices: objects of either \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{QCat}_{*}\right)\) and \(\mathcal{Q} \mathcal{C}_{*}\) can be identified with pairs \((\mathcal{C}, C)\), where \(\mathcal{C}\) is an \(\infty\)-category and \(C\) is an object of \(\mathcal{C}\). However, it is not bijective on edges (and is therefore not an isomorphism of simplicial sets). If ( \(\mathcal{C}, C\) ) and \((\mathcal{D}, D)\) are objects of \(\mathcal{Q C}_{*}\), then a morphism from \((\mathcal{C}, C)\) to \((\mathcal{D}, D)\) in the \(\infty\)-category \(\mathcal{Q C}_{*}\) can be identified with a pair \((F, \alpha)\), where \(F: \mathcal{C} \rightarrow \mathcal{D}\) is a functor of \(\infty\)-categories and \(\alpha: F(C) \rightarrow D\) is an isomorphism in the \(\infty\)-category \(\mathcal{D}\). The pair \((F, \alpha)\) belongs to the image of \(U\) if and only if the isomorphism \(\alpha\) is a degenerate edge of \(\mathcal{D}\) (which guarantees in particular that \(F(C)=D)\).

We now introduce an enlargement of the \(\infty\)-category \(\mathcal{Q C}_{*}\).

Construction 5.5.6.8. Let \(\mathcal{Q C}\) denote the ( \(\infty, 2\) )-category of \(\infty\)-categories (Construction 0210 5.5.5.1, and regard the Kan complex \(\Delta^{0}\) as an object of \(\mathcal{Q C}\). We let \(\mathcal{Q} \mathcal{C}_{\text {Obj }}\) denote the coslice simplicial set \(\mathcal{Q C}_{\Delta^{0} /}\).

Proposition 5.5.6.9. The simplicial set \(\mathcal{Q C}_{\mathrm{Obj}}\) is an \((\infty, 2)\)-category. Moreover, the 0211 projection map \(\mathcal{Q C}_{\mathrm{Obj}} \rightarrow \mathcal{Q C}\) is an interior fibration of \((\infty, 2)\)-categories.

Proof. It follows from Proposition 5.5.5.2 that \(\mathcal{Q C}\) is an \((\infty, 2)\)-category. The desired conclusion now follows from Corollary 5.4.3.4 and Proposition 5.4.3.1.

Definition 5.5.6.10. Let \(\mathcal{Q C}_{\text {Obj }}\) denote the pith of the \((\infty, 2)\)-category \(\mathcal{Q C}_{\text {Obj }}\) (see Con- 0212 struction 5.4.5.1.

Proposition 5.5.6.11.
(1) The simplicial set \(\mathcal{Q C}_{\mathrm{Obj}}\) is an \(\infty\)-category.
(2) The projection map \(\tilde{V}: \mathcal{Q C}_{*}=\mathcal{Q C}_{\Delta^{0} /} \rightarrow \mathcal{Q C}\) restricts to a functor
\[
V: \mathcal{Q C}_{\mathrm{Obj}}=\operatorname{Pith}\left(\mathcal{Q C}_{\mathrm{Obj}}\right) \rightarrow \operatorname{Pith}(\mathcal{Q C})=\mathcal{Q C}
\]
(3) The diagram

is a pullback square of simplicial sets.
(4) The functor \(V\) is a cocartesian fibration of \(\infty\)-categories.

Proof. Assertion (1) follows from Proposition 5.4.5.6. Since \(\widetilde{V}\) is an interior fibration (Proposition 5.5.6.9), assertions (2) and (3) follow from Proposition 5.4.7.10. Assertion (4) is a special case of Corollary 5.4.7.11.

Example 5.5.6.12 (Objects and Morphisms of \(\mathcal{Q C}_{\text {Obj }}\) ). The inclusion of simplicial sets \(\mathcal{Q C} \hookrightarrow \mathcal{Q C}\) induces a functor of \(\infty\)-categories \(\iota: \mathcal{Q C}_{*} \hookrightarrow \mathcal{Q C} \mathcal{O b j}\). The functor \(\iota\) is bijective on vertices. In particular, we can identify the objects of \(\mathcal{Q C}_{\text {Obj }}\) with pairs \((\mathcal{C}, C)\), where \(\mathcal{C}\) is a (small) \(\infty\)-category and \(C \in \mathcal{C}\) is an object. However, it is not bijective on edges. Unwinding the definitions, we see that a morphism \(\widetilde{F}\) from \((\mathcal{C}, C)\) to \((\mathcal{D}, D)\) in the \(\infty\)-category \(\mathcal{Q C}_{\text {Obj }}\) can be identified with a pair \((F, \alpha)\), where \(F: \mathcal{C} \rightarrow \mathcal{D}\) is a functor of \(\infty\)-categories and \(\alpha: F(C) \rightarrow D\) is a morphism in the \(\infty\)-category \(\mathcal{D}\). For every such pair \((F, \alpha)\), the following conditions are equivalent:
- The morphism \(\widetilde{F}=(F, \alpha)\) belongs to the image of the inclusion map \(\iota: \mathcal{Q C}_{*} \hookrightarrow \mathcal{Q C}_{\text {Obj }}\).
- The morphism \(\alpha: F(C) \rightarrow D\) is an isomorphism in the \(\infty\)-category \(\mathcal{D}\).
- The morphism \(\widetilde{F}\) is \(V\)-cocartesian, where \(V: \mathcal{Q C}_{\text {Obj }} \rightarrow \mathcal{Q C}\) is the cocartesian fibration of Proposition 5.5.6.11.

02S4 Remark 5.5.6.13 (Fibers of \(V\) ). Let \(\mathcal{C}\) be a small \(\infty\)-category, which we regard as an object of the \(\infty\)-category \(\mathcal{Q C}\). Then Construction 4.6.8.3 supplies a comparison map
\[
\begin{aligned}
& \mathcal{C}=\operatorname{Hom}_{\mathbf{Q C a t}}\left(\Delta^{0}, \mathcal{C}\right) \\
& \xrightarrow{\theta_{\mathcal{C}}} \operatorname{Hom}_{\mathcal{Q} \mathcal{L}}^{\mathrm{L}}\left(\Delta^{0}, \mathcal{C}\right) \\
&=\{\mathcal{C}\} \times_{\mathcal{Q C}} \mathcal{Q C}_{\mathrm{Obj}} \\
&=\{\mathcal{C}\} \times_{\mathcal{Q C}} \mathcal{Q C}_{\mathrm{Obj}},
\end{aligned}
\]
which is an equivalence of \(\infty\)-categories (Theorem 4.6.8.9). Beware that \(\theta_{\mathcal{C}}\) is generally not an isomorphism of simplicial sets (though it is bijective on \(n\)-simplices for \(n \leq 1\); see Example 5.5.6.12.

We have the following generalization of Proposition 5.5.3.6.
02 S 5 Proposition 5.5.6.14. Let \(V: \mathcal{Q C}_{\mathrm{Obj}} \rightarrow \mathcal{Q C}\) be the cocartesian fibration of Proposition 5.5.6.11 and let
\[
\mathrm{h} \operatorname{Tr}_{\mathcal{Q C}_{\mathrm{Obj}} / \mathcal{Q C}}: \mathrm{h} \mathcal{Q C} \rightarrow \mathrm{hQCat}
\]
denote the enriched homotopy transport representation of Construction 5.2.8.9. Then \(\mathrm{h} \operatorname{Tr}_{\mathcal{Q C}_{\mathrm{Obj}} / \mathcal{Q C}}\) is homotopy inverse (as an hKan-enriched functor) to the isomorphism \(\mathrm{hQCat} \simeq \mathrm{h} \mathcal{Q C}\) supplied by Remark 5.5.4.6. In particular, \(\mathrm{h}_{\operatorname{Tr}_{\mathcal{Q}} \mathrm{O}_{\text {obj }} / \mathcal{Q C}}\) is an equivalence of hKan-enriched categories.

Proof. Apply Theorem 5.4.9.2 to the simplicial category QCat.
02S6 Remark 5.5.6.15. The statement of Proposition 5.5.6.14 can be made more precise: Theorem 5.4.9.2 supplies an explicit hKan-enriched isomorphism from the identity functor \(i^{i d Q C a t}\) to the composition
\[
\mathrm{hQCat} \xrightarrow{\sim} \mathrm{hQC} \xrightarrow{\mathrm{hTr}_{\mathcal{Q}}^{\mathrm{Obj}}} / \mathcal{Q C} \mathrm{hQCat},
\]
which carries each small \(\infty\)-category \(\mathcal{C}\) to the equivalence
\[
\theta_{\mathcal{C}}: \mathcal{C} \rightarrow\{\mathcal{C}\} \times_{\mathcal{Q C}} \mathcal{Q C}_{\mathrm{Obj}}=\mathrm{h} \operatorname{Tr}_{\mathcal{Q C}_{\mathrm{Obj}} / \mathcal{Q C}}(\mathcal{C})
\]
described in Remark 5.5.6.13,

Remark 5.5.6.16. The inclusion map \(\iota: \mathcal{Q C}_{*} \hookrightarrow \mathcal{Q C}_{\text {Obj }}\) is an isomorphism from \(\mathcal{Q C}_{*}\) to the 0215 (non-full) subcategory of \(\mathcal{Q C}_{\text {Obj }}\) spanned by those morphisms which satisfy the conditions of Example 5.5.6.12 In other words, the projection map \(\mathcal{Q C} * \rightarrow \mathcal{Q C}\) is the underlying left fibration of the cocartesian fibration \(\mathcal{Q C}_{\text {Obj }} \rightarrow \mathcal{Q C}\) (see Corollary 5.4.7.12).

Note that the inclusion map \(\mathcal{Q C}_{\text {Obj }}=\operatorname{Pith}\left(\mathcal{Q C}_{\text {Obj }}\right) \hookrightarrow \mathcal{Q C}_{\text {Obj }}\) is bijective on simplices of dimension \(\leq 1\) (Remark 5.4.5.2). However, it is not bijective at the level of 2 -simplices.
Example 5.5.6.17 (2-Simplices of \(\mathcal{Q C}_{\text {Obj }}\) ). By virtue of Example 5.5.6.12, a morphism of 0216 simplicial sets \(\sigma_{0}: \partial \Delta^{2} \rightarrow \mathcal{Q C}_{\text {Obj }}\) can be identified with the following data:
- A collection of \(\infty\)-categories \(\mathcal{C}, \mathcal{D}\), and \(\mathcal{E}\) equipped with distinguished objects \(C \in \mathcal{C}\), \(D \in \mathcal{D}\), and \(E \in \mathcal{E}\).
- A collection of functors \(F: \mathcal{C} \rightarrow \mathcal{D}, G: \mathcal{D} \rightarrow \mathcal{E}\), and \(H: \mathcal{C} \rightarrow \mathcal{E}\).
- A collection of morphisms \(\alpha: F(C) \rightarrow D, \beta: G(D) \rightarrow E\), and \(\gamma: H(C) \rightarrow E\) in the \(\infty\)-categories \(\mathcal{D}\) and \(\mathcal{E}\).
Unwinding the definitions, we see that extending \(\sigma_{0}\) to a 2 -simplex \(\sigma\) of \(\mathcal{Q C}_{\text {Obj }}\) is equivalent to choosing a natural transformation of functors \(\mu:(G \circ F) \rightarrow H\) and a morphism of simplicial sets \(\theta: \square^{2} \rightarrow \mathcal{E}\) whose restriction to the boundary \(\partial \square^{2}\) is indicated in the diagram

Moreover:
- The 2 -simplex \(\sigma\) belongs to the image of \(\mathcal{Q C}_{\mathrm{Obj}} \hookrightarrow \mathcal{Q C}_{\text {Obj }}\) if and only if \(\mu: G \circ F \rightarrow H\) is an isomorphism in the functor \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{E})\).
 are all isomorphisms.
- The 2-simplex \(\sigma\) belongs to the image of \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{QCat}_{*}\right) \hookrightarrow \mathcal{Q} \mathcal{C}_{\mathrm{Obj}}\) if and only if \(\mu, \alpha, \beta\), and \(\gamma\) are identity morphisms (so that \(H=G \circ F, D=F(C)\), and \(E=G(D)\) ) and the morphism \(\theta: \square^{2} \rightarrow \mathcal{E}\) is constant.

Variant 5.5.6.18. Let \(\kappa\) be an uncountable cardinal. We let \(\mathcal{Q C}_{\text {Obj }}^{<\kappa}\) denote the full simplicial 03UY subset of \(\mathcal{Q C}_{\text {Obj }}\) spanned by those pairs \((\mathcal{C}, C)\) where the \(\infty\)-category \(\mathcal{C}\) is \(\kappa\)-small, and we define \(\mathcal{Q C}_{\mathrm{Obj}}^{<\kappa}=\operatorname{Pith}\left(\mathcal{Q C}_{\mathrm{Obj}}^{<\kappa}\right)\) similarly. The projection map \(\mathcal{Q C} \mathcal{O b j}_{<\kappa}^{\mathcal{L}} \rightarrow \mathcal{Q C}^{<\kappa}\) is then a cocartesian fibration of \(\infty\)-categories, whose fibers are \(\kappa\)-small.

\subsection*{5.6 Classification of Cocartesian Fibrations}

Our goal in this section is to address the following:
0380 Question 5.6.0.1. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of \(\infty\)-categories. To what extent can \(U\) be recovered from the collection of \(\infty\)-categories \(\left\{\mathcal{E}_{C}\right\}_{C \in \mathcal{C}}\) ?

In \(\$ 5.2 .7\), we gave an answer to Question 5.6.0.1 under the assumption that \(U\) is a left covering map. In this case, the construction \(C \mapsto \mathcal{E}_{C}\) determines a functor \(\mathrm{hTr} \mathcal{E} / \mathcal{C}: \mathrm{hC} \rightarrow\) Set. Moreover, the \(\infty\)-category \(\mathcal{E}\) can be recovered (up to isomorphism) as the fiber product \(\mathcal{C} \times_{\mathrm{N}_{\mathbf{\bullet}}(\mathrm{hC})} \int_{\mathrm{h} \mathrm{\mathcal{C}}} \mathrm{hTr}_{\mathcal{E} / \mathcal{C}}\) (Proposition 5.2.7.2), where the second factor denotes the category of elements of the set-valued functor \(\mathrm{hTr}_{\mathcal{E} / \mathcal{C}}\) (Construction 5.2.6.1).

In the setting of classical category theory, Grothendieck gave a complete answer to Question 5.6.0.1 Let \(\mathcal{C}\) be an ordinary category, and let Cat denote the (strict) 2-category of small categories (Example 2.2.0.4), and let \(\mathscr{F}: \mathcal{C} \rightarrow\) Cat be a functor of 2-categories. In 5.6.1 we introduce a category \(\int_{\mathcal{C}} \mathscr{F}\) whose objects are pairs \((C, X)\) where \(C\) is an object of \(\mathcal{C}\) and \(X\) is an object of the category \(\mathscr{F}(C)\). We will refer to \(\int_{\mathcal{C}} \mathscr{F}\) as the category of elements of the functor \(\mathscr{F}\) (Definition 5.6.1.1). The category \(\int_{\mathcal{C}} \mathscr{F}\) is equipped with a cocartesian fibration \(U: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\), given on objects by the construction \((C, X) \mapsto C\). Moreover, the cocartesian fibration \(U\) is essentially small: that is, for each object \(C \in \mathcal{C}\), the fiber \(U^{-1}\{C\}\) is an essentially small category (since it is equivalent to the small category \(\mathscr{F}(C)\) ). In [27], Grothendieck showed that, up to isomorphism, every essentially small cocartesian fibration can be obtained in this way (Corollary 5.6.5.19).

In \(\$ 5.6 .2\) we introduce an \(\infty\)-categorical counterpart of the preceding construction. Let \(\mathcal{Q C}_{\text {Obj }}\) denote the \(\infty\)-category of Construction 5.5.6.10, whose objects are pairs \((\mathcal{A}, X)\) where \(\mathcal{A}\) is a (small) \(\infty\)-category and \(X\) is an object of \(\mathcal{A}\). For every morphism of simplicial sets \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\), we let \(\int_{\mathcal{C}} \mathscr{F}\) denote the fiber product \(\mathcal{C} \times{ }_{\mathcal{Q C}} \mathcal{Q C} \mathcal{O b j}\). By construction, vertices of \(\int_{\mathcal{C}} \mathscr{F}\) can be identified with pairs \((C, X)\), where \(C\) is a vertex of \(\mathcal{C}\) and \(X\) is an object of the \(\infty\)-category \(\mathscr{F}(C)\). Projection onto the first factor determines a cocartesian fibration of simplicial sets \(U: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\), given on objects by the construction \((C, X) \mapsto C\) (Proposition 5.6.2.2. In particular, if \(\mathcal{C}\) is an \(\infty\)-category, then the simplicial set \(\int_{\mathcal{C}} \mathscr{F}\) is also an \(\infty\)-category, which we refer to as the \(\infty\)-category of elements of \(\mathscr{F}\) (Definition 5.6.2.4). This construction has the following features:
- Let \(\mathcal{C}\) be an ordinary category and let \(\mathscr{F}: \mathcal{C} \rightarrow \mathbf{C a t}\) be a functor of 2-categories, so that the construction \(C \mapsto \mathrm{~N}_{\bullet}(\mathscr{F}(C))\) determines a functor of \(\infty\)-categories \(\mathrm{N}_{\bullet}(\mathscr{F})\) : \(\mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathcal{Q C}\). In \(\$ 5.6 .3\), we construct a canonical isomorphism of simplicial sets
\[
\int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}(\mathscr{F}) \simeq \mathrm{N}_{\bullet}\left(\int_{\mathcal{C}} \mathscr{F}\right)
\]
where the left hand side is the \(\infty\)-category of elements of the functor \(\mathrm{N}_{\bullet}(\mathscr{F})\) and the right hand side is the nerve of the ordinary category of elements of the functor \(\mathscr{F}\) (Proposition 5.6.3.4). Consequently, we can view the \(\infty\)-category of elements construction as a generalization of the classical category of elements construction.
- Let \(\mathcal{C}\) be an ordinary category and let \(\mathscr{F}: \mathcal{C} \rightarrow\) QCat be a functor of ordinary categories. Passing to the homotopy coherent nerve, we obtain a functor of \(\infty\) categories \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathscr{F}): \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathcal{Q C}\). In \(\S 5.6 .4\), we construct a comparison map
\[
\theta: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathscr{F})
\]
and show that it is an equivalence of \(\infty\)-categories (Proposition 5.6.4.8). In other words, we can think of the \(\infty\)-category of elements as a variant of the weighted nerve construction, which can be applied to homotopy coherent diagrams which are not strictly commutative. Beware that \(\theta\) is usually not an isomorphism of simplicial sets.

It is not difficult to show that if diagrams \(\mathscr{F}, \mathscr{F}^{\prime}: \mathcal{C} \rightarrow \mathcal{Q C}\) are isomorphic (as objects of the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{Q C})\) ), then the cocartesian fibrations
\[
\int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C} \quad \int_{\mathcal{C}} \mathscr{F}^{\prime} \rightarrow \mathcal{C}
\]
are equivalent (see Proposition 5.6.2.19). It follows that the construction \(\mathscr{F} \mapsto \int_{\mathcal{C}} \mathscr{F}\) determines a function from the collection of isomorphism classes in the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{Q C})\) to the collection of equivalence classes of cocartesian fibrations over \(\mathcal{C}\). We will show that, modulo set-theoretic technicalities, this function is a bijection.

Theorem 5.6.0.2 (Universality Theorem). Let \(\mathcal{C}\) be a simplicial set. Then the construction 028 K
\[
(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}) \mapsto\left(\int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\right)
\]
induces a bijection from \(\pi_{0}\left(\operatorname{Fun}(\mathcal{C}, \mathcal{Q C})^{\sim}\right)\) to the set of equivalence classes of essentially small cocartesian fibrations \(U: \mathcal{E} \rightarrow \mathcal{C}\).

Warning 5.6.0.3. In the statement of Theorem 5.6.0.2, the essential smallness assumption 027 Q cannot be omitted: if the cocartesian fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\) is equivalent to \(\int_{\mathcal{C}} \mathscr{F}\) for some diagram \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\), then each fiber \(\mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E}\) is equivalent to the small \(\infty\)-category \(\mathscr{F}(C)\) (see Example 5.6.2.18).

Remark 5.6.0.4. We can summarize Theorem 5.6.0.2 more informally by saying that the 028 M projection map \(V: \mathcal{Q C}_{\text {Obj }} \rightarrow \mathcal{Q C}\) is universal among essentially small cocartesian fibrations. Note that this property characterizes the \(\infty\)-category \(\mathcal{Q C}\) (and the cocartesian fibration \(V\) ) up to equivalence.

028 N Remark 5.6.0.5. We will later show that the bijection of Theorem 5.6.0.2 can be upgraded to an equivalence of \(\infty\)-categories; see Theorem [?].

028 T Corollary 5.6.0.6. Let \(\mathcal{C}\) be a simplicial set. Then the construction
\[
(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}) \mapsto\left(\int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\right)
\]
induces a bijection from \(\pi_{0}\left(\operatorname{Fun}(\mathcal{C}, \mathcal{S})^{\simeq}\right)\) to the set of equivalence classes of essentially small left fibrations \(U: \mathcal{E} \rightarrow \mathcal{C}\).

0381 Example 5.6.0.7. Let \(\mathcal{C}\) be a locally small \(\infty\)-category and let \(X\) be an object of \(\mathcal{C}\). It follows from Corollary 5.6.0.6 that there is an essentially unique functor \(h^{X}: \mathcal{C} \rightarrow \mathcal{S}\) for \(\int_{\mathcal{C}} h^{X}\) is equivalent to \(\mathcal{C}_{X /}\) as left fibrations over \(\mathcal{C}\). We will refer to \(h^{X}: \mathcal{C} \rightarrow \mathcal{S}\) as the functor corepresented by \(X\). For every object \(Y \in \mathcal{C}\), we have isomorphisms
\[
h^{X}(Y) \simeq\{Y\} \times_{\mathcal{C}} \int_{\mathcal{C}} h^{X} \simeq\{Y\} \times_{\mathcal{C}} \mathcal{C}_{X /}=\operatorname{Hom}_{\mathcal{C}}^{\mathrm{L}}(X, Y) \simeq \operatorname{Hom}_{\mathcal{C}}(X, Y)
\]
in the homotopy category hKan, depending functorially on \(Y\). In 85.6 .6 , we will show that this property characterizes the functor \(h^{X}\) up to isomorphism (Theorem 5.6.6.13).

Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets. We will say that a diagram \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) is a covariant transport representation for \(U\) if there exists an equivalence \(\alpha: \mathcal{E} \rightarrow \int_{\mathcal{C}} \mathscr{F}\) of cocartesian fibrations over \(\mathcal{C}\) (Definition 5.6.5.1). Theorem 5.6.0.2 asserts that if \(U\) is essentially small, then there exists a covariant transport representation for \(U\) which is uniquely determined up to isomorphism (as an object of the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{Q C})\) ). In fact, we will prove something stronger: the covariant transport representation of \(U\) is unique up to a contractible space of choices. In \(\$ 5.6 .8\), we formulate this statement more precisely by introducing a Kan complex \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) whose vertices are pairs \((\mathscr{F}, \alpha)\) as above (see Notation 5.6.8.1. We prove the contractibility of \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) in \(\S 5.6 .9\) as we will see, it is a formal consequence of the fact that the homotopy transport representation of the cocartesian fibration \(V: \mathcal{Q C}_{\text {Obj }} \rightarrow \mathcal{Q C}\) determines an equivalence of hKan-enriched categories \(\mathrm{h}_{\operatorname{Tr}_{\mathcal{Q}} \mathrm{Obj} / \mathcal{Q C}}: \mathrm{hQC} \rightarrow \mathrm{hQCat}\) (Proposition 5.5.6.14).

0382 Remark 5.6.0.8. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration between (small) simplicial sets. We will denote the covariant transport representation of \(U\) by \(\operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\); it can be regarded as a homotopy coherent refinement of the homotopy transport representation \(\mathrm{h} \operatorname{Tr}_{\mathcal{E}} / \mathcal{C}\) introduced in Construction 5.2.5.2 (see Remark 5.6.5.8 for a precise statement). We can summarize the situation with the following informal answer to Question 5.6.0.1.
- For every essentially small cocartesian fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\), the construction \(C \mapsto \mathcal{E}_{C}\) determines a functor of \(\infty\)-categories \(\operatorname{Tr}_{\mathcal{E} / \mathcal{C}}: \mathcal{C} \rightarrow \mathcal{Q C}\). Moreover, we can recover \(\mathcal{E}\) (up to equivalence) as the \(\infty\)-category of elements \(\int_{\mathcal{C}} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\).

Remark 5.6.0.9. In the statement of Theorem 5.6 .0 .2 it is not necessary to assume that
0383 the simplicial set \(\mathcal{C}\) is an \(\infty\)-category. This additional generality will play an essential role in our proof (which will require us to analyze the restriction of the cocartesian fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\) to simplicial subsets of \(\mathcal{C}\) ). Moreover, it has a number of pleasant consequences: since \(\mathcal{Q C}\) is an \(\infty\)-category, it guarantees that every cocartesian fibration of simplicial sets is equivalent to the pullback of a cocartesian fibration between \(\infty\)-categories. In \(\S 5.6 .7\), we use this to prove a sharper statement: every cocartesian fibration of simplicial sets is isomorphic to the pullback of a cocartesian fibration between \(\infty\)-categories (Corollary 5.6.7.3). From this, we deduce that every cocartesian fibration of simplicial sets is an isofibration (Corollary 5.6.7.5, and that the collection of categorical equivalences of simplicial sets is stable under the formation of pullback by cocartesian fibrations (Corollary 5.6.7.6).

\subsection*{5.6.1 Elements of Category-Valued Functors}

Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow\) Set be a functor. In \(\$ 5.2 .6\) we introduced the 0 category of elements \(\int_{\mathcal{C}} \mathscr{F}\), whose objects are pairs \((C, x)\) where \(C\) is an object of \(\mathcal{C}\) and \(x\) is an element of the set \(\mathscr{F}(C)\) (Construction 5.2.6.1). In this section, we study a generalization of this construction, where we allow \(\mathscr{F}\) to be a \(\mathcal{C}\)-indexed diagram of categories (rather than a \(\mathcal{C}\)-indexed diagram of sets). In what follows, we let Cat denote the (strict) 2-category of small categories (Example 2.2.0.4).

Definition 5.6.1.1 (The Category of Elements: Covariant Version). Let \(\mathcal{C}\) be a category 025 N and let \(\mathscr{F}: \mathcal{C} \rightarrow\) Cat be a functor of 2-categories. We define a category \(\int_{\mathcal{C}} \mathscr{F}\) as follows:
- The objects of \(\int_{\mathcal{C}} \mathscr{F}\) are pairs \((C, X)\), where \(C\) is an object of \(\mathcal{C}\) and \(X\) is an object of the category \(\mathscr{F}(C)\).
- Let \((C, X)\) and \((D, Y)\) be objects of \(\int_{\mathcal{C}} \mathscr{F}\). Then a morphism from \((C, X)\) to \((D, Y)\) in the category \(\int_{\mathcal{C}} \mathscr{F}\) is a pair \((f, u)\), where \(f: C \rightarrow D\) is a morphism in the category \(\mathcal{C}\) and \(u: \mathscr{F}(f)(X) \rightarrow Y\) is a morphism in the category \(\mathscr{F}(D)\).
- Let \((f, u):(C, X) \rightarrow(D, Y)\) and \((g, v):(D, Y) \rightarrow(E, Z)\) be morphisms in the category \(\int_{\mathcal{C}} \mathscr{F}\). Then the composition \((g, v) \circ(f, u)\) is the pair \((g \circ f, w)\), where \(w: \mathscr{F}(g \circ f)(X) \rightarrow Z\) is the morphism of \(\mathscr{F}(E)\) given by the composition
\[
\mathscr{F}(g \circ f)(X) \xrightarrow{\mu_{g, f}^{-1}(X)}(\mathscr{F}(g) \circ \mathscr{F}(f))(X) \xrightarrow{\mathscr{F}(g)(u)} \mathscr{F}(g)(Y) \xrightarrow{v} Z,
\]
where \(\mu_{g, f}: \mathscr{F}(g) \circ \mathscr{F}(f) \simeq \mathscr{F}(g \circ f)\) denotes the composition constraint for the functor \(\mathscr{F}\).

We will refer to \(\int_{\mathcal{C}} \mathscr{F}\) as the category of elements of \(\mathscr{F}\).

025M Remark 5.6.1.2. The category of elements \(\int_{\mathcal{C}} \mathscr{F}\) was originally introduced by Grothendieck in [27]. For this reason, many authors refer to the category \(\int_{\mathcal{C}} \mathscr{F}\) as the Grothendieck construction on the functor \(\mathscr{F}\).

01R3 Proposition 5.6.1.3. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow \mathbf{C a t}\) be a functor of 2-categories. Then the category of elements \(\int_{\mathcal{C}} \mathscr{F}\) is well-defined: that is, the composition law described in Definition 5.6.1.1 is unital and associative.

Proof. Let \((D, Y)\) be an object of \(\int_{\mathcal{C}} \mathscr{F}\). We let \(\operatorname{id}_{(D, Y)}\) denote the morphism from \((D, Y)\) to itself given by the pair \(\left(\operatorname{id}_{D}, \epsilon_{D}^{-1}(Y)\right)\), where \(\epsilon_{D}: \operatorname{id}_{\mathscr{F}(D)} \xrightarrow{\sim} \mathscr{F}\left(\operatorname{id}_{D}\right)\) is the identity constraint for the functor \(\mathscr{F}\). We first show that \(\operatorname{id}_{(D, Y)}\) is a (two-sided) unit for the composition law on \(\int_{\mathcal{C}} \mathscr{F}\). We consider two cases:
- Let \((C, X)\) be another object of \(\int_{\mathcal{C}} \mathscr{F}\) and let \((f, u):(C, X) \rightarrow(D, Y)\) be a morphism in \(\int_{\mathcal{C}} \mathscr{F}\). We wish to show that the composition \(\operatorname{id}_{(D, Y)} \circ(f, u)\) is equal to \((f, u)\) (as a morphism from \((C, X)\) to \((D, Y))\). Unwinding the definitions, this is equivalent to the assertion that the morphism \(u: \mathscr{F}(f)(X) \rightarrow Y\) is equal to the composition
\[
\mathscr{F}(f)(X) \xrightarrow{\mu_{\mathrm{id}_{D}, f}^{-1}(X)}\left(\mathscr{F}\left(\operatorname{id}_{D}\right) \circ \mathscr{F}(f)\right)(X) \xrightarrow{\mathscr{F}\left(\mathrm{id}_{D}\right)(u)} \mathscr{F}\left(\mathrm{id}_{D}\right)(Y) \xrightarrow{\epsilon_{D}^{-1}(Y)} Y .
\]

Using the commutativity of the diagram

we are reduced to showing that the composition
\[
\mathscr{F}(f)(X) \xrightarrow{\mu_{\mathrm{id}_{D}, f}^{-1}(X)}\left(\mathscr{F}\left(\operatorname{id}_{D}\right) \circ \mathscr{F}(f)\right)(X) \xrightarrow{\epsilon_{D}^{-1}(\mathscr{F}(f)(X))} \mathscr{F}(f)(X)
\]
is equal to the identity, which follows from axiom (a) of Definition 2.2.4.5.
- Let \((E, Z)\) be another object of \(\int_{\mathcal{C}} \mathscr{F}\), and let \((g, v):(D, Y) \rightarrow(E, Z)\) be a morphism in \(\int_{\mathcal{C}} \mathscr{F}\). We wish to show that the composition \((g, v) \circ \operatorname{id}_{(D, Y)}\) is equal to \((g, v)\) (as a morphism from \((D, Y)\) to \((E, Z)\) ). Unwinding the definitions, this is equivalent to the assertion that the morphism \(v: \mathscr{F}(g)(Z) \rightarrow Y\) is equal to the composition
\[
\mathscr{F}(g)(Y) \xrightarrow{\mu_{g, i d_{D}}^{-1}(Y)}\left(\mathscr{F}(g) \circ \mathscr{F}\left(\operatorname{id}_{D}\right)\right)(Y) \xrightarrow{\mathscr{F}(g)\left(\epsilon_{D}^{-1}(Y)\right)} \mathscr{F}(g)(Y) \xrightarrow{v} Z,
\]
which follows from from axiom (b) of Definition 2.2.4.5.

We now show that composition of morphisms in \(\int_{\mathcal{C}} \mathscr{F}\) is associative. Suppose we are given a composable sequence
\[
(B, W) \xrightarrow{(e, t)}(C, X) \xrightarrow{(f, u)}(D, Y) \xrightarrow{(g, v)}(E, Z)
\]
of morphisms of \(\int_{\mathcal{C}} \mathscr{F}\). Unwinding the definitions, we obtain equalities
\[
\begin{aligned}
(g, v) \circ((f, u) \circ(e, t)) & =(g \circ f \circ e, v \circ \mathscr{F}(g)(u) \circ w) \\
((g, v) \circ(f, u)) \circ(e, t)) & =\left(g \circ f \circ e, v \circ \mathscr{F}(g)(u) \circ w^{\prime}\right)
\end{aligned}
\]
where \(w, w^{\prime}: \mathscr{F}(g \circ f \circ e)(W) \rightarrow(\mathscr{F}(e) \circ \mathscr{F}(f))(X)\) are the morphisms in the category \(\mathscr{F}(E)\) given by clockwise and counterclockwise composition in the diagram

It will therefore suffice to show that this diagram commutes. For the upper square, this follows from axiom \((c)\) of Definition 2.2.4.5. For the lower square, it follows from the naturality of the composition constraint \(\mu_{g, f}\).

Definition 5.6.1.1 has a counterpart for contravariant functors:
Definition 5.6.1.4 (The Category of Elements: Contravariant Version). Let \(\mathcal{C}\) be a category 025P and let \(\mathscr{F}: \mathcal{C}^{\text {op }} \rightarrow \mathbf{C a t}\) be a functor of 2 -categories (Definition 2.2.4.5). We define a category \(\int^{\mathcal{C}} \mathscr{F}\) as follows:
- The objects of \(\int^{\mathcal{C}} \mathscr{F}\) are pairs \((C, X)\), where \(C\) is an object of \(\mathcal{C}\) and \(X\) is an object of the category \(\mathscr{F}(C)\).
- Let \((C, X)\) and \((D, Y)\) be objects of \(\int^{\mathcal{C}} \mathscr{F}\). Then a morphism from \((C, X)\) to \((D, Y)\) in the category \(\int^{\mathcal{C}} \mathscr{F}\) is a pair \((f, u)\), where \(f: C \rightarrow D\) is a morphism in the category \(\mathcal{C}\) and \(u: X \rightarrow \mathscr{F}(f)(Y)\) is a morphism in the category \(\mathscr{F}(C)\).
- Let \((f, u):(C, X) \rightarrow(D, Y)\) and \((g, v):(D, Y) \rightarrow(E, Z)\) be morphisms in the category \(\int^{\mathcal{C}} \mathscr{F}\). Then the composition \((g, v) \circ(f, u)\) is the pair \((g \circ f, w)\), where \(w: X \rightarrow \mathscr{F}(g \circ f)(Z)\) is the morphism of \(\mathscr{F}(C)\) given by the composition
\[
X \xrightarrow{u} \mathscr{F}(f)(Y) \xrightarrow{\mathscr{F}(f)(v)}(\mathscr{F}(f) \circ \mathscr{F}(g))(Z) \xrightarrow{\mu_{f, g}(Z)} \mathscr{F}(g \circ f)(Z),
\]
where \(\mu_{f, g}: \mathscr{F}(f) \circ \mathscr{F}(g) \simeq \mathscr{F}(g \circ f)\) denotes the composition constraint for the lax functor \(\mathscr{F}\).

We will refer to \(\int^{\mathcal{C}} \mathscr{F}\) as the category of elements of the functor \(\mathscr{F}\).
\(025 Q\) Remark 5.6.1.5. The category of elements \(\int^{\mathcal{C}} \mathscr{F}\) can be defined more generally when \(\mathscr{F}: \mathcal{C}^{\text {op }} \rightarrow\) Cat is a lax functor of 2-categories. We will return to this point in \(\S[?]\) (see Definition [?]).

01R5 Remark 5.6.1.6. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow \mathbf{C a t}\) be a functor of 2-categories. Then the construction \((C \in \mathcal{C}) \mapsto \mathscr{F}(C)^{\text {op }}\) determines a functor of 2-categories \(\mathscr{F}{ }^{\circ}\) : \(: \mathcal{C}=\) \(\left(\mathcal{C}^{\mathrm{op}}\right)^{\mathrm{op}} \rightarrow\) Cat. In this case, we have a canonical isomorphism of categories
\[
\int^{\mathcal{C}^{\mathrm{op}}}\left(\mathscr{F}^{\mathrm{op}}\right) \simeq\left(\int_{\mathcal{C}} \mathscr{F}\right)^{\mathrm{op}},
\]
where the left hand side is given by Definition 5.6.1.4 and the right hand side is given by Definition 5.6.1.1.

01 R6 Example 5.6.1.7 (Set-Valued Functors). Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow\) Set be a functor from \(\mathcal{C}\) to the category of sets. Then we can also regard \(\mathscr{F}\) as a functor from \(\mathcal{C}\) to the 2-category Cat (by composing with the fully faithful embedding Set \(\hookrightarrow \mathbf{C a t}\), carrying each set \(S\) to the associated discrete category). In this case, the category \(\int_{\mathcal{C}} \mathscr{F}\) of Definition 5.6.1.1 agrees with the category of elements of \(\mathscr{F}\) defined in Construction 5.2.6.1 Similarly, for every functor \(\mathscr{F}: \mathcal{C}^{\text {op }} \rightarrow\) Set, the category \(\int^{\mathcal{C}} \mathscr{F}\) can be identified with the category of elements of \(\mathscr{F}\) defined in Variant 5.2.6.2.

0260 Example 5.6.1.8. Let Cat denote the category whose objects are (small) categories and whose morphisms are functors, and let \(\mathscr{F}: \mathcal{C} \rightarrow\) Cat be a functor of ordinary categories. Composing with the nerve functor \(\mathrm{N}_{\bullet}:\) Cat \(\rightarrow \operatorname{Set}_{\Delta}\), we obtain a functor \(\mathscr{F}^{\prime}: \mathcal{C} \rightarrow \operatorname{Set}_{\Delta}\). There is a canonical isomorphism of simplicial sets \(\mathrm{N}_{\bullet}^{\mathscr{F}^{\prime}}(\mathcal{C}) \simeq \mathrm{N}_{\bullet}\left(\int_{\mathcal{C}} \mathscr{F}\right)\), where the left hand side denotes the weighted nerve of Definition 5.3.3.1 and \(\int_{\mathcal{C}} \mathscr{F}\) denotes the category of elements introduced in Definition 5.6.1.1. See Exercise 5.3.3.17

01R7 Example 5.6.1.9. Let \(\mathscr{I}\) denote the inclusion from the ordinary category Cat (regarded as a 2 -category having only identity 2 -morphisms) to the 2 -category Cat, and let Cat \({ }_{*}^{\text {lax }}\) denote the category of elements \(\int_{\text {Cat }} \mathscr{I}\). The category Cat \({ }_{*}^{\text {lax }}\) can be described concretely as follows:
- The objects of Cat \({ }_{*}^{\text {lax }}\) are pairs \((\mathcal{C}, X)\), where \(\mathcal{C}\) is a category and \(X\) is an object of \(\mathcal{C}\).
- A morphism from \((\mathcal{C}, X)\) to \((\mathcal{D}, Y)\) is a pair \((F, u)\), where \(F: \mathcal{C} \rightarrow \mathcal{D}\) is a functor and \(u: F(X) \rightarrow Y\) is a morphism in the category \(\mathcal{D}\).
- If \((F, u):(\mathcal{C}, X) \rightarrow(\mathcal{D}, Y)\) and \((G, v):(\mathcal{D}, Y) \rightarrow(\mathcal{E}, Z)\) are morphisms in Cat \({ }_{*}^{\text {lax }}\), then their composition is the pair \((G \circ F, w)\), where \(w\) is the morphism of \(\mathcal{E}\) given by the composition
\[
(G \circ F)(X) \xrightarrow{G(u)} G(Y) \xrightarrow{v} Z .
\]

Example 5.6.1.10. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow \mathbf{C a t}\) denote the (strict) functor
0384 given on objects by the formula \(\mathscr{F}(C)=\mathcal{C}_{/ C}\). Then the category of elements \(\int_{\mathcal{C}} \mathscr{F}\) can be identified with the arrow category \(\operatorname{Fun}([1], \mathcal{C})\).

Notation 5.6.1.11. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow \mathbf{C a t}\) be a functor of 2-categories. 01RA Then the category of elements \(\int_{\mathcal{C}} \mathscr{F}\) is equipped with a forgetful functor \(U: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\), given on objects by the construction \((C, X) \mapsto C\) and on morphisms by the construction \((f, u) \mapsto f\). Similarly, for every functor of 2-categories \(\mathscr{F}: \mathcal{C}^{\text {op }} \rightarrow \mathbf{C a t}\), the category of \(\int^{\mathcal{C}} \mathscr{F}\) of Definition 5.6.1.4 is equipped with a forgetful functor \(U: \int^{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\).

Remark 5.6.1.12 (Fibers of the Forgetful Functor). Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow 025 \mathrm{R}\) Cat be a functor of 2-categories. For every object \(C \in \mathcal{C}\), there is a canonical isomorphism of categories
\[
\mathscr{F}(C) \simeq\{C\} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathscr{F},
\]
which carries each object \(X \in \mathscr{F}(C)\) to the object \((C, X) \in \int_{\mathcal{C}} \mathscr{F}\) and each morphism \(u: X \rightarrow Y\) in \(\mathscr{F}\) to the morphism \(\left(\mathrm{id}_{C}, u \circ \epsilon_{C}(X)\right):(C, X) \rightarrow(C, Y)\) of \(\int_{\mathcal{C}} \mathscr{F}\) (here \(\epsilon_{C}: \mathscr{F}\left(\operatorname{id}_{C}\right) \simeq \mathrm{id}_{\mathscr{F}(C)}\) denotes the identity constraint on the functor \(\left.\mathscr{F}\right)\). Similarly, for each functor \(\mathscr{F}: \mathcal{C}^{\text {op }} \rightarrow \mathbf{C a t}\), we have a canonical isomorphism
\[
\mathscr{F}(C) \simeq\{C\} \times_{\mathcal{C}} \int^{\mathcal{C}} \mathscr{F} .
\]

Remark 5.6.1.13. Let \(V: \mathcal{D} \rightarrow \mathcal{C}\) be a functor between categories. If \(\mathscr{F}: \mathcal{C} \rightarrow \mathbf{C a t}\) is 01 RB a functor of 2-categories, then the composition \((\mathscr{F} \circ V): \mathcal{D} \rightarrow\) Cat is also a functor of 2 -categories, and we have a pullback diagram of categories

where the vertical maps are the forgetful functors of Notation 5.6.1.11. Similarly, for every functor of 2-categories \(\mathscr{F}: \mathcal{C}^{\text {op }} \rightarrow \mathbf{C a t}\), we have a pullback diagram

01RC Example 5.6.1.14. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow\) Cat be a functor between ordinary categories, which we can identify with a strict functor from \(\mathcal{C}\) to the 2-category Cat. Applying Remark 5.6.1.13, we deduce that the category of elements \(\int_{\mathcal{C}} \mathscr{F}\) fits into a pullback diagram

025S Proposition 5.6.1.15. Let \(\mathcal{C}\) be a category, let \(\mathscr{F}: \mathcal{C} \rightarrow\) Cat be a functor of 2-categories, and let \(U: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) denote the forgetful functor. Then a morphism \((f, u):(C, X) \rightarrow(D, Y)\) of \(\int_{\mathcal{C}} \mathscr{F}\) is \(U\)-cocartesian if and only if \(u: \mathscr{F}(f)(X) \rightarrow Y\) is an isomorphism in the category \(\mathscr{F}(D)\).

Proof. Assume first that \(u\) is an isomorphism; we wish to show that \((f, u)\) is a \(U\)-cocartesian morphism of the category \(\int_{\mathcal{C}} \mathscr{F}\). Fix a morphism \(g: D \rightarrow E\) of \(\mathcal{C}\) and an object \(Z \in \mathscr{F}(E)\); we wish to show that every morphism \((g \circ f, w):(C, X) \rightarrow(E, Z)\) in the category \(\int_{\mathcal{C}} \mathscr{F}\) can be written uniquely as a composition \((g, v) \circ(f, u)\) for some morphism \((g, v):(D, Y) \rightarrow(E, Z)\). Unwinding the definitions, we wish to show that there is a unique morphism \(v: \mathscr{F}(g)(Y) \rightarrow Z\) in the category \(\mathscr{F}(E)\) for which the composition
\[
\mathscr{F}(g \circ f)(X) \xrightarrow{\mu_{g, f}^{-1}(X)}(\mathscr{F}(g) \circ \mathscr{F}(f))(X) \xrightarrow{\mathscr{F}(g)(u)} \mathscr{F}(g)(Y) \xrightarrow{v} Z
\]
is equal to \(w\). This is clear, since \(\mu_{g, f}^{-1}(X)\) and \(\mathscr{F}(g)(u)\) are isomorphisms.
Now suppose that \((f, u)\) is a \(U\)-cocartesian morphism of the category \(\int_{\mathcal{C}} \mathscr{F}\); we wish to show that \(u\) is an isomorphism. Let \(\iota: \mathscr{F}(D) \rightarrow\{D\} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathscr{F}\) be the isomorphism of Remark 5.6.1.12. Then the morphism \((f, u)\) factors as a composition
\[
(C, X) \xrightarrow{(f, \mathrm{id})}(D, \mathscr{F}(f)(X)) \xrightarrow{\iota(u)}(D, Y) .
\]

The first half of the argument shows that the morphism \((f, \mathrm{id})\) is also \(U\)-cocartesian, so that \(\iota(u)\) is an isomorphism in the fiber \(\{D\} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathscr{F}\). Since \(\iota\) is an isomorphism of categories, it follows that \(u\) is an isomorphism in the category \(\mathscr{F}(D)\).

Corollary 5.6.1.16. Let \(\mathcal{C}\) be a category. If \(\mathscr{F}: \mathcal{C} \rightarrow \mathbf{C a t}\) is a functor of 2-categories, then the forgetful functor \(U: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) is a cocartesian fibration of categories. If \(\mathscr{F}: \mathcal{C}^{\mathrm{op}} \rightarrow \mathbf{C a t}\) is a functor of 2-categories, then the forgetful functor \(\int^{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) is a cartesian fibration of categories.

Proof. We will prove the first assertion; the second follows by a similar argument. Let ( \(C, X\) ) be an object of the category \(\int_{\mathcal{C}} \mathscr{F}\) and let \(f: C \rightarrow D\) be a morphism in \(\mathcal{C}\); we wish to show that \(f\) can be lifted to a \(U\)-cocartesian morphism \((f, u):(C, X) \rightarrow(D, Y)\) of \(\int_{\mathcal{C}} \mathscr{F}\). This follows immediately from the criterion of Proposition 5.6.1.15. for example, we can take \(Y=\mathscr{F}(f)(X)\) and \(u\) to be the identity morphism.

Remark 5.6.1.17. In \(\$ 5.6 .5\) we will prove a converse to Corollary 5.6.1.16 for every cocartesian fibration of categories \(U: \mathcal{E} \rightarrow \mathcal{C}\), there exists a functor of 2-categories \(\mathscr{F}: \mathcal{C} \rightarrow\) Cat and an isomorphism of categories \(\int_{\mathcal{C}} \mathscr{F} \simeq \mathcal{E}\) whose composition with \(U\) is the forgetful functor of Notation 5.6.1.11. See Corollary 5.6.5.19.

Remark 5.6.1.18 (Covariant Transport). Let \(\mathcal{C}\) be a category, let \(\mathscr{F}: \mathcal{C} \rightarrow\) Cat be a functor of 2-categories, and let \(U: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) be the forgetful functor of Notation 5.6.1.11. For each object \(C \in \mathcal{C}\), let
\[
\iota_{C}: \mathscr{F}(C) \simeq\{C\} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathscr{F} \subseteq \int_{\mathcal{C}} \mathscr{F}
\]
be the isomorphism of Remark 5.6.1.12. Note that every morphism \(f: C \rightarrow D\) in \(\mathcal{C}\) determines a natural transformation of functors \(\widetilde{f}: \iota_{C} \rightarrow \iota_{D} \circ \mathscr{F}(f)\), which carries an object \(X \in \mathscr{F}(C)\) to the \(U\)-cocartesian morphism \((f, \mathrm{id}):(C, X) \rightarrow(D, \mathscr{F}(f)(X))\). It follows that \(\tilde{f}\) identifies \(\mathscr{F}(f)\) with the covariant transport functor \(f\) ! of Notation 5.2.2.2.

\subsection*{5.6.2 Elements of \(\mathcal{Q C}\)-Valued Functors}

Let QCat denote the ordinary category whose objects are \(\infty\)-categories and whose 026H morphisms are functors (Construction 5.5.4.1). To every functor \(\mathscr{F}: \mathcal{C} \rightarrow\) QCat, the weighted nerve construction of Definition 5.3.3.1 supplies a cocartesian fibration of \(\infty\) categories \(U: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) (Corollary 5.3.3.16), whose fiber over an object \(C \in \mathcal{C}\) is isomorphic to the \(\infty\)-category \(\mathscr{F}(C)\) (Example 5.3.3.8). The utility of this construction is limited by the fact that it applies only to strictly commutative diagrams in QCat: that is, Definition 5.3.3.1 requires \(\mathcal{C}\) to be an ordinary category and \(\mathscr{F}\) to be a functor of ordinary categories. Our goal in this section is to introduce a homotopy coherent variant of the
weighted nerve which is associated to any functor of \(\infty\)-categories \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\); here \(\mathcal{Q C}\) denotes the \(\infty\)-category of \(\infty\)-categories introduced in Construction 5.5.4.1.

026J Definition 5.6.2.1. Let \(\mathcal{C}\) be a simplicial set and let \(\mathscr{F}: \mathcal{C} \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Set}_{\Delta}\right)\) be a morphism of simplicial sets. We let \(\int_{\mathcal{C}} \mathscr{F}\) denote the fiber product \(\mathcal{C} \times{ }_{\mathrm{N}_{\bullet} \mathrm{c}\left(\operatorname{Set}_{\Delta}\right)} \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Set}_{\Delta}\right)_{\Delta^{0}} /\), so that we have a pullback diagram of simplicial sets

We will refer to \(U: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) as the projection map.
The simplicial set \(\int_{\mathcal{C}} \mathscr{F}\) of Definition 5.6.2.1 is defined for an arbitrary morphism \(\mathscr{F}\) : \(\mathcal{C} \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Set}_{\Delta}\right)\). However, we will be primarily interested in the case where \(\mathscr{F}\) takes values in the simplicial subset \(\mathcal{Q C} \subseteq \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Set}_{\Delta}\right)\) introduced in Construction 5.5.4.1.

026K Proposition 5.6.2.2. Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) be a morphism of simplicial sets. Then the projection map \(U: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) is a cocartesian fibration of simplicial sets.

Proof. By construction, the morphism \(U\) fits into a pullback diagram

where
\[
\mathcal{Q C} \mathrm{Obj}=\mathcal{Q C} \times_{\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Set}_{\Delta}\right)} \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Set}_{\Delta}\right)_{\Delta^{0}}
\]
is the \(\infty\)-category introduced in Construction 5.5.6.10. It will therefore suffice to show that the projection map \(\mathcal{Q C}_{\text {Obj }} \rightarrow \mathcal{Q C}\) is a cocartesian fibration of simplicial sets, which follows from Proposition 5.5.6.11.

026L Corollary 5.6.2.3. Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) be a functor of \(\infty\)-categories. Then the simplicial set \(\int_{\mathcal{C}} \mathscr{F}\) of Definition 5.6.2.1 is an \(\infty\)-category.

026 M Definition 5.6.2.4. Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) be a functor of \(\infty\)-categories. We will refer to \(\int_{\mathcal{C}} \mathscr{F}\) as the \(\infty\)-category of elements of \(\mathscr{F}\).

Remark 5.6.2.5. Let \(\mathcal{C}\) be an ordinary category equipped with a strictly unitary functor 026 N of 2-categories \(\mathscr{F}: \mathcal{C} \rightarrow \mathbf{C a t}\). Then the construction \(C \mapsto \mathrm{~N}_{\bullet}(\mathscr{F}(C))\) determines a functor of \(\infty\)-categories \(\mathrm{N}_{\bullet}(\mathscr{F}): \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathcal{Q C}\) (see Remark 5.5.4.9). In 5.6.3, we will construct a canonical isomorphism
\[
\int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}(\mathscr{F}) \simeq \mathrm{N}_{\bullet}\left(\int_{\mathcal{C}} \mathscr{F}\right),
\]
where the simplicial set on the left hand side is given by Definition 5.6.2.1 and \(\int_{\mathcal{C}} \mathscr{F}\) is the category of elements introduced in Definition 5.6.1.1 (see Proposition 5.6.3.4). Stated more informally, we can regard the \(\infty\)-category of elements construction (Definition 5.6.2.4) as a generalization of the classical category of elements construction (Definition 5.6.1.1).

Warning 5.6.2.6. In \(\S 5.6 .1\), we introduced a variant of the category of elements construction for contravariant Cat-valued functors \(\mathscr{F}: \mathcal{C}^{\text {op }} \rightarrow\) Cat (see Definition 5.6.1.4), which is characterized by the formula
\[
\int^{\mathcal{C}} \mathscr{F}=\left(\int_{\mathcal{C}^{\mathrm{op}}} \mathscr{F}^{\mathrm{op}}\right)^{\mathrm{op}} .
\]

In the \(\infty\)-categorical setting, the situation is more subtle: the involution \(\mathcal{E} \mapsto \mathcal{E}^{\mathrm{op}}\) does not preserve the simplicial structure on the category QCat and therefore does not induce an involution on the simplicial set \(\mathcal{Q C}=\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathrm{QCat})\). We will return to this point in \(\S[?]\).

Warning 5.6.2.7. Let \(\mathscr{F}: \mathcal{C} \rightarrow\) QCat be a functor of ordinary categories. Passing to 026Q the homotopy coherent nerve, we obtain a functor of \(\infty\)-categories \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathscr{F}): \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathcal{Q C}\). Beware that the simplicial set \(\int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\text {hc }}(\mathscr{F})\) is usually not isomorphic to the weighted nerve \(\mathrm{N}_{0}^{\mathscr{F}}(\mathcal{C})\) of Definition 5.3.3.1, even in the special case \(\mathcal{C}=\Delta^{0}\). However, in 5.6 .4 we will construct a comparison map
\[
\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathscr{F})
\]
which is an equivalence of \(\infty\)-categories (Proposition 5.6.4.8).
Example 5.6.2.8 (Set-Valued Functors). Let Set denote the category of sets, and let us regard the nerve \(\mathrm{N}_{\bullet}(\mathrm{Set})\) as a simplicial subset of the homotopy coherent nerve \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Set}_{\Delta}\right)\). Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathrm{N}_{\bullet}\) (Set) be a morphism of simplicial sets, which we can identify with a functor of categories h \(\mathscr{F}: \mathrm{hC} \rightarrow\) Set. Using Example 5.5.3.12 and Remark 5.2.6.6, we obtain a canonical isomorphism of simplicial sets
\[
\int_{\mathcal{C}} \mathscr{F} \simeq \mathcal{C} \times_{\mathrm{N}_{\bullet}(\mathrm{hC})} \mathrm{N}_{\bullet}\left(\int_{\mathrm{hC}} \mathrm{~h} \mathscr{F}\right),
\]
where \(\int_{\mathcal{C}} \mathscr{F}\) is the simplicial set of Definition 5.6.2.1 and \(\int_{\mathrm{h} \mathcal{C}} \mathrm{h} \mathscr{F}\) is the category of elements introduced in Construction 5.2.6.1. In particular, the projection map \(\int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) is a left covering map.

026 S Example 5.6.2.9 ( \(\mathcal{S}\)-Valued Functors). Let \(\mathcal{S}\) denote the \(\infty\)-category of spaces (Construction 5.5.1.1 , which we view as a full simplicial subset of \(\mathrm{N}_{\bullet}^{\text {hc }}\left(\operatorname{Set}_{\Delta}\right)\), and let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}\) be a morphism of simplicial sets. Then the simplicial set \(\int_{\mathcal{C}} \mathscr{F}\) fits into pullback diagram

where \(\mathcal{S}_{*}\) is the \(\infty\)-category of pointed spaces (Construction 5.5.3.1). In this case, Proposition 5.5.3.2 guarantees that the projection map \(\pi: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) is a left fibration of simplicial sets.

026 T Example 5.6.2.10 ( \(\mathcal{Q}\) - -Valued Functors). Let \(\mathcal{Q C}\) denote the \((\infty, 2)\)-category of \(\infty\) categories (Construction 5.5.5.1), which we view as a full simplicial subset of \(\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Set}_{\Delta}\right)\), and let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) be a morphism of simplicial sets. We then have a pullback diagram of simplicial sets

where \(\mathcal{Q C}_{\text {Obj }}\) is the \((\infty, 2)\)-category of Construction 5.5.6.10 (Construction 5.5.6.8). If \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) is a functor of \((\infty, 2)\)-categories, then Proposition 55.5.6.9 and Remark 5.4.2.4 guarantee that \(\pi: \int_{\mathcal{C}} \mathscr{F}\) is an interior fibration; in particular, \(\int_{\mathcal{C}} \mathscr{F}\) is also an \((\infty, 2)\)-category.

026U Warning 5.6.2.11. Let \(\mathcal{C}\) be an \((\infty, 2)\)-category and let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) be a morphism of simplicial sets. If \(\mathscr{F}\) is not a functor, then \(\int_{\mathcal{C}} \mathscr{F}\) need not be an \((\infty, 2)\)-category (this phenomenon arises already in the case \(\mathcal{C}=\Delta^{2}\) ).

026V Example 5.6.2.12 (Objects of the \(\infty\)-Category of Elements). Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Set}_{\Delta}\right)\) be a morphism of simplicial sets. Then vertices of the simplicial set \(\int_{\mathcal{C}} \mathscr{F}\) can be identified with pairs \((C, X)\), where \(C\) is a vertex of \(\mathcal{C}\) and \(X\) is a vertex of the simplicial set \(\mathscr{F}(C)\) (see Example 5.5.6.12). Moreover, the projection map \(U: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) is given on vertices by the construction \(U(C, X)=C\).

026W Example 5.6.2.13 (Morphisms of the \(\infty\)-Category of Elements). Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Set}_{\Delta}\right)\) be a morphism of simplicial sets. Let \((C, X)\) and \((D, Y)\) be vertices of the simplicial set \(\int_{\mathcal{C}} \mathscr{F}\). Edges of \(\int_{\mathcal{C}} \mathscr{F}\) from \((C, X)\) to \((D, Y)\) can be identified with pairs \((f, u)\), where \(f: C \rightarrow D\) is an edge of the simplicial set \(\mathcal{C}\) and \(u: \mathscr{F}(f)(X) \rightarrow Y\) is an edge of the simplicial set \(\mathscr{F}(D)\)
(see Example 5.5.6.12). Moreover, the projection map \(U: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) is given on edges by the construction \(U(f, u)=f\).

Remark 5.6.2.14 (Cocartesian Morphisms of the \(\infty\)-Category of Elements). Let \(\mathscr{F}: \mathcal{C} \rightarrow 026 \mathrm{x}\) \(\mathcal{Q C}\) be a morphism of simplicial sets, so that the projection map \(U: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) is a cocartesian fibration of simplicial sets (Proposition 5.6.2.2). Then an edge \((f, u):(C, X) \rightarrow(D, Y)\) of \(\int_{\mathcal{C}} \mathscr{F}\) is \(U\)-cocartesian if and only if \(u: \mathscr{F}(f)(X) \rightarrow Y\) is an isomorphism in the \(\infty\)-category \(\mathscr{F}(D)\) (see Example 5.5.6.12.
Example 5.6.2.15 (2-Simplices of the \(\infty\)-Category of Elements). Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Set}_{\Delta}\right) 0262\) be a morphism of simplicial sets and let \(\sigma_{0}: \partial \Delta^{2} \rightarrow \int_{\mathcal{C}} \mathscr{F}\) be a morphism of simplicial sets, which we depict informally as a diagram

Extensions of \(\sigma_{0}\) to a 2 -simplex of \(\int_{\mathcal{C}} \mathscr{F}\) can be identified with pairs \((\mu, \theta)\), where \(\mu\) : \(\mathscr{F}(g) \circ \mathscr{F}(f) \rightarrow \mathscr{F}(h)\) is an edge of the simplicial set Fun \((\mathscr{F}(C), \mathscr{F}(E))\), and \(\theta: \square^{2} \rightarrow \mathscr{F}(E)\) is a morphism of simplicial sets whose restriction to the boundary \(\partial \square^{2}\) is indicated in the diagram

(see Example 5.5.6.17). Moreover, the projection map \(U: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) is given on 2-simplices by the construction \(U(\mu, \theta)=\mu\).
Example 5.6.2.16. Let \(\mathcal{E}\) be a simplicial set, which we identify with the morphism of 0270 simplicial sets \(\Delta^{0} \rightarrow \mathrm{~N}_{\bullet}^{\text {hc }}\left(\operatorname{Set}_{\Delta}\right)\) taking the value \(\mathcal{E}\). Then the simplicial set \(\int_{\Delta^{0}} \mathcal{E}\) can be identified with the left-pinched morphism space \(\operatorname{Hom}_{\mathrm{Nh}_{\bullet}\left(\operatorname{Set}_{\Delta}\right)}^{\mathrm{L}}\left(\Delta^{0}, \mathcal{E}\right)\). In particular, Construction 4.6.8.3 supplies a comparison morphism
\[
\theta_{\mathcal{E}}: \mathcal{E}=\operatorname{Hom}_{\operatorname{Set}_{\Delta}}\left(\Delta^{0}, \mathcal{E}\right) \bullet \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet}\left(\operatorname{Set}_{\Delta}\right)}^{\mathrm{L}}\left(\Delta^{0}, \mathcal{E}\right)=\int_{\Delta^{0}} \mathcal{E}
\]

If \(\mathcal{E}\) is an \(\infty\)-category, then \(\operatorname{Hom}_{\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Set}_{\Delta}\right)}^{\mathrm{L}}\left(\Delta^{0}, \mathcal{E}\right)\) is also an \(\infty\)-category, and the comparison morphism \(\rho\) is an equivalence of \(\infty\)-categories (Theorem 4.6.8.9). Beware that \(\theta_{\mathcal{E}}\) is generally
not an isomorphism (though it is always a monomorphism which is bijective on simplices of dimension \(\leq 1\) ). For example, Example 5.6.2.15 implies that 2 -simplices of \(\int_{\Delta^{0}} \mathcal{E}\) can be identified with morphisms of simplicial sets \(\rho: \Delta^{1} \times \Delta^{1} \rightarrow \mathcal{E}\) for which the restriction \(\left.\rho\right|_{\Delta^{1} \times\{0\}}\) is a degenerate edge of \(\mathcal{E}\), as indicated in the diagram

The corresponding 2 -simplex of \(\int_{\Delta^{0}} \mathcal{E}\) belongs to the image of \(\theta_{\mathcal{E}}\) if and only if \(\sigma\) is a left-degenerate 2 -simplex of \(\mathcal{E}\) (in which case it is given by \(\theta_{\mathcal{E}}(\tau)\) ).

0271 Remark 5.6.2.17. Let \(U: \mathcal{C}^{\prime} \rightarrow \mathcal{C}\) and \(\mathscr{F}: \mathcal{C} \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{Set}_{\Delta}\right)\) be morphisms of simplicial sets, and let \(\mathscr{F}^{\prime}\) denote the composition \(\left(\mathscr{F}^{\prime} \circ U\right): \mathcal{C}^{\prime} \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Set}_{\Delta}\right)\). Then the simplicial set \(\int_{\mathcal{C}^{\prime}} \mathscr{F}^{\prime}\) can be identified with the fiber product \(\mathcal{C}^{\prime} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathscr{F}\).

0272 Example 5.6.2.18 (Fibers of the \(\infty\)-Category of Elements). Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) be a morphism of simplicial sets. For each vertex \(C \in \mathcal{C}\), Remark 5.6.2.17 and Example 5.6.2.16 supply a canonical isomorphism
\[
\{C\} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathscr{F} \simeq \operatorname{Hom}_{\mathcal{Q} \mathcal{C}}^{\mathrm{L}}\left(\Delta^{0}, \mathscr{F}(C)\right)
\]

In particular, Construction 4.6.8.3 supplies a comparison functor \(\theta_{C}: \mathscr{F}(C) \rightarrow\{C\} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathscr{F}\) which is an equivalence of \(\infty\)-categories (Theorem4.6.8.9), but generally not an isomorphism of simplicial sets.

02 S 7 Proposition 5.6.2.19. Let \(\mathcal{C}\) be a simplicial set, let \(\mathscr{F}, \mathscr{F}^{\prime}: \mathcal{C} \rightarrow \mathcal{Q C}\) be diagrams, and let \(U: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) and \(U^{\prime}: \int_{\mathcal{C}} \mathscr{F}^{\prime} \rightarrow \mathcal{C}\) be the projection maps. If \(\mathscr{F}\) and \(\mathscr{F}^{\prime}\) are isomorphic as objects of the diagram \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{Q C})\), then \(U\) and \(U^{\prime}\) are equivalent as cocartesian fibrations over \(\mathcal{C}\) (in the sense of Definition 5.1.7.1).

Proof. Apply Proposition 5.1.7.10 to the cocartesian fibration \(\mathcal{Q C}_{\text {Obj }} \rightarrow \mathcal{Q C}\) of Proposition 5.5.6.11.

02S8 Proposition 5.6.2.20. Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) be a functor of \(\infty\)-categories, let \(\mathcal{E}=\int_{\mathcal{C}} \mathscr{F}\) denote the \(\infty\)-category of elements of \(\mathscr{F}\), and let
\[
\mathrm{h} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}: \mathrm{hC} \rightarrow \mathrm{~h} \mathcal{Q C}
\]
denote the enriched homotopy transport representation associated to the cocartesian fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\) (see Construction 5.2.8.9). Then there is a canonical isomorphism of hKanenriched functors \(\theta: \mathrm{h} \mathscr{F} \rightarrow \mathrm{h} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\), which carries each object \(C \in \mathcal{C}\) to the comparison map
\[
\theta_{C}: \mathscr{F}(C) \rightarrow \operatorname{hTr}_{\mathcal{E} / \mathcal{C}}(C)=\{C\} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathscr{F}
\]
of Example 5.6.2.18.
Proof. By virtue of Remarks 5.2.8.10 and 5.6.2.17, we may assume without loss of generality that \(\mathcal{C}=\mathcal{Q C}\) and that \(\mathscr{F}\) is the identity functor. In this case, the desired result is a restatement of Proposition 5.5.6.14.

Corollary 5.6.2.21. Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) be a morphism of simplicial sets, let \(U: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C} 027 \mathrm{~K}\) be the cocartesian fibration of Proposition 5.6.2.2, and let
\[
f_{!}:\{C\} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathscr{F} \rightarrow\{D\} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathscr{F}
\]
be a functor which is given by covariant transport along an edge \(f: C \rightarrow D\) of \(\mathcal{C}\) (Definition 5.2.2.4). Then the diagram

commutes in the homotopy category hQCat (where the horizontal maps are the equivalences described in Example 5.6.2.18.

Proof. Without loss of generality, we may assume that \(\mathcal{C}=\Delta^{1}\), in which case the desired result reduces to Proposition 5.6.2.20

Corollary 5.6.2.22. Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) be a functor of \(\infty\)-categories and set \(\mathcal{E}=\int_{\mathcal{C}} \mathscr{F}\). 027 L Then there is a canonical isomorphism \(\mathrm{h} \mathscr{F} \xrightarrow{\sim} \mathrm{h}_{\operatorname{Tr}}^{\mathcal{E} / \mathcal{C}}\) in the functor category \(\operatorname{Fun}(\mathrm{hC}, \mathrm{h} \mathcal{Q C})\), which carries each vertex \(C \in \mathcal{C}\) to the comparison map
\[
\theta_{C}: \mathscr{F}(C) \rightarrow \operatorname{hTr}_{\mathcal{E} / \mathcal{C}}(C)=\{C\} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathscr{F}
\]
of Example 5.6.2.18

\subsection*{5.6.3 Comparison with the Category of Elements}

0273 Let Cat denote the 2-category of small categories (Example 2.2.0.4) and let \(\mathcal{Q C}\) denote the \((\infty, 2)\)-category of small \(\infty\)-categories (Construction 5.5.5.1). Suppose we are given a category \(\mathcal{C}\) equipped with a functor \(\mathscr{F}: \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathcal{Q C}\). Composing with the functor
\[
\mathcal{Q C} \rightarrow \mathrm{N}_{\bullet}^{\mathrm{D}}(\text { Cat }) \quad \mathcal{C} \mapsto \mathrm{hC}
\]
of Remark 5.5.5.8 and invoking Corollary 2.3.4.5, we obtain a (strictly unitary) functor of 2-categories h \(\mathscr{F}: \mathcal{C} \rightarrow \mathbf{C a t}\), which carries each object \(C \in \mathcal{C}\) to the homotopy category of the \(\infty\)-category \(\mathscr{F}(C)\). Our goal in this section is to compare the \(\infty\)-category \(\int_{\mathrm{N}}^{\bullet}(\mathcal{C}) ~ \mathscr{F}\) of Definition 5.6.2.1 with the ordinary category \(\int_{\mathcal{C}} \mathrm{h} \mathscr{F}\) of Definition 5.6.1.1. We begin with two simple observations:
- Objects of the \(\infty\)-category \(\int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathscr{F}\) can be identified with pairs \((C, X)\), where \(C\) is an object of \(\mathcal{C}\) and \(X\) is an object of the \(\infty\)-category \(\mathscr{F}(C)\) (Example 5.6.2.12). Since the \(\infty\)-category \(\mathscr{F}(C)\) and its homotopy category \(\mathrm{h} \mathscr{F}(\mathscr{C})\) have the same objects, we can also identify such pairs with objects of the ordinary category \(\int_{\mathcal{C}} \mathrm{h} \mathscr{F}\).
- Let \((C, X)\) and \((D, Y)\) be objects of the \(\infty\)-category \(\int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathscr{F}\). By definition, morphisms from \((C, X)\) to \((D, Y)\) in the \(\infty\)-category \(\int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathscr{F}\) can be identified with pairs \((f, u)\), where \(f: C \rightarrow D\) is a morphism in the category \(\mathcal{C}\) and \(u: \mathscr{F}(f)(X) \rightarrow Y\) is a morphism in the \(\infty\)-category \(\mathscr{F}(D)\) (Example 5.6.2.13). Every such pair determines a morphism \((f,[u])\) in the ordinary category \(\int_{\mathcal{C}} \mathrm{h} \mathscr{F}\), where \([u]\) denotes the homotopy class of \(u\) (regarded as a morphism in the homotopy category \(\mathrm{h} \mathscr{F}(D)\) ).

Proposition 5.6.3.1. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathcal{Q C}\) be a functor of \(\infty\)-categories. Then there is a unique functor of \(\infty\)-categories
\[
T: \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathscr{F} \rightarrow \mathrm{N}_{\bullet}\left(\int_{\mathcal{C}} \mathrm{h} \mathscr{F}\right)
\]
which is the identity on objects and which carries each morphism \((f, u)\) of \(\int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathscr{F}\) to the pair \((f,[u])\), regarded as a morphism in the ordinary category \(\int_{\mathcal{C}} \mathrm{h} \mathscr{F}\). Moreover, the functor \(T\) exhibits the classical category of elements \(\int_{\mathcal{C}} \mathrm{h} \mathscr{F}\) as the homotopy category of the \(\infty\)-category of elements \(\int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathscr{F}\).

Stated more informally, Proposition 5.6.3.1 asserts that there is a canonical isomorphism of categories
\[
\mathrm{h} \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathscr{F} \xrightarrow{\sim} \int_{\mathcal{C}} \mathrm{h} \mathscr{F} .
\]

In other words, passage to the homotopy category intertwines the classical category of elements construction (Definition 5.6.1.1) with the \(\infty\)-category of elements construction introduced in \(\$ 5.6 .2\).

Proof of Proposition 5.6.3.1. We first prove the existence of the functor \(T\) appearing in the statement of Proposition 5.6.3.1 (the uniqueness is immediate). Since the induced functor of 2-categories \(\mathrm{h} \mathscr{F}: \mathcal{C} \rightarrow\) Cat is strictly unitary, the construction \((f, u) \mapsto(f,[u])\) carries degenerate edges of the \(\infty\)-category \(\int_{\mathrm{N} \cdot(\mathcal{C})} \mathscr{F}\) to identity morphisms in the category \(\int_{\mathcal{C}} \mathrm{h} \mathscr{F}\). It will therefore suffice to show that, for every 2 -simplex \(\sigma\) of the simplicial set \(\int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathscr{F}\) whose boundary is indicated in the diagram

we have an identity \((h,[w])=(g,[v]) \circ(f,[u])\) in the category \(\int_{\mathcal{C}} \mathscr{F}\). Note that the functor \(\mathscr{F}\) determines a natural isomorphism \(\mu: \mathscr{F}(g) \circ \mathscr{F}(f) \xrightarrow{\sim} \mathscr{F}(h)\) in the \(\infty\)-category \(\operatorname{Fun}(\mathscr{F}(C), \mathscr{F}(E))\). Unwinding the definitions, we see that the composition \((g,[v]) \circ(f,[u])\) is equal to \(\left(h,[v] \circ[\mathscr{F}(f)(u)] \circ[\mu(X)]^{-1}\right)\). We are therefore reduced to proving the commutativity of the diagram

in the homotopy category \(\mathrm{h} \mathscr{F}(Z)\). This commutativity is witnessed by the existence of a diagram

in the \(\infty\)-category \(\mathscr{F}(Z)\) itself, which is supplied by the datum of the 2 -simplex \(\sigma\) (see Example 5.6.2.15). This completes the construction of the functor \(T\).

It follows immediately from the definitions that the functor \(T\) is bijective at the level of objects and that, for every pair of objects \((C, X)\) and \((D, Y)\), the induced map
\[
\theta: \pi_{0}\left(\operatorname{Hom}_{\int_{\mathrm{N} \cdot(\mathcal{C})} \mathscr{F}}((C, X),(D, Y)) \rightarrow \operatorname{Hom}_{\int_{\mathcal{C}} \mathrm{h} \mathscr{F}}((C, X),(D, Y))\right.
\]
is surjective. To complete the proof, we must show that \(\theta\) is also injective. Fix a pair of morphisms \((f, u):(C, X) \rightarrow(D, Y)\) and \(\left(f^{\prime}, u^{\prime}\right):(C, X) \rightarrow(D, Y)\) in the \(\infty\)-category \(\int_{\mathrm{N}_{\mathbf{\bullet}}(\mathcal{C})} \mathscr{F}\) having the same image under \(T\), so that \(f=f^{\prime}\) as elements of \(\operatorname{Hom}_{\mathcal{C}}(C, D)\) and the morphisms \(u, u^{\prime}: \mathscr{F}(f)(X) \rightarrow Y\) are homotopic in the \(\infty\)-category \(\mathscr{F}(D)\). By virtue of Corollary 1.4.3.7, there exists a morphism of simplicial sets \(\theta: \square^{2} \rightarrow \mathscr{F}(D)\) whose restriction to the boundary \(\partial \square^{2}\) is indicated in the diagram

By virtue of Example 5.6.2.15, \(\theta\) determines a 2 -simplex of the \(\infty\)-category \(\int_{\mathrm{N}_{\mathbf{\bullet}}(\mathcal{C})} \mathscr{F}\) whose boundary is indicated in the diagram

which we can regard as a homotopy from \((f, u)\) to \(\left(f^{\prime}, u^{\prime}\right)\).
In the statement of Proposition 5.6.3.1, it is essential that the source of the functor \(\mathscr{F}\) is (the nerve of) an ordinary category. For a more general functor of \(\infty\)-categories \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\), one cannot expect to obtain the homotopy category of \(\int_{\mathcal{C}} \mathscr{F}\) from the construction of Definition 5.6.1.1, because the forgetful functor \(\mathrm{h} \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathrm{hC}\) need not be a cocartesian fibration. However, this difficulty does not arise in the case where \(\mathscr{F}\) is a set-valued functor:

0275 Proposition 5.6.3.2. Let \(\mathcal{C}\) be a simplicial set equipped with a morphism \(\mathscr{F}: \mathcal{C} \rightarrow \mathrm{N}_{\bullet}\) (Set), which we can identify with a functor \(\mathrm{h} \mathscr{F}: \mathrm{hC} \rightarrow\) Set. Then the isomorphism of simplicial sets
\[
\int_{\mathcal{C}} \mathscr{F} \simeq \mathcal{C} \times_{\mathrm{N}_{\bullet}(\mathrm{hC})} \mathrm{N}_{\bullet}\left(\int_{\mathrm{hC}} \mathrm{~h} \mathscr{F}\right)
\]
of Example 5.6.2.8 induces an isomorphism of categories
\[
\mathrm{h} \int_{\mathcal{C}} \mathscr{F} \rightarrow \int_{\mathrm{hC}} \mathrm{~h} \mathscr{F} .
\]

Proof. Using Proposition 4.1.3.2, we can factor the unit map \(\mathcal{C} \rightarrow \mathrm{N}_{\bullet}(\mathrm{hC})\) as a composition
\[
\mathcal{C} \xrightarrow{F} \mathcal{C}^{\prime} \xrightarrow{G} \mathrm{~N}_{\bullet}(\mathrm{hC})
\]
where \(F\) is inner anodyne and \(G\) is an inner fibration of simplicial sets (so that \(\mathcal{C}^{\prime}\) is an \(\infty\)-category). It follows that \(\mathscr{F}\) extends uniquely to a morphism \(\mathscr{F}^{\prime}: \mathcal{C}^{\prime} \rightarrow \mathrm{N}_{\bullet}\) (Set). Using Remark 5.6.2.17, we obtain a pullback diagram of simplicial sets

where the vertical maps are cocartesian fibrations (Proposition 5.6.2.2). Since \(F\) is inner anodyne, the map \(\widetilde{F}\) is a categorical equivalence of simplicial sets (Proposition 5.3.6.1). Moreover, since \(F\) is bijective at the level of vertices, \(\widetilde{F}\) is also bijective at the level of vertices. It follows that \(F\) and \(\widetilde{F}\) induce isomorphisms of homotopy categories
\[
\mathrm{h} F: \mathrm{hC} \rightarrow \mathrm{~h} \mathcal{C}^{\prime} \quad \mathrm{h} \widetilde{F}^{\prime}: \mathrm{h} \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathrm{h} \int_{\mathcal{C}^{\prime}} \mathscr{F}^{\prime} .
\]

Replacing \(\mathcal{C}\) by \(\mathcal{C}^{\prime}\), we are reduced to proving Proposition 5.6.3.2 in the special case where \(\mathcal{C}\) is an \(\infty\)-category.

Let \(\mathcal{D}\) be the category of elements \(\int_{\mathrm{h} \mathcal{C}} \mathrm{h} \mathscr{F}\), so that Example 5.6.2.8 supplies a pullback diagram of simplicial sets

We wish to show that \(G\) exhibits \(\mathcal{D}\) as a homotopy category of the \(\infty\)-category \(\int_{\mathcal{C}} \mathscr{F}\). Note that, since \(\bar{G}\) is bijective at the level of vertices, the functor \(G\) has the same property. It will therefore suffice to show that, for every pair of objects \(X, Y \in \int_{\mathcal{C}} \mathscr{F}\), the induced map
\[
\theta_{X, Y}: \operatorname{Hom}_{\int_{\mathcal{C}} \mathscr{F}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(G(X), G(Y))
\]
exhibits \(\operatorname{Hom}_{\mathcal{D}}(G(X), G(Y))\) as the set of connected components of the Kan complex \(\operatorname{Hom}_{\int_{\mathcal{C}} \mathscr{F}}(X, Y)\). Equivalently, we wish to show that each fiber of the map \(\theta_{X, Y}\) is a connected (and therefore nonempty) Kan complex. This is clear, since \(\theta_{X, Y}\) is a pullback of the map
\[
\bar{\theta}_{X, Y}: \operatorname{Hom}_{\mathcal{C}}(U(X), U(Y)) \rightarrow \pi_{0}\left(\operatorname{Hom}_{\mathcal{C}}(U(X), U(Y))\right)=\operatorname{Hom}_{\mathrm{h} \mathcal{C}}(U(X), U(Y)),
\]
whose fibers are the connected components of \(\operatorname{Hom}_{\mathcal{C}}(U(X), U(Y))\).

027 Y Corollary 5.6.3.3. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a morphism of simplicial sets. Then \(U\) is a left covering map (in the sense of Definition 4.2.3.8) if and only if the following pair of conditions is satisfied:
(1) The induced map \(\mathrm{h} U: \mathrm{hE} \rightarrow \mathrm{hC}\) is a left covering functor (in the sense of Definition 4.2.3.1).
(2) The diagram of simplicial sets

is a pullback square.
Proof. The sufficiency of conditions (1) and (2) follows from Proposition 4.2.3.16 and Remark 4.2.3.15. To prove the converse, assume that \(U\) is a left covering map. By virtue of Corollary 5.2.7.4 we may assume that \(\mathcal{E}=\int_{\mathcal{C}} \mathscr{F}\) for some morphism of simplicial sets \(\mathscr{F}: \mathcal{C} \rightarrow \mathrm{N}_{\bullet}\) (Set). Let us abuse notation by identifying \(\mathscr{F}\) with a functor from the homotopy category hC to the category of sets. Using Proposition 5.6.3.2, we can identify hE with the category of elements \(\int_{\mathrm{h} \mathcal{C}} \mathscr{F}\) of Construction 5.2.6.1. Condition (1) now follows from Remark 5.2.6.9, and condition (2) by combining Example 5.6.2.8 with Remark 5.6.2.17.

We now consider a variant of the situation described in Proposition 5.6.3.1. Let \(\mathcal{C}\) be an ordinary category and suppose we are given a strictly unitary functor of 2-categories \(\mathscr{F}: \mathcal{C} \rightarrow\) Cat. Passing to the Duskin nerve (and using Remark 5.5.5.7 to identify \(\mathrm{N}_{\bullet}^{\mathrm{D}}\) (Cat) with a full subcategory of \(\mathcal{Q C})\), we obtain a functor of \(\infty\)-categories \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathscr{F}): \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathcal{Q C}\). Identifying \(\mathrm{hN}_{\bullet}^{\mathrm{D}}(\mathscr{F})\) with the original functor \(\mathscr{F}\), Proposition 5.6.3.1 yields a comparison functor
\[
T: \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{D}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}\left(\int_{\mathcal{C}} \mathscr{F}\right) .
\]

0276 Proposition 5.6.3.4. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}: \mathcal{C} \rightarrow \mathbf{C a t}\) be a strictly unitary functor of 2-categories. Then the comparison map
\[
T: \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{D}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}\left(\int_{\mathcal{C}} \mathscr{F}\right)
\]
is an isomorphism of simplicial sets.
Stated more informally, Proposition 5.6.3.4 asserts that we can regard the classical category of elements construction (Definition 5.6.1.1) as a special case of Definition 5.6.2.4.

Proof of Proposition 5.6.3.4. By virtue of Proposition 5.6.3.1, it will suffice to show that the simplicial set \(\int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{D}}(\mathscr{F})\) is isomorphic to the nerve of a category. We will prove this by verifying the criterion of Proposition 1.3.4.1. Fix \(0<i<n\); we wish to show that every morphism of simplicial sets \(\sigma_{0}: \Lambda_{i}^{n} \rightarrow \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{D}}(\mathscr{F})\) can be extended uniquely to an \(n\)-simplex \(\sigma\) of \(\int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{D}}(\mathscr{F})\). Let \(\bar{\sigma}_{0}\) denote the composition of \(\sigma_{0}\) with the projection map \(\int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{D}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\). Proposition 1.3.4.1 then guarantees that \(\bar{\sigma}_{0}\) extends uniquely to a morphism of simplicial sets \(\bar{\sigma}: \Delta^{n} \rightarrow \mathrm{~N}_{\bullet}(\mathcal{C})\). It will therefore suffice to show that the lifting problem

has a unique solution.
We begin by treating the special case \(n=2\) (so that \(i=1\) ). In this case, we can identify \(\sigma_{0}\) with a pair of composable morphisms
\[
(C, X) \xrightarrow{(f, u)}(D, Y) \xrightarrow{(g, v)}(E, Z)
\]
in the \(\infty\)-category \(\int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{D}}(\mathscr{F})\). Set \(h=g \circ f \in \operatorname{Hom}_{\mathcal{C}}(C, E)\), so that the composition constraint of \(\mathscr{F}\) determines an isomorphism of functors \(\mu: \mathscr{F}(g) \circ \mathscr{F}(f) \xrightarrow{\sim} \mathscr{F}(h)\). Unwinding the definitions (using Example 5.6.2.15, we are reduced to proving that there is a unique morphism \(w: \mathscr{F}(h)(X) \rightarrow Z\) in the category \(\mathscr{F}(E)\) for which the diagram

commutes. This is clear, since \(\mu(X)\) is an isomorphism in the category \(\mathscr{F}(E)\).
We now treat the case \(n \geq 3\). Note that the existence of a solution to the lifting problem (5.28) is automatic (since the projection map \(\pi\) is a cocartesian fibration; see Proposition 5.6.2.2. It will therefore suffice to show that \(\sigma\) is unique. Using Lemma 4.3.6.15 and Remark
5.5.5.7 we can rewrite (5.28) as a lifting problem

The uniqueness of its solution is now an immediate consequence of Proposition 2.3.1.9, since the horn \(\Lambda_{i+1}^{n+1}\) contains the 2-skeleton of \(\Delta^{n+1}\).

0278 Corollary 5.6.3.5. Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) be a morphism of simplicial sets which factors through the full subcategory \(\mathrm{N}_{\bullet}^{\mathrm{D}}(\operatorname{Pith}(\mathbf{C a t})) \subset \mathcal{Q C}\) of Remark 5.5.4.9. Then the projection map \(\int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) is an inner covering map of simplicial sets.

Proof. By virtue of Corollary 4.1.5.11, we may assume without loss of generality that \(\mathcal{C}=\Delta^{n}\) is a standard simplex. In this case, we wish to show that the simplicial set \(\int_{\mathcal{C}} \mathscr{F}\) is isomorphic to the nerve of an ordinary category (see Proposition 4.1.5.10), which is a special case of Proposition 5.6.3.4.

05DZ Warning 5.6.3.6. Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) be a morphism of simplicial sets. In the language of \$4.8. Corollary 5.6.3.5 asserts that if each of the \(\infty\)-categories \(\mathscr{F}(C)\) is a \((1,1)\)-category, then the cocartesian fibration \(U: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) is 1-categorical (see Example 4.8.6.26). Beware that for \(n \geq 2\), the assumption that each \(\mathscr{F}(C)\) is an \((n, 1)\)-category does not guarantee that the cocartesian fibration \(U\) is \(n\)-categorical. However, if \(\mathcal{C}\) is an \(\infty\)-category, then it is essentially \(n\)-categorical: this is an immediate consequence of Variant 5.1.5.17.

\subsection*{5.6.4 Comparison with the Weighted Nerve}

0279 Let \(\mathcal{C}\) be a category which is equipped with a functor \(\mathscr{F}: \mathcal{C} \rightarrow\) QCat. In \(\$ 5.3 .3\) and \(\$ 5.6 .3\) we introduced two different cocartesian fibrations associated to \(\mathscr{F}\) :
- The projection map \(U: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\), where \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) denotes the \(\mathscr{F}\)-weighted nerve of \(\mathcal{C}\) (Definition 5.3.3.1). For each object \(C \in \mathcal{C}\), the fiber \(U^{-1}\{C\}\) is isomorphic (as a simplicial set) to the \(\infty\)-category \(\mathscr{F}(C)\) (Example 5.3.3.8).
- The projection map \(U^{\prime}: \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathscr{F}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\), where \(\int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\text {hc }}(\mathscr{F})\) denotes the \(\infty\)-category of elements of the functor \(\mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathscr{F}): \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathrm{QCat})=\mathcal{Q C}\). For each object \(C \in \mathcal{C}\), the fiber \(U^{\prime-1}\{C\}\) is equivalent (but not necessarily isomorphic) to the \(\infty\)-category \(\mathscr{F}(C)\) (Example 5.6.2.18.

Our goal in this section is to show that these constructions are equivalent (though not necessarily isomorphic).

Construction 5.6.4.1 (The Comparison Map). Let \(\mathcal{C}\) be a category and let \(\vec{C}\) be an 027A \(n\)-simplex of the nerve \(\mathrm{N}_{\bullet}(\mathcal{C})\), given by a diagram
\[
C_{0} \rightarrow C_{1} \rightarrow C_{2} \rightarrow \cdots \rightarrow C_{n-1} \rightarrow C_{n}
\]
in the category \(\mathcal{C}\). Let \(\mathscr{F}\) be a functor from \(\mathcal{C}\) to the category of simplicial sets and suppose that we are given a collection of simplices \(\vec{\sigma}=\left\{\sigma_{j}: \Delta^{j} \rightarrow \mathscr{F}\left(C_{j}\right)\right\}_{0 \leq j \leq n}\) which fit into a commutative diagram

To this data, we can associate a commutative diagram of simplicial sets

027B
where the upper horizontal map is given by the simplicial functor
\[
F: \operatorname{Path}[\{x\} \star[n]] \bullet \rightarrow \operatorname{Set}_{\Delta}
\]
described as follows:
- The functor \(F\) carries \(x\) to the simplicial set \(\Delta^{0}\) (so that \(F\) can be identified with an \(n\)-simplex of the coslice simplicial set \(\left.\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Set}_{\Delta}\right)_{\Delta^{0} /}\right)\).
- The restriction of \(F\) to the simplicial path category Path \([n]\) • is given by the composition
\[
\operatorname{Path}[n] \bullet \rightarrow[n] \xrightarrow{\vec{C}} \mathcal{C} \xrightarrow{\mathscr{F}} \operatorname{Set}_{\Delta}
\]
(as required by the commutativity of the diagram (5.29).
- For \(0 \leq m \leq n\), the induced map of simplicial sets
\[
\operatorname{Hom}_{\operatorname{Path}[\{x\} \star[n]]}(x, m) \bullet \rightarrow \operatorname{Hom}_{\text {Set }_{\Delta}}(F(x), F(m)) \bullet=\mathscr{F}\left(C_{m}\right)
\]
is given by the composition \(\operatorname{Hom}_{\text {Path }[\{x\} \star[n]]}(x, m) \stackrel{\rho}{\rightarrow} \Delta^{m} \xrightarrow{\sigma_{m}} \mathscr{F}\left(C_{m}\right)\), where \(\rho\) is induced by the morphism of partially ordered sets
\[
\operatorname{Hom}_{\text {Path }[\{x\} \star[n]]}(x, m) \rightarrow[m] \quad(S \subseteq\{x\} \star[n]) \mapsto \min (S \backslash\{x\}) .
\]

Note that we can identify the diagram with an \(n\)-simplex \(\theta(\vec{C}, \vec{\sigma})\) of the simplicial set \(\int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathscr{F})\). The construction \((\vec{C}, \vec{\sigma}) \mapsto \theta(\vec{C}, \vec{\sigma})\) then determines a morphism of simplicial sets \(\theta: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathscr{F})\), which we will refer to as the comparison map.
027C Example 5.6.4.2 (The Comparison Map on Vertices). Let \(\mathcal{C}\) be a category and let \(\mathscr{F}\) be a functor from \(\mathcal{C}\) to the category of simplicial sets. Let us identify vertices of the weighted nerve \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) with pairs \((C, X)\), where \(C\) is an object of \(\mathcal{C}\) and \(X\) is a vertex of the simplicial set \(\mathscr{F}(C)\) (Remark 5.3.3.3). Under this identification, the comparison map
\[
\theta: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathscr{F})
\]
of Construction 5.6.4.1 is given on vertices by the construction \((C, X) \mapsto(C, X)\), where we identify \((C, X)\) with a vertex of \(\int_{\mathrm{N}_{\mathbf{0}}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathscr{F})\) using Example 5.6.2.12 In particular, the morphism \(\theta\) is bijective at the level of vertices.

027D Example 5.6.4.3 (The Comparison Map on Edges). Let \(\mathcal{C}\) be a category and let \(\mathscr{F}\) be a functor from \(\mathcal{C}\) to the category of simplicial sets. Let \((C, X)\) and \((D, Y)\) be vertices of the weighted nerve \(\mathrm{N}_{\bullet}^{\mathscr{Y}}(\mathcal{C})\). Using Remark 5.3.3.4 we can identify edges of \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) having source \((C, X)\) and target \((D, Y)\) with pairs \((f, u)\), where \(f: C \rightarrow D\) is a morphism in the category \(\mathcal{C}\) and \(u: \mathscr{F}(f)(X) \rightarrow Y\) is an edge of the simplicial set \(\mathscr{F}(D)\). Under this identification, the comparison map
\[
\theta: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathscr{F})
\]
of Construction 5.6.4.1 is given on edges by the construction \((f, u) \mapsto(f, u)\), where we identify \((f, u)\) with an edge of the simplicial set \(\int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathscr{F})\) using Example 5.6.2.13. In particular, the morphism \(\theta\) is bijective at the level of edges.

027E Warning 5.6.4.4. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}\) be a functor from \(\mathcal{C}\) to the category of simplicial sets. The comparison map \(\theta: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathscr{F})\) of Construction 5.6.4.1 is generally not bijective on \(n\)-simplices for \(n \geq 2\) (even in the special case \(\mathcal{C}=[0]\) ).

027 F Exercise 5.6.4.5. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}\) be a functor from \(\mathcal{C}\) to the category of simplicial sets. Show that the comparison map \(\theta: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathscr{F})\) of Construction 5.6.4.1 is a monomorphism of simplicial sets.

Remark 5.6.4.6. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}\) be a functor from \(\mathcal{C}\) to the category of 027 G simplicial sets. Then the diagram of simplicial sets

is commutative, where the vertical morphisms are the projection maps of Definitions 5.3.3.1 and 5.6.2.1 and \(\theta\) is the comparison morphism of Construction 5.6.4.1
Example 5.6.4.7. Let \(\mathcal{C}\) be a category and let \(\mathscr{F}\) be a functor from \(\mathcal{C}\) to the category of 027 H simplicial sets. For every object \(C \in \mathcal{C}\), the comparison morphism \(\theta: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\text {hc }}(\mathscr{F})\) of Construction 5.6.4.1 induces a morphism of simplicial sets
\[
\theta_{C}:\{C\} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow\{C\} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathscr{F}) .
\]

Under the isomorphisms
\[
\mathscr{F}(C) \simeq\{C\} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \quad \operatorname{Hom}_{\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\operatorname{Set}_{\Delta}\right)}^{\mathrm{L}}\left(\Delta^{0}, \mathscr{F}(C)\right) \simeq\{C\} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathscr{F})
\]
supplied by Examples 5.3.3.8 and 5.6.2.18, we can identify \(\theta_{C}\) with the comparison map \(\mathscr{F}(C) \rightarrow \operatorname{Hom}_{\mathrm{N}_{\bullet}{ }^{\mathrm{hc}\left(\mathrm{Set}_{\Delta}\right)}}^{\mathrm{L}}\left(\Delta^{0}, \mathscr{F}(C)\right)\) of Construction 4.6.8.3.
Proposition 5.6.4.8. Let \(\mathcal{C}\) be a category equipped with a functor \(\mathscr{F}: \mathcal{C} \rightarrow\) QCat, and let 027 J

be the commutative diagram of Remark 5.6.4.6. Then:
(1) For each object \(C \in \mathcal{C}\), the morphism \(\theta\) induces an equivalence of \(\infty\)-categories
\[
\theta_{C}:\{C\} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow\{C\} \times_{\mathrm{N}_{\bullet}(\mathcal{C})} \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathscr{F})
\]
(2) A morphism \(f\) of the weighted nerve \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) is \(U\)-cocartesian if and only if \(\theta(f)\) is a \(U^{\prime}\)-cocartesian morphism of the \(\infty\)-category \(\int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathscr{F})\).
(3) The functor \(\theta\) is an equivalence of \(\infty\)-categories.

Proof. Assertion (1) follows from Example 5.6.4.7 and Theorem 4.6.8.9. Assertion (2) follows from Example 5.6.4.3 together with the descriptions of \(U\)-cocartesian and \(U^{\prime}\)-cocartesian morphisms supplied by Corollary 5.3.3.16 and Remark 5.6.2.14. Assertion (3) follows by combining (1) and (2) with Theorem 5.1.6.1 (since \(U\) and \(U^{\prime}\) are cocartesian fibrations, by virtue of Corollary 5.3.3.16 and Proposition 5.6.2.2.

\subsection*{5.6.5 The Universality Theorem}

028 U Throughout this section, we let \(\mathcal{Q C}_{\text {Obj }}\) denote the \(\infty\)-category of pairs \((\mathcal{C}, C)\), where \(\mathcal{C}\) is a small \(\infty\)-category and \(C\) is an object of \(\mathcal{C}\) (Definition 5.5.6.10), and we let \(V: \mathcal{Q C}_{\text {Obj }} \rightarrow \mathcal{Q C}\) denote the forgetful functor (given on objects by the formula \(V(\mathcal{C}, C)=\mathcal{C}\) ).

028 V Definition 5.6.5.1. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets. We will say that a commutative diagram of simplicial sets

witnesses \(\mathscr{F}\) as a covariant transport representation of \(U\) if the induced map
\[
\mathcal{E} \rightarrow \mathcal{C} \times_{\mathcal{Q C}} \mathcal{Q C}_{\mathrm{Obj}}=\int_{\mathcal{C}} \mathscr{F}
\]
is an equivalence of cocartesian fibrations over \(\mathcal{C}\), in the sense of Definition 5.1.7.1. We say that \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) is a covariant transport representation of \(U\) if there exists a diagram which witnesses \(\mathscr{F}\) as a covariant transport representation of \(U\).

028W Remark 5.6.5.2. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of \(\infty\)-categories and let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) be a functor. By virtue of Proposition 5.1.7.5, a diagram

witnesses \(\mathscr{F}\) as a covariant transport representation for \(U\) if and only if the induced map \(\mathcal{E} \rightarrow \int_{\mathcal{C}} \mathscr{F}\) is an equivalence of \(\infty\)-categories. We will later extend this observation to the case where \(\mathcal{C}\) is a general simplicial set (Corollary 5.6.7.8).

Remark 5.6.5.3. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets. A commutative 028 X diagram

witnesses \(\mathscr{F}\) as a covariant transport representation of \(U\) if and only if it satisfies the following pair of conditions:
(a) For every vertex \(C \in \mathcal{C}\), the map of fibers
\[
\widetilde{\mathscr{F}}_{C}: \mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E} \rightarrow\{C\} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathscr{F}
\]
is an equivalence of \(\infty\)-categories.
(b) The morphism \(\widetilde{\mathscr{F}}\) carries \(U\)-cocartesian edges of \(\mathcal{E}\) to \(V\)-cocartesian edges of \(\mathcal{Q} \mathcal{C}_{\text {Obj }}\).

See Proposition 5.1.7.14. Moreover, we can replace (b) by the following a priori weaker condition (see Remark 5.1.6.8):
( \(\left.b^{\prime}\right)\) For every vertex \(X \in \mathcal{E}\) and every edge \(\bar{e}: U(X) \rightarrow \bar{Y}\) in \(\mathcal{C}\), there exists a \(U\)-cocartesian edge \(e: X \rightarrow Y\) of \(\mathcal{E}\) for which \(U(e)=\bar{e}\) and and \(\widetilde{\mathscr{F}}(e)\) is a \(V\)-cocartesian edge of \(\mathcal{Q C}_{\text {Obj }}\).

Example 5.6.5.4 (Left Covering Maps). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a left covering map of \(\qquad\) simplicial sets and let \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}: \mathrm{hC} \rightarrow\) Set be the homotopy transport representation of \(U\) (Example 5.2.5.3), so that \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) can be identified with a morphism of simplicial sets \(\operatorname{Tr}_{\mathcal{E} / \mathcal{C}}: \mathcal{C} \rightarrow \mathrm{N}_{\bullet}(\) Set \()\). Combining Proposition 5.2.7.2 with Example 5.6.2.8, we obtain a canonical isomorphism of simplicial sets \(\mathcal{E} \simeq \int_{\mathcal{C}} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\), which exhibits \(\operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) as a covariant transport representation of \(U\) (in the sense of Definition 5.6.5.1.

Example 5.6.5.5 (Fibrations over a Point). Let \(\mathcal{E}\) be a small \(\infty\)-category, which we identify
with a morphism \(\mathscr{F}: \Delta^{0} \rightarrow \mathcal{Q C}\). Then \(\mathscr{F}\) is a covariant transport representation of the projection map \(U: \mathcal{E} \rightarrow \Delta^{0}\). More precisely, Example 5.6.2.16 supplies an equivalence of \(\infty\)-categories \(\mathcal{E} \rightarrow \int_{\Delta^{0}} \mathscr{F}\) which witnesses \(\mathscr{F}\) as a covariant transport representation of \(U\). More generally, a functor \(\Delta^{0} \rightarrow \mathcal{Q C}\) is a covariant transport representation of \(U\) if and only if it corresponds to an \(\infty\)-category which is equivalent to \(\mathcal{E}\).

Example 5.6.5.6 (Weighted Nerves). Let \(\mathcal{C}\) be an ordinary category, let \(\mathscr{F}: \mathcal{C} \rightarrow\) QCat be 0385 a functor, and let \(\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C})\) be the weighted nerve of Definition 5.3.3.1. Then the projection
\(\operatorname{map} U: \mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is a cocartesian fibration (Corollary 5.3.3.16). Moreover, the equivalence
\[
\mathrm{N}_{\bullet}^{\mathscr{F}}(\mathcal{C}) \rightarrow \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathscr{F})
\]
of Proposition 5.6.4.8 exhibits \(\mathrm{N}_{\bullet}^{\text {hc }}(\mathscr{F})\) as a covariant transport representation for \(U\).
0386 Example 5.6.5.7 (Strict Transport). Let \(\mathcal{C}\) be an ordinary category, let \(U: \mathcal{E} \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) be a cocartesian fibration of \(\infty\)-categories, and let \(\operatorname{Tr}_{\mathcal{E} / \mathcal{C}}: \mathcal{C} \rightarrow\) QCat be the strict transport representation of \(U\) (Construction 5.3.1.5). Then the functor
\[
\mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{sTr}_{\mathcal{E} / \mathcal{C}}\right): \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathrm{QCat})=\mathcal{Q C}
\]
is a covariant transport representation for \(U\) (in the sense of Definition 5.6.5.1). In other words, \(U\) is equivalent to the cocartesian fibration \(U^{\prime}: \int_{\mathcal{C}} \mathrm{N}_{\bullet}^{\mathrm{hc}}\left(\mathrm{sTr}_{\mathcal{E} / \mathcal{C}}\right) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\). To see this, we observe that both \(U\) and \(U^{\prime}\) are equivalent to the cocartesian fibration \(\mathrm{N}_{\bullet}^{\mathrm{sTr}} \mathcal{E} / \mathcal{C}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) : this follows from Theorem 5.3.5.6 and Proposition 5.6.4.8.

0291 Remark 5.6.5.8. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets, and let \(\mathrm{h} \operatorname{Tr}_{\mathcal{E}} / \mathcal{C}\) be the homotopy transport representation of \(U\) (Construction 5.2.5.2). Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) be a morphism of simplicial sets and let \(\mathrm{h} \mathscr{F}: \mathrm{hC} \rightarrow \mathrm{hQCat}\) be the induced functor between homotopy categories. Let \(\alpha: \mathcal{E} \rightarrow \int_{\mathcal{C}} \mathscr{F}\) be an equivalence of cocartesian fibrations over \(\mathcal{C}\). By virtue of Corollary 5.6.2.22, \(\alpha\) induces an isomorphism from \(\mathrm{hr}_{\mathcal{E} / \mathcal{C}}\) to \(\mathrm{h} \mathscr{F}\) in the functor category \(\operatorname{Fun}(h \mathcal{C}\), hQCat). Stated more informally, any covariant transport representation of \(U\) provides a lifting of the homotopy transport representation \(h \operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) from the ordinary category \(\operatorname{Fun}(\mathrm{hC}, \mathrm{hQCat})\) to the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{Q C})\). Moreover, if the simplicial set \(\mathcal{C}\) is an \(\infty\)-category, then the identification \(\mathrm{h} \operatorname{Tr}_{\mathcal{E} / \mathcal{C}} \simeq \mathrm{h} \mathscr{F}\) is an isomorphism of hKan-enriched functors (Proposition 5.6.2.20).

0292 Remark 5.6.5.9. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets and let \(\mathscr{F}, \mathscr{F}^{\prime}: \mathcal{C} \rightarrow \mathcal{Q C}\) be morphisms which are isomorphic as objects of the diagram \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{Q C})\). Then \(\mathscr{F}\) is a covariant transport representation of \(U\) if and only if \(\mathscr{F}^{\prime}\) is a covariant transport representation of \(U\). This follows immediately from Proposition 5.6.2.19

We now formulate a stronger version of Theorem 5.6.0.2

0293 Theorem 5.6.5.10 (Relative Universality Theorem). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an essentially small cocartesian fibration of simplicial sets, let \(\mathcal{C}_{0} \subseteq \mathcal{C}\) be a simplicial subset having inverse image \(\mathcal{E}_{0}=\mathcal{C}_{0} \times_{\mathcal{C}} \mathcal{E} \subseteq \mathcal{E}\), and let \(U_{0}: \mathcal{E}_{0} \rightarrow \mathcal{C}_{0}\) be the restriction \(\left.U\right|_{\mathcal{E}_{0}}\). Suppose we are given a
commutative diagram of simplicial sets

which witnesses \(\mathscr{F}_{0}\) as a covariant transport representation of \(U_{0}\). Then there exists a commutative diagram of simplicial sets

which witnesses \(\mathscr{F}\) as a covariant transport representation of \(U\), where \(\mathscr{F}_{0}=\left.\mathscr{F}\right|_{\mathcal{C}_{0}}\) and \(\widetilde{\mathscr{F}_{0}}=\left.\widetilde{\mathscr{F}}\right|_{\mathcal{E}_{0}}\).

We will give a reformulation of Theorem 5.6.5.10 in \(\S 5.6 .8\) (see Theorem 5.6.8.3), which we prove in \(\$ 5.6 .9\).

Corollary 5.6.5.11. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an essentially small cocartesian fibration of simplicial sets, let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a simplicial subset, and let \(\mathscr{F}^{\prime}: \mathcal{C}^{\prime} \rightarrow \mathcal{Q C}\) be a covariant transport representation for the projection map \(\mathcal{C}^{\prime} \times \mathcal{C} \mathcal{E} \rightarrow \mathcal{C}^{\prime}\). Then there exists a morphism \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) satisfying \(\mathscr{F}^{\prime}=\left.\mathscr{F}\right|_{\mathcal{C}^{\prime}}\) which is a covariant transport representation of \(U\).

Corollary 5.6.5.12. Let \(\mathcal{Q}\) be a full subcategory of \(\mathcal{Q C}\) and let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian 0295 fibration of simplicial sets having the property that, for each vertex \(C \in \mathcal{C}\), the fiber \(\mathcal{E}_{C}=\) \(\{C\} \times_{\mathcal{C}} \mathcal{E}\) is equivalent to an \(\infty\)-category which belongs to \(\mathcal{Q}\). Then there exists a morphism \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q} \subseteq \mathcal{Q C}\) which is a covariant transport representation of \(U\).

Proof. For each vertex \(C \in \mathcal{C}\), choose an \(\infty\)-category \(\mathscr{F}^{\prime}(C) \in \mathcal{Q}\) which is equivalent to the fiber \(\mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E}\). The construction \(C \mapsto \mathscr{F}^{\prime}(C)\) determines a morphism of simplicial sets \(\mathscr{F}^{\prime}: \mathcal{C}^{\prime} \rightarrow \mathcal{Q}\), where \(\mathcal{C}^{\prime}=\operatorname{sk}_{0}(\mathcal{C})\) is the 0 -skeleton of \(\mathcal{C}\), which is a covariant transport representation of the projection map \(\mathcal{C}^{\prime} \times \mathcal{C} \mathcal{E} \rightarrow \mathcal{C}^{\prime}\) (see Example 5.6.5.5). Applying Corollary 5.6.5.11, we can extend \(\mathscr{F}^{\prime}\) to a morphism \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\) which is a covariant transport representation of \(U\). By construction, the morphism \(\mathscr{F}\) takes values in the full subcategory \(\mathcal{Q} \subseteq \mathcal{Q C}\).

0296 Corollary 5.6.5.13. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets and let \(\mathscr{F}_{0}, \mathscr{F}_{1}: \mathcal{C} \rightarrow \mathcal{Q C}\) be covariant transport representations for \(U\). Then \(\mathscr{F}_{0}\) and \(\mathscr{F}_{1}\) are isomorphic as objects of the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{Q C})\).

Proof. Let \(U_{\Delta^{1}}: \Delta^{1} \times \mathcal{E} \rightarrow \Delta^{1} \times \mathcal{C}\) be the product of \(U\) with the identity map id \(\Delta_{\Delta^{1}}\), and define \(U_{\partial \Delta^{1}}: \partial \Delta^{1} \times \mathcal{E} \rightarrow \partial \Delta^{1} \times \mathcal{C}\) similarly. Note that the map \(\left(\mathscr{F}_{0}, \mathscr{F}_{1}\right): \partial \Delta^{1} \times \mathcal{C} \rightarrow \mathcal{Q C}\) is a covariant transport representation of \(U_{\partial \Delta^{1}}\). Applying Corollary 5.6.5.11, we deduce that \(U_{\Delta^{1}}\) admits a covariant transport representation \(\mathscr{F}: \Delta^{1} \times \mathcal{C} \rightarrow \mathcal{Q C}\) which satisfies \(\left.\mathscr{F}\right|_{\{0\} \times \mathcal{C}}=\mathscr{F}_{0}\) and \(\left.\mathscr{F}\right|_{\{1\} \times \mathcal{C}}=\mathscr{F}_{1}\). Let us identify \(\mathscr{F}\) with a morphism \(u: \mathscr{F}_{0} \rightarrow \mathscr{F}_{1}\) in the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{Q})\). We will complete the proof by showing that \(u\) is an isomorphism. By virtue of Theorem 4.4.4.4, it will suffice to show that for each vertex \(C \in \mathcal{C}\), the induced map \(u_{C}: \mathscr{F}_{0}(C) \rightarrow \mathscr{F}_{1}(C)\) is an isomorphism in \(\mathcal{Q C}\). Using Remark 5.6.5.8 (and Remark 5.2.8.5 , we see that the homotopy class \(\left[u_{C}\right]\) is isomorphic (as an object of the arrow category Fun([1], hQCat)) to the homotopy class of the functor \(\mathcal{E}_{C} \rightarrow \mathcal{E}_{C}\) given by covariant transport along the degenerate edge \(\operatorname{id}_{C}\) of \(\mathcal{C}\) : that is, the homotopy class of the identity functor \(\operatorname{id}_{\mathcal{E}_{C}}\).

Proof of Theorem 5.6.0.2. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an essentially small cocartesian fibrations of simplicial sets. We wish to show that \(U\) admits a covariant transport representation \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\), which is uniquely determined up to isomorphism (as an object of the functor \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{Q C})\) ). The existence statement follows by applying Theorem 5.6.5.10 in the special case \(\mathcal{C}_{0}=\emptyset\), and the uniqueness follows from Corollary 5.6.5.13.

019 S Notation 5.6.5.14 (The Covariant Transport Representation). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an essentially small cocartesian fibration. We let \(\operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) denote a covariant transport representation of \(U\), regarded as an object of the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{Q C})\) (which exists by virtue of Corollary 5.6.5.12]. We write \(\left[\operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\right]\) for the isomorphism class of the diagram \(\operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\), regarded as an object of the set \(\pi_{0}\left(\operatorname{Fun}(\mathcal{C}, \mathcal{Q C})^{\simeq}\right)\). By virtue of Corollary 5.6.5.13, the isomorphism class \(\left[\operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\right]\) is well-defined: that is, it depends only on the cocartesian fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\). Beware that \(\operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) is not uniquely determined: in fact, any diagram isomorphic to \(\operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) is also a covariant transport representation of \(U\) (Remark 5.6.5.9). Nevertheless, it will be convenient to abuse terminology and refer to \(\operatorname{Tr}_{\mathcal{E} / \mathcal{C}}\) as the covariant transport representation of \(U\), with the caveat that it is well-defined only up to isomorphism.

0297 Remark 5.6.5.15. Let \(\mathcal{C}\) be a simplicial set equipped with a functor \(\overline{\mathscr{F}}: \mathrm{hC} \rightarrow \mathrm{hQCat}\). It follows from Corollary 5.6.5.12 that the functor \(\overline{\mathscr{F}}\) is isomorphic to the homotopy transport representation of a cocartesian fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\) if and only if it can be promoted to a diagram \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\).

Corollary 5.6.5.16. Let \(\mathcal{C}\) be a small category. Then passage to the homotopy coherent
nerve induces a bijection
\{Functors of ordinary categories \(\mathcal{C} \rightarrow \mathrm{QCat}\} /\) Levelwise equivalence
\(\left\{\right.\) Functors of \(\infty\)-categories \(\left.\mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathcal{Q C}\right\} /\) Isomorphism.
Proof. Combine Example 5.6.5.7, Theorem 5.3.5.6, and Theorem 5.6.0.2.
Remark 5.6.5.17 (Rectification). Corollary 5.6.5.16 is a prototypical example of a rectifi- 0388 cation result. If \(\mathcal{C}\) is an ordinary category, then a functor of \(\infty\)-categories \(\mathscr{F}: \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathcal{Q C}\) can be viewed as a homotopy coherent diagram in the simplicial category QCat:
- To every object \(X\) of the category \(\mathcal{C}\), the functor \(\mathscr{F}\) associates an \(\infty\)-category \(\mathscr{F}(X)\).
- To every morphism \(u: X \rightarrow Y\) of the category \(\mathcal{C}\), the functor \(\mathscr{F}\) associates a functor of \(\infty\)-categories \(\mathscr{F}(u): \mathscr{F}(X) \rightarrow \mathscr{F}(Y)\).
- To every pair of composable morphisms \(u: X \rightarrow Y\) and \(v: Y \rightarrow Z\) in the category \(\mathcal{C}\), the functor \(\mathscr{F}\) associates an isomorphism of functors \(\alpha_{u, v}: \mathscr{F}(v) \circ \mathscr{F}(u) \rightarrow \mathscr{F}(v \circ u)\).
- When applied to higher-dimensional simplices of \(\mathrm{N}_{\bullet}(\mathcal{C})\), the functor \(\mathscr{F}\) provides additional data which encode coherence laws satisfied by the isomorphisms \(\alpha_{u, v}\).

Corollary 5.6.5.16 asserts that we can always find a strictly commutative diagram \(\mathscr{G}: \mathcal{C} \rightarrow\) QCat which is isomorphic to \(\mathscr{F}\) in the \(\infty\)-category \(\operatorname{Fun}\left(\mathrm{N}_{\bullet}(\mathcal{C}), \mathcal{Q C}\right)\). In particular, the diagram \(\mathscr{G}\) carries each object \(X \in \mathcal{C}\) to an \(\infty\)-category \(\mathscr{G}(X)\) which is equivalent to \(\mathscr{F}(X)\) (beware that we generally cannot arrange that \(\mathscr{G}(X)\) is isomorphic to \(\mathscr{F}(X)\) as a simplicial set).

In \(\S[?]\), we will prove a more refined version of this result, which allows us to describe the entire \(\infty\)-category \(\operatorname{Fun}\left(\mathrm{N}_{\bullet}(\mathcal{C}), \mathcal{Q C}\right)\) in terms of strictly commutative diagrams indexed by \(\mathcal{C}\) (Proposition [?]).

Using Theorem 5.6.5.10, we obtain the following converse of Corollary 5.6.3.5
Proposition 5.6.5.18. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a morphism of simplicial sets. The following 029A conditions are equivalent:
(1) The morphism \(U\) is an inner covering map (Definition 4.1.5.1), a cocartesian fibration, and each fiber of \(U\) is small.
(2) There exists a morphism of simplicial sets \(\mathscr{F}: \mathcal{C} \rightarrow \mathrm{N}_{\bullet}^{\mathrm{D}}(\operatorname{Pith}(\mathbf{C a t})) \subseteq \mathcal{Q C}\) and an isomorphism \(G: \mathcal{E} \simeq \int_{\mathcal{C}} \mathscr{F}\) in the category \(\left(\operatorname{Set}_{\Delta}\right)_{/ \mathcal{C}}\).

Proof. The implication (2) \(\Rightarrow\) (1) follows from Corollary 5.6.3.5 and Proposition 5.6.2.2. For each vertex \(C \in \mathcal{C}\), our assumption that \(U\) is an inner covering map guarantees that the fiber \(\{C\} \times_{\mathcal{C}} \mathcal{E}\) is isomorphic to the nerve of a (small) category \(\mathscr{F}_{0}(C)\) (Example 4.1.5.3). Let \(\mathcal{C}_{0}\) be the 0 -skeleton of \(\mathcal{C}\), so that the construction \(C \mapsto \mathscr{F}_{0}(C)\) determines a morphism of simplicial sets \(\mathscr{F}_{0}: \mathcal{C}_{0} \rightarrow \mathrm{~N}_{\bullet}^{\mathrm{D}}(\operatorname{Pith}(\mathbf{C a t}))\). Let \(\mathcal{E}_{0}\) denote the inverse image \(\mathcal{C}_{0} \times \mathcal{C} \mathcal{E}\), so that Proposition 5.6.3.4 supplies an isomorphism of simplicial sets \(G_{0}: \mathcal{E}_{0} \simeq \int_{\mathcal{C}_{0}} \mathscr{F}_{0}\). In particular, \(G_{0}\) is an equivalence of cocartesian fibrations over \(\mathcal{C}_{0}\). Invoking Theorem 5.6.5.10 we can extend \(\mathscr{F}_{0}\) to a diagram \(\mathscr{F}: \mathcal{C} \rightarrow \mathrm{N}_{\bullet}^{\mathrm{D}}(\operatorname{Pith}(\) Cat \())\) and \(G_{0}\) to a morphism of simplicial sets \(G: \mathcal{E} \rightarrow \int_{\mathcal{C}} \mathscr{F}\) which is an equivalence of cocartesian fibrations over \(\mathcal{C}\). We will complete the proof by showing that \(G\) is an isomorphism of simplicial sets. To prove this, it will suffice to show that for every simplex \(\sigma: \Delta^{n} \rightarrow \mathcal{C}\), the induced map
\[
G_{\sigma}: \Delta^{n} \times_{\mathcal{C}} \mathcal{E} \rightarrow \Delta^{n} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathscr{F}
\]
is an isomorphism of simplicial sets. Replacing \(U\) by the projection map \(\Delta^{n} \times_{\mathcal{C}} \mathcal{E} \rightarrow \Delta^{n}\), we are reduced to proving that \(G\) is an isomorphism under the additional assumption that \(\mathcal{C}=\Delta^{n}\) is a standard simplex. Since \(U\) and the projection map \(\int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) are inner covering maps, the simplicial sets \(\mathcal{E}\) and \(\int_{\mathcal{C}} \mathscr{F}\) are isomorphic to the nerves of their homotopy categories hE and \(\mathrm{h} \int_{\mathcal{C}} \mathscr{F}\), respectively; it will therefore suffice to show that the functor of ordinary categories \(\mathrm{h} G: \mathrm{h} \mathcal{E} \rightarrow \mathrm{h} \int_{\mathcal{C}} \mathscr{F}\) is an isomorphism. Our assumption that \(G\) is an equivalence of cocartesian fibrations over \(\mathcal{C}=\Delta^{n}\) guarantees that it is an equivalence of \(\infty\)-categories (Corollary 5.1.7.8), so that \(\mathrm{h} G\) is an equivalence of ordinary categories. It will therefore suffice to show that the functor \(\mathrm{h} G\) is bijective on objects: that is, that the morphism \(G\) is bijective on vertices. This is clear, since the morphism \(G_{0}=G \mid \mathcal{E}_{0}\) is an isomorphism.

01 SU Corollary 5.6.5.19 (Grothendieck). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be functor between categories. The following conditions are equivalent:
(1) The functor \(U\) is a cocartesian fibration and each fiber of \(U\) is a small category.
(2) There exists a functor of 2 -categories \(\mathscr{F}: \mathcal{C} \rightarrow \mathbf{C a t}\) and an isomorphism \(\int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{E}\) whose composition with \(U\) coincides with the forgetful functor \(\int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\).

Proof. We will show that \((1) \Rightarrow(2)\); the reverse implication follows from Corollary 5.6.1.16 Note that the map \(\mathrm{N}_{\bullet}(U): \mathrm{N}_{\bullet}(\mathcal{E}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) is a cocartesian fibration of simplicial sets (Example 5.1.4.2) and an inner covering map (Proposition 4.1.5.10). By virtue of Proposition 5.6.5.18, there exists a morphism of simplicial sets \(\mathscr{F}^{\prime}: \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{D}}(\) Pith \((\) Cat \())\) and an isomorphism of simplicial sets \(V: \int_{\mathrm{N}_{\bullet}(\mathcal{C})} \mathscr{F} \simeq \mathrm{N}_{\bullet}(\mathcal{E})\) which is compatible with \(\mathrm{N}_{\bullet}(U)\). By virtue of Theorem 2.3.4.1 (and Corollary 2.3.4.5), we have \(\mathscr{F}^{\prime}=\mathrm{N}_{\bullet}^{\mathrm{D}}(\mathscr{F})\) for a unique functor of 2-categories \(\mathscr{F}: \mathcal{C} \rightarrow \mathbf{C a t}\). In this case, we can use Proposition 5.6.3.4 to identify
\(\int_{\mathrm{N}}(\mathcal{C}) \mathscr{F}^{\prime}\) with the nerve of the ordinary category of elements \(\int_{\mathcal{C}} \mathscr{F}\). Under this identification, \(V\) corresponds to the nerve of an isomorphism \(\int_{\mathcal{C}} \mathscr{F}^{\prime} \simeq \mathcal{E}\) which is compatible with \(U\).

Let \(\mathbf{G p d} \subseteq\) Cat denote the full subcategory spanned by the groupoids.
Corollary 5.6.5.20. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a functor between categories. The following conditions 01SZ are equivalent:
- The functor \(U\) is an opfibration in groupoids (Variant 4.2.2.4) and each fiber of \(U\) is a small groupoid.
- There exists a functor of 2-categories \(\mathscr{F}: \mathcal{C} \rightarrow \mathbf{G p d}\) and an isomorphism of categories \(\int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{E}\) which carries \(U\) to the forgetful functor \(\int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\).

Proof. Combine Corollary 5.6.5.19 with Exercise 5.0.0.6.

\subsection*{5.6.6 Application: Corepresentable Functors}

Let \(\mathcal{C}\) be a category. Every object \(X \in \mathcal{C}\) determines a functor
\[
h^{X}: \mathcal{C} \rightarrow \text { Set } \quad Y \mapsto \operatorname{Hom}_{\mathcal{C}}(X, Y),
\]
which we refer to as the functor corepresented by \(X\). We say that a functor from \(\mathcal{C}\) to Set is corepresentable if it is isomorphic to \(h^{X}\) for some object \(X \in \mathcal{C}\). Our goal in this section is to develop an \(\infty\)-categorical counterpart of the notion of corepresentable functor (and the dual notion of representable functor), where we replace the ordinary category Set by the \(\infty\)-category \(\mathcal{S}\) of Construction 5.5.1.1.

We begin with an elementary observation. Let \(\mathscr{F}: \mathcal{C} \rightarrow\) Set be a functor between ordinary categories. For each object \(X \in \mathcal{C}\), Yoneda's lemma supplies a bijection
\[
\mathscr{F}(X) \xrightarrow{\sim} \operatorname{Hom}_{\operatorname{Fun}(\mathcal{C}, \text { Set })}\left(h^{X}, \mathscr{F}\right) .
\]

Concretely, this bijection carries each element \(x \in \mathscr{F}(X)\) to a natural transformation \(\alpha_{x}: h^{X} \rightarrow \mathscr{F}\), characterized by the requirement that it carries each \(Y \in \mathcal{C}\) to the composite map
\[
\begin{equation*}
h^{X}(Y)=\operatorname{Hom}_{\mathcal{C}}(X, Y) \xrightarrow{\mathscr{F}} \operatorname{Hom}_{\mathrm{Set}}(\mathscr{F}(X), \mathscr{F}(Y)) \xrightarrow{\text { ev }{ }_{x}} \mathscr{F}(Y) . \tag{5.30}
\end{equation*}
\]

The functor \(\mathscr{F}\) is corepresentable if it is possible to choose the object \(X \in \mathcal{C}\) and the element \(x \in \mathscr{F}(X)\) so that the map (5.30) is bijective, for each \(Y \in \mathcal{C}\). This motivates the following:

Definition 5.6.6.1 (Corepresentable Functors). Let \(\mathcal{C}\) be an \(\infty\)-category containing an 038A object \(X\), let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}\) be a functor, and let \(x\) be a vertex of the Kan complex \(\mathscr{F}(X)\). We
will say that \(x\) exhibits \(\mathscr{F}\) as corepresented by \(X\) if, for every object \(Y \in \mathcal{C}\), the composite map
\[
\begin{aligned}
& \operatorname{Hom}_{\mathcal{C}}(X, Y) \xrightarrow{\mathscr{F}} \quad \operatorname{Hom}_{\mathcal{S}}(\mathscr{F}(X), \mathscr{F}(Y)) \\
& \simeq \\
& \xrightarrow{\text { ev }} \quad \operatorname{Fun}(\mathscr{F}(X), \mathscr{F}(Y)) \\
& \mathscr{F}(Y)
\end{aligned}
\]
is an isomorphism in the homotopy category hKan; here the second map is the inverse of the homotopy equivalence \(\operatorname{Fun}(\mathscr{F}(X), \mathscr{F}(Y)) \rightarrow \operatorname{Hom}_{\mathcal{S}}(X, Y)\) supplied by Remark 5.5.1.5.

We say that the functor \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}\) is corepresentable by \(X\) if there exists a vertex \(x \in \mathscr{F}(X)\) which exhibits \(\mathscr{F}\) as corepresented by \(X\). We say that the functor \(\mathscr{F}\) is corepresentable if it is corepresentable by \(X\), for some object \(X \in \mathcal{C}\).

038B Variant 5.6.6.2 (Representable Functors). Let \(\mathcal{C}\) be an \(\infty\)-category, let \(X\) be an object of \(\mathcal{C}\), and write \(X^{\mathrm{op}}\) for the corresponding object of the opposite \(\infty\)-category \(\mathcal{C}^{\mathrm{op}}\). Given a functor \(\mathscr{F}: \mathcal{C}^{\mathrm{op}} \rightarrow \mathcal{S}\), we say that a vertex \(x \in \mathscr{F}\left(X^{\mathrm{op}}\right)\) exhibits \(\mathscr{F}\) as represented by \(X\) if it exhibits \(\mathscr{F}\) as corepresented by the object \(X^{\mathrm{op}}\), in the sense of Definition 5.6.6.1. We say that a functor \(\mathscr{F}: \mathcal{C}^{\mathrm{op}} \rightarrow \mathcal{S}\) is representable by \(X\) if it is corepresentable by \(X^{\mathrm{op}}\), and that \(\mathscr{F}\) is representable if it is representable by \(X\) for some object \(X \in \mathcal{C}\).

038C Remark 5.6.6.3. Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}\) be a functor of \(\infty\)-categories and let \(X \in \mathcal{C}\) be an object, and let \(x \in \mathscr{F}(X)\) be a vertex. The condition that \(x\) exhibits \(\mathscr{F}\) as corepresented by \(X\) depends only on the connected component \([x] \in \pi_{0}(\mathscr{F}(X))\).

038D Remark 5.6.6.4. Let \(\mathcal{C}\) be an \(\infty\)-category containing an object \(X\), let \(\alpha: \mathscr{F} \rightarrow \mathscr{G}\) be a morphism in the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{S})\), and let \(x\) be a vertex of the Kan complex \(\mathscr{F}(X)\). Then any two of the following conditions imply the third:

The vertex \(x \in \mathscr{F}(X)\) exhibits the functor \(\mathscr{F}\) as corepresented by \(X\).
The vertex \(\alpha(x) \in \mathscr{G}(X)\) exhibits the functor \(\mathscr{G}\) as corepresented by \(X\).
The natural transformation \(\alpha\) is an isomorphism.
In particular, if \(\mathscr{F}\) and \(\mathscr{G}\) are isomorphic objects of \(\operatorname{Fun}(\mathcal{C}, \mathcal{S})\), then \(\mathscr{F}\) is corepresentable by \(X\) if and only if \(\mathscr{G}\) is corepresentable by \(X\).

03LN Remark 5.6.6.5. Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}\) and \(U: \mathcal{D} \rightarrow \mathcal{C}\) be functors of \(\infty\)-categories. Suppose we are given an object \(Y \in \mathcal{D}\) and a vertex \(\eta \in \mathscr{F}(U(Y))\). Then:
- If \(U\) is fully faithful and \(\eta\) exhibits the functor \(\mathscr{F}\) as corepresented by \(U(Y)\), then it also exhibits the functor \(\mathscr{F} \circ U\) as \(Y\).
- If \(U\) is an equivalence of \(\infty\)-categories and \(\eta\) exhibits the functor \(\mathscr{F} \circ U\) as corepresented by \(\eta\), then it also exhibits \(\mathscr{F}\) as corepresented by \(U(Y)\).
- If \(U\) is an equivalence of \(\infty\)-categories, then the functor \(\mathscr{F}\) is corepresentable if and only if \(\mathscr{F} \circ U\) is corepresentable.

Remark 5.6.6.6. Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}\) be a functor of \(\infty\)-categories, let \(u: X \rightarrow Y\) be a \(\qquad\) morphism in \(\mathcal{C}\), and let \(x \in \mathscr{F}(X)\) be a vertex having image \(y=\mathscr{F}(u)(x) \in \mathscr{F}(Y)\). Then any two of the following conditions imply the third:
- The vertex \(x\) exhibits the functor \(\mathscr{F}\) as corepresented by \(X\).
- The vertex \(y\) exhibits the functor \(\mathscr{F}\) as corepresented by \(Y\).
- The morphism \(u\) is an isomorphism.

Remark 5.6.6.7 (Uniqueness of the Corepresenting Object). Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}\) be a functor of \(\infty\)-categories which is corepresentable by an object \(X \in \mathcal{C}\). Let \(Y\) be another object of \(\mathcal{C}\). Then \(\mathscr{F}\) is corepresentable by \(Y\) if and only if \(Y\) is isomorphic to \(X\). The "if" direction follows immediately from Remark 5.6.6.6. Conversely, suppose that \(\mathscr{F}\) is corepresentable by \(Y\). Choose vertices \(x \in \mathscr{F}(X)\) and \(y \in \mathscr{F}(Y)\) which exhibit \(\mathscr{F}\) as corepresented by \(X\) and \(Y\), respectively. Since evaluation at \(x\) induces a homotopy equivalence \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \mathscr{F}(Y)\), we can choose a morphism \(u: X \rightarrow Y\) such that \(\mathscr{F}(u)(x)\) and \(y\) belong to the same connected component of \(\mathscr{F}(Y)\). Then \(\mathscr{F}(u)(x)\) also exhibits \(\mathscr{F}\) as corepresented by \(Y\) (Remark 5.6.6.3), so that \(u\) is an isomorphism in \(\mathcal{C}\) by virtue of Remark 5.6.6.6.

Remark 5.6.6.8. Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}\) be a functor of \(\infty\)-categories. Then the construction \(Y \mapsto \pi_{0}(\mathscr{F}(Y))\) determines a functor from the homotopy category hC to the category of sets, which we will denote by \(\pi_{0}(\mathscr{F})\). Suppose that \(X\) is an object of \(\mathcal{C}\) and \(x \in \mathscr{F}(X)\) exhibits \(\mathscr{F}\) as corepresented by \(X\). Then, for every object \(Y \in \mathcal{C}\), evaluation on the connected component \([x] \in \pi_{0}(\mathscr{F}(X))\) induces a bijection
\[
\operatorname{Hom}_{\mathrm{h} \mathcal{C}}(X, Y)=\pi_{0}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)\right) \rightarrow \pi_{0}(\mathscr{F}(Y))
\]

It follows that the functor \(\pi_{0}(\mathscr{F}): \mathrm{hC} \rightarrow\) Set is corepresentable by \(X\), in the sense of classical category theory.

Warning 5.6.6.9. The converse of Remark 5.6 .6 .8 is false in general. For example, let \(\mathcal{C}\) be 038G an \(\infty\)-category containing an object \(X\), and let \(\mathscr{F}: \mathcal{C} \rightarrow\) Set \(\subset \mathcal{S}\) be the functor given on objects by the formula \(\mathscr{F}(Y)=\pi_{0}\left(\operatorname{Hom}_{\mathcal{C}}(X, Y)\right)\). Then \(\pi_{0}(\mathscr{F})\) is corepresentable by the object \(X\) (when regarded as a functor from hC to the category of sets), but the functor \(\mathscr{F}\) is usually not corepresentable.

In spite of Warning 5.6.6.9, the corepresentability of a functor \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}\) can be tested at the level of the homotopy category hC . The caveat is that we must equip \(\mathrm{h} \mathrm{\mathcal{C}}\) with the enrichment described in Construction 4.6.9.13.

02FR Definition 5.6.6.10. Let hKan denote the homotopy category of Kan complexes (Construction 3.1.5.10 and let \(\mathcal{C}\) be an hKan-enriched category containing an object \(X\). We will say that an hKan-enriched functor \(\mathscr{F}: \mathcal{C} \rightarrow \mathrm{hKan}\) is corepresentable by \(X\) if there exists a vertex \(x \in \mathscr{F}(X)\) such that, for every object \(Y \in \mathcal{C}\), the induced map
\[
\underline{\operatorname{Hom}}_{\mathcal{C}}(X, Y) \times\{x\} \hookrightarrow \underline{\operatorname{Hom}}_{\mathcal{C}}(X, Y) \times \mathscr{F}(X) \rightarrow \mathscr{F}(Y)
\]
is an isomorphism in the homotopy category hKan. In this case, we also say that \(x\) exhibits \(\mathscr{F}\) as corepresented by the object \(X\). We say that the functor \(\mathscr{F}\) is corepresentable if it is corepresentable by \(X\) for some object \(X \in \mathcal{C}\).

We say that an hKan-enriched functor \(\mathscr{F}: \mathcal{C}^{\mathrm{op}} \rightarrow\) hKan is representable by \(X\) if it is corepresentable by the object \(X^{\mathrm{op}} \in \mathcal{C}^{\mathrm{op}}\), and that \(\mathscr{F}\) is representable if it is representable by some object of \(\mathcal{C}\).

038H Remark 5.6.6.11. Let \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}\) be a functor of \(\infty\)-categories, and let \(\mathrm{h} \mathscr{F}: \mathrm{hC} \rightarrow\) \(\mathrm{h} \mathcal{S}=\mathrm{hKan}\) be the induced functor of hKan-enriched homotopy categories (see Construction 4.6.9.13). Then:
- A vertex \(x \in \mathscr{F}(X)\) exhibits \(\mathscr{F}\) as corepresented by an object \(X \in \mathcal{C}\) (in the sense of Definition 5.6.6.1 if and only if it exhibits \(\mathrm{h} \mathscr{F}\) as corepresented by the object \(X \in \mathrm{~h} \mathcal{C}\) (in the sense of Definition 5.6.6.10.
- The functor \(\mathscr{F}\) is corepresentable by an object \(X \in \mathcal{C}\) if and only if \(\mathrm{h} \mathscr{F}\) is corepresentable by \(X \in \mathrm{hC}\).
- The functor \(\mathscr{F}\) is corepresentable if and only if \(\mathrm{h} \mathscr{F}\) is corepresentable as an hKanenriched functor.

02FT Remark 5.6.6.12. Let \(\mathcal{C}\) be an hKan-enriched category. Then an hKan-enriched functor \(\mathscr{F}: \mathcal{C} \rightarrow\) hKan is corepresentable by an object \(X \in \mathcal{C}\) if and only if it is isomorphic (as an hKan-enriched functor) to the functor
\[
\mathcal{C} \rightarrow \text { hKan } \quad Y \mapsto \underline{\operatorname{Hom}}_{\mathcal{C}}(X, Y) .
\]

Let \(\mathcal{C}\) be an \(\infty\)-category. It follows from Remarks 5.6.6.4 and 5.6.6.7 that there is a
unique function
\(\{\) Isomorphism classes of corepresentable functors \(\mathcal{C} \rightarrow \mathcal{S}\}\)

which carries (the isomorphism class of) a corepresentable functor \(\mathscr{F}\) to (the isomorphic class of) an object \(X \in \mathcal{C}\) which corepresents \(\mathscr{F}\). Our main goal in this section is to show that, modulo set-theoretic considerations, this map is bijective.

Theorem 5.6.6.13. Let \(\mathcal{C}\) be a locally small \(\infty\)-category. Then, for every object \(X \in \mathcal{C}\), 038J there exists a functor \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}\) which is corepresentable by \(X\). Moreover, the functor \(\mathscr{F}\) is uniquely determined up to isomorphism.

Notation 5.6.6.14 (Corepresentable Functors). Let \(\mathcal{C}\) be a locally small \(\infty\)-category. For 038L every object \(X \in \mathcal{C}\), Theorem 5.6.6.13 asserts that there exists a functor \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}\) which is corepresented by \(X\), which is uniquely determined up to isomorphism. To emphasize this uniqueness, we will typically denote the functor \(\mathscr{F}\) by \(h^{X}\) and refer to it as the functor corepresented by \(X\). For every object \(Y \in \mathcal{C}\), we can apply the same argument to the opposite \(\infty\)-category \(\mathcal{C}^{\mathrm{op}}\) to obtain a functor represented by \(Y\), which we will typically denote by \(h_{Y}: \mathcal{C}^{\mathrm{op}} \rightarrow \mathcal{S}\) and refer to as the functor represented by \(Y\). Note that Remark 5.6.6.12 supplies isomorphisms \(h^{X}(Y) \simeq \operatorname{Hom}_{\mathcal{C}}(X, Y) \simeq h_{Y}(X)\) in the homotopy category hKan, depending functorially on the pair \((X, Y) \in \mathrm{h} \mathcal{C}^{\mathrm{op}} \times \mathrm{hC}\).

Remark 5.6.6.15. Let \(\mathcal{C}\) be an \(\infty\)-category. Then every object \(X \in \mathcal{C}\) determines an 038M hKan-enriched functor
\[
\operatorname{Hom}_{\mathcal{C}}(X, \bullet): \mathrm{hC} \rightarrow \mathrm{hKan} \quad Y \mapsto \operatorname{Hom}_{\mathcal{C}}(X, Y) .
\]

Theorem 5.6.6.13 asserts \(\operatorname{Hom}_{\mathcal{C}}(X, \bullet)\) can be promoted, in an essentially unique way, to a functor of \(\infty\)-categories \(h^{X}: \mathcal{C} \rightarrow \mathcal{S}\) (see Remark 5.6.6.12). Beware that this is a special feature of corepresentable functors. In general, an hKan-enriched functor \(\mathscr{F}: \mathrm{hC} \rightarrow \mathrm{hKan}\) cannot be promoted to a functor of \(\infty\)-categories. Moreover, when such a promotion exists, it need not be unique.

Remark 5.6.6.16 (Functoriality). Let \(\mathcal{C}\) be a locally small \(\infty\)-category. We will see later 038 N that the corepresentable functor \(h^{X}: \mathcal{C} \rightarrow \mathcal{S}\) and the representable functor \(h_{Y}: \mathcal{C}^{\text {op }} \rightarrow \mathcal{S}\) of Notation 5.6.6.14 depend functorially on the objects \(X\) and \(Y\), respectively. More precisely, the construction
\[
\operatorname{Hom}_{\mathcal{C}}(\bullet, \bullet): \mathrm{hC} \mathcal{C}^{\mathrm{op}} \times \mathrm{hC} \rightarrow \mathrm{hKan} \quad(X, Y) \mapsto \operatorname{Hom}_{\mathcal{C}}(X, Y)
\]
can be promoted to a functor of \(\infty\)-categories \(H: \mathcal{C}^{\mathrm{op}} \times \mathcal{C} \rightarrow \mathcal{S}\) with the following properties:
- For each object \(X \in \mathcal{C}\), the restriction \(\left.H\right|_{\{X\} \times \mathcal{C}}\) is corepresentable by \(X\).
- For each object \(Y \in \mathcal{C}\), the restriction \(\left.H\right|_{\mathcal{C}^{\text {op }} \times\{Y\}}\) is representable by \(Y\).

See Proposition 8.3.3.2.
Unlike its classical counterpart, Theorem 5.6.6.13 is nontrivial: given an object \(X\) of an \(\infty\)-category \(\mathcal{C}\), there is no immediately obvious candidate for a functor \(h^{X}: \mathcal{C} \rightarrow \mathcal{S}\) which is corepresented by \(X\). However, the situation is better when \(\mathcal{C}\) arises from a simplicially enriched category.

038P Proposition 5.6.6.17. Let \(\mathcal{C}\) be a locally Kan simplicial category, let \(X\) be an object of \(\mathcal{C}\), and let
\[
\mathscr{F}: \mathrm{N}_{\bullet}^{\mathrm{hc}}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}^{\mathrm{hc}}(\text { Kan })=\mathcal{S} .
\]
denote the homotopy coherent nerve of the simplicial functor \(Y \mapsto \operatorname{Hom}_{\mathcal{C}}(X, Y)\). . Then the identity morphism \(\operatorname{id}_{X} \in \operatorname{Hom}_{\mathcal{C}}(X, X) \bullet=\mathscr{F}(X)\) exhibits the functor \(\mathscr{F}\) as corepresented by \(X\), in the sense of Definition 5.6.6.1.

Proof. Fix an object \(Y \in \mathcal{C}\). We then have a commutative diagram of Kan complexes

where the vertical maps are supplied by Construction 4.6.8.3 (applied in the simplicial categories \(\mathcal{C}\) and Kan, respectively) and ev is given by evaluation at the vertex \(\operatorname{id}_{X} \in \mathscr{F}(X)\). Let \(\theta^{\prime-1}\) denote a homotopy inverse to \(\theta^{\prime}\) (which exists by virtue of Theorem 4.6.8.5). Proposition 5.6.6.17 asserts that the composition ev \(\circ \theta^{\prime-1} \circ V\) is a homotopy equivalence. Since \(\theta\) is also a homotopy equivalence (Theorem 4.6.8.5), this is equivalent to the assertion that ev \(\circ U\) is a homotopy equivalence. This is clear: the composition ev \(\circ U\) is the identity map from the Kan complex \(\mathscr{F}(Y)=\operatorname{Hom}_{\mathcal{C}}(X, Y)\) • to itself.

038 Q Remark 5.6.6.18. Let \(\mathcal{C}\) be a locally Kan simplicial category. The preceding proof shows that if \(\mathcal{C}\) satisfies the conclusion of Proposition 5.6.6.17, then it also satisfies the conclusion of Theorem 4.6.8.5 that is, the comparison map \(\theta: \operatorname{Hom}_{\mathcal{C}}(X, Y) \bullet \rightarrow \operatorname{Hom}_{\text {Nhc }_{\bullet}(\mathcal{C})}(X, Y)\) is a homotopy equivalence for every pair of objects \(X, Y \in \mathcal{C}\). Note however that we have already used Theorem 4.6.8.5 (applied to the simplicial category Kan) implicitly to give the definition of a corepresentable functor in the \(\infty\)-categorical setting.

The rest of this section is devoted to the proof of Theorem 5.6.6.13. Fix a locally small \(\infty\)-category \(\mathcal{C}\) and an object \(X \in \mathcal{C}\). We can then use the dictionary of Corollary 5.6.0.6 to identify functors \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}\) with essentially small left fibrations \(U: \mathcal{E} \rightarrow \mathcal{C}\). We will show that \(\mathscr{F}\) is corepresentable by an object \(X \in \mathcal{C}\) if and only if the \(\infty\)-category \(\mathcal{E}\) has an initial object \(\widetilde{X}\) satisfying \(U(\widetilde{X})=X\) (Proposition 5.6.6.21). We will then show that this condition guarantees that \(U\) is equivalent to the left fibration \(U_{0}: \mathcal{C}_{X /} \rightarrow \mathcal{C}\) (Proposition 5.6.6.21). Combining these assertions, we see that a functor \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}\) is corepresentable by \(X\) if and only if it is a covariant transport representation for \(U_{0}\), so that the existence and uniqueness assertions of Theorem 5.6.6.13 follow from Theorem 5.6.0.2.

Proposition 5.6.6.19. Let \(U: \mathcal{D} \rightarrow \mathcal{C}\) be a left fibration of \(\infty\)-categories and let \(\widetilde{X} \in \mathcal{D}\) be 038 R an object having image \(X=U(\widetilde{X})\). The following conditions are equivalent:
(1) There exists an equivalence \(F: \mathcal{C}_{X /} \rightarrow \mathcal{D}\) of left fibrations over \(\mathcal{C}\) satisfying \(F\left(\operatorname{id}_{X}\right)=\widetilde{X}\).
(2) The object \(\tilde{X} \in \mathcal{D}\) is initial (Definition 4.6.7.1).
(3) For every left fibration \(V: \mathcal{E} \rightarrow \mathcal{C}\), evaluation on the object \(\tilde{X}\) induces a trivial Kan fibration \(\mathrm{Fun}_{/ \mathcal{C}}(\mathcal{D}, \mathcal{E}) \rightarrow\{X\} \times_{\mathcal{C}} \mathcal{E}\).
(4) For every left fibration \(V: \mathcal{E} \rightarrow \mathcal{C}\), evaluation on the object \(\widetilde{X}\) induces a bijection
\[
\pi_{0}\left(\operatorname{Fun}_{/ \mathcal{C}}(\mathcal{D}, \mathcal{E})\right) \rightarrow \pi_{0}\left(\{X\} \times_{\mathcal{C}} \mathcal{E}\right)
\]

Proof. If \(F: \mathcal{C}_{X /} \rightarrow \mathcal{D}\) is an equivalence of left fibrations over \(\mathcal{C}\), then it is an equivalence of \(\infty\)-categories (Proposition 5.1.7.5). Since id \({ }_{X}: X \rightarrow X\) is initial when regarded as an object of the \(\infty\)-category \(\mathcal{C}_{X /}\) (Proposition 4.6.7.22, Corollary 4.6.7.20 guarantees that \(\widetilde{X}\) is an initial object of \(\mathcal{D}\). This proves the implication \((1) \Rightarrow(2)\). The implication \((2) \Rightarrow(3)\) follows by combining Corollary 4.6.7.24 with Proposition 4.2.5.4, and the implication \((3) \Rightarrow(4)\) is immediate.

We will complete the proof by showing that (4) implies (1). Note that the object \(\operatorname{id}_{X} \in \mathcal{C}_{X /}\) satisfies condition (1) and therefore also satisfies condition (3). It follows that there exists a commutative diagram

satisfying \(F\left(\operatorname{id}_{X}\right)=\tilde{X}\). To complete the proof, it will suffice to show that if condition (4) is satisfied, then \(F\) is an equivalence of left fibrations over \(\mathcal{C}\). For every left fibration \(V: \mathcal{E} \rightarrow \mathcal{C}\),
we have a commutative diagram of sets

where the vertical maps are given by evaluation on the objects \(\tilde{X} \in \mathcal{D}\) and \(\mathrm{id}_{X} \in \mathcal{C}_{X /}\), and are therefore bijective. It follows that the horizontal map is also bijective.

03 J 6 Corollary 5.6.6.20. Suppose we are given a commutative diagram of \(\infty\)-categories

where \(U\) and \(V\) are left fibrations. Let \(\widetilde{X} \in \mathcal{D}\) be an initial object. Then \(F\) is an equivalence of \(\infty\)-categories if and only if \(F(\widetilde{X})\) is an initial object of \(\mathcal{E}\).

Proof. If \(F\) is an equivalence of \(\infty\)-categories, then it carries initial objects to initial objects by virtue of Corollary 4.6.7.20. Conversely, suppose that \(F(\tilde{X})\) is an initial object of \(\mathcal{E}\); we wish to show that \(F\) is an equivalence of \(\infty\)-categories. Set \(X=U(\widetilde{X})\). Applying Proposition 5.6.6.19. we deduce that there is a functor \(G \in \operatorname{Fun}_{/ \mathcal{C}}(\mathcal{E}, \mathcal{D})\) such that \((G \circ F)(\tilde{X})\) is isomorphic to \(X\) as an object of the \(\infty\)-category \(\mathcal{D}_{X}=\{X\} \times_{\mathcal{C}} \mathcal{D}\). Applying Proposition 5.6.6.19 again, we deduce that \(G \circ F\) is isomorphic to \(\mathrm{id}_{\mathcal{D}}\) as an object of the \(\infty\)-category Fun \(_{/ \mathcal{C}}(\mathcal{D}, \mathcal{D})\); in particular, \(F\) is a right homotopy inverse to \(G\). Since \(G\) carries \(F(\tilde{X})\) to an initial object of \(\mathcal{D}\), we can apply the same argument (with the roles of \(\mathcal{D}\) and \(\mathcal{E}\) reversed) to show that \(G\) has a left homotopy inverse. It follows that \(G\) is an equivalence of \(\infty\)-categories, so that \(F\) is also an equivalence of \(\infty\)-categories.

02J8 Proposition 5.6.6.21. Let \(U: \mathcal{D} \rightarrow \mathcal{C}\) be an essentially small left fibration of \(\infty\)-categories and let \(X \in \mathcal{C}\) be an object. Then:
(1) Let \(\widetilde{X} \in \mathcal{D}\) be an object satisfying \(U(\widetilde{X})=X\). Then \(\widetilde{X}\) is an initial object of \(\mathcal{D}\) if and only if, for every object \(Y \in \mathcal{C}\), the composition
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \xrightarrow{\theta} \operatorname{Fun}\left(\mathcal{D}_{X}, \mathcal{D}_{Y}\right) \xrightarrow{\mathrm{ev}_{\widetilde{X}}} \mathcal{D}_{Y}
\]
is a homotopy equivalence, where \(\theta\) is given by parametrized covariant transport (see Definition 5.2.8.1).
(2) Let \(h \operatorname{Tr}_{\mathcal{D} / \mathcal{C}}: \mathrm{hC} \rightarrow \mathrm{hKan}\) be the homotopy transport representation of \(U\), which we regard as an hKan-enriched functor (Variant 5.2.8.12). Then \(\tilde{X}\) is an initial object of \(\mathcal{D}\) if and only if it exhibits \(\mathrm{h} \operatorname{Tr}_{\mathcal{D} / \mathcal{C}}\) as corepresented by \(X\), in the sense of Definition 5.6.6.10
(3) The homotopy transport representation \(\mathrm{h} \operatorname{Tr}_{\mathcal{D} / \mathcal{C}}\) is corepresentable by the object \(X\) if and only if there exists an initial object \(\widetilde{X} \in \mathcal{D}\) satisfying \(U(\widetilde{X})=X\).
(4) Let \(\operatorname{Tr}_{\mathcal{D} / \mathcal{C}}: \mathcal{C} \rightarrow \mathcal{S}\) be a covariant transport representation for \(U\). Then \(\operatorname{Tr}_{\mathcal{D} / \mathcal{C}}\) is corepresentable by the object \(X\) if and only if there exists an initial object \(\widetilde{X} \in \mathcal{D}\) satisfying \(U(\widetilde{X})=X\).

Proof. Let \(\{X\} \tilde{x}_{\mathcal{C}} \mathcal{C}\) be the oriented fiber product of Definition 4.6.4.1, and let us regard \(\mathrm{id}_{X}\) as an initial object of \(\{X\} \tilde{x}_{\mathcal{C}} \mathcal{C}\) (Proposition 4.6.7.22). Using Proposition 5.6.6.19, we can choose a functor of \(\infty\)-categories \(F:\{X\} \tilde{x}_{\mathcal{C}} \mathcal{C} \rightarrow \mathcal{D}\) satisfying \(F\left(\mathrm{id}_{X}\right)=\tilde{X}\) which fits into a commutative diagram

Using Proposition 5.6.6.19, we see that \(\tilde{X}\) is an initial object of \(\mathcal{D}\) if and only if \(F\) is an equivalence of left fibrations over \(\mathcal{C}\). By virtue of Corollary 5.1.7.15, this is equivalent to the requirement that for each object \(Y \in \mathcal{C}\), the functor \(F\) restricts to a homotopy equivalence of Kan complexes
\[
F_{Y}: \operatorname{Hom}_{\mathcal{C}}(X, Y)=\{X\} \tilde{x}_{\mathcal{C}}\{Y\} \rightarrow \mathcal{D}_{Y}
\]

Assertion (1) follows from the observation that \(F_{Y}\) is homotopic to the composition of the parametrized covariant transport morphism \(\theta: \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Fun}\left(\mathcal{D}_{X}, \mathcal{D}_{Y}\right)\) with the evaluation map ev \(\widetilde{X}: \operatorname{Fun}\left(\mathcal{D}_{X}, \mathcal{D}_{Y}\right) \rightarrow \mathcal{D}_{Y}\) (see Remark 5.2.8.5 and Proposition 5.2.8.7). The implication \((1) \Rightarrow(2)\) follows from Remark 5.6.5.8, the implication \((2) \Rightarrow(3)\) is immediate, and the implication (3) \(\Rightarrow(4)\) follows from Remark 5.6.6.11.

Proof of Theorem 5.6.6.13. Let \(\mathcal{C}\) be a locally small \(\infty\)-category and let \(X\) be an object of \(\mathcal{C}\). We wish to show that there exists a functor \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}\) which is corepresentable by \(X\), and that \(\mathscr{F}\) is uniquely determined up to isomorphism (as an object of the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{S})\) ). By virtue of Proposition 5.6.6.21 and Corollary 5.6.0.6, this is equivalent to the assertion that there exists a left fibration \(U: \mathcal{D} \rightarrow \mathcal{C}\) together with an initial object \(\widetilde{X} \in \mathcal{D}\) satisfying \(U(\widetilde{X})=X\), and that the left fibration \(U\) is uniquely determined up to equivalence
(in the sense of Definition 5.1.7.1. To prove existence, we can take \(\mathcal{D}=\mathcal{C}_{X /}\) and \(\widetilde{X}\) to be the identity morphism \(\operatorname{id}_{X}\) (Proposition 4.6.7.22). The uniqueness assertion follows from Proposition 5.6.6.19.

\subsection*{5.6.7 Application: Extending Cocartesian Fibrations}

029B In \(\S 3.3 .8\), we showed that every Kan fibration of simplicial sets \(f: X \rightarrow S\) can be obtained as the pullback of a Kan fibration between Kan complexes. Our goal in this section is to prove an analogous result for cocartesian fibrations of simplicial sets (Corollary 5.6.7.3). Our starting point is the following:

029C Lemma 5.6.7.1. Suppose we are given a commutative diagram of simplicial sets

where the vertical maps are inner fibrations, the bottom horizontal map exhibits \(\mathcal{C}_{0}\) as a simplicial subset of \(\mathcal{C}\), and \(G_{0}\) induces an equivalence \(\mathcal{E}_{0} \rightarrow \mathcal{C}_{0} \times_{\mathcal{C}} \mathcal{E}^{\prime}\) of inner fibrations over \(\mathcal{C}_{0}\). Then (5.31) can be extended to a commutative diagram

where \(U\) is an inner fibration, \(G\) is an equivalence of inner fibrations over \(\mathcal{C}\), and the square on the left induces an isomorphism of simplicial sets \(\mathcal{E}_{0} \simeq \mathcal{C}_{0} \times \mathcal{C}\).

Proof. Choose a monomorphism of simplicial sets \(\mathcal{E}_{0} \hookrightarrow \mathcal{Q}\), where \(\mathcal{Q}\) is a contractible Kan complex (see Exercise 3.1.7.11). Replacing \(\mathcal{E}^{\prime}\) with the product \(\mathcal{E}^{\prime} \times \mathcal{Q}\), we can reduce to the case where \(G_{0}\) is a monomorphism of simplicial sets. Let \(\mathcal{E}\) denote the simplicial subset of \(\mathcal{E}^{\prime}\) consisting of those simplices \(\sigma: \Delta^{m} \rightarrow \mathcal{E}^{\prime}\) for which the induced map \(\mathcal{C}_{0} \times{ }_{\mathcal{C}} \Delta^{m} \rightarrow \mathcal{C}_{0} \times{ }_{\mathcal{C}} \mathcal{E}^{\prime}\) factors through \(G_{0}\). To complete the proof, it will suffice to verify the following:
(a) The morphism \(U=\left.V\right|_{\mathcal{E}}\) is an inner fibration from \(\mathcal{E}\) to \(\mathcal{C}\).
(b) The inclusion \(\mathcal{E} \hookrightarrow \mathcal{E}^{\prime}\) is an equivalence of inner fibrations over \(\mathcal{C}\).

By virtue of Remark 4.1.1.13 and Proposition 5.1.7.9. it suffices to prove (a) and (b) in the special case where \(\mathcal{C}=\Delta^{n}\) is a standard simplex. In this case, the morphism \(V: \mathcal{E}^{\prime} \rightarrow \mathcal{C}\) is an isofibration (Example 4.4.1.6).

Let \(\mathcal{E}_{0}^{\prime}\) denote the fiber product \(\mathcal{C}_{0} \times \mathcal{C}^{\mathcal{E}}\). Applying Lemma 5.1.7.12 to the morphism \(G_{0}: \mathcal{E}_{0} \rightarrow \mathcal{E}_{0}^{\prime}\) (which is an equivalence of inner fibrations over \(\mathcal{C}_{0}\) ), we deduce that there exists a morphism \(R_{0}: \mathcal{E}_{0}^{\prime} \rightarrow \mathcal{E}_{0}\) in the category \(\left(\operatorname{Set}_{\Delta}\right) / \mathcal{C}_{0}\) such that \(R_{0} \circ G_{0}=\mathrm{id}_{\mathcal{E}_{0}}\), and an isomorphism \(\alpha_{0}: \operatorname{id}_{\mathcal{E}_{0}^{\prime}} \rightarrow G_{0} \circ R_{0}\) in the \(\infty\)-category Fun \(/ \mathcal{C}_{0}\left(\mathcal{E}_{0}^{\prime}, \mathcal{E}_{0}^{\prime}\right)\) whose image in \(\operatorname{Fun}_{/ \mathcal{C}_{0}}\left(\mathcal{E}_{0}, \mathcal{E}_{0}^{\prime}\right)\) is degenerate. Applying Proposition 4.4.5.8 (and the criterion of Proposition 4.4.4.9), we can choose a morphism \(R: \mathcal{E}^{\prime} \rightarrow \mathcal{E}^{\prime}\) in \(\left(\operatorname{Set}_{\Delta}\right) / \mathcal{C}\) such that \(\left.R\right|_{\mathcal{E}_{0}^{\prime}}=G_{0} \circ R_{0}\) and an isomorphism \(\alpha: \mathrm{id}_{\mathcal{E}^{\prime}} \rightarrow R\) in the \(\infty\)-category \(\operatorname{Fun}_{/ \mathcal{C}}\left(\mathcal{E}^{\prime}, \mathcal{E}^{\prime}\right)\) whose image in Fun \(/ \mathcal{C}_{0}\left(\mathcal{E}_{0}^{\prime}, \mathcal{E}_{0}^{\prime}\right)\) is equal to \(\alpha_{0}\).

We now prove (a). Suppose we are given a lifting problem

where the left vertical map is inner anodyne. Since \(V: \mathcal{E}^{\prime} \rightarrow \mathcal{C}\) is an inner fibration, we can extend \(f_{0}\) to a morphism \(f^{\prime}: B \rightarrow \mathcal{E}\) satisfying \(V \circ f^{\prime}=\bar{f}\). Set \(B_{0}=\mathcal{C}_{0} \times{ }_{\mathcal{C}} B\) and \(A_{0}=\mathcal{C}_{0} \times{ }_{\mathcal{C}} A\), and define
\[
f_{1}:\left(A \coprod_{A_{0}} B_{0}\right) \rightarrow \mathcal{E}
\]
by the formula \(\left.f_{1}\right|_{A}=f_{0}\) and \(\left.f_{1}\right|_{B_{0}}=\left.R \circ f^{\prime}\right|_{B_{0}}\). Note that there is an isomorphism
\[
\beta:\left.f^{\prime}\right|_{A} ^{\coprod_{A_{0}} B_{0}} ⿵ 冂 f_{1}
\]
in the \(\infty\)-category Fun \(/ \mathcal{C}\left(A \amalg_{A_{0}} B_{0}, \mathcal{E}^{\prime}\right)\), whose image in Fun \(/ \mathcal{C}\left(A, \mathcal{E}^{\prime}\right)\) is degenerate and whose image in \(\operatorname{Fun}_{/ \mathcal{C}}\left(B_{0}, \mathcal{E}^{\prime}\right)\) is the restriction of \(\alpha\). Applying Proposition 4.4.5.8 we deduce that \(f_{1}\) admits an extension \(f: B \rightarrow \mathcal{C}\) satisfying \(U \circ f=\bar{f}\).

To prove (b), we observe that the morphism \(R: \mathcal{E}^{\prime} \rightarrow \mathcal{E}\) is a homotopy inverse of the inclusion \(\iota: \mathcal{E} \hookrightarrow \mathcal{E}^{\prime}\) relative to \(\mathcal{C}\). By construction, \(\alpha\) determines an isomorphism from \(\operatorname{id}_{\mathcal{E}^{\prime}}\) to the composition \(\iota \circ R\) in the \(\infty\)-category \(\operatorname{Fun}_{/ \mathcal{C}}\left(\mathcal{E}^{\prime}, \mathcal{E}^{\prime}\right)\), and the restriction of \(\alpha\) determines an isomorphism from id \(\mathcal{E}\) to \(R \circ \iota\) in the \(\infty\)-category Fun \(/ \mathcal{C}(\mathcal{E}, \mathcal{E})\).

Proposition 5.6.7.2 (Extending Cocartesian Fibrations). Let \(\mathcal{C}\) be a simplicial set, let \(\mathcal{C}_{0} \subseteq \mathcal{C}\) be a simplicial subset, and let \(U_{0}: \mathcal{E}_{0} \rightarrow \mathcal{C}_{0}\) be a cocartesian fibration of simplicial sets. Suppose that the inclusion \(\mathcal{C}_{0} \hookrightarrow \mathcal{C}\) is a categorical equivalence of simplicial sets. Then
there exists a pullback diagram of simplicial sets

where \(U\) is a cocartesian fibration.
Proof. By virtue of Theorem 5.6.0.2, there exists a morphism of simplicial sets \(\mathscr{F}_{0}: \mathcal{C}_{0} \rightarrow \mathcal{Q C}\) and an equivalence \(G_{0}: \mathcal{E}_{0} \rightarrow \int_{\mathcal{C}_{0}} \mathscr{F}_{0}\) of cocartesian fibrations over \(\mathcal{C}_{0}\). Since \(\mathcal{Q C}\) is an \(\infty\)-category (Proposition 5.5.4.3), our assumption that the inclusion \(\mathcal{C}_{0} \hookrightarrow \mathcal{C}\) is a categorical equivalence guarantees that we can extend \(\mathscr{F}_{0}\) to a morphism of simplicial sets \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{Q C}\). We can then identify \(G_{0}\) with an equivalence \(\mathcal{E}_{0} \rightarrow \mathcal{C}_{0} \times_{\mathcal{C}} \int_{\mathcal{C}} \mathscr{F}\) of cocartesian fibrations over \(\mathcal{C}_{0}\). Applying Lemma 5.6.7.1, we can write \(U_{0}\) as the pullback of an inner fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\) which is equivalent to the projection map \(V: \int_{\mathcal{C}} \mathscr{F} \rightarrow \mathcal{C}\) as an inner fibration over \(\mathcal{C}\). Since \(V\) is a cocartesian fibration (Proposition 5.6.2.2), it follows that \(U\) is also a cocartesian fibration (Proposition 5.1.7.13).

029 F Corollary 5.6.7.3. Let \(U_{0}: \mathcal{E}_{0} \rightarrow \mathcal{C}_{0}\) be a cocartesian fibration of simplicial sets. Then there exists a pullback diagram

where \(U\) is a cocartesian fibration of \(\infty\)-categories and \(F\) is inner anodyne.
Proof. Using Corollary 4.1.3.3, we can choose an inner anodyne map \(F: \mathcal{C}_{0} \hookrightarrow \mathcal{C}\), where \(\mathcal{C}\) is an \(\infty\)-category. Since \(F\) is a categorical equivalence of simplicial sets (Corollary 4.5.3.14, Proposition 5.6.7.2 guarantees that \(U_{0}\) is the pullback of a cocartesian fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\).

02LR Remark 5.6.7.4. In the situation of Corollary 5.6.7.3 if \(U_{0}\) is a left fibration, then \(U\) is also a left fibration. To see this, it suffices to show that the fibers of \(U\) are Kan complexes (Proposition 5.1.4.14). This is clear, since every fiber of \(U\) is also a fiber of \(U_{0}\) (note that the inner anodyne morphism \(F: \mathcal{C}_{0} \rightarrow \mathcal{C}\) is bijective at the level of vertices; see Exercise 1.5.6.6.

029G Corollary 5.6.7.5. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets. Then \(U\) is an isofibration.

Proof. By virtue of Corollary 5.6.7.3, we may assume without loss of generality that \(U\) is a cocartesian fibration of \(\infty\)-categories, in which case the desired result follows from Proposition 5.1.4.8.

Corollary 5.6.7.6. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets. Then \(U\) is exponentiable (Definition 4.5.9.10). In particular, for any pullback diagram of simplicial sets

if \(\bar{F}\) is a categorical equivalence, then \(F\) is also a categorical equivalence.
Proof. By virtue of Corollary 5.6.7.3 and Remark 4.5.9.13, we may assume that \(U\) is a cocartesian fibration of \(\infty\)-categories, in which case the desired result follows from Proposition 5.3.6.1

Corollary 5.6.7.7. Let \(\kappa\) be an uncountable regular cardinal, let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian 03TX fibration of simplicial sets, and suppose that \(\mathcal{C}\) is essentially \(\kappa\)-small. The following conditions are equivalent:
(1) The \(\infty\)-category \(\mathcal{E}\) is essentially \(\kappa\)-small.
(2) For every vertex \(C \in \mathcal{C}\), the \(\infty\)-category \(\mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E}\) is essentially \(\kappa\)-small.

Proof. Using Corollaries 5.6.7.3 and 5.6.7.6, we can reduce to the situation where \(\mathcal{C}\) is an \(\infty\)-category. In this case, the desired result is a special case of Corollary 5.1.5.16.

Corollary 5.6.7.8. Suppose we are given a commutative diagram of simplicial sets

where \(U\) and \(V\) are cocartesian fibrations. Then \(F\) is an equivalence of cocartesian fibrations over \(\mathcal{C}\) (Definition 5.1.7.1) if and only if it is a categorical equivalence of simplicial sets.

Proof. Combine Proposition 5.1.7.5 with Corollary 5.6.7.5.

\subsection*{5.6.8 Transport Witnesses}

02S9 Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an essentially small cocartesian fibration of \(\infty\)-categories. Theorem 5.6.0.2 asserts that there exists a commutative diagram

which witnesses \(\mathscr{F}\) as a covariant transport representation for \(U\); here \(V: \mathcal{Q C}_{\text {Obj }} \rightarrow \mathcal{Q C}\) is the cocartesian fibration of Proposition 5.5.6.11. In this section, we formulate a stronger statement, which asserts that the collection of all such diagrams is parametrized by a contractible Kan complex (Theorem 5.6.8.3).

02SA Notation 5.6.8.1. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets. We let \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) denote the simplicial subset of the fiber product
\[
\operatorname{Fun}(\mathcal{C}, \mathcal{Q C}) \times_{\operatorname{Fun}(\mathcal{E}, \mathcal{Q C})} \operatorname{Fun}\left(\mathcal{E}, \mathcal{Q C}_{\mathrm{Obj}}\right)
\]
whose \(n\)-simplices are diagrams

which witness \(\mathscr{F}\) as a covariant transport representation for the cocartesian fibration \(\left(\mathrm{id}_{\Delta^{n}} \times U\right): \Delta^{n} \times \mathcal{E} \rightarrow \Delta^{n} \times \mathcal{C}\).

02SB Example 5.6.8.2. Let \(\mathcal{E}\) be an \(\infty\)-category and let \(U: \mathcal{E} \rightarrow \Delta^{0}\) denote the projection map. Note that projection onto the first factor determines a morphism of simplicial sets
\[
\operatorname{TW}\left(\mathcal{E} / \Delta^{0}\right) \rightarrow \operatorname{Fun}\left(\Delta^{0}, \mathcal{Q C}\right)=\mathcal{Q C}
\]

Unwinding the definitions, we see that the fiber of this morphism over a small \(\infty\)-category \(\mathcal{E}^{\prime}\) can be identified with the full subcategory
\[
\operatorname{Equiv}\left(\mathcal{E},\left\{\mathcal{E}^{\prime}\right\} \times_{\mathcal{Q C}} \mathcal{Q} \mathcal{C}_{\mathrm{Obj}}\right) \subseteq \operatorname{Fun}\left(\mathcal{E},\left\{\mathcal{E}^{\prime}\right\} \times_{\mathcal{Q C}} \mathcal{Q} \mathcal{C}_{\mathrm{Obj}}\right) \simeq
\]
spanned by the equivalences of \(\infty\)-categories \(\mathcal{E} \rightarrow\left\{\mathcal{E}^{\prime}\right\} \times_{\mathcal{Q C}} \mathcal{Q C} \mathcal{O b j}\).

We will prove the following result in \(\$ 5.6 .9\)
Theorem 5.6.8.3. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an essentially small cocartesian fibration of simplicial 02 SC sets. Then the simplicial set \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) is a contractible Kan complex.

Remark 5.6.8.4. Theorem 5.6 .8 .3 is an immediate consequence of Theorem 5.6.5.10. We 02SD will see at the end of this section that the converse is also true.

The remainder of this section is devoted to establishing some formal properties of the simplicial sets \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) which will be useful for the proof of Theorem 5.6.8.3

Lemma 5.6.8.5. Suppose we are given a commutative diagram of simplicial sets

where \(U\) is a cocartesian fibration. Let \(j: \mathcal{C}_{0} \hookrightarrow \mathcal{C}\) be an inner anodyne morphism of simplicial sets, let \(\mathcal{E}_{0}\) denote the fiber product \(\mathcal{C}_{0} \times{ }_{\mathcal{C}} \mathcal{E}\), and let \(U_{0}: \mathcal{E}_{0} \rightarrow \mathcal{C}_{0}\) denote the projection map. If \(\left.\widetilde{\mathscr{F}}\right|_{\mathcal{E}_{0}}\) witnesses \(\left.\mathscr{F}\right|_{\mathcal{C}_{0}}\) as a covariant transport representation for \(U_{0}\), then \(\widehat{\mathscr{F}}\) witnesses \(\mathscr{F}\) as a covariant transport representation for \(U\).

Proof. Let \(S\) denote the collection of all morphisms of simplicial sets \(i: A \rightarrow B\) with the following property: for every morphism of simplicial sets \(B \rightarrow \mathcal{C}\), if the restriction \(\left.\widetilde{\mathscr{F}}\right|_{A \times \mathcal{C}} \mathcal{E}\) witnesses \(\left.\mathscr{F}\right|_{A}\) as a covariant transport representation for the projection map \(A \times_{\mathcal{C}} \mathcal{E} \rightarrow A\), then \(\left.\widetilde{\mathscr{F}}\right|_{B \times_{\mathcal{C}} \mathcal{E}}\) witnesses \(\left.\mathscr{F}\right|_{B}\) as a covariant transport representation for the projection map \(B \times_{\mathcal{C}} \mathcal{E} \rightarrow B\). To prove Lemma 5.6.8.5, it will suffice to show that every inner anodyne morphism of simplicial sets belongs to \(S\). It is not difficult to see that the collection of morphisms \(S\) is weakly saturated, in the sense of Definition 1.5.4.12. It will therefore suffice to show that, for every pair of integers \(0<i<n\), the inner horn inclusion \(\Lambda_{i}^{n} \hookrightarrow \Delta^{n}\) belongs to \(S\). We may therefore assume without loss of generality that \(\mathcal{C}=\Delta^{n}\) and \(\mathcal{C}_{0}=\Lambda_{i}^{n}\) is an inner horn.

Since every vertex of \(\Delta^{n}\) is contained in \(\Lambda_{i}^{n}\), it follows immediately that the pair ( \(\mathscr{F}, \widetilde{\mathscr{F}}\) ) satisfies condition (a) of Remark 5.6.5.3. To verify (b), let \(e: X \rightarrow Z\) be an \(U\)-cocartesian edge of \(\mathcal{E}\) having image \(\bar{e}=U(e)\) in \(\Delta^{n}\); we wish to show that \(\widetilde{\mathscr{F}}(e)\) is a \(V\)-cocartesian edge of \(\mathcal{E}^{\prime}\). If \(\bar{e}\) belongs to the horn \(\Lambda_{i}^{n}\), then this follows from our assumption on \(\left.\widetilde{F}\right|_{\mathcal{E}_{0}}\). We may therefore assume without loss of generality that \(\mathcal{C}=\Delta^{2}\) and that \(\bar{e}: 0 \rightarrow 2\) is the "long" edge of the simplex \(\Delta^{2}\). Since \(U\) is a cocartesian fibration, there exists a \(U\)-cocartesian edge
\(e^{\prime}: X \rightarrow Y\) of \(\mathcal{E}\), where \(U(Y)=1\). Our assumption that \(e^{\prime}\) is \(U\)-cocartesian guarantees the existence of a 2 -simplex

of \(\mathcal{E}\), and Proposition 5.1.4.12 implies that \(e^{\prime \prime}\) is also \(U\)-cocartesian. Since \(\left.\widetilde{\mathscr{F}}\right|_{\mathcal{C}_{0}}\) carries \(U_{0}\)-cocartesian morphisms of \(\mathcal{E}_{0}\) to \(V\)-cocartesian morphisms of \(\mathcal{Q} \mathcal{C}_{\mathrm{Obj}}\), it follows that \(\widetilde{\mathscr{F}}\left(e^{\prime}\right)\) and \(\widetilde{\mathscr{F}}\left(e^{\prime \prime}\right)\) are \(V\)-cocartesian edges of \(\mathcal{E}^{\prime}\). Applying Proposition 5.1.4.12 again, we deduce that \(\widetilde{\mathscr{F}}(e)\) is also \(V\)-cocartesian.

02SF Lemma 5.6.8.6. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets. Then:
(1) The fiber product \(\mathcal{M}=\operatorname{Fun}(\mathcal{C}, \mathcal{Q C}) \times_{\operatorname{Fun}(\mathcal{E}, \mathcal{Q C})} \operatorname{Fun}\left(\mathcal{E}, \mathcal{Q C}_{\mathrm{Obj}}\right)\) is an \(\infty\)-category.
(2) The simplicial set \(\mathrm{TW}(\mathcal{E} / \mathcal{C})\) is a replete subcategory of \(\mathcal{M}\) (see Example 4.4.1.12).

In particular, the simplicial set \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) is an \(\infty\)-category.
Proof. Since \(V\) is an inner fibration, the induced map \(V^{\prime}: \operatorname{Fun}\left(\mathcal{E}, \mathcal{Q C}_{\text {Obj }}\right) \rightarrow \operatorname{Fun}(\mathcal{E}, \mathcal{Q C})\) is also an inner fibration (Corollary 4.1.4.3). The projection map \(\mathcal{M} \rightarrow \operatorname{Fun}(\mathcal{C}, \mathcal{Q C})\) is a pullback of \(V^{\prime}\), and is therefore also an inner fibration. Since \(\operatorname{Fun}(\mathcal{C}, \mathcal{Q C})\) is an \(\infty\)-category (Theorem 1.5.3.7), assertion (1) follows from Remark 4.1.1.9

We now prove (2). We first show that \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) is a subcategory of \(\mathcal{M}\) : that is, that the inclusion map \(\operatorname{TW}(\mathcal{E} / \mathcal{C}) \hookrightarrow \mathcal{M}\) is an inner fibration. Fix integers \(0<i<n\) and let \(\sigma\) be an \(n\)-simplex of \(\mathcal{M}\) for which the restriction \(\left.\sigma\right|_{\Lambda_{i}^{n}}\) belongs to \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\); we wish to show that \(\sigma\) is an \(n\)-simplex of \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\). Unwinding the definitions, we can identify \(\sigma\) with a commutative diagram

we wish to show that \(\widetilde{\mathscr{F}}\) witnesses \(\mathscr{F}\) as a covariant transport representation for the cocartesian fibration id \(\Delta^{n} \times U\). This follows from Lemma 5.6.8.5, since the inclusion \(\Lambda_{i}^{n} \times \mathcal{C} \hookrightarrow\) \(\Delta^{n} \times \mathcal{C}\) is inner anodyne (Lemma 1.5.7.5).

We now complete the proof by showing that the subcategory \(\operatorname{TW}(\mathcal{E} / \mathcal{C}) \subseteq \mathcal{M}\) is replete. Let \(u\) be an isomorphism in the \(\infty\)-category \(\mathcal{M}\), which we identify with a commutative diagram

Set \(\mathscr{F}_{0}=\left.\mathscr{F}\right|_{\{0\} \times \mathcal{C}}\) and \(\widetilde{\mathscr{F}}_{0}=\left.\widetilde{\mathscr{F}}\right|_{\{0\} \times \mathcal{E}}\), and suppose that the pair \(\left(\mathscr{F}_{0}, \widetilde{\mathscr{F}}_{0}\right)\) is an object of the \(\infty\)-category \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) (that is, \(\widetilde{\mathscr{F}}_{0}\) witnesses \(\mathscr{F}_{0}\) as a covariant transport representation for \(U\). We wish to show that \(\widetilde{\mathscr{F}}\) witnesses \(\mathscr{F}\) as a covariant transport representation for \(\left(\mathrm{id}_{\Delta^{1}} \times U\right): \Delta^{1} \times \mathcal{E} \rightarrow \Delta^{1} \times \mathcal{C}\).

We first verify condition (b) of Remark 5.6.5.3. Let \(e\) be an (id \(\left.\Delta_{\Delta^{1}} \times U\right)\)-cocartesian edge of the simplicial set \(\Delta^{1} \times \mathcal{E}\); we wish to show that \(\mathscr{F}(e)\) is a \(V\)-cocartesian morphism of \(\mathcal{Q} \mathcal{O}_{\text {Obj }}\). Write \(e=\left(\varphi_{i j}, \bar{e}\right)\), where \(\varphi_{i j}: i \rightarrow j\) is an edge of \(\Delta^{1}\) and \(\bar{e}: X \rightarrow Y\) is a \(U\)-cocartesian edge of \(\mathcal{E}\). We consider three cases:
(1) Suppose that \(i=j=0\). Then \(\widetilde{\mathscr{F}}(e)=\widetilde{\mathscr{F}}_{0}(\bar{e})\) is \(V\)-cocartesian by virtue of our assumption that \(\widetilde{\mathscr{F}}_{0}\) witnesses \(\mathscr{F}_{0}\) as a covariant transport representation for \(U\).
(2) Suppose that \(i=0\) and \(j=1\). In this case, there exists a 2 -simplex of \(\Delta^{1} \times \mathcal{E}\) whose boundary is indicated in the diagram

Our assumption that \(u\) is an isomorphism in the \(\infty\)-category \(\mathcal{M}\) guarantees that \(\widetilde{\mathscr{F}}\left(\varphi_{01}, \mathrm{id}_{Y}\right)\) is an isomorphism in the \(\infty\)-category \(\mathcal{Q C}{ }_{\text {Obj }}\), and is therefore \(V\)-cocartesian (Proposition 5.1.1.8. It follows from case (1) that \(\widetilde{\mathscr{F}}\left(\varphi_{00}, \bar{e}\right)\) is also a \(V\)-cocartesian morphism of \(\mathcal{Q C}_{\text {Obj }}\). Since the collection of \(V\)-cocartesian morphisms of \(\mathcal{Q C}_{\text {Obj }}\) is closed under composition (Corollary 5.1.2.4 , we conclude that \(\widetilde{\mathscr{F}}\left(\varphi_{01}, \bar{e}\right)\) is also \(V\)-cocartesian.
(3) Suppose that \(i=j=1\). In this case, there exists a 2 -simplex of \(\Delta^{1} \times \mathcal{E}\) whose boundary
is indicated in the diagram

Our assumption that \(u\) is an isomorphism in the \(\infty\)-category \(\mathcal{M}\) guarantees that \(\widetilde{\mathscr{F}}\left(\varphi_{01}, \mathrm{id}_{X}\right)\) is an isomorphism in the \(\infty\)-category \(\mathcal{Q C}_{\text {Obj }}\), and is therefore \(V\)-cocartesian (Proposition 5.1.1.8. It follows from case (2) that \(\mathscr{\mathscr { F }}\left(\varphi_{01}, \bar{e}\right)\) is also a \(V\)-cocartesian morphism of \(\mathcal{Q C}_{\mathrm{Obj}}\), so that \(\widetilde{\mathscr{F}}\left(\varphi_{11}, \bar{e}\right)\) is \(V\)-cocartesian by virtue of Corollary 5.1.2.4.
We now complete the proof by showing that the pair \((\widetilde{\mathscr{F}}, \mathscr{F})\) satisfies condition \((a)\) of Remark 5.6.5.3. Let \((i, C)\) be a vertex of the product \(\Delta^{1} \times \mathcal{C}\), so that \(\widetilde{\mathscr{F}}\) restricts to a functor of \(\infty\)-categories
\[
\widetilde{\mathscr{F}}_{(i, C)}:\{i\} \times \mathcal{E}_{C} \rightarrow\{\mathscr{F}(i, C)\} \times_{\mathcal{Q C}} \mathcal{Q C}_{\mathrm{Obj}}
\]

We wish to show that the functor \(\widetilde{\mathscr{F}}_{(i, C)}\) is an equivalence of \(\infty\)-categories. If \(i=0\), this follows from our assumption that \(\widetilde{\mathscr{F}}_{0}\) witnesses \(\mathscr{F}_{0}\) as a covariant transport representation for \(U\). We may therefore assume without loss of generality that \(i=1\). Set \(v=\mathscr{F}\left(\varphi_{01}, \mathrm{id}_{C}\right)\) and let
\[
v_{!}:\{\mathscr{F}(0, C)\} \times_{\mathcal{Q C}} \mathcal{Q C}_{\mathrm{Obj}} \rightarrow\{\mathscr{F}(1, C)\} \times_{\mathcal{Q C}} \mathcal{Q} \mathcal{C}_{\mathrm{Obj}}
\]
be the functor given by covariant transport along \(v\). Since \(u\) is an isomorphism in the \(\infty\)-category \(\mathcal{M}, v\) is an isomorphism in the \(\infty\)-category \(\mathcal{Q C}\) so that \(v_{!}\)is an equivalence of \(\infty\)-categories (Remark 5.2.5.5). Combining the first part of the proof with Remark 5.2.8.5, we deduce that the diagram of \(\infty\)-categories

commutes up to isomorphism (that is, it determines a commutative diagram in the homotopy category hQCat). Since \(v_{!}\)and \(\widetilde{\mathscr{F}}_{(0, C)}\) are equivalences of \(\infty\)-categories, it follows that \(\widetilde{\mathscr{F}}_{(1, C)}\) is also an equivalence of \(\infty\)-categories.

02SG Lemma 5.6.8.7. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets. Then the simplicial set \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) is a Kan complex.

Proof. Since \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) is an \(\infty\)-category (Lemma 5.6.8.6), it will suffice to show that every morphism \(u\) of \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) is an isomorphism (Proposition 4.4.2.1). Let us identify \(u\) with a commutative diagram of simplicial sets

satisfying conditions (a) and (b) of Remark 5.6.5.3.
Passing to homotopy categories, we see that \(\mathscr{F}\) induces a functor \(\mathrm{h} \mathscr{F}:[1] \times \mathrm{hC} \rightarrow \mathrm{hQC} \simeq\) hQCat. Applying Remark 5.6.5.8, we see that \(\mathrm{h} \mathscr{F}\) is isomorphic to the composite functor \([1] \times \mathrm{hC} \rightarrow \mathrm{hC} \xrightarrow{\mathrm{hTr}_{\mathcal{E}} / \mathcal{C}} \mathrm{hQCat}\), where \(\mathrm{hTr}_{\mathcal{E} / \mathcal{C}}\) denotes the homotopy transport representation of Construction 5.2.5.2. It follows that, for every vertex \(C \in \mathcal{C}\), the morphism \(\mathscr{F}\) carries the edge \(\Delta^{1} \times\{C\}\) to an isomorphism \(\bar{e}\) in \(\mathcal{Q C}\). If \(X\) is an object of \(\mathcal{E}\) satisfying \(U(X)=C\), then \(\widetilde{\mathscr{F}}\) carries \(\Delta^{1} \times\{X\}\) to a \(V\)-cocartesian morphism \(e\) of \(\mathcal{Q C}_{\text {Obj }}\) satisfying \(V(e)=\bar{e}\), which is then also an isomorphism by virtue of Corollary 5.1.1.10. Allowing \(C\) and \(X\) to vary and applying Theorem 4.4.4.4, we deduce that \(\mathscr{F}\) and \(\mathscr{F}\) are isomorphisms when regarded as morphisms in the \(\infty\)-categories \(\operatorname{Fun}(\mathcal{C}, \mathcal{Q C})\) and \(\operatorname{Fun}\left(\mathcal{E}, \mathcal{Q C}_{\text {Obj }}\right)\), respectively.

Set \(\mathcal{M}=\operatorname{Fun}(\mathcal{C}, \mathcal{Q C}) \times_{\mathrm{Fun}(\mathcal{E}, \mathcal{Q C})} \operatorname{Fun}\left(\mathcal{E}, \mathcal{Q C}_{\mathrm{Obj}}\right)\). Applying Corollary 4.4.3.19 to the pullback diagram

we deduce that \(u\) is an isomorphism when regarded as a morphism of the \(\infty\)-category \(\mathcal{M}\). Since \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) is replete subcategory of \(\mathcal{M}\) (Lemma 5.6.8.6), it follows that \(u\) is also an isomorphism when regarded as a morphism of \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) (Example 4.4.2.9).

Remark 5.6.8.8. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets. It follows 02SH from Lemmas 5.6.8.6 and 5.6.8.7 that \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) can be identified with the full subcategory of the Kan complex
\[
\operatorname{Fun}(\mathcal{C}, \mathcal{Q C}) \simeq \times_{\operatorname{Fun}(\mathcal{E}, \mathcal{Q C}) \simeq} \operatorname{Fun}\left(\mathcal{E}, \mathcal{Q} \mathcal{C}_{\mathrm{Obj}}\right) \simeq
\]
spanned by those pairs \((\mathscr{F}, \widetilde{\mathscr{F}})\) which witness \(\mathscr{F}\) as a covariant transport representation for \(U\).

02SJ Notation 5.6.8.9 (Functoriality). Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets. Suppose we are given an arbitrary morphism of simplicial sets \(f: \mathcal{C}_{0} \rightarrow \mathcal{C}\), and set \(\mathcal{E}_{0}=\mathcal{C}_{0} \times \mathcal{C} \mathcal{E}\). Precomposition with \(f\) and with the projection map \(\mathcal{E}_{0} \rightarrow \mathcal{E}\) determines a morphism of simplicial sets
\[
f^{*}: \operatorname{TW}(\mathcal{E} / \mathcal{C}) \rightarrow \operatorname{TW}\left(\mathcal{E}_{0} / \mathcal{C}_{0}\right),
\]
which we will refer to as the restriction map. Note that the construction \(\mathcal{C}_{0} \mapsto \mathrm{TW}\left(\mathcal{E}_{0} / \mathcal{C}_{0}\right)\) carries colimits in the category \(\left(\operatorname{Set}_{\Delta}\right) / \mathcal{C}\) to limits in the category of simplicial sets.
02SK Lemma 5.6.8.10. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets. Let \(\mathcal{C}_{0}\) be a simplicial subset of \(\mathcal{C}\) and set \(\mathcal{E}_{0}=\mathcal{C}_{0} \times_{\mathcal{C}} \mathcal{E}\). Then:
(1) The restriction map \(\theta: \operatorname{TW}(\mathcal{E} / \mathcal{C}) \rightarrow \operatorname{TW}\left(\mathcal{E}_{0} / \mathcal{C}_{0}\right)\) of Notation 5.6.8.9 is a Kan fibration between Kan complexes.
(2) If the inclusion \(\mathcal{C}_{0} \hookrightarrow \mathcal{C}\) is inner anodyne, then \(\theta\) is a trivial Kan fibration.

Proof. We first prove (1). Since the simplicial set \(\operatorname{TW}\left(\mathcal{E}_{0} / \mathcal{C}_{0}\right)\) is a Kan complex (Lemma 5.6.8.7), it will suffice to show that \(\theta\) is an isofibration. Define fiber products
\[
\begin{gathered}
\mathcal{M}=\operatorname{Fun}(\mathcal{C}, \mathcal{Q C}) \times_{\operatorname{Fun}(\mathcal{E}, \mathcal{Q C})} \operatorname{Fun}\left(\mathcal{E}, \mathcal{Q C}_{\mathrm{Obj}}\right) \\
\mathcal{M}_{0}=\operatorname{Fun}\left(\mathcal{C}_{0}, \mathcal{Q C}\right) \times_{\operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{Q C}\right)} \operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{Q C}_{\mathrm{Obj}}\right),
\end{gathered}
\]
so that we have a commutative diagram

It follows from Lemma 5.6.8.6 that \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) is a replete subcategory of \(\mathcal{M}\), and therefore also a replete subcategory of the fiber product \(\operatorname{TW}\left(\mathcal{E}_{0} / \mathcal{C}_{0}\right) \times{ }_{\mathcal{M}_{0}} \mathcal{M}\). It will therefore suffice to show that the projection map \(\operatorname{TW}\left(\mathcal{E}_{0} / \mathcal{C}_{0}\right) \times_{\mathcal{M}_{0}} \mathcal{M} \rightarrow \operatorname{TW}\left(\mathcal{E}_{0} / \mathcal{C}_{0}\right)\) is an isofibration of \(\infty\)-categories. Since the collection of isofibrations is stable under pullback, we are reduced to showing that the map \(\bar{\theta}: \mathcal{M} \rightarrow \mathcal{M}_{0}\) is an isofibration. We now observe that \(\bar{\theta}\) factors as a composition
\[
\begin{aligned}
\mathcal{M} & =\operatorname{Fun}(\mathcal{C}, \mathcal{Q C}) \times \times_{\operatorname{Fun}(\mathcal{E}, \mathcal{Q C})} \operatorname{Fun}\left(\mathcal{E}, \mathcal{Q C}_{\mathrm{Obj}}\right) \\
& \xrightarrow{\bar{\theta}^{\prime}} \\
& \operatorname{Fun}(\mathcal{C}, \mathcal{Q C}) \times_{\operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{Q C}\right)} \operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{Q C}_{\mathrm{Obj}}\right) \\
& \xrightarrow{\bar{\theta}^{\prime \prime}} \operatorname{Fun}\left(\mathcal{C}_{0}, \mathcal{Q C}\right) \times \times_{\operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{Q C}\right)} \operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{Q C}_{\mathrm{Obj}}\right) \\
& \mathcal{M}_{0},
\end{aligned}
\]
where \(\bar{\theta}^{\prime \prime}\) is a pullback of the restriction map
\[
\psi^{\prime \prime}: \operatorname{Fun}\left(\mathcal{E}, \mathcal{Q C}_{\mathrm{Obj}}\right) \rightarrow \operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{Q C}_{\mathrm{Obj}}\right) \times_{\mathrm{Fun}\left(\mathcal{E}_{0}, \mathcal{Q C}\right)} \operatorname{Fun}(\mathcal{E}, \mathcal{Q C})
\]

Since the forgetful functor \(V: \mathcal{Q C}_{\mathrm{Obj}} \rightarrow \mathcal{Q C}\) is an isofibration, \(\psi^{\prime \prime}\) is also an isofibration (Propositions 4.4.5.1). Similarly, \(\bar{\theta}^{\prime}\) is a pullback of the restriction map \(\psi^{\prime}: \operatorname{Fun}(\mathcal{C}, \mathcal{Q C}) \rightarrow\) \(\operatorname{Fun}\left(\mathcal{C}_{0}, \mathcal{Q C}\right)\), which is an isofibration by virtue of Corollary 4.4.5.3. It follows that \(\bar{\theta}=\bar{\theta}^{\prime \prime} \circ \bar{\theta}^{\prime}\) is also an isofibration. This completes the proof of (1).

We now prove (2). Suppose that the inclusion map \(\mathcal{C}_{0} \hookrightarrow \mathcal{C}\) is inner anodyne; we wish to show that \(\theta\) is a trivial Kan fibration. Applying Proposition 1.5.7.6, we deduce that \(\psi^{\prime}\) is a trivial Kan fibration of simplicial sets. Since \(U\) is a cocartesian fibration, the inclusion \(\operatorname{map} \mathcal{E}_{0} \hookrightarrow \mathcal{E}\) is a categorical equivalence (Lemma 5.3.6.5). Applying Proposition 4.5.5.18, we deduce that \(\psi^{\prime \prime}\) is a trivial Kan fibration. It follows that the morphisms \(\bar{\theta}^{\prime}\) and \(\bar{\theta}^{\prime \prime}\) are also trivial Kan fibrations, so that \(\bar{\theta}=\bar{\theta}^{\prime \prime} \circ \bar{\theta}^{\prime}\) is a trivial Kan fibration. Applying Lemma 5.6.8.5, we see that the diagram (5.33) is a pullback square, so that \(\theta\) is also a trivial Kan fibration.

Proof of Theorem 5.6.5.10 from Theorem 5.6.8.3. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an essentially small cocartesian fibration of simplicial. Let \(\mathcal{C}_{0} \subseteq \mathcal{C}\) be a simplicial subset and set \(\mathcal{E}_{0}=\mathcal{C}_{0} \times \mathcal{C}\). Applying Theorem 5.6.8.3, we see that the simplicial sets \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) and \(\operatorname{TW}\left(\mathcal{E}_{0} / \mathcal{C}_{0}\right)\) are contractible Kan complexes. It follows that the restriction map \(\theta: \mathrm{TW}(\mathcal{E} / \mathcal{C}) \rightarrow \mathrm{TW}\left(\mathcal{E}_{0} / \mathcal{C}_{0}\right)\) is a homotopy equivalence. Since \(\theta\) is also Kan fibration (Lemma 5.6.8.10), it is a trivial Kan fibration (Proposition 3.2.7.2). In particular, \(\theta\) is surjective on vertices, which is a restatement of Theorem 5.6.5.10

\subsection*{5.6.9 Proof of the Universality Theorem}

Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an essentially small cocartesian fibration of simplicial sets. Our goal in this section is to prove Theorem 5.6.8.3, which that the space of transport witnesses \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) of Notation 5.6.8.1 is a contractible Kan complex. The main step is to establish the following:

Lemma 5.6.9.1. Let \(U: \mathcal{E} \rightarrow \Delta^{1}\) be a cocartesian fibration having fibers \(\mathcal{E}_{0}=\{0\} \times_{\Delta^{1}} \mathcal{E} 02 \mathrm{SN}\) and \(\mathcal{E}_{1}=\{1\} \times_{\Delta^{1}} \mathcal{E}\). Then the restriction map
\[
\theta: \operatorname{TW}\left(\mathcal{E} / \Delta^{1}\right) \rightarrow \operatorname{TW}\left(\mathcal{E}_{0} \amalg \mathcal{E}_{1} / \partial \Delta^{1}\right)
\]
is a trivial Kan fibration of simplicial sets.
Proof. It follows from Lemma 5.6.8.10 that \(\theta\) is a Kan fibration; we wish to show that it is a trivial Kan fibration. Fix a pair of small \(\infty\)-categories \(\mathcal{D}_{0}\) and \(\mathcal{D}_{1}\). Set \(\mathcal{E}_{0}^{\prime}=\left\{\mathcal{D}_{0}\right\} \times \mathcal{Q C}^{\mathcal{Q C}}\) Obj
and \(\mathcal{E}_{1}^{\prime}=\left\{\mathcal{D}_{1}\right\} \times_{\mathcal{Q C}} \mathcal{Q C}_{\text {Obj }}\), and let \(\operatorname{Equiv}\left(\mathcal{E}_{0}, \mathcal{E}_{0}^{\prime}\right)\) and \(\operatorname{Equiv}\left(\mathcal{E}_{1}, \mathcal{E}_{1}^{\prime}\right)\) be the Kan complexes introduced in Example 5.6.8.2, so that the fiber
\[
\left\{\left(\mathcal{D}_{0}, \mathcal{D}_{1}\right)\right\} \times_{\text {Fun }\left(\partial \Delta^{1}, \mathcal{Q C}\right)} \operatorname{TW}\left(\mathcal{E}_{0} \amalg \mathcal{E}_{1} / \partial \Delta^{1}\right)
\]
can be identified with the product \(\operatorname{Equiv}\left(\mathcal{E}_{0}, \mathcal{E}_{0}^{\prime}\right) \times \operatorname{Equiv}\left(\mathcal{E}_{1}, \mathcal{E}_{1}^{\prime}\right)\). Let \(\operatorname{TW}\left(\mathcal{E} / \Delta^{1}\right)_{\mathcal{D}_{0}, \mathcal{D}_{1}}\) denote the fiber product \(\left\{\left(\mathcal{D}_{0}, \mathcal{D}_{1}\right)\right\} \times_{\operatorname{Fun}\left(\partial \Delta^{1}, \mathcal{Q C}\right)} \operatorname{TW}\left(\mathcal{E} / \Delta^{1}\right)\), so that \(\theta\) restricts to a Kan fibration
\[
\theta_{\mathcal{D}_{0}, \mathcal{D}_{1}}: \operatorname{TW}\left(\mathcal{E} / \Delta^{1}\right)_{\mathcal{D}_{0}, \mathcal{D}_{1}} \rightarrow \operatorname{Equiv}\left(\mathcal{E}_{0}, \mathcal{E}_{0}^{\prime}\right) \times \operatorname{Equiv}\left(\mathcal{E}_{1}, \mathcal{E}_{1}^{\prime}\right) .
\]

Note that every fiber of \(\theta\) can also be viewed as a fiber of \(\theta_{\mathcal{D}_{0}, \mathcal{D}_{1}}\) for suitably chosen \(\infty\) categories \(\mathcal{D}_{0}\) and \(\mathcal{D}_{1}\). Consequently, to show that \(\theta\) is a trivial Kan fibration, it will suffice to show that each of the morphisms \(\theta_{\mathcal{D}_{0}, \mathcal{D}_{1}}\) is a trivial Kan fibration, or alternatively that it is a homotopy equivalence (see Proposition 3.2.7.2).

For the remainder of the proof, we will regard the \(\infty\)-categories \(\mathcal{D}_{0}\) and \(\mathcal{D}_{1}\) as fixed. Let \(\mathcal{B}^{+}\)denote the fiber product
\[
\operatorname{Hom}_{\mathcal{Q} \mathcal{C}}\left(\mathcal{D}_{0}, \mathcal{D}_{1}\right) \times_{\operatorname{Fun}\left(\Delta^{1} \times \mathcal{E}_{0}, \mathcal{Q C}\right) \simeq} \operatorname{Fun}\left(\Delta^{1} \times \mathcal{E}_{0}, \mathcal{Q} \mathcal{C}_{\mathrm{Obj}}\right) \simeq
\]

Let \(\pi^{+}: \mathcal{B}^{+} \rightarrow \operatorname{Hom}_{\mathcal{Q} C}\left(\mathcal{D}_{0}, \mathcal{D}_{1}\right)\) be given by projection onto the first factor, and let
\[
r_{0}^{+}: \mathcal{B}^{+} \rightarrow \operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{E}_{0}^{\prime}\right)^{\simeq} \quad r_{1}^{+}: \mathcal{B}^{+} \rightarrow \operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{E}_{1}^{\prime}\right)^{\simeq}
\]
be given by restriction to the simplicial subsets \(\{0\} \times \mathcal{E}_{0}\) and \(\{1\} \times \mathcal{E}_{0}\), respectively. Combining Propositions 4.4.5.1 and 4.4.3.7, we deduce that the map
\[
\left(r_{0}^{+}, r_{1}^{+}, \pi^{+}\right): \mathcal{B}^{+} \rightarrow \operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{E}_{0}^{\prime}\right) \simeq \times \operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{E}_{1}^{\prime}\right) \simeq \times \operatorname{Hom}_{\mathcal{Q C}}\left(\mathcal{D}_{0}, \mathcal{D}_{1}\right)
\]
is a Kan fibration. In particular, the simplicial set \(\mathcal{B}^{+}\)is a Kan complex.
Let \(\mathcal{B}\) denote the summand \(\mathcal{B}^{+}\)spanned by those pairs \((e, \widetilde{e})\), where \(e: \mathcal{D}_{0} \rightarrow \mathcal{D}_{1}\) is a functor and \(\widetilde{e}: \Delta^{1} \times \mathcal{E}_{0} \rightarrow \mathcal{Q C}_{\text {Obj }}\) is a morphism fitting into a commutative diagram

which satisfies the following pair of conditions:
(i) The restriction \(\left.\widetilde{e}\right|_{\{0\} \times \mathcal{E}_{0}}: \mathcal{E}_{0} \rightarrow \mathcal{E}_{0}^{\prime}\) is an equivalence of \(\infty\)-categories.
(ii) For each object \(Z \in \mathcal{E}_{0}\), the composite map
\[
\Delta^{1} \times\{Z\} \hookrightarrow \Delta^{1} \times \mathcal{E}_{0} \xrightarrow{\widetilde{e}} \mathcal{Q} \mathcal{C}_{\mathrm{Obj}}
\]
is a \(V\)-cocartesian morphism of \(\mathcal{Q C}_{\text {Obj }}\).
Condition (i) ensures that \(r_{0}^{+}\)restricts to a morphism of Kan complexes \(r_{0}: \mathcal{B} \rightarrow\) Equiv \(\left(\mathcal{E}_{0}, \mathcal{E}_{0}^{\prime}\right)\). Moreover, \(\pi^{+}\)and \(r_{1}^{+}\)restrict to morphisms \(\pi: \mathcal{B} \rightarrow \operatorname{Hom}_{\mathcal{Q} C}\left(\mathcal{D}_{0}, \mathcal{D}_{1}\right)\) and \(r_{1}: \mathcal{B} \rightarrow \operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{E}_{1}^{\prime}\right)^{\simeq}\), respectively. Since \(\mathcal{B}\) is a summand of \(\mathcal{B}^{+}\), the map
\[
\left(r_{0}, r_{1}, \pi\right): \mathcal{B} \rightarrow \operatorname{Equiv}\left(\mathcal{E}_{0}, \mathcal{E}_{0}^{\prime}\right) \times \operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{E}_{1}^{\prime}\right) \simeq \times \operatorname{Hom}_{\mathcal{Q C}}\left(\mathcal{D}_{0}, \mathcal{D}_{1}\right)
\]
is also a Kan fibration.
It follows from Theorem 5.2.1.1 that composition with \(V\) induces a cocartesian fibration \(V^{\prime}: \operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{Q C}_{\text {Obj }}\right) \rightarrow \operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{Q C}\right)\). Moreover, a morphism of the \(\infty\)-category \(\operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{Q C}_{\mathrm{Obj}}\right)\) is \(V^{\prime}\)-cocartesian if and only if it corresponds to a morphism of simplicial sets \(\widetilde{e}: \Delta^{1} \times \mathcal{E}_{0} \rightarrow \mathcal{Q C}_{\text {Obj }}\) satisfying condition (ii). Let \(\operatorname{Fun}^{\prime}\left(\Delta^{1} \times \mathcal{E}_{0}, \mathcal{Q C}_{\text {Obj }}\right)\) denote the full subcategory of \(\operatorname{Fun}\left(\Delta^{1} \times \mathcal{E}_{0}, \mathcal{Q C}_{\mathrm{Obj}}\right)\) spanned by morphisms which satisfy this condition. Unwinding the definitions, we have a pullback square

where the bottom right map is a trivial Kan fibration (Proposition 5.2.1.3). It follows that the map \(\left(r_{0}, \pi\right): \mathcal{B} \rightarrow \operatorname{Equiv}\left(\mathcal{E}_{0}, \mathcal{E}_{0}^{\prime}\right) \times \operatorname{Hom}_{\mathcal{Q C}}\left(\mathcal{D}_{0}, \mathcal{D}_{1}\right)\) is a trivial Kan fibration of simplicial sets.

Let \(s: \operatorname{Equiv}\left(\mathcal{E}_{0}, \mathcal{E}_{0}^{\prime}\right) \times \operatorname{Hom}_{\mathcal{Q} \mathcal{C}}\left(\mathcal{D}_{0}, \mathcal{D}_{1}\right) \rightarrow \mathcal{B}\) be a section of the trivial Kan fibration \(\left(r_{0}, \pi\right)\), and let \(T\) denote the composite map
\[
\operatorname{Equiv}\left(\mathcal{E}_{0}, \mathcal{E}_{0}^{\prime}\right) \times \operatorname{Hom}_{\mathcal{Q C}}\left(\mathcal{D}_{0}, \mathcal{D}_{1}\right) \xrightarrow{s} \mathcal{B} \xrightarrow{\left(r_{0}, r_{1}\right)} \operatorname{Equiv}\left(\mathcal{E}_{0}, \mathcal{E}_{0}^{\prime}\right) \times \operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{E}_{1}^{\prime}\right) \simeq
\]

For every equivalence of \(\infty\)-categories \(F: \mathcal{E}_{0} \rightarrow \mathcal{E}_{0}^{\prime}\), we can regard \(\left.T\right|_{\{F\} \times \operatorname{Hom}_{\mathcal{C} \mathcal{C}}\left(\mathcal{D}_{0}, \mathcal{D}_{1}\right)}\) as a morphism of Kan complexes \(T_{F}: \operatorname{Hom}_{\mathcal{Q} \mathcal{C}}\left(\mathcal{D}_{0}, \mathcal{D}_{1}\right) \rightarrow \operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{E}_{1}^{\prime}\right) \simeq\). Unwinding the
definitions, we can identify \(T_{F}\) with the composition
\[
\operatorname{Hom}_{\mathcal{Q C}}\left(\mathcal{D}_{0}, \mathcal{D}_{1}\right) \xrightarrow{T^{\prime}} \operatorname{Fun}\left(\mathcal{E}_{0}^{\prime}, \mathcal{E}_{1}^{\prime}\right) \xrightarrow{\sim} \xrightarrow{\circ F} \operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{E}_{1}^{\prime}\right)^{\simeq},
\]
where \(T^{\prime}\) is given by parametrized covariant transport for the cocartesian fibration \(V\) : \(\mathcal{Q C}_{\text {Obj }} \rightarrow \mathcal{Q C}\) (Definition 5.2.8.1). It follows from Proposition 5.5 .6 .14 that \(T^{\prime}\) is a homotopy equivalence. Our assumption that \(F\) is an equivalence of \(\infty\)-categories then guarantees that \(T_{F}\) is also a homotopy equivalence. Allowing \(F \in \operatorname{Equiv}\left(\mathcal{E}_{0}, \mathcal{E}_{0}^{\prime}\right)\) to vary and applying Proposition 3.2.8.1, we conclude that \(T\) is a homotopy equivalence. Since \(s\) is homotopy inverse to the trivial Kan fibration \(\left(r_{0}, \pi\right)\), it is also a homotopy equivalence. Applying the two-out-of-three property (Remark 3.1.6.7), we conclude that the map
\[
\left(r_{0}, r_{1}\right): \mathcal{B} \rightarrow \operatorname{Equiv}\left(\mathcal{E}_{0}, \mathcal{E}_{0}^{\prime}\right) \times \operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{E}_{1}^{\prime}\right) \simeq
\]
is also a homotopy equivalence. Since \(\left(r_{0}, r_{1}\right)\) is also a Kan fibration, it is a trivial Kan fibration (Proposition 3.3.7.6).

Using Proposition 5.2.2.8, we can choose a functor \(\lambda: \mathcal{E}_{0} \rightarrow \mathcal{E}_{1}\) and a natural transformation \(h: \Delta^{1} \times \mathcal{E}_{0} \rightarrow \mathcal{E}\) which witnesses \(\lambda\) as given by covariant transport along the nondegenerate edge of \(\Delta^{1}\) (in the sense of Definition 5.2.2.4). Form a pullback diagram

Let \(\mathcal{M}\) denote the pushout \(\left(\Delta^{1} \times \mathcal{E}_{0}\right) \coprod_{\left(\{1\} \times \mathcal{E}_{0}\right)} \mathcal{E}_{1}\), so that we can identify \(\widetilde{\mathcal{B}}\) with a summand of the Kan complex

Note that \(h\) induces a categorical equivalence of simplicial sets \(h^{+}: \mathcal{M} \rightarrow \mathcal{E}\) (Corollary
5.2.4.2. We have a commutative diagram of Kan complexes

where the upper vertical are homotopy equivalences (since \(h^{+}\)is a categorical equivalence) and the horizontal maps are Kan fibrations (Corollary 4.4.5.7). Note that the top and bottom squares of (5.35) are homotopy pullback squares (Example 3.4.1.3 and Corollary 3.4.1.5). It follows that the outer rectangle is also a homotopy pullback square (Proposition 3.4.1.11): that is, precomposition with \(h^{+}\)induces a homotopy equivalence of Kan complexes

Applying Remark 5.6.5.3, we see that \(\operatorname{TW}\left(\mathcal{E} / \Delta^{1}\right)_{\mathcal{D}_{0}, \mathcal{D}_{1}}\) can be identified with the inverse image of \(\widetilde{\mathcal{B}}\) under the homotopy equivalence \(\varphi\). In particular, \(\varphi\) restricts to a homotopy equivalence \(\varphi_{0}: \operatorname{TW}\left(\mathcal{E} / \Delta^{1}\right)_{\mathcal{D}_{0}, \mathcal{D}_{1}} \rightarrow \widetilde{\mathcal{B}}\). Unwinding the definitions, we see that the morphism
\[
\theta_{\mathcal{D}_{0}, \mathcal{D}_{1}}: \operatorname{TW}\left(\mathcal{E} / \Delta^{1}\right)_{\mathcal{D}_{0}, \mathcal{D}_{1}} \rightarrow \operatorname{Equiv}\left(\mathcal{E}_{0}, \mathcal{E}_{0}^{\prime}\right) \times \operatorname{Equiv}\left(\mathcal{E}_{1}, \mathcal{E}_{1}^{\prime}\right)
\]
coincides with the the composition \(\left(\widetilde{r}_{0}, \widetilde{r}_{1}\right) \circ \varphi_{0}\). Since \(\left(\widetilde{r}_{0}, \widetilde{r}_{1}\right)\) is a pullback of the trivial Kan fibration \(\left(r_{0}, r_{1}\right): \mathcal{B} \rightarrow \operatorname{Equiv}\left(\mathcal{E}_{0}, \mathcal{E}_{0}^{\prime}\right) \times \operatorname{Fun}\left(\mathcal{E}_{0}, \mathcal{E}_{1}^{\prime}\right)^{\simeq}\), it is also a trivial Kan fibration. In a particular, \(\left(\widetilde{r}_{0}, \widetilde{r}_{1}\right)\) is a homotopy equivalence, so that the composite map \(\theta_{\mathcal{D}_{0}, \mathcal{D}_{1}}=\left(\widetilde{r}_{0}, \widetilde{r}_{1}\right) \circ \varphi_{0}\) is also a homotopy equivalence, as desired.

Lemma 5.6.9.2. Let \(\mathcal{E}\) be an essentially small \(\infty\)-category. Then the simplicial set 02 SR \(\operatorname{TW}\left(\mathcal{E} / \Delta^{0}\right)\) is a contractible Kan complex.

Proof. It follows from Lemma 5.6.8.7 that the simplicial set \(\operatorname{TW}\left(\mathcal{E} / \Delta^{0}\right)\) is a Kan complex. Since \(\mathcal{E}\) is essentially small, the Kan complex \(\operatorname{TW}\left(\mathcal{E} / \Delta^{0}\right)\) is nonempty. It will therefore suffice to show that the diagonal map
\[
\delta: \operatorname{TW}\left(\mathcal{E} / \Delta^{0}\right) \rightarrow \operatorname{TW}\left(\mathcal{E} / \Delta^{0}\right) \times \operatorname{TW}\left(\mathcal{E} / \Delta^{0}\right)
\]
is a homotopy equivalence (Corollary 3.5.1.33). Unwinding the definitions, we see that \(\delta\) factors as a composition
\[
\begin{aligned}
\operatorname{TW}\left(\mathcal{E} / \Delta^{0}\right) & \xrightarrow{\delta^{\prime}} \operatorname{Fun}\left(\Delta^{1}, \operatorname{TW}\left(\mathcal{E} / \Delta^{0}\right)\right) \\
& \simeq \operatorname{TW}\left(\Delta^{1} \times \mathcal{E} / \Delta^{1}\right) \\
& \xrightarrow{\delta^{\prime \prime}} \operatorname{TW}\left(\partial \Delta^{1} \times \mathcal{E} / \partial \Delta^{1}\right) \\
& \simeq \operatorname{TW}\left(\mathcal{E} / \Delta^{0}\right) \times \operatorname{TW}\left(\mathcal{E} / \Delta^{0}\right) .
\end{aligned}
\]

Since the 1 -simplex \(\Delta^{1}\) is contractible (Example 3.2.4.2), the morphism \(\delta^{\prime}\) is a homotopy equivalence. It will therefore suffice to show that the restriction map \(\delta^{\prime \prime}\) is a homotopy equivalence, which follows from Lemma 5.6.9.1.

Proof of Theorem 5.6.8.3. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be an essentially small cocartesian fibration of simplicial sets. We wish to show that the simplicial set \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) is a contractible Kan complex.

For every simplicial set \(\mathcal{C}_{0}\) equipped with a morphism \(\mathcal{C}_{0} \rightarrow \mathcal{C}\), let \(X\left(\mathcal{C}_{0}\right)\) denote the simplicial set \(\operatorname{TW}\left(\mathcal{E}_{0} / \mathcal{C}_{0}\right)\), where \(\mathcal{E}_{0}\) is the fiber product \(\mathcal{C}_{0} \times \mathcal{C} \mathcal{E}\). Note that the simplicial set \(X(\mathcal{C})=\operatorname{TW}(\mathcal{E} / \mathcal{C})\) can be realized as the inverse limit of the tower
\[
\cdots \rightarrow X\left(\operatorname{sk}_{2}(\mathcal{C})\right) \rightarrow X\left(\operatorname{sk}_{1}(\mathcal{C})\right) \rightarrow X\left(\operatorname{sk}_{0}(\mathcal{C})\right)
\]
where each of the transition maps is a Kan fibration (Lemma 5.6.8.10. Consequently, to show that \(X(\mathcal{C})\) is a contractible Kan complex, it will suffice to show that each of the simplicial sets \(X\left(\operatorname{sk}_{k}(\mathcal{C})\right)\) is a contractible Kan complex. Replacing \(\mathcal{C}\) by \(\operatorname{sk}_{k}(\mathcal{C})\), we can assume that the simplicial set \(\mathcal{C}\) has dimension \(\leq k\), for some integer \(k \geq-1\).

We now proceed by induction on \(k\). In the case \(k=-1\), the simplicial set \(\mathcal{C}\) is empty and \(\operatorname{TW}(\mathcal{E} / \mathcal{C})\) is isomorphic to \(\Delta^{0}\). We may therefore assume without loss of generality that \(k \geq 0\). Let \(S\) be the collection of nondegenerate \(k\)-simplices of \(\mathcal{C}\), so that Proposition 1.1.4.12 supplies a pushout diagram of simplicial sets

where \(\mathcal{C}_{0}=\operatorname{sk}_{k-1}(\mathcal{C})\) is the \((k-1)\)-skeleton of \(\mathcal{C}\). It follows from our inductive hypothesis that the simplicial set \(X\left(\mathcal{C}_{0}\right)\) is a contractible Kan complex. Consequently, to show that \(X(\mathcal{C})\) is a contractible Kan complex, it will suffice to show that the restriction map \(\theta: X(\mathcal{C}) \rightarrow X\left(\mathcal{C}_{0}\right)\) is a trivial Kan fibration. Note that \(\theta\) is a pullback of the restriction map
\[
\theta_{0}: X\left(\coprod_{\sigma \in S} \Delta^{k}\right) \rightarrow X\left(\coprod_{\sigma \in S} \partial \Delta^{k}\right) .
\]

We will complete the proof by showing that \(\theta_{0}\) is a trivial Kan fibration. Since \(\theta_{0}\) is a Kan fibration (Lemma 5.6.8.10), this is equivalent to the assertion that \(\theta_{0}\) is a homotopy equivalence (Proposition 3.2.7.2). Our inductive hypothesis guarantees that the Kan complex \(X\left(\underset{\sigma \in S}{ } \coprod^{k}\right)\) is contractible. We are therefore reduced to showing that the Kan complex \(X\left(\underset{\sigma \in S}{\amalg} \Delta^{k}\right)\) is also contractible. Since the collection of contractible Kan complexes is closed under products, we are reduced to verifying the contractibility of the simplicial set \(X\left(\mathcal{C}_{0}\right)\) in the special case where \(\mathcal{C}_{0}=\Delta^{k}\) is a standard simplex of dimension \(k\). We now consider several cases:
- In the case \(k=0\), the desired result follows from Lemma 5.6.9.2,
- In the case \(k=1\), Lemma 5.6.9.1 supplies a trivial Kan fibration \(X\left(\Delta^{1}\right) \rightarrow X\left(\partial \Delta^{1}\right)\). Our inductive hypothesis guarantees that the Kan complex \(X\left(\partial \Delta^{1}\right)\) is contractible, so that \(X\left(\Delta^{1}\right)\) is also contractible.
- In the case \(k \geq 2\), we can choose an integer \(0<i<k\). In this case, the inclusion \(\Lambda_{i}^{k} \hookrightarrow \Delta^{k}\) is inner anodyne, so the restriction map \(X\left(\Delta^{k}\right) \rightarrow X\left(\Lambda_{i}^{k}\right)\) is a trivial Kan fibration (Lemma 5.6.8.10). Our inductive hypothesis guarantees that the Kan complex \(X\left(\Lambda_{i}^{k}\right)\) is contractible, so that \(X\left(\Delta^{k}\right)\) is also contractible.

\section*{Higher Category Theory}

\section*{Chapter 6}

\section*{Adjoint Functors}

\subsection*{6.1 Adjunctions in 2-Categories}

We begin by reviewing the theory of adjoint functors in the setting of classical category 02CA theory, originally introduced in [34].

Definition 6.1.0.1 (Kan). Let \(\mathcal{C}\) and \(\mathcal{D}\) be categories, and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) 02CB be functors. A Hom-adjunction between \(F\) and \(G\) is a collection of bijections
\[
\rho_{C, D}: \operatorname{Hom}_{\mathcal{D}}(F(C), D) \simeq \operatorname{Hom}_{\mathcal{C}}(C, G(D))
\]
which depend functorially on \(C \in \mathcal{C}\) and \(D \in \mathcal{D}\) (that is, the construction \((C, D) \mapsto \rho_{C, D}\) is an isomorphism in the functor category \(\operatorname{Fun}\left(\mathcal{C}^{\text {op }} \times \mathcal{D}\right.\), Set) \()\). In this case, we say that the construction \((C, D) \mapsto \rho_{C, D}\) exhibits \(F\) as a left adjoint to \(G\) and \(G\) as a right adjoint to \(F\).

In the situation of Definition 6.1.0.1, functoriality imposes strong constraints on the construction \((C, D) \mapsto \rho_{C, D}\). For each object \(C \in \mathcal{C}\), let \(\eta_{C}: C \rightarrow(G \circ F)(C)\) be the morphism of \(\mathcal{C}\) given by the image of the identity morphism \(\operatorname{id}_{F(C)}\) under the bijection
\[
\rho_{C, F(C)}: \operatorname{Hom}_{\mathcal{D}}(F(C), F(C)) \simeq \operatorname{Hom}_{\mathcal{C}}(C,(G \circ F)(C)) .
\]

For every morphism \(f: F(C) \rightarrow D\) in \(\mathcal{D}\), the commutativity of the diagram

supplies an equality
\[
\rho_{C, D}(f)=\rho_{C, D}\left(f \circ \operatorname{id}_{F(C)}\right)=G(f) \circ \rho_{C, F(C)}\left(\operatorname{id}_{F(C)}\right)=G(f) \circ \eta_{C} .
\]

In particular, the bijection \(\rho_{C, D}\) is completely determined by the morphism \(\eta_{C}\). Moreover, the functoriality of \(\rho_{\bullet}, \mathbf{\bullet}\) in the first variable guarantees that the construction \(C \mapsto \eta_{C}\) is a natural transformation from the identity functor id \(\mathrm{id}_{\mathcal{C}}\) to the composition \(G \circ F\). Similarly, the inverse bijections \(\rho_{C, D}^{-1}: \operatorname{Hom}_{\mathcal{C}}(C, G(D)) \simeq \operatorname{Hom}_{\mathcal{D}}(F(C), D)\) can be recovered from the collection of morphisms \(\left\{\epsilon_{D}=\rho_{G(D), D}^{-1}\left(\operatorname{id}_{G(D)}\right)\right\}_{D \in \mathcal{D}}\), which comprise a natural transformation of functors \(\epsilon:(F \circ G) \rightarrow \operatorname{id}_{\mathcal{D}}\). This leads to a reformulation of Definition 6.1.0.1:

02CC Definition 6.1.0.2. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) be functors between categories. An adjunction between \(F\) and \(G\) is a pair \((\eta, \epsilon)\), where \(\eta: \operatorname{id}_{\mathcal{C}} \rightarrow G \circ F\) and \(\epsilon: F \circ G \rightarrow \mathrm{id}_{\mathcal{D}}\) are natural transformations satisfying the following compatibility conditions:
(Z1) For each object \(C \in \mathcal{C}\), the composite morphism
\[
F(C) \xrightarrow{F\left(\eta_{C}\right)}(F \circ G \circ F)(C) \xrightarrow{\epsilon_{F(C)}} F(C)
\]
is equal to the identity \(\operatorname{id}_{F(C)}\).
(Z2) For each object \(D \in \mathcal{D}\), the composite morphism
\[
G(D) \xrightarrow{\eta_{G(D)}}(G \circ F \circ G)(D) \xrightarrow{G\left(\epsilon_{D}\right)} G(D)
\]
is equal to the identity \(\operatorname{id}_{G(D)}\).
If these conditions are satisfied, then we will refer to \(\eta\) as the unit of the adjunction ( \(\eta, \epsilon\) ) and to \(\epsilon\) as the counit of the adjunction \((\eta, \epsilon)\). In this case, we will say that \((\eta, \epsilon)\) exhibits \(F\) as a left adjoint to \(G\) and also that it exhibits \(G\) as a right adjoint to \(F\).
02CD Example 6.1.0.3. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) be functors between categories, and let \(\left\{\rho_{C, D}\right\}_{C \in \mathcal{C}, D \in \mathcal{D}}\) be a Hom-adjunction between \(F\) and \(G\) (in the sense of Definition 6.1.0.1). Let \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) and \(\epsilon: F \circ G \rightarrow \mathrm{id}_{\mathcal{D}}\) be the natural transformations given by the formulae
\[
\begin{gathered}
\eta_{C}=\rho_{C, F(C)}\left(\operatorname{id}_{F(C)}\right) \in \operatorname{Hom}_{\mathcal{C}}(C,(G \circ F)(C)) \\
\epsilon_{D}=\rho_{G(D), D}^{-1}\left(\operatorname{id}_{G(D)}\right) \in \operatorname{Hom}_{\mathcal{D}}((F \circ G)(D), D) .
\end{gathered}
\]

Then the pair \((\eta, \epsilon)\) is an adjunction between \(F\) and \(G\) (in the sense of Definition 6.1.0.2). Condition (Z1) follows from the observation that for each object \(C \in \mathcal{C}\), we have
\[
\begin{aligned}
\operatorname{id}_{F(C)} & =\rho_{C, F(C)}^{-1}\left(\rho_{C, F(C)}\left(\operatorname{id}_{F(C)}\right)\right) \\
& =\rho_{C, F(C)}^{-1}\left(\eta_{C}\right) \\
& =\rho_{C, F(C)}^{-1}\left(\mathrm{id}_{(G \circ F)(C)} \circ \eta_{C}\right) \\
& =\rho_{(G \circ F)(C), F(C)}^{-1}\left(\mathrm{id}_{(G \circ F)(C)}\right) \circ F\left(\eta_{C}\right) \\
& =\epsilon_{F(C)} \circ F\left(\eta_{C}\right) .
\end{aligned}
\]

The verification of \((Z 2)\) is similar.
Exercise 6.1.0.4. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) be functors between categories. Show that \(\qquad\) every adjunction \((\eta, \epsilon)\) between \(F\) and \(G\) can be obtained by applying the construction of Example 6.1.0.3 to a unique Hom-adjunction \(\left\{\rho_{C, D}\right\}_{C \in \mathcal{C}, D \in \mathcal{D}}\) between \(F\) and \(G\) (see Example 6.1.2.7).

It follows from Exercise 6.1.0.4 that Definitions 6.1.0.1 and 6.1.0.2 are essentially equivalent to one another. However, an advantage of Definition 6.1.0.2 is that it can be formulated entirely in the language of functors and natural transformations: that is, it uses only the structure of the 2-category Cat of Example 2.2.0.4. In \(\S 6.1 .1\), we exploit this observation to generalize the notion of adjunction to an arbitrary 2-category. Given a 2 -category \(\mathcal{C}\) containing 1-morphisms \(f: C \rightarrow D\) and \(g: D \rightarrow C\), we define an adjunction between \(f\) and \(g\) to be a pair of 2-morphisms
\[
\eta: \operatorname{id}_{C} \Rightarrow g \circ f \quad \epsilon: f \circ g \Rightarrow \operatorname{id}_{D}
\]
satisfying analogues of the compatibility conditions \((Z 1)\) and ( \(Z 2\) ) above (Definition 6.1.1.1).
Our first goal is to adapt Exercise 6.1.0.4 to the setting of a general 2-category \(\mathcal{C}\). Suppose we are given 1-morphisms \(f: C \rightarrow D, g: D \rightarrow C, c: T \rightarrow C\), and \(d: T \rightarrow D\) in \(\mathcal{C}\). In §6.1.2, we show that every adjunction \((\eta, \epsilon)\) between \(f\) and \(g\) determines a bijection
\[
\operatorname{Hom}_{\operatorname{Hom}_{\mathcal{C}}(T, D)}(f \circ c, d) \simeq \operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(T, C)}(c, g \circ d),
\]
depending functorially on \(c\) and \(d\) (see Corollary 6.1.2.6 and Remark 6.1.2.4). Here the map from right to left is constructed using the unit map \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\), and from left to right using the counit \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\). As an application, we show that an adjunction \((\eta, \epsilon)\) is completely determined by the unit \(\eta\) (or the counit \(\epsilon\) ), and give a criterion which can be used to test if an arbitrary 2-morphism \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) is the unit of an adjunction (see Proposition 6.1.2.9, Variant 6.1.2.12, and Proposition 6.1.2.13

Let \(\mathcal{C}\) be a 2-category and let \(f: C \rightarrow D\) be a 1 -morphism in \(\mathcal{C}\). In \(\S 6.1 .3\), we show that if \(f\) admits a right adjoint \(g\), then \(g\) is uniquely determined up to (canonical) isomorphism (Corollary 6.1.3.3). Moreover, the formation of right adjoints can be regarded as a (partially defined) functor from \(\underline{\operatorname{Hom}}_{\mathcal{C}}(C, D)^{\text {op }}\) to \(\underline{\operatorname{Hom}}_{\mathcal{C}}(D, C)\) (Notation 6.1.3.5), with a (partially defined) inverse given by the formation of left adjoints (Notation 6.1.3.8. In 6.1.4 we consider the special case where \(f: C \xrightarrow{\sim} D\) is an isomorphism in \(\mathcal{C}\) : in this case, \(f\) automatically admits a right adjoint (and a left adjoint), which can be identified with a homotopy inverse isomorphism \(D \xrightarrow{\sim} C\) (Proposition 6.1.4.1).

In 6.1.5 we show that the formation of adjoints is compatible with composition. More precisely, if \(f: C \rightarrow D\) and \(f^{\prime}: D \rightarrow E\) are 1-morphisms in a 2-category \(\mathcal{C}\) which admit right adjoints \(g: D \rightarrow C\) and \(g^{\prime}: E \rightarrow D\), respectively, then the composition \(\left(f^{\prime} \circ f\right): C \rightarrow E\) also
admits a right adjoint, which is canonically isomorphic to the composition \(\left(g \circ g^{\prime}\right): E \rightarrow C\) (Corollary 6.1.5.5).

The theory of adjunctions can be usefully applied to many 2 -categories \(\mathcal{C}\) other than Cat (for example, we will use it in \(\$ 6.2\) to generalize the theory of adjoint functors to the setting of \(\infty\)-categories). In \(\S 6.1 .6\), we consider the case where \(\mathcal{C}\) has a single object \(X\), and can therefore be identified with the monoidal category \(\mathcal{E}=\underline{\operatorname{End}}_{\mathcal{C}}(X)\) (see Example 2.2.2.5). Specializing the theory of adjunctions to this situation, we recover the classical notion of a duality datum in \(\mathcal{E}\) (Definition 6.1.6.1).

\subsection*{6.1.1 Adjunctions}

02CF Our goal in this section is to generalize the notion of an adjunction to an arbitrary 2 -category \(\mathcal{C}\). Here Definition 6.1.0.2 adapts without essential change; the only additional complications are the fact that the associativity and unit constraints of \(\mathcal{C}\) need not be strict.

02CG Definition 6.1.1.1. Let \(\mathcal{C}\) be a 2 -category, let \(C\) and \(D\) be objects of \(\mathcal{C}\), and let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1-morphisms in \(\mathcal{C}\). An adjunction between \(f\) and \(g\) is a pair of 2 -morphisms \((\eta, \epsilon)\), where \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) is a morphism in the category \(\operatorname{Hom}_{\mathcal{C}}(C, C)\) and \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) is a morphism in the category \(\operatorname{Hom}_{\mathcal{C}}(D, D)\), which satisfy the following compatibility conditions:
(Z1) The composition
\[
f \stackrel{\rho_{f}^{-1}}{\sim} f \circ \mathrm{id}_{C} \stackrel{\mathrm{id}_{f} \circ \eta}{\Longrightarrow} f \circ(g \circ f) \xrightarrow[\sim]{\alpha_{f, g, f}}(f \circ g) \circ f \xrightarrow{\epsilon \operatorname{id}_{f}} \operatorname{id}_{D} \circ f \xrightarrow[\sim]{\lambda_{f}} f
\]
is the identity 2-morphism from \(f\) to itself. Here \(\lambda_{f}\) and \(\rho_{f}\) are the left and right unit constraints of the 2-category \(\mathcal{C}\) (Construction 2.2.1.11) and \(\alpha_{f, g, f}\) is the associativity constraint for the 2-category \(\mathcal{C}\).
(Z2) The composition
\[
g \xrightarrow[\sim]{\lambda_{g}^{-1}} \operatorname{id}_{C} \circ g \xrightarrow{\eta \operatorname{oid}_{g}}(g \circ f) \circ g \xrightarrow[\sim]{\alpha_{g, f, g}^{-1}} g \circ(f \circ g) \xrightarrow{\mathrm{id}_{g} \circ \epsilon} g \circ \operatorname{id}_{D} \xrightarrow[\sim]{\rho_{g}} g
\]
is the identity 2 -morphism from \(g\) to itself.
If these conditions are satisfied, then we will refer to \(\eta\) as the unit of the adjunction ( \(\eta, \epsilon\) ) and to \(\epsilon\) as the counit of the adjunction \((\eta, \epsilon)\). In this case, we say that \((\eta, \epsilon)\) exhibits \(f\) as a left adjoint of \(g\), and also that it exhibits \(g\) as a right adjoint of \(f\).

02CH Example 6.1.1.2. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) be functors between categories, which we regard as 1-morphisms in the strict 2-category Cat of Example 2.2.0.4. An adjunction between \(F\) and \(G\) in the 2-category Cat is an adjunction between \(F\) and \(G\) in the usual category-theoretic sense: that is, a pair of natural transformations \(\eta\) : id \(\mathcal{C}_{\mathcal{C}} \rightarrow G \circ F\) and \(\epsilon: F \circ G \rightarrow \mathrm{id}_{\mathcal{D}}\) which satisfy the requirements of Definition 6.1.0.2.

Remark 6.1.1.3. Let \(\mathcal{C}\) be a 2-category, let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1-morphisms of 02CJ \(\mathcal{C}\), and let \(\eta: \operatorname{id}_{C} \Rightarrow g \circ f\) and \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) be 2 -morphisms of \(\mathcal{C}\). Then the pair \((\eta, \epsilon)\) is an adjunction between \(f\) and \(g\) in the 2-category \(\mathcal{C}\) if and only if the pair ( \(\eta^{\mathrm{op}}, \epsilon^{\mathrm{op}}\) ) it is an adjunction between \(g^{\mathrm{op}}\) and \(f^{\mathrm{op}}\) in the opposite 2-category \(\mathcal{C}^{\mathrm{op}}\) (Construction 2.2.3.1). Note that in this case, \(g^{\mathrm{op}}\) is the left adjoint, while \(f^{\mathrm{op}}\) is the right adjoint.

Remark 6.1.1.4. Let \(\mathcal{C}\) be a 2-category, let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1-morphisms 02CK of \(\mathcal{C}\), and let \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) and \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) be 2 -morphisms of \(\mathcal{C}\). Then the pair ( \(\eta, \epsilon\) ) is an adjunction between \(f\) and \(g\) in the 2-category \(\mathcal{C}\) if and only if the pair \(\left(\epsilon^{\mathrm{c}}, \eta^{\mathrm{c}}\right)\) is an adjunction between \(g^{\mathrm{c}}\) and \(f^{\mathrm{c}}\) in the conjugate 2-category \(\mathcal{C}^{\mathrm{c}}\) (Construction 2.2.3.4). Note that in this case, \(\epsilon^{\mathrm{c}}\) is the unit of the adjunction and \(\eta^{\mathrm{c}}\) is the counit. Similarly, \(g^{\mathrm{c}}\) is the left adjoint and \(f^{c}\) is the right adjoint.
Remark 6.1.1.5 (Isomorphism Invariance). Let \(\mathcal{C}\) be a 2-category, let \(f, f^{\prime}: C \rightarrow D\) 02CL and \(g, g^{\prime}: D \rightarrow C\) be 1-morphisms in \(\mathcal{C}\), and let \((\eta, \epsilon)\) be an adjunction between \(f\) and \(g\). Suppose we are given invertible 2-morphisms \(\beta: g \xlongequal{\Longrightarrow} g^{\prime}\) and \(\gamma: f \xlongequal{\Longrightarrow} f^{\prime}\). Let \(\eta^{\prime}\) denote the composition \(\operatorname{id}_{C} \stackrel{\eta}{\Rightarrow} g \circ f \stackrel{\sim}{\sim} g^{\prime} \circ f^{\prime}\) and let \(\epsilon^{\prime}\) denote the composition \(f^{\prime} \circ g^{\prime} \xrightarrow[\sim]{\gamma^{-1} \circ \beta^{-1}} f \circ g \stackrel{\epsilon}{\Rightarrow} \operatorname{id}_{D}\). Then the pair \(\left(\eta^{\prime}, \epsilon^{\prime}\right)\) is an adjunction between \(f^{\prime}\) and \(g^{\prime}\).

Exercise 6.1.1.6 (Functoriality). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of 2-categories. Suppose we 02 CM are given 1-morphisms \(f: C \rightarrow D\) and \(g: D \rightarrow C\) in \(\mathcal{C}\). Let \((\eta, \epsilon)\) be an adjunction between \(f\) and \(g\) in the 2-category \(\mathcal{C}\), let \(\eta^{\prime}\) denote the composition
\[
\mathrm{id}_{F(C)} \Rightarrow F\left(\mathrm{id}_{C}\right) \stackrel{F(\eta)}{\Longrightarrow} F(g \circ f) \xrightarrow[\sim]{\mu_{g, f}^{-1}} F(g) \circ F(f),
\]
and let \(\epsilon^{\prime}\) denote the composition
\[
F(f) \circ F(g) \xrightarrow[\sim]{\mu_{f, g}} F(f \circ g) \xrightarrow{F(\epsilon)} F\left(\operatorname{id}_{D}\right) \underset{\sim}{\Longrightarrow} \operatorname{id}_{F(D)},
\]
where \(\mu_{f, g}\) and \(\mu_{g, f}\) are the composition constraints of the functor \(F\) and the unlabeled isomorphisms are the identity constraints of \(F\). Show that the pair \(\left(\eta^{\prime}, \epsilon^{\prime}\right)\) is an adjunction between \(F(f)\) and \(F(g)\) in the 2-category \(\mathcal{D}\).
Example 6.1.1.7. Let \(\mathcal{C}\) be an ordinary category which admits fiber products, and let 02CN \(\operatorname{Corr}(\mathcal{C})\) denote the 2 -category of correspondences in \(\mathcal{C}\) (Example 2.2.2.1). Every morphism \(f: X \rightarrow Y\) in \(\mathcal{C}\) determines diagrams

which we can regard as 1-morphisms \(f_{!}: X \rightarrow Y\) and \(f^{!}: Y \rightarrow X\) in the 2-category \(\operatorname{Corr}(\mathcal{C})\). Unwinding the definitions, we see that the compositions \(f^{!} \circ f_{!}\)and \(f!\circ f^{!}\)are given (up to isomorphism) by the diagrams

where \(\pi_{0}, \pi_{1}: X \times_{Y} X \rightarrow X\) are the projection maps. We can therefore regard the diagonal \(\operatorname{map} \delta: X \rightarrow X \times_{Y} X\) as a 2-morphism from id \({ }_{X}\) to \(f^{!} \circ f_{!}\)in \(\operatorname{Corr}(\mathcal{C})\), and the morphism \(f: X \rightarrow Y\) as a 2 -morphism from \(f_{!} \circ f^{!}\)to \(\operatorname{id}_{Y}\) in \(\operatorname{Corr}(\mathcal{C})\). The pair \((\delta, f)\) is an adjunction between \(f\) ! and \(f\) !.

\subsection*{6.1.2 Adjuncts}

02CP Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) be functors between categories. By virtue of Exercise 6.1.0.4 every adjunction \((\eta, \epsilon)\) between \(F\) and \(G\) determines a collection of bijections
\[
\rho_{C, D}: \operatorname{Hom}_{\mathcal{D}}(F(C), D) \simeq \operatorname{Hom}_{\mathcal{C}}(C, G(D)),
\]
depending functorially on \(C \in \mathcal{C}\) and \(D \in \mathcal{D}\). In this section, we establish an analogue of this statement for adjunctions in an arbitrary 2-category.

02CQ Construction 6.1.2.1. Let \(\mathcal{C}\) be a 2-category containing objects \(T, C\), and \(D\), together with 1-morphisms \(f: C \rightarrow D, g: D \rightarrow C, c: T \rightarrow C\), and \(d: T \rightarrow D\).
- Let \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) and \(\beta: c \Rightarrow g \circ d\) be 2 -morphisms of \(\mathcal{C}\). We will refer to the composition
\[
f \circ c \stackrel{\mathrm{id}_{f} \circ \beta}{\Longrightarrow} f \circ(g \circ d) \xrightarrow[\sim]{\alpha_{f, g, d}}(f \circ g) \circ d \xrightarrow{\epsilon \circ \mathrm{oid}_{d}} \operatorname{id}_{D} \circ d \xrightarrow[\sim]{\lambda_{d}} d
\]
as the left adjunct of \(\beta\) with respect to \(\epsilon\), or more simply as the left adjunct of \(\beta\) if the 2 -morphism \(\epsilon\) is clear from context. Here \(\lambda_{d}\) and \(\alpha_{f, g, d}\) are the left unit and associativity constraints for the 2 -category \(\mathcal{C}\).
- Let \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) and \(\gamma: f \circ c \Rightarrow d\) be 2-morphisms of \(\mathcal{C}\). We will refer to the composition
\[
c \stackrel{\lambda_{c}^{-1}}{\sim} \mathrm{id}_{C} \circ c \stackrel{\eta}{\Rightarrow}(g \circ f) \circ c \stackrel{\alpha_{g, f, c}^{-1}}{\sim} g \circ(f \circ c) \xrightarrow{\mathrm{id}_{g} \circ \gamma} g \circ d
\]
as the right adjunct of \(\gamma\) with respect to \(\eta\), or more simply as the right adjunct of \(\gamma\) if the 2-morphism \(\eta\) is clear from context. Here again \(\lambda_{c}\) and \(\alpha_{g, f, c}\) are the left unit and associativity constraints for the 2 -category \(\mathcal{C}\).

Example 6.1.2.2. Let \(\mathcal{C}\) be a 2-category containing 1-morphisms \(f: C \rightarrow D\) and \(g: D \rightarrow C .02 \mathrm{CR}\) Then:
- Every 2-morphism \(\eta: \operatorname{id}_{C} \Rightarrow g \circ f\) is equal to the right adjunct of the right unit constraint \(\rho_{f}: f \circ \mathrm{id}_{D} \xlongequal{\Longrightarrow} f\) (with respect to \(\eta\) ).
- Every 2-morphism \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) is equal to the left adjunct of \(\rho_{g}^{-1}: g \xlongequal{\Longrightarrow} g \circ \operatorname{id}_{D}\) (with respect to \(\epsilon\) ).
Example 6.1.2.3. Let \(\mathcal{C}\) be a 2-category containing 1-morphisms \(f: C \rightarrow D\) and \(g: D \rightarrow C, 02 \mathrm{CS}\) and suppose we are given 2 -morphisms \(\eta: \operatorname{id}_{C} \Rightarrow g \circ f\) and \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\). Then \((\eta, \epsilon)\) is an adjunction between \(f\) and \(g\) if and only if the following conditions are satisfied:
(Z1) The left adjunct of \(\eta\) (with respect to \(\epsilon\) ) is equal to the right unit constraint \(\rho_{f}\) : \(f \circ \mathrm{id}_{C} \stackrel{\sim}{\Rightarrow} f\).
(Z2) The right adjunct of \(\epsilon\) (with respect to \(\eta\) ) is the inverse \(\rho_{g}^{-1}: g \xlongequal{\sim} g \circ \mathrm{id}_{D}\) of the right unit constraint.

Remark 6.1.2.4 (Functoriality). Let \(\mathcal{C}\) be a 2-category containing objects \(T, C\), and \(D\), 02CT together with 1-morphisms \(f: C \rightarrow D, g: D \rightarrow C, c, c^{\prime}: T \rightarrow C\), and \(d, d^{\prime}: T \rightarrow D\). Then:
- If \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) and \(\varphi: c \Rightarrow c^{\prime}\) are 2-morphisms of \(\mathcal{C}\), then the diagram of sets

is commutative, where the horizontal maps are given by the formation of right adjuncts with respect to \(\eta\).
- If \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) and \(\varphi: c \Rightarrow c^{\prime}\) are 2-morphisms of \(\mathcal{C}\), then the diagram of sets

is commutative, where the horizontal maps are given by the formation of left adjuncts with respect to \(\epsilon\).
- If \(\eta: \operatorname{id}_{C} \Rightarrow g \circ f\) and \(\psi: d \Rightarrow d^{\prime}\) are 2-morphisms of \(\mathcal{C}\), then the diagram of sets

is commutative, where the horizontal maps are given by the formation of right adjuncts with respect to \(\eta\).
- If \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) and \(\psi: d \Rightarrow d^{\prime}\) are 2-morphisms of \(\mathcal{C}\), then the diagram of sets

is commutative, where the horizontal maps are given by the formation of left adjuncts with respect to \(\epsilon\).

Stated more informally, Construction 6.1.2.1 depends functorially on the 1-morphisms \(c: T \rightarrow C\) and \(d: T \rightarrow D\).

02CU Proposition 6.1.2.5. Let \(\mathcal{C}\) be a 2-category, let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1-morphisms of \(\mathcal{C}\), and let \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) and \(\epsilon: f \circ g \Rightarrow \mathrm{id}_{D}\) be 2 -morphisms. Suppose we are given another object \(T \in \mathcal{C}\) equipped with 1-morphisms \(c: T \rightarrow C\) and \(d: T \rightarrow D\), together with 2 -morphisms \(\beta: c \Rightarrow g \circ d\) and \(\gamma: f \circ c \Rightarrow d\). Then:
(1) If the pair \((\eta, \epsilon)\) satisfies condition (Z1) of Definition 6.1.1.1 and \(\beta\) is the right adjunct of \(\gamma\), then \(\gamma\) is the left adjunct of \(\beta\).
(2) If the pair \((\eta, \epsilon)\) satisfies condition (Z2) of Definition 6.1.1.1 and \(\gamma\) is the left adjunct of \(\beta\), then \(\beta\) is the right adjunct of \(\gamma\).

Proof. We will prove (1); the proof of (2) follows by applying the same argument in the
conjugate 2 -category \(\mathcal{C}^{\mathrm{c}}\). Consider the diagram

in the category \(\underline{\operatorname{Hom}}_{\mathcal{C}}(T, D)\), where the unlabeled morphisms are given by the associativity constraints of \(\mathcal{C}\) (and their inverses). Our assumption that \(\beta\) is the right adjunct of \(\gamma\) guarantees that the composition along the top line coincides with \(\operatorname{id}_{f} \circ \beta\). Consequently, the left adjunct of \(\beta\) is the 2 -morphism of \(\mathcal{C}\) given by clockwise composition around the outside of the diagram. On the other hand, axiom (Z1) of Definition 6.1.1.1 guarantees counterclockwise composition around the outside of the diagram coincides with \(\gamma\). To complete the proof, it will suffice to show that the diagram commutes. The commutativity of the triangular regions follows from Propositions 2.2.1.14 and 2.2.1.16. The commutativity of the bottom right square follows from the naturality of left unit constraints (Remark 2.2.1.13) and the commutativity of the middle right square from the functoriality of composition. The remaining squares commute by the naturality of the associativity constraints of \(\mathcal{C}\), and the five-sided region commutes by virtue of the pentagon identity.

Corollary 6.1.2.6. Let \(\mathcal{C}\) be a 2-category, let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1-morphisms of 02CV \(\mathcal{C}\), and suppose we are given 2-morphisms \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) and \(\epsilon: f \circ g \Rightarrow \mathrm{id}_{D}\). The following conditions are equivalent:
(1) The pair \((\eta, \epsilon)\) is an adjunction between \(f\) and \(g\) (in the sense of Definition 6.1.1.1).
(2) For every object \(T \in \mathcal{C}\) and every pair of 1-morphisms \(c: T \rightarrow C\) and \(d: T \rightarrow D\), the formation of left and right adjuncts (Construction 6.1.2.1) supplies mutually inverse bijections
\[
\operatorname{Hom}_{\operatorname{Hom}_{\mathcal{C}}(T, D)}(f \circ c, d) \simeq \operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(T, C)}(c, g \circ d) .
\]

Proof. The implication (1) \(\Rightarrow(2)\) follows from Proposition 6.1.2.5. For the converse, we first observe that \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) is equal to the right adjunct of the right unit constraint \(\rho_{f}: f \circ \operatorname{id}_{D} \stackrel{\sim}{\Rightarrow} f\) with respect to \(\eta\) (Example 6.1.2.2. If assumption (2) is satisfied, then \(\rho_{f}\) is the left adjunct of \(\eta\) with respect to \(\epsilon\). Similarly, assumption (2) guarantees that \(\rho_{g}^{-1}: g \stackrel{\sim}{\Rightarrow} g \circ \mathrm{id}_{D}\) is the right adjunct of \(\epsilon\) with respect to \(\eta\), so that the pair \((\eta, \epsilon)\) is an adjunction by virtue of Example 6.1.2.3.

02CW Example 6.1.2.7. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) be functors between categories, and let \((\eta, \epsilon)\) be an adjunction between \(F\) and \(G\). Suppose we are given objects \(C \in \mathcal{C}\) and \(D \in \mathcal{D}\), which we identify with functors \(C:\{*\} \rightarrow \mathcal{C}\) and \(D:\{*\} \rightarrow \mathcal{D}\), respectively. Applying Corollary 6.1.2.6 to the 2-category Cat, we obtain a bijection
\[
\rho_{C, D}: \operatorname{Hom}_{\mathcal{D}}(F(C), D) \simeq \operatorname{Hom}_{\mathcal{D}}(C, G(D))
\]

This bijection depends functorially on \(C\) and \(D\) (Remark 6.1.2.4), and can therefore be regarded as a Hom-adjunction between \(F\) and \(G\) in the sense of Definition 6.1.0.1. Note that, for every morphism \(f: F(C) \rightarrow D\) in \(\mathcal{C}\), the image \(\rho_{C, D}(f) \in \operatorname{Hom}_{\mathcal{C}}(C, G(D))\) is given explicitly by the composition \(C \xrightarrow{\eta_{C}}(G \circ F)(C) \xrightarrow{G(f)} G(D)\). In particular, the morphism \(\eta_{C}: C \rightarrow(G \circ F)(C)\) can be recovered by applying \(\rho_{C, F(C)}\) to the identity morphism id \({ }_{F(C)}\). Similarly, for each object \(D \in \mathcal{D}\), the morphism \(\epsilon_{D}:(F \circ G)(D) \rightarrow D\) can be recovered by applying \(\rho_{G(D), D}^{-1}\) to the identity morphism \(\operatorname{id}_{G(D)}\). In other words, the adjunction \((\eta, \epsilon)\) is obtained by applying the construction of Example 6.1.0.3 to the Hom-adjunction \(\left\{\rho_{C, D}\right\}_{C \in \mathcal{C}, D \in \mathcal{D}}\).
02CX Corollary 6.1.2.8. Let \(\mathcal{C}\) be a 2-category, let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1-morphisms of \(\mathcal{C}\), and suppose we are given 2-morphisms \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) and \(\epsilon: f \circ g \Rightarrow \mathrm{id}_{D}\) satisfying condition (Z1) of Definition 6.1.1.1, Let \(\gamma: g \Rightarrow g\) denote the 2 -morphism given by the composition
\[
g \xrightarrow[\sim]{\lambda_{g}^{-1}} \mathrm{id}_{C} \circ g \xrightarrow{\eta \circ \mathrm{oid}_{g}}(g \circ f) \circ g \xrightarrow[\sim]{\alpha_{g, f, g}^{-1}} g \circ(f \circ g) \xrightarrow{\mathrm{id}_{g} \circ \epsilon} g \circ \operatorname{id}_{D} \xrightarrow[\sim]{\rho_{g}} g
\]

Then \(\gamma\) is idempotent: that is, \(\gamma^{2}=\gamma\) in the category \(\underline{\operatorname{Hom}}_{\mathcal{C}}(D, C)\). In particular, if \(\gamma\) has either a left or a right inverse, then \(\gamma=\operatorname{id}_{g}\) (so that \((\eta, \epsilon)\) is an adjunction between \(f\) and \(g)\).

Proof. Let \(\gamma^{\prime}\) denote the composition \(g \stackrel{\gamma}{\Rightarrow} g \stackrel{\rho_{g}^{-1}}{\Longrightarrow} g \circ \operatorname{id}_{D}\). Then \(\gamma^{\prime}\) is the right adjunct of \(\epsilon\) with respect to \(\eta\) (see Example 6.1.2.3). Invoking Remark 6.1.2.4, we deduce that the horizontal composition \(\gamma^{\prime} \gamma\) is the right adjunct of \(\epsilon^{\prime}\) with respect to \(\eta\), where \(\epsilon^{\prime}\) denotes the composite map \(f \circ g \stackrel{\mathrm{id}_{f} \circ \gamma}{\Longrightarrow} f \circ g \stackrel{\epsilon}{\Rightarrow} \mathrm{id}_{D}\). Combining Example 6.1.2.2 with Remark 6.1.2.4. we see that \(\epsilon^{\prime}\) is the left adjunct of \(\gamma^{\prime}\) with respect to \(\epsilon\). Since the pair \((\eta, \epsilon)\) satisfies \((Z 1)\),
it follows that \(\gamma^{\prime} \gamma=\gamma^{\prime}\), Composing with the right unit constraint \(\rho_{g}\), we conclude that \(\gamma \gamma=\gamma\).

Proposition 6.1.2.9. Let \(\mathcal{C}\) be a 2-category, let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1-morphisms of \(\mathcal{C}\), and let \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) be a 2-morphism of \(\mathcal{C}\). The following conditions are equivalent:
(1) For every object \(T \in \mathcal{C}\) and every pair of 1-morphisms \(c: T \rightarrow C\) and \(d: T \rightarrow D\), the formation of right adjuncts with respect to \(\eta\) (Construction 6.1.2.1) induces a bijection
\[
\operatorname{Hom}_{\operatorname{Hom}_{\mathcal{C}}(T, D)}(f \circ c, d) \rightarrow \operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(T, C)}(c, g \circ d) .
\]
(2) There exists a 2-morphism \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) for which \((\eta, \epsilon)\) is an adjunction between \(f\) and \(g\).

Moreover, if these conditions are satisfied, then the 2-morphism \(\epsilon\) is uniquely determined.
Proof. The implication \((2) \Rightarrow(1)\) follows from Corollary 6.1.2.6. Conversely, suppose that condition (1) is satisfied. Applying (1) in the case \(T=D, c=g\), and \(d=\mathrm{id}_{D}\), we conclude that there is a unique 2 -morphism \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) whose right adjunct is equal to the inverse \(\rho_{g}^{-1}: g \stackrel{\sim}{\Longrightarrow} g \circ \operatorname{id}_{D}\) of the right unit constraint \(\rho_{g}\), so that the pair \((\eta, \epsilon)\) satisfies condition \((Z 2)\) of Definition 6.1.1.1 (Example 6.1.2.3). We will complete the proof by showing that \((\eta, \epsilon)\) also satisfies condition \((Z 1)\). Let \(\gamma: f \circ \operatorname{id}_{C} \Rightarrow f\) be the left adjunct of \(\eta\). It follows from Proposition 6.1.2.5 that the right adjunct of \(\gamma\) is equal to \(\eta\), which is also the right adjunct of the unit constraint \(\rho_{f}: f \circ \mathrm{id}_{C} \xlongequal{\Longrightarrow} f\). Invoking assumption (1), we conclude that \(\gamma=\rho_{f}\), which is a restatement of (Z1) (Example 6.1.2.3).

Definition 6.1.2.10. Let \(\mathcal{C}\) be a 2-category and let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1- 02CZ morphisms of \(\mathcal{C}\). We say that a 2-morphism \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) is the unit of an adjunction if it satisfies the equivalent conditions of Proposition 6.1.2.9. that is, if there exists a 2 -morphism \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) for which the pair \((\eta, \epsilon)\) is an adjunction. If this condition is satisfied, we will say that \(\eta\) exhibits \(f\) as a left adjoint of \(g\) and also that \(\eta\) exhibits \(g\) as a right adjoint of \(f\).

In the 2-category Cat, we can formulate a sharper version of Proposition 6.1.2.9.
Variant 6.1.2.11. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) be functors between categories and let 02D0 \(\eta:\) id \(_{\mathcal{C}} \rightarrow G \circ F\) be a natural transformation. The following conditions are equivalent:
(1) For every pair of objects \(C \in \mathcal{C}\) and \(D \in \mathcal{D}\), the formation of right adjuncts with respect to \(\eta\) induces a bijection \(\operatorname{Hom}_{\mathcal{D}}(F(C), D) \rightarrow \operatorname{Hom}_{\mathcal{C}}(C, G(D))\).
(2) There exists a natural transformation \(\epsilon: F \circ G \rightarrow \operatorname{id}_{\mathcal{D}}\) for which \((\eta, \epsilon)\) is an adjunction between \(F\) and \(G\).

Moreover, if these conditions are satisfied, then the natural transformation \(\epsilon\) is uniquely determined.

Proof. We will prove that \((1) \Rightarrow(2)\); the remaining assertions follow immediately from Proposition 6.1.2.9. Fix an object \(D \in \mathcal{D}\). Applying assertion (1) in the case \(C=G(D)\), we deduce that there is a unique morphism \(\epsilon_{D}:(F \circ G)(D) \rightarrow D\) for which the composition
\[
G(D) \xrightarrow{\eta_{G(D)}}(G \circ F \circ G)(D) \xrightarrow{G\left(\epsilon_{D}\right)} G(D)
\]
is the identity morphism from \(G(D)\) to itself.
We first claim that the construction \(D \mapsto \epsilon_{D}\) is a natural transformation of functors from \(F \circ G\) to \(\operatorname{id}_{\mathcal{D}}\). Let \(h: D \rightarrow D^{\prime}\) be a morphism in the category \(\mathcal{D}\); we wish to show that the diagram

commutes. Consider the diagram

in the category \(\mathcal{C}\). It follows from the definitions of \(\epsilon_{D}\) and \(\epsilon_{D^{\prime}}\) that both horizontal compositions are equal to the identity, so the outer rectangle commutes. Since \(\eta\) is a natural transformation, the left square commutes. It follows that the compositions \(G(h) \circ G\left(\epsilon_{D}\right) \circ \eta_{G(D)}\) and \(G\left(\epsilon_{D^{\prime}}\right) \circ G(F(G(h))) \circ \eta_{G(D)}\) are the same: that is, the morphisms
\[
h \circ \epsilon_{D}, \epsilon_{D^{\prime}} \circ F(G(h)) \in \operatorname{Hom}_{\mathcal{D}}\left((F \circ G)(D), D^{\prime}\right)
\]
have the same right adjunct. Invoking assumption (1), we deduce that \(h \circ \epsilon_{D}=\epsilon_{D^{\prime}} \circ F(G(h))\), as desired.

It follows immediately from the construction that the pair of natural transformations \((\eta, \epsilon)\) satisfies condition (Z2) of Definition 6.1.0.2 To complete the proof, it will suffice to show that it also satisfies condition \((Z 1)\). Let \(C\) be an object of \(\mathcal{C}\); we wish to show that the composite map
\[
F(C) \xrightarrow{F\left(\eta_{C}\right)}(F \circ G \circ F)(C) \xrightarrow{\epsilon_{F(C)}} F(C)
\]
is equal to the identity map \(\operatorname{id}_{F(C)}\). Note that the right adjunct of \(\epsilon_{F(C)} \circ F\left(\eta_{C}\right)\) is the composite map
\[
C \xrightarrow{\eta_{C}}(G \circ F)(C) \xrightarrow{(G \circ F)\left(\eta_{C}\right)}(G \circ F \circ G \circ F)(C) \xrightarrow{G\left(\epsilon_{F(C)}\right)}(G \circ F)(C) .
\]

By virtue of the fact that \((\eta, \epsilon)\) satisfies \((Z 2)\), this composition is equal to \(\eta_{C}\), which is also the right adjunct of the identity map \(\mathrm{id}_{F(C)}\). Invoking assumption (1), we conclude that \(\epsilon_{F(C)} \circ F\left(\eta_{C}\right)=\operatorname{id}_{F(C)}\), as desired.

We can give another characterization of the units of adjunctions by applying Proposition 6.1.2.9 in the opposite 2-category \(\mathcal{C}^{\text {op }}\) :

Variant 6.1.2.12. Let \(\mathcal{C}\) be a 2-category, let \(f: C \rightarrow D\) and \(g: C \rightarrow D\) be 1-morphisms of \(\mathcal{C}\), and let \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) be a 2 -morphism of \(\mathcal{C}\). Then \(\eta\) is the unit of an adjunction if and only if the following condition is satisfied:
- For every object \(T \in \mathcal{C}\) and every pair of morphisms \(c: C \rightarrow T\) and \(d: D \rightarrow T\), the 2-morphism \(\eta\) determines a bijection
\[
\operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(D, T)}(c \circ g, d) \rightarrow \operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(C, T)}(c, d \circ f),
\]
carrying each 2-morphism \(\beta: c \circ g \Rightarrow d\) to the composition
\[
c \stackrel{\rho_{c}^{-1}}{\sim} c \circ \mathrm{id}_{C} \stackrel{\mathrm{id}_{c} \circ \eta}{\Longrightarrow} c \circ(g \circ f) \xrightarrow[\sim]{\alpha_{c, g, f}}(c \circ g) \circ f \stackrel{\beta \circ \mathrm{id}_{f}}{\Longrightarrow} d \circ f .
\]

For the reader's convenience, let us also record a conjugate version of the preceding discussion:

Proposition 6.1.2.13. Let \(\mathcal{C}\) be a 2-category, let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1-morphisms 02D2 of \(\mathcal{C}\), and let \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) be a 2-morphism of \(\mathcal{C}\). The following conditions are equivalent:
(1) For every object \(T \in \mathcal{C}\) and every pair of 1-morphisms \(c: T \rightarrow C\) and \(d: T \rightarrow D\), the formation of left adjuncts with respect to \(\epsilon\) (Construction 6.1.2.1) induces a bijection
\[
\operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(T, C)}(c, g \circ d) \rightarrow \operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(T, D)}(f \circ c, d)
\]
(2) For every object \(T \in \mathcal{C}\) and every pair of 1-morphisms \(c: C \rightarrow T\) and \(d: D \rightarrow T\), the 2-morphism \(\epsilon\) determines a bijection
\[
\operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(C, T)}(c, d \circ f) \rightarrow \operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(D, T)}(c \circ g, d)
\]
carrying each 2-morphism \(\gamma: c \Rightarrow d \circ f\) to the composition
\[
c \circ g \xrightarrow{\gamma \circ \mathrm{id}_{g}}(d \circ f) \circ g \xrightarrow[\sim]{\alpha_{d, f, g}^{-1}} d \circ(f \circ g) \xrightarrow{\operatorname{id}_{d} \circ \epsilon} d \circ \mathrm{id}_{D} \xrightarrow[\sim]{\rho_{d}} d .
\]
(3) There exists a 2-morphism \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) for which \((\eta, \epsilon)\) is an adjunction between \(f\) and \(g\).

Moreover, if these conditions are satisfied, then the 2-morphism \(\eta\) is uniquely determined.
Proof. Apply Proposition 6.1.2.9 and Variant 6.1.2.12 to the conjugate 2-category \(\mathcal{C}^{\mathrm{c}}\).
02D3 Definition 6.1.2.14. Let \(\mathcal{C}\) be a 2-category and let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1morphisms of \(\mathcal{C}\). We say that a 2-morphism \(\epsilon: f \circ g \Rightarrow \mathrm{id}_{D}\) is the counit of an adjunction if it satisfies the equivalent conditions of Proposition 6.1.2.13; that is, there exists a 2 -morphism \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) for which the pair \((\eta, \epsilon)\) is an adjunction. If this condition is satisfied, we will say that \(\epsilon\) exhibits \(f\) as a left adjoint of \(g\) and also that \(\epsilon\) exhibits \(g\) as a right adjoint of \(f\).

\subsection*{6.1.3 Uniqueness of Adjoints}

02D4 Let \(\mathcal{C}\) be a 2-category and let \(f: C \rightarrow D\) be a 1-morphism of \(\mathcal{C}\). We will say that a 1-morphism \(g: D \rightarrow C\) is a right adjoint of \(f\) if there exists an adjunction \((\eta, \epsilon)\) between \(f\) and \(g\), in the sense of Definition 6.1.1.1. Beware that the right adjoint of \(f\) is usually not unique: if \(g\) is a right adjoint of \(f\), then any 1-morphism \(g^{\prime}: D \rightarrow C\) which is isomorphic to \(g\) can also be regarded as a right adjoint to \(f\) (see Remark 6.1.1.5). However, we will show in this section that this is the only source of ambiguity: the right adjoint of a 1-morphism \(f\) (if it exists) is well-defined up to canonical isomorphism.

02D5 Proposition 6.1.3.1. Let \(\mathcal{C}\) be a 2-category, let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1-morphisms of \(\mathcal{C}\), and let \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) be the unit of an adjunction. Then:
(1) For every 1-morphism \(f^{\prime}: C \rightarrow D\), the function
\[
\operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(C, D)}\left(f, f^{\prime}\right) \rightarrow \operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(C, C)}\left(\operatorname{id}_{C}, g \circ f^{\prime}\right) \quad \gamma \mapsto\left(\operatorname{id}_{g} \circ \gamma\right) \eta
\]
is a bijection.
(2) For every 1-morphism \(g^{\prime}: D \rightarrow C\), the function
\[
\operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(D, C)}\left(g, g^{\prime}\right) \rightarrow \operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(C, C)}\left(\operatorname{id}_{C}, g^{\prime} \circ f\right) \quad \beta \mapsto\left(\beta \circ \mathrm{id}_{f}\right) \eta
\]
is a bijection.
Proof. Let \(\rho_{f}: f \circ \mathrm{id}_{C} \xlongequal{\Longrightarrow} f\) be the right unit constraint. To prove (1), we observe that the composition
\[
\operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(C, D)}\left(f \circ \operatorname{id}_{C}, f^{\prime}\right) \xrightarrow[\sim]{\rho_{f}^{-1}} \operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(C, D)}\left(f, f^{\prime}\right) \rightarrow \operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(C, C)}\left(\operatorname{id}_{C}, g \circ f^{\prime}\right)
\]
is given by the formation of right adjuncts (see Example 6.1.2.2 and Remark 6.1.2.4), and is therefore bijective by (Proposition 6.1.2.5). Assertion (2) follows by a similar argument.

Variant 6.1.3.2. Let \(\mathcal{C}\) be a 2-category, let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1-morphisms of 02D6 \(\mathcal{C}\), and let \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) be the counit of an adjunction. Then:
(1) For every 1-morphism \(f^{\prime}: C \rightarrow D\), the function
\[
\operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(C, D)}\left(f^{\prime}, f\right) \rightarrow \operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(D, D)}\left(f^{\prime} \circ g, \operatorname{id}_{D}\right) \quad \gamma \mapsto \epsilon\left(\gamma \circ \operatorname{id}_{g}\right)
\]
is a bijection.
(2) For every 1-morphism \(g^{\prime}: D \rightarrow C\), the function
\[
\operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(D, C)}\left(g^{\prime}, g\right) \rightarrow \operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(D, D)}\left(f \circ g^{\prime}, \operatorname{id}_{D}\right) \quad \beta \mapsto \epsilon\left(\operatorname{id}_{f} \circ \beta\right)
\]
is a bijection.
Proof. Apply Proposition 6.1.3.1 to the conjugate 2-category \(\mathcal{C}^{\mathrm{c}}\).
Corollary 6.1.3.3. Let \(\mathcal{C}\) be a 2-category, let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1-morphisms of 02D7 \(\mathcal{C}\), and let \((\eta, \epsilon)\) be an adjunction between \(f\) and \(g\). Let \(g^{\prime}: D \rightarrow C\) be another 1-morphism of \(\mathcal{C}\). Then:
(1) For every 2-morphism \(\eta^{\prime}: \operatorname{id}_{C} \Rightarrow g^{\prime} \circ f\), there is a unique 2-morphism \(\beta: g \Rightarrow g^{\prime}\) for which \(\eta^{\prime}\) is equal to the composition \(\operatorname{id}_{C} \stackrel{\eta}{\Rightarrow} g \circ f \stackrel{\beta \text { oid }_{f}}{\Longrightarrow} g^{\prime} \circ f\). Moreover, \(\beta\) is an isomorphism if and only if \(\eta^{\prime}\) is the unit of an adjunction.
(2) For every 2-morphism \(\epsilon^{\prime}: f \circ g^{\prime} \Rightarrow \operatorname{id}_{D}\), there is a unique 2-morphism \(\gamma: g^{\prime} \Rightarrow g\) for which \(\epsilon^{\prime}\) factors as a composition \(f \circ g^{\prime} \stackrel{\mathrm{id}_{f} \circ \gamma}{ } f \circ g \stackrel{\epsilon}{\Rightarrow} \operatorname{id}_{D}\). Moreover, \(\gamma\) is an isomorphism if and only \(\epsilon^{\prime}\) is the counit of an adjunction.
Proof. We will prove (1); the proof of (2) similar. Let \(\eta^{\prime}: \mathrm{id}_{C} \Rightarrow g^{\prime} \circ f\) be a 2 -morphism of \(\mathcal{C}\). It follows from Proposition 6.1.3.1 that there is a unique 2-morphism \(\beta: g \Rightarrow g^{\prime}\) satisfying \(\eta^{\prime}=\left(\beta \circ \mathrm{id}_{f}\right) \eta\). If \(\beta\) is an isomorphism, then \(\eta^{\prime}\) is the unit of an adjunction by virtue of Remark 6.1.1.5. Conversely, suppose that \(\eta^{\prime}\) is the unit of an adjunction. To prove that \(\beta\) is an isomorphism, it will suffice to show that for every 1-morphism \(g^{\prime \prime}: D \rightarrow C\), precomposition with \(\beta\) induces a bijection \(\operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(D, C)}\left(g^{\prime}, g^{\prime \prime}\right) \rightarrow \operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(D, C)}\left(g, g^{\prime \prime}\right)\). This is clear: we have a commutative diagram

where the vertical maps are bijective by virtue of Proposition 6.1.3.1.

02D8 Proposition 6.1.3.4. Let \(\mathcal{C}\) be a 2-category containing 1-morphisms \(f, f^{\prime}: C \rightarrow D\) and \(g, g^{\prime}: D \rightarrow C\). Let \((\eta, \epsilon)\) be an adjunction between \(f\) and \(g\), and let \(\left(\eta^{\prime}, \epsilon^{\prime}\right)\) be an adjunction between \(f^{\prime}\) and \(g^{\prime}\). Then every 2 -morphism \(\beta: f \Rightarrow f^{\prime}\) determines a 2 -morphism \(\beta^{R}: g^{\prime} \Rightarrow g\), which is uniquely determined by either of the following properties:
(1) The diagram

commutes (in the category \(\underline{\operatorname{Hom}}_{\mathcal{C}}(C, C)\) ).
(2) The diagram

commutes (in the category \(\operatorname{Hom}_{\mathcal{C}}(D, D)\) ).

Proof. It follows from Corollary 6.1.3.3 that there is a unique morphism \(\beta^{R}\) satisfying condition (1). We will prove that \(\beta^{R}\) also satisfies condition (2) (it is also uniquely determined by condition (2), by virtue of Corollary 6.1.3.3). Note (2) is equivalent to the assertion that \(\epsilon^{\prime}\left(\beta \circ \mathrm{id}_{g^{\prime}}\right)\) is the left adjunct of \(\rho_{g}^{-1} \beta^{R}\) with respect to \(\epsilon\) (in the sense of Construction 6.1.2.1. By virtue of Proposition 6.1.2.5. this is equivalent to the assertion that \(\rho_{g}^{-1} \beta^{R}\) is the right adjunct of \(\epsilon^{\prime}\left(\beta \circ \mathrm{id}_{g^{\prime}}\right)\) with respect to \(\eta\). This follows from the commutativity of
the outer rectangle in the diagram

in the category \(\underline{\operatorname{Hom}}_{\mathcal{C}}(D, C)\). Here the upper middle square commutes by virtue of condition (1), the rectangle on the left commutes by virtue of the assumption that \(\left(\eta^{\prime}, \epsilon^{\prime}\right)\) is an adjunction, and the commutativity of the rest of the diagram follows by the naturality properties of the associativity and unit constraints of the 2 -category \(\mathcal{C}\).

Notation 6.1.3.5. Let \(\mathcal{C}\) be a 2 -category containing a pair of objects \(C\) and \(D\), and let \(\underline{\text { LHom }}_{\mathcal{C}}(C, D)\) denote the full subcategory of \(\underline{\operatorname{Hom}}_{\mathcal{C}}(C, D)\) spanned by those 1-morphisms \(f: C \rightarrow D\) which admit a right adjoint \(g: D \rightarrow C\). In this case, Corollary 6.1.3.3 guarantees that the 1 -morphism \(g\) is determined uniquely up to isomorphism. We will sometimes abuse terminology by referring to \(g\) as the right adjoint of \(f\) and denoting it by \(f^{R}\). The construction \(f \mapsto f^{R}\) extends to a functor of categories \(\operatorname{LHom}_{\mathcal{C}}(C, D)^{\mathrm{op}} \rightarrow \underline{\operatorname{Hom}}_{\mathcal{C}}(D, C)\), which carries each 2-morphism \(\beta: f \Rightarrow f^{\prime}\) to the 2-morphism \(\beta^{R}: f^{\prime R} \Rightarrow f^{R}\) described in Proposition 6.1.3.4.
Warning 6.1.3.6. Let \(\mathcal{C}\) be a 2 -category and let \(f: C \rightarrow D\) be a 1 -morphism of \(\mathcal{C}\). It follows from Corollary 6.1.3.3 that if \(f\) admits a right adjoint \(f^{R}\), then \(f^{R}\) is characterized (up to canonical isomorphism) by the requirement that it represents the functor
\[
\underline{\operatorname{Hom}}_{\mathcal{C}}(D, C)^{\mathrm{op}} \rightarrow \text { Set } \quad g \mapsto \operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(D, D)}\left(f \circ g, \mathrm{id}_{D}\right) .
\]

Beware that it is possible for this functor to be representable by a 1-morphism \(g: D \rightarrow C\) which is not a right adjoint to \(f\) (in which case \(f\) cannot admit any right adjoint); see Warning 6.1.6.16.

The preceding discussion has an obvious counterpart for left adjoints:
02DB Corollary 6.1.3.7. Let \(\mathcal{C}\) be a 2-category, let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 2-morphisms of \(\mathcal{C}\), and let \((\eta, \epsilon)\) be an adjunction between \(f\) and \(g\). Let \(f^{\prime}: C \rightarrow D\) be another 1-morphism of \(\mathcal{C}\). Then:
(1) For every 2-morphism \(\eta^{\prime}: \operatorname{id}_{C} \Rightarrow g \circ f^{\prime}\), there is a unique 2-morphism \(\beta: f \Rightarrow f^{\prime}\) for which \(\eta^{\prime}\) is equal to the composition \(\mathrm{id}_{C} \stackrel{\eta}{\Rightarrow} g \circ f \stackrel{\mathrm{id} g \circ \beta}{\Longrightarrow} g \circ f^{\prime}\). Moreover, \(\beta\) is an isomorphism if and only if \(\eta^{\prime}\) is the unit of an adjunction.
(2) For every 2-morphism \(\epsilon^{\prime}: f^{\prime} \circ g \Rightarrow \operatorname{id}_{D}\), there is a unique 2-morphism \(\gamma: f^{\prime} \Rightarrow f\) for which \(\epsilon^{\prime}\) factors as a composition \(f^{\prime} \circ g \xlongequal{\gamma \circ \mathrm{oid} g} f \circ g \stackrel{\epsilon}{\Rightarrow} \mathrm{id}_{D}\). Moreover, \(\gamma\) is an isomorphism if and only \(\epsilon^{\prime}\) is the counit of an adjunction.

Proof. Apply Corollary 6.1.3.7 to the opposite 2-category \(\mathcal{C}^{\text {op }}\).
02DC Notation 6.1.3.8. Let \(\mathcal{C}\) be a 2-category containing a pair of objects \(C\) and \(D\), and let \(\operatorname{RHom}_{\mathcal{C}}(D, C)\) denote the full subcategory of \(\operatorname{Hom}_{\mathcal{C}}(D, C)\) spanned by those 1-morphisms \(g: D \rightarrow C\) which admit a left adjoint \(f: C \rightarrow D\). In this case, Corollary 6.1.3.3 guarantees that the 1 -morphism \(f\) is uniquely determined up to isomorphism. We will sometimes abuse terminology by referring to \(f\) as the left adjoint of \(g\) and denoting it by \(g^{L}\). The construction \(g \mapsto g^{L}\) determines an equivalence of categories \(\underline{\mathrm{RHom}}_{\mathcal{C}}(D, C) \rightarrow \underline{\operatorname{LHom}}_{\mathcal{C}}(C, D)^{\text {op }}\), which is homotopy inverse to the functor \(f \mapsto f^{R}\) described in Notation 6.1.3.5.

\subsection*{6.1.4 Adjoints of Isomorphisms}

02DD Let \(\mathcal{C}\) be a 2-category and let \(f: C \rightarrow D\) be an isomorphism in \(\mathcal{C}\), so that \(f\) admits a homotopy inverse \(g: D \rightarrow C\) (Definition 2.2.8.17). Then the 1 -morphism \(g\) is both right adjoint and left adjoint to \(f\). More precisely, we have the following:
02DE Proposition 6.1.4.1. Let \(\mathcal{C}\) be a 2-category, let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1-morphisms of \(\mathcal{C}\), and let \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) be a 2-morphism of \(\mathcal{C}\). Assume that either \(f\) or \(g\) is an isomorphism in \(\mathcal{C}\). Then \(\eta\) is the unit of an adjunction (in the sense of Definition 6.1.2.10) if and only if it is an isomorphism in the category \(\underline{\operatorname{Hom}}_{\mathcal{C}}(C, C)\).

We will give the proof of Proposition 6.1.4.1 at the end of this section.
02DF Corollary 6.1.4.2. Let \(\mathcal{C}\) be a 2 -category and let \(f: C \rightarrow D\) be an isomorphism in \(\mathcal{C}\). Then any homotopy inverse to \(f\) is both a left adjoint and a right adjoint of \(f\).

Proof. Let \(g: D \rightarrow C\) be a homotopy inverse to \(f\), so that there exists an isomorphism \(\eta: \mathrm{id}_{C} \xlongequal{\Longrightarrow} g \circ f\) in the category \(\operatorname{Hom}_{\mathcal{C}}(C, C)\). It follows from Proposition 6.1.4.1 that \(\eta\) is the unit of an adjunction, and therefore exhibits \(g\) as a right adjoint to \(f\). A similar argument shows that \(g\) is left adjoint to \(f\).

Remark 6.1.4.3. Let \(\mathcal{C}\) be a 2 -category and let \(f: C \rightarrow D\) be a 1 -morphism of \(\mathcal{C}\). By 02DG definition, \(f\) is an isomorphism if and only if there exists a 1-morphism \(g: D \rightarrow C\) together with isomorphisms
\[
\eta: \operatorname{id}_{C} \xlongequal{\Longrightarrow} g \circ f \quad \epsilon: f \circ g \stackrel{\sim}{\Longrightarrow} \operatorname{id}_{D}
\]
in the categories \(\underline{\operatorname{Hom}}_{\mathcal{C}}(C, C)\) and \(\underline{\operatorname{Hom}}_{\mathcal{C}}(D, D)\), respectively. The main content of Proposition 6.1.4.1 is that, if such isomorphisms exist, then we can choose \(\eta\) and \(\epsilon\) to be compatible in the sense that they satisfy conditions \((Z 1)\) and \((Z 2)\) of Definition 6.1.1.1. Note that in this case, \(\eta\) is determined by \(\epsilon\) and vice versa (Proposition 6.1.2.9).

Corollary 6.1.4.4. Let \(\mathcal{C}\) be a 2-category, let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1-morphisms of 02DH \(\mathcal{C}\), and let \((\eta, \epsilon)\) be an adjunction between \(f\) and \(g\). The following conditions are equivalent:
(1) The 1 -morphism \(f\) is an isomorphism in \(\mathcal{C}\).
(2) The 1-morphism \(g\) is an isomorphism in \(\mathcal{C}\).
(3) The 2-morphisms \(\eta\) and \(\epsilon\) are isomorphisms in \(\underline{\operatorname{Hom}}_{\mathcal{C}}(C, C)\) and \(\underline{\operatorname{Hom}}_{\mathcal{C}}(D, D)\), respectively. In particular, \(f\) and \(g\) are homotopy inverse to one another.

Proof. The implication \((3) \Rightarrow(1)\) and \((3) \Rightarrow(2)\) are immediate from the definitions, and the reverse implications follow by applying Proposition 6.1.4.1 to \(\mathcal{C}\) and the conjugate 2-category \(\mathcal{C}^{\mathrm{c}}\).

Warning 6.1.4.5. In the situation of Corollary 6.1.4.4 it is possible for the unit \(\eta: \mathrm{id}_{C} \Rightarrow\) 02DJ \(g \circ f\) to be an isomorphism while the counit \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) is not, or vice versa (in which case, the 1-morphisms \(f\) and \(g\) cannot be isomorphisms).

We will deduce Proposition 6.1.4.1 from the following more general result:
Proposition 6.1.4.6. Let \(\mathcal{C}\) be a 2-category, let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1-morphisms 02DK of \(\mathcal{C}\), and let \(\eta: \mathrm{id}_{\mathcal{C}} \Rightarrow g \circ f\) be a 2-morphism of \(\mathcal{C}\) which satisfies the following conditions:
- The 2-morphisms
\[
\left(\operatorname{id}_{f} \circ \eta\right): f \circ \operatorname{id}_{C} \Rightarrow f \circ(g \circ f) \quad\left(\eta \circ \operatorname{id}_{g}\right): \operatorname{id}_{C} \circ g \Rightarrow(g \circ f) \circ g
\]
are isomorphisms.
- For every object \(T \in \mathcal{C}\), the composition functor \(\underline{\operatorname{Hom}}_{\mathcal{C}}(T, D) \xrightarrow{\text { g॰ }} \underline{\operatorname{Hom}}_{\mathcal{C}}(T, C)\) is fully faithful.

Then \(\eta\) is the unit of an adjunction \((\eta, \epsilon)\). Moreover, the counit map \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) is an isomorphism.

Proof. Since postcomposition with \(g\) induces a fully faithful functor
\[
\underline{\operatorname{Hom}}_{\mathcal{C}}(D, D) \rightarrow \underline{\operatorname{Hom}}_{\mathcal{C}}(D, C),
\]
there is a unique 2-morphism \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) for which the horizontal composition \(\operatorname{id}_{g} \circ \epsilon\) is equal to the composite map
\[
g \circ(f \circ g) \xrightarrow{\alpha_{g, f, g}}(g \circ f) \circ g \xrightarrow{\left(\eta \circ \mathrm{id}_{g}\right)^{-1}} \operatorname{id}_{C} \circ g \xrightarrow{\lambda_{g}} g \xrightarrow{\rho_{g}^{-1}} g \otimes \operatorname{id}_{D} .
\]

Moreover, \(\epsilon\) is an isomorphism and the pair \((\eta, \epsilon)\) automatically satisfies condition (Z2) of Definition 6.1.1.1. Let \(\beta\) denote the composition
\[
f \xlongequal[\sim]{\rho_{f}^{-1}} f \circ \mathrm{id}_{C} \xrightarrow{\mathrm{id}_{f} \circ \eta} f \circ(g \circ f) \xrightarrow[\sim]{\alpha_{f, g, f}}(f \circ g) \circ f \stackrel{\epsilon \mathrm{id}_{f}}{\longrightarrow} \operatorname{id}_{D} \circ f \xrightarrow[\sim]{\lambda_{f}} f
\]

Since \(\epsilon\) and \(\operatorname{id}_{f} \circ \eta\) are isomorphisms, it follows that \(\beta\) is an isomorphism. Applying Corollary 6.1.2.8 we see that \(\beta^{2}=\beta\), so that \(\beta=\mathrm{id}_{f}\).

Proof of Proposition 6.1.4.1. Let \(\mathcal{C}\) be a 2-category, let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1-morphisms in \(\mathcal{C}\), and assume that \(g\) is an isomorphism (the case where \(f\) is an isomorphism can be treated by applying a similar argument in the opposite 2-category \(\left.\mathcal{C}^{\text {op }}\right)\). Suppose first that \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) is an isomorphism in the category \(\underline{\operatorname{Hom}}_{\mathcal{C}}(C, C)\). It follows that the horizontal compositions
\[
\left(\operatorname{id}_{f} \circ \eta\right): f \Rightarrow f \circ(g \circ f) \quad\left(\eta \circ \mathrm{id}_{g}\right): g \Rightarrow(g \circ f) \circ g
\]
are isomorphisms in \(\operatorname{Hom}_{\mathcal{C}}(C, D)\) and \(\operatorname{Hom}_{\mathcal{D}}(D, C)\), respectively. For each object \(T \in\) \(\mathcal{C}\), our assumption that \(g\) is an isomorphism guarantees that the composition functor \(\underline{\operatorname{Hom}}_{\mathcal{C}}(T, D) \xrightarrow{g \circ} \underline{\operatorname{Hom}}_{\mathcal{C}}(T, C)\) is an equivalence of categories, and therefore fully faithful. Invoking the criterion of Proposition 6.1.4.7, we conclude that \(\eta\) is the unit of an adjunction.

We now prove the converse. Suppose that the 2-morphism \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) is the unit of an adjunction. Our assumption that \(g\) is an isomorphism guarantees that we can choose a 1-morphism \(f^{\prime}: C \rightarrow D\) and an isomorphism \(\eta^{\prime}: \operatorname{id}_{C} \xlongequal{\Longrightarrow} g \circ f^{\prime}\) in the category \(\operatorname{Hom}_{\mathcal{C}}(C, C)\). It follows from the first part of the proof that \(\eta^{\prime}\) is the unit of an adjunction. Applying Corollary 6.1.3.7. we deduce that there is a unique isomorphism \(\beta: f \xlongequal{\Longrightarrow} f^{\prime}\) for which \(\eta^{\prime}\) is equal to the composition
\[
\mathrm{id}_{C} \stackrel{\eta}{\Rightarrow} g \circ f \xlongequal{\mathrm{id}_{g} \circ \beta} g \circ f^{\prime} .
\]

Since \(\eta^{\prime}\) and \(\left(\mathrm{id}_{g} \circ \beta\right)\) are isomorphisms in the category \(\operatorname{Hom}_{\mathcal{C}}(C, C)\), it follows that \(\eta\) is also an isomorphism.

We close this section by proving a converse of Proposition 6.1.4.6, which characterizes adjunctions ( \(\eta, \epsilon\) ) for which the counit \(\epsilon\) is an isomorphism.

Proposition 6.1.4.7. Let \(\mathcal{C}\) be a 2-category, let \(f: C \rightarrow D\) and \(g: D \rightarrow C\) be 1-morphisms of \(\mathcal{C}\), and let \((\eta, \epsilon)\) be an adjunction between \(f\) and \(g\). The following conditions are equivalent:
(1) The 2-morphism \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) is an isomorphism.
(1') The 1-morphism \(f \circ g\) is an isomorphism.
(2) The 2-morphisms
\[
\left(\operatorname{id}_{f} \circ \eta\right): f \circ \operatorname{id}_{C} \Rightarrow f \circ(g \circ f) \quad\left(\eta \circ \operatorname{id}_{g}\right): \operatorname{id}_{C} \circ g \Rightarrow(g \circ f) \circ g
\]
are isomorphisms. Moreover, for every object \(T \in \mathcal{C}\), the functor \(\underline{\operatorname{Hom}}_{\mathcal{C}}(T, C) \xrightarrow{f \circ}\) \(\operatorname{Hom}_{\mathcal{C}}(T, D)\) is essentially surjective.
(2') The 2-morphism \(\eta \circ \operatorname{id}_{g}: \mathrm{id}_{C} \circ g \Rightarrow(g \circ f) \circ g\) is an isomorphism. Moreover, for every object \(T \in \mathcal{C}\), the composite functor
\[
\underline{\operatorname{Hom}}_{\mathcal{C}}(T, D) \xrightarrow{g \circ} \underline{\operatorname{Hom}}_{\mathcal{C}}(T, C) \xrightarrow{f \circ} \underline{\operatorname{Hom}}_{\mathcal{C}}(T, D)
\]
is essentially surjective.
(3) For every object \(T \in \mathcal{C}\), the functor \(\underline{\operatorname{Hom}}_{\mathcal{C}}(T, D) \xrightarrow{g \circ} \underline{\operatorname{Hom}}_{\mathcal{C}}(T, C)\) is fully faithful.
(3') The functor \(\underline{\operatorname{Hom}_{\mathcal{D}}}(D, D) \xrightarrow{g \circ} \underline{\operatorname{Hom}}_{\mathcal{C}}(D, C)\) is fully faithful.
Proof. We first show that (1) and ( \(1^{\prime}\) ) are equivalent. If \(\epsilon\) is an isomorphism, then \(f \circ g\) is isomorphic to \(\mathrm{id}_{D}\) (as an object of the category \({\underline{\operatorname{Hom}_{\mathcal{D}}}}^{( } D, D)\) ) and is therefore an isomorphism of \(\mathcal{C}\) (Remark 2.2.8.23). Conversely, suppose that \(f \circ g\) is an isomorphism. Then it is invertible when viewed as an object of the monoidal category \(\operatorname{End}_{\mathcal{C}}(D)\). Since \((\eta, \epsilon)\) is an adjunction, we can regard \(f \circ g\) as a coalgebra object of \(\operatorname{End}_{\mathcal{C}}(D)\) with counit \(\epsilon\) (see Remark [?]). Applying Proposition 2.1.5.23 (to the monoidal category \(\operatorname{End}_{\mathcal{C}}(D)^{\text {op }}\) ), we deduce that \(\epsilon\) is an isomorphism.

We now show that (1) implies (2). Assume that \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) is an isomorphism. Axiom ( \(Z 1\) ) of Definition 6.1.1.1 guarantees that the composition
\[
f \xlongequal{\sim} f \circ \mathrm{id}_{C} \stackrel{\mathrm{id}_{f} \circ \eta}{\Longrightarrow} f \circ(g \circ f) \xlongequal{\sim}(f \circ g) \circ f \xlongequal[\sim]{\epsilon \operatorname{oid}_{f}} \operatorname{id}_{D} \circ f \xlongequal{\sim} f
\]
is equal to the identity 2 -morphism \(\operatorname{id}_{f}\), which proves that the horizontal composition \(\mathrm{id}_{f} \circ \eta\) is an isomorphism in \(\operatorname{Hom}_{\mathcal{C}}(C, D)\). Similarly, it follows from axiom (Z2) of Definition
6.1.1.1 that the horizontal composition \(\eta \circ \mathrm{id}_{g}\) is an isomorphism in \(\operatorname{Hom}_{\mathcal{C}}(D, C)\). For every 1-morphism \(d: T \rightarrow D\) in \(\mathcal{C}\), the map
\[
f \circ(g \circ d) \xrightarrow[\sim]{\alpha_{f, g, d}}(f \circ g) \circ d \xrightarrow[\sim]{\not \operatorname{\epsilon id}_{d}} \operatorname{id}_{D} \circ d \xrightarrow[\sim]{\lambda_{d}} d
\]
is an isomorphism, so that \(d\) belongs to the essential image of the functor \(\underline{\operatorname{Hom}}_{\mathcal{C}}(T, C) \xrightarrow{f \circ}\) \(\operatorname{Hom}_{\mathcal{C}}(T, D)\).

We now show that (2) implies (2'). Let \(d: T \rightarrow D\) be a 1 -morphism of \(\mathcal{C}\). If the functor \(\underline{\operatorname{Hom}}_{\mathcal{C}}(T, C) \xrightarrow{f \circ} \underline{\operatorname{Hom}}_{\mathcal{C}}(T, D)\) is essentially surjective, then \(d\) is isomorphic to \(f \circ c\) for some 1-morphism \(c: T \rightarrow C\) of \(\mathcal{C}\). If \(\operatorname{id}_{f} \circ \eta\) is an isomorphism, then the chain of isomorphisms
\[
f \circ c \stackrel{\sim}{\Rightarrow}\left(f \circ \operatorname{id}_{C}\right) \circ c \xlongequal{\left(\operatorname{id}_{f} \circ \eta\right) \mathrm{iid}_{c}}(f \circ(g \circ f)) \circ c \stackrel{\sim}{\Longrightarrow} f \circ((g \circ f) \circ c) \xrightarrow{\Longrightarrow} f \circ(g \circ(f \circ c))
\]
shows that \(d\) belongs to the essential image of the composite functor
\[
\underline{\operatorname{Hom}}_{\mathcal{C}}(T, D) \xrightarrow{g \circ} \underline{\operatorname{Hom}}_{\mathcal{C}}(T, C) \xrightarrow{f \circ} \underline{\operatorname{Hom}}_{\mathcal{C}}(T, D) .
\]

We next show that ( \(2^{\prime}\) ) implies (3). Fix an object \(T \in \mathcal{C}\) and a pair of 1 -morphisms \(d, d^{\prime}: T \rightarrow D\); we wish to show that the composition map
\[
\operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(T, D)}\left(d^{\prime}, d\right) \rightarrow \operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(T, C)}\left(g \circ d^{\prime}, g \circ d\right)
\]
is a bijection. By virtue of assumption (2'), we may assume that \(d^{\prime}=f \circ c\), where \(c: T \rightarrow C\) is a 1 -morphism of the form \(g \circ d^{\prime \prime}\). By virtue of Proposition 6.1.2.9, the composition
\[
\begin{aligned}
\operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(T, D)}(f \circ c, d) & \rightarrow \quad \operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(T, C)}(g \circ(f \circ c), g \circ d) \\
& \simeq \operatorname{Hom}_{\underline{\operatorname{Hom}}_{\mathcal{C}}(T, C)}((g \circ f) \circ c, g \circ d) \\
& \xrightarrow{\eta \text { oid }_{c}} \\
& \simeq \operatorname{Hom}_{\underline{\underline{H o m}_{\mathcal{C}}(T, C)}}\left(\mathrm{id}_{C} \circ c, g \circ d\right) \\
& \operatorname{Hom}_{\mathcal{C}}(T, C) \\
& (c, g \circ d)
\end{aligned}
\]
is a bijection. It will therefore suffice to show that the 2-morphism \(\left(\eta \circ \mathrm{id}_{c}\right): \mathrm{id}_{C} \circ c \Rightarrow(g \circ f) \circ c\) is an isomorphism. This follows from assumption (2'), since ( \(\eta \circ \mathrm{id}_{c}\) ) can be rewritten as a composition
\[
\operatorname{id}_{C} \circ\left(g \circ d^{\prime \prime}\right) \xlongequal{\simeq}\left(\mathrm{id}_{C} \circ g\right) \circ d^{\prime \prime} \xlongequal{\left(\eta \circ \mathrm{id}_{g}\right) \circ \operatorname{id}_{d^{\prime \prime}}}((g \circ f) \circ g) \circ d^{\prime \prime} \simeq(g \circ f) \circ\left(g \circ d^{\prime \prime}\right) .
\]

The implication \((3) \Rightarrow\left(3^{\prime}\right)\) is clear. We will complete the proof by showing that ( \(3^{\prime}\) ) implies (1). Assume that ( \(3^{\prime}\) ) is satisfied; we wish to show that the 2 -morphism \(\epsilon: f \circ g \Rightarrow \mathrm{id}_{D}\) is an isomorphism. To prove this, it will suffice to show that for every 1-morphism \(u: D \rightarrow D\),
vertical precomposition with \(\epsilon\) induces a bijection \(\operatorname{Hom}_{\text {End }_{\mathcal{C}}(D)}\left(\operatorname{id}_{D}, u\right) \rightarrow \operatorname{Hom}_{\text {End }_{\mathcal{C}}(D)}(f \circ\) \(g, u)\). We now observe that this map fits into a commutative diagram

where the bottom horizontal map is induced by the right unit constraint \(\rho_{g}: g \circ \mathrm{id}_{D} \xlongequal{\sim} g\), the right vertical map is given by the formation of right adjuncts with respect to \(\eta\) (and is therefore bijective by virtue of Corollary 6.1.2.6), and the left vertical map is bijective by virtue of assumption ( \(3^{\prime}\) ).

\subsection*{6.1.5 Composition of Adjunctions}

We now show that the formation of right and left adjoints is compatible with composition 02DM of 1-morphisms.

Construction 6.1.5.1. Let \(\mathcal{C}\) be a 2 -category containing objects \(C, D\), and \(E\), together 02DN with 1-morphisms
\[
f: C \rightarrow D \quad f^{\prime}: D \rightarrow E \quad g: D \rightarrow C \quad g^{\prime}: E \rightarrow D
\]
and 2-morphisms \(\eta: \operatorname{id}_{C} \Rightarrow g \circ f\) and \(\eta^{\prime}: \operatorname{id}_{D} \Rightarrow g^{\prime} \circ f^{\prime}\). We let \(c\left(\eta, \eta^{\prime}\right)\) denote the 2-morphism given by the composition
\(\operatorname{id}_{C} \stackrel{\eta}{\Rightarrow} g \circ f \stackrel{\sim}{\Rightarrow} g \circ\left(\operatorname{id}_{D} \circ f\right) \stackrel{\eta^{\prime}}{\Rightarrow} g \circ\left(\left(g^{\prime} \circ f^{\prime}\right) \circ f\right) \stackrel{\sim}{\Longrightarrow} g \circ\left(g^{\prime} \circ\left(f^{\prime} \circ f\right)\right) \stackrel{\sim}{\Longrightarrow}\left(g \circ g^{\prime}\right) \circ\left(f^{\prime} \circ f\right)\),
where the unlabeled isomorphisms are given by the unit and associativity constraints of \(\mathcal{C}\). We will refer to \(c\left(\eta, \eta^{\prime}\right)\) as the contraction of \(\eta\) and \(\eta^{\prime}\).
Remark 6.1.5.2. In the situation of Construction 6.1.5.1. let \(\mathcal{C}^{\text {op }}\) be the opposite of the 02DP 2 -category \(\mathcal{C}\), so that we can identify \(\eta\) and \(\eta^{\prime}\) with 2-morphisms
\[
\eta^{\mathrm{op}}: \operatorname{id}_{C^{\mathrm{op}}} \Rightarrow f^{\mathrm{op}} \circ g^{\mathrm{op}} \quad \eta^{\prime \mathrm{op}}: \operatorname{id}_{D^{\mathrm{op}}} \Rightarrow f^{\prime \mathrm{op}} \circ g^{\prime \mathrm{op}}
\]

Then the 2-morphism \(c\left(\eta, \eta^{\prime}\right)^{\mathrm{op}}\) can be identified with the contraction \(c\left(\eta^{\prime \mathrm{op}}, \eta^{\mathrm{op}}\right)\), formed in the 2-category \(\mathcal{C}^{\text {op }}\). In other words, \(c\left(\eta, \eta^{\prime}\right)\) can also be computed as the composition
\[
\left.\operatorname{id}_{C} \stackrel{\eta}{\Rightarrow} g \circ f \xlongequal{\Longrightarrow}\left(g \circ \operatorname{id}_{D}\right) \circ f \stackrel{\eta^{\prime}}{\Rightarrow}\left(g \circ\left(g^{\prime} \circ f^{\prime}\right)\right)\right) \circ f \stackrel{\Longrightarrow}{\Longrightarrow}\left(\left(g \circ g^{\prime}\right) \circ f^{\prime}\right) \circ f \stackrel{\Longrightarrow}{\Longrightarrow}\left(g \circ g^{\prime}\right) \circ\left(f^{\prime} \circ f\right) .
\]

This follows from the commutativity of the diagram

in the category \(\operatorname{Hom}_{\mathcal{C}}(C, C)\). Here the upper triangle commutes by virtue of the triangle identity (Proposition 2.2.1.14), the middle square commutes by the naturality of the associativity constraints of \(\mathcal{C}\), and the lower region commutes by virtue of the pentagon identity.

02DQ Proposition 6.1.5.3. Let \(\mathcal{C}\) be a 2-category containing objects \(C, D\), and \(E\), together with 1-morphisms
\[
f: C \rightarrow D \quad g: D \rightarrow C \quad f^{\prime}: D \rightarrow E \quad g^{\prime}: E \rightarrow D
\]
and 2-morphisms \(\eta: \operatorname{id}_{C} \Rightarrow g \circ f\) and \(\eta^{\prime}: \operatorname{id}_{D} \Rightarrow g^{\prime} \circ f^{\prime}\). Let \(T\) be another object of \(\mathcal{C}\) equipped with 1-morphisms \(c: T \rightarrow C\) and \(e: T \rightarrow E\). Then the diagram

02DR
is commutative. Here the right vertical maps are given by the formation of right adjuncts with respect to \(\eta\) and \(\eta^{\prime}\) (in the sense of Construction 6.1.2.1), while the left vertical map is given by the formation of right adjuncts with respect to the contraction \(c\left(\eta, \eta^{\prime}\right)\) of Construction 6.1.5.1.

Proof. Fix a 2-morphism \(\beta:\left(f^{\prime} \circ f\right) \circ c \Rightarrow e\) in \(\mathcal{C}\). Clockwise and counterclockwise composition around the outside of the diagram (6.1) determines two elements of \(\operatorname{Hom}_{\underline{H o m}_{\mathcal{C}}(T, C)}\left(c,\left(g \circ g^{\prime}\right) \circ e\right)\), and we wish to prove that these two elements are the same. Unwinding the definitions, we see that these elements can be obtained as the vertical composition of \(c \stackrel{\sim}{\lambda_{c}^{-1}} \operatorname{id}_{C} \circ c \stackrel{\eta \mathrm{oid}_{c}}{\Longrightarrow}\) \((g \circ f) \circ c\) with 2-morphisms given by clockwise and counterclockwise composition around
the outside of the diagram

in the category \(\underline{\operatorname{Hom}}_{\mathcal{C}}(T, C)\); here denote the composition of 1-morphisms \(u\) and \(v\) in \(\mathcal{C}\) by \(u v\) (rather than \(u \circ v\) ) to simplify the notation, and the unlabeled isomorphisms are given by the associativity constraints of \(\mathcal{C}\). It will therefore suffice to observe that this diagram is commutative. The commutativity of the pentagonal regions follows from the pentagon identity in \(\mathcal{C}\), the commutativity of the triangle from Proposition 2.2.1.16, and the commutativity of each square from the naturality of the associativity constraints of \(\mathcal{C}\).

02DS Corollary 6.1.5.4. Let \(\mathcal{C}\) be a 2-category containing objects \(C\), \(D\), and \(E\), together with 1-morphisms
\[
f: C \rightarrow D \quad g: D \rightarrow C \quad f^{\prime}: D \rightarrow E \quad g^{\prime}: E \rightarrow D
\]
and 2-morphisms \(\eta: \mathrm{id}_{C} \Rightarrow g \circ f\) and \(\eta^{\prime}: \mathrm{id}_{D} \Rightarrow g^{\prime} \circ f^{\prime}\). If \(\eta\) and \(\eta^{\prime}\) are units of adjunctions, then the contraction \(c\left(\eta, \eta^{\prime}\right): \operatorname{id}_{C} \Rightarrow\left(g \circ g^{\prime}\right) \circ\left(f^{\prime} \circ f\right)\) is also the unit of an adjunction.

Proof. Combine Proposition 6.1.5.3 with the criterion of Proposition 6.1.2.9.
From Corollary 6.1.5.4 we can extract the following slightly less precise consequence:

Corollary 6.1.5.5. Let \(\mathcal{C}\) be a 2-category containing objects \(C\), \(D\), and \(E\), together with 02DT 1-morphisms
\[
f: C \rightarrow D \quad g: D \rightarrow C \quad f^{\prime}: D \rightarrow E \quad g^{\prime}: E \rightarrow D
\]

If \(f\) is left adjoint to \(g\) and \(f^{\prime}\) is left adjoint to \(g^{\prime}\), then \(f^{\prime} \circ f\) is left adjoint to \(g \circ g^{\prime}\).
Corollary 6.1.5.6. Let \(\mathcal{C}\) be a 2 -category containing 1 -morphisms \(u: C \rightarrow D\) and \(v: D \rightarrow E\). 02DU If \(u\) and \(v\) admit left adjoints, then \(v \circ u\) admits a left adjoint. If \(u\) and \(v\) admit right adjoints, then \(v \circ u\) admits a right adjoint.

We can also formulate a more precise version of Corollary 6.1.5.4 which explicitly describes the counit of a composite adjunction. For this, we need a variant of Construction 6.1.5.1

Construction 6.1.5.7. Let \(\mathcal{C}\) be a 2 -category containing objects \(C, D\), and \(E\), together 02DV with 1-morphisms
\[
f: C \rightarrow D \quad g: D \rightarrow C \quad f^{\prime}: D \rightarrow E \quad g^{\prime}: E \rightarrow D
\]
and 2-morphisms \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{D}\) and \(\epsilon^{\prime}: f^{\prime} \circ g^{\prime} \Rightarrow \operatorname{id}_{E}\) be 2-morphisms of \(\mathcal{C}\). We let \(c\left(\epsilon, \epsilon^{\prime}\right)\) denote the 2 -morphism given by the composition
\[
\left(f^{\prime} \circ f\right) \circ\left(g \circ g^{\prime}\right) \xlongequal{\Longrightarrow} f^{\prime} \circ\left(f \circ\left(g \circ g^{\prime}\right)\right) \xlongequal{\Longrightarrow} f^{\prime} \circ\left((f \circ g) \circ g^{\prime}\right) \stackrel{\epsilon}{\Rightarrow} f^{\prime} \circ\left(\operatorname{id}_{D} \circ g^{\prime}\right) \xlongequal{\Longrightarrow} f^{\prime} \circ g^{\prime} \stackrel{\epsilon^{\prime}}{\Longrightarrow} \operatorname{id}_{E}
\]

We will refer to \(c\left(\epsilon, \epsilon^{\prime}\right)\) as the contraction of \(\epsilon\) and \(\epsilon^{\prime}\).
Remark 6.1.5.8. In the situation of Construction 6.1.5.7. we can identify \(\epsilon\) and \(\epsilon^{\prime}\) with 02DW 2-morphisms
\[
\epsilon^{\mathrm{c}}: \operatorname{id}_{D^{\mathrm{c}}} \Rightarrow f^{\mathrm{c}} \circ g^{\mathrm{c}} \quad \epsilon^{\prime \mathrm{c}}: \operatorname{id}_{E^{\mathrm{c}}} \Rightarrow f^{\prime \mathrm{c}} \circ g^{\prime \mathrm{c}}
\]
in the conjugate 2 -category \(\mathcal{C}^{\mathrm{c}}\) (Construction 2.2.3.4). The contraction \(c\left(\epsilon, \epsilon^{\prime}\right)\) can then be described as the conjugate of the 2 -morphism \(c\left(\epsilon^{\prime \mathrm{c}}, \epsilon^{\mathrm{c}}\right)\) obtained by applying Construction 6.1.5.1 to the 2-category \(\mathcal{C}^{\mathrm{C}}\).

Corollary 6.1.5.9. Let \(\mathcal{C}\) be a 2-category containing objects \(C\), \(D\), and \(E\), together with 02DX 1-morphisms
\[
f: C \rightarrow D \quad g: D \rightarrow C \quad f^{\prime}: D \rightarrow E \quad g^{\prime}: E \rightarrow D .
\]

Let \((\eta, \epsilon)\) be an adjunction between \(f\) and \(g\), and let \(\left(\eta^{\prime}, \epsilon^{\prime}\right)\) be an adjunction between \(f^{\prime}\) and \(g^{\prime}\). Then the pair \(\left(c\left(\eta, \eta^{\prime}\right), c\left(\epsilon, \epsilon^{\prime}\right)\right)\) is an adjunction between \(f^{\prime} \circ f\) and \(g \circ g^{\prime}\). Here \(c\left(\eta, \eta^{\prime}\right)\) is the contraction of \(\eta\) with \(\eta^{\prime}\) (in the sense of Construction 6.1.5.1), and \(c\left(\epsilon, \epsilon^{\prime}\right)\) is the contraction of \(\epsilon\) with \(\epsilon^{\prime}\) (in the sense of Construction 6.1.5.7).

Proof. By virtue of Proposition 6.1.5.3 and Corollary 6.1.2.6, it will suffice to show that for every object \(T \in \mathcal{C}\) equipped with 1-morphisms \(c: T \rightarrow C\) and \(e: T \rightarrow E\), the diagram

commutes, where the right vertical maps are given by the formation of left adjuncts with respect to \(\epsilon\) and \(\epsilon^{\prime}\), and the left vertical map is given by the formation of left adjuncts with respect to the contraction \(c\left(\epsilon, \epsilon^{\prime}\right)\) of Construction 6.1.5.7. This follows by applying Proposition 6.1.5.3 to the conjugate 2 -category \(\mathcal{C}^{\mathrm{c}}\).

\subsection*{6.1.6 Duality in Monoidal Categories}

02DY
We now specialize the theory of adjunctions to the setting of 2-categories of the form \(B \mathcal{C}\) (Example 2.2.2.5), where \(\mathcal{C}\) is a monoidal category. Throughout this section, we write \(\mathbf{1}\) for the unit object of a monoidal category \(\mathcal{C}\).

02DZ Definition 6.1.6.1. Let \(\mathcal{C}\) be a monoidal category containing objects \(X\) and \(Y\). A duality datum is a pair (coev, ev), where coev : \(\mathbf{1} \rightarrow Y \otimes X\) and ev : \(X \otimes Y \rightarrow \mathbf{1}\) are morphisms of \(\mathcal{C}\) satisfying the following compatibility conditions:
(Z1) The composition
\[
X \xrightarrow[\sim]{\rho_{X}^{-1}} X \otimes \mathbf{1} \xrightarrow{\mathrm{id}_{X} \otimes \mathrm{coev}} X \otimes(Y \otimes X) \xrightarrow[\sim]{\alpha_{X, Y, X}}(X \otimes Y) \otimes X \xrightarrow{\mathrm{ev} \otimes \mathrm{id}_{X}} \mathbf{1} \otimes X \xrightarrow[\sim]{\lambda_{X}} X
\]
is equal to the identity morphism \(\operatorname{id}_{X}\). Here the isomorphism \(\alpha_{X, Y, X}\) is the associativity constraint for the monoidal category \(\mathcal{C}\), and the isomorphisms \(\lambda_{X}\) and \(\rho_{X}\) are the left and right unit constraints of Construction 2.1.2.17.
(Z2) The composition
\[
Y \xrightarrow[\sim]{\lambda_{Y}^{-1}} \mathbf{1} \otimes Y \xrightarrow{\operatorname{coev} \otimes \mathrm{id}_{Y}}(Y \otimes X) \otimes Y \xrightarrow[\sim]{\alpha_{Y, X, Y}^{-1}} Y \otimes(X \otimes Y) \xrightarrow{\mathrm{id}_{Y} \otimes \mathrm{ev}} Y \otimes \mathbf{1} \xrightarrow[\sim]{\rho_{Y}} Y
\]
is equal to the identity morphism \(\operatorname{id}_{Y}\).

If these conditions are satisfied, then we will refer to coev as the coevaluation morphism of the duality datum (coev, ev), and to ev as the evaluation morphism of the duality datum (coev, ev). In this case, we say that the pair (coev, ev) exhibits \(X\) as a left dual of \(Y\), also that it exhibits \(Y\) as a right dual of \(X\).

Remark 6.1.6.2 (Duals as Adjoints). Let \(\mathcal{C}\) be a monoidal category containing objects \(X\) and \(Y\), which we regard as 1-morphisms of the 2-category \(B \mathcal{C}\) described in Example 2.2.2.5. Suppose we are given a pair of morphisms
\[
\text { coev : } \mathbf{1} \rightarrow Y \otimes X \quad \text { ev : } X \otimes Y \rightarrow \mathbf{1}
\]
in \(\mathcal{C}\), which we identify with 2 -morphisms of \(B \mathcal{C}\). Then the pair (coev, ev) is a duality datum in the monoidal category \(\mathcal{C}\) (in the sense of Definition 6.1.6.1) if and only if it is an adjunction in the 2-category \(B \mathcal{C}\) (in the sense of Definition 6.1.1.1).

Remark 6.1.6.3 (Adjoints as Duals). Let \(\mathcal{C}\) be a 2-category, let \(X\) be an object of \(\mathcal{C}\), 02E1 let \(f, g: X \rightarrow X\) be 1-morphisms of \(\mathcal{C}\), and let \(\eta: \operatorname{id}_{X} \Rightarrow g \circ f\) and \(\epsilon: f \circ g \Rightarrow \operatorname{id}_{X}\) be 2 -morphisms of \(\mathcal{C}\). Then the pair \((\eta, \epsilon)\) is an adjunction in the 2 -category \(\mathcal{C}\) (in the sense of Definition 6.1.1.1) if and only if it is a duality datum in the monoidal category \(\operatorname{End}_{\mathcal{C}}(X)\) of Remark 2.2.1.7

Remark 6.1.6.4. Let \(\mathcal{C}\) be a monoidal category containing objects \(X\) and \(Y\) and morphisms 02E2
\[
\text { coev : } \mathbf{1} \rightarrow Y \otimes X \quad \text { ev : } X \otimes Y \rightarrow \mathbf{1}
\]

Then:
- The pair (coev, ev) is a duality datum in the monoidal category \(\mathcal{C}\) if and only if it is a duality datum in the reverse monoidal category \(\mathcal{C}^{\text {rev }}\) of Example 2.1.3.5. Note that passage to the reverse monoidal category reverses the roles of \(X\) and \(Y\) : if \(X\) is the left dual of \(Y\) in the monoidal category \(\mathcal{C}\), then it is the right dual of \(Y\) in the monoidal category \(\mathcal{C}^{\text {rev }}\) (and vice-versa).
- The pair (coev, ev) is a duality datum in \(\mathcal{C}\) if and only if the pair ( \(\left.\mathrm{ev}^{\mathrm{op}}, \mathrm{coev}^{\mathrm{op}}\right)\) is a duality datum in the opposite monoidal category \(\mathcal{C}^{\mathrm{op}}\) (see Example 2.1.3.4). Note that passage to the opposite monoidal category reverses the roles of evaluation and coevaluation: \(\mathrm{ev}^{\mathrm{op}}\) is the coevaluation morphism for the duality datum ( \(\mathrm{ev}^{\mathrm{op}}, \mathrm{coev}^{\mathrm{op}}\) ), while coevop is the evaluation morphism. Similarly, if \(X\) is the left dual of \(Y\) in the monoidal category \(\mathcal{C}\), then it is the right dual of \(Y\) in the opposite monoidal category \(\mathcal{C}^{\text {op }}\) (and vice-versa).

Proposition 6.1.6.5. Let \(\mathcal{C}\) be a monoidal category and let ev : \(X \otimes Y \rightarrow \mathbf{1}\) be a morphism 02E3 of \(\mathcal{C}\). The following conditions are equivalent:
(1) For every pair of objects \(C, D \in \mathcal{C}\), the composite map
\[
\begin{aligned}
\operatorname{Hom}_{\mathcal{C}}(C, Y \otimes D) & \rightarrow \operatorname{Hom}_{\mathcal{C}}(X \otimes C, X \otimes(Y \otimes D)) \\
& \simeq \operatorname{Hom}_{\mathcal{C}}(X \otimes C,(X \otimes Y) \otimes D) \\
& \xrightarrow{\text { ev }} \operatorname{Hom}_{\mathcal{C}}(X \otimes C, \mathbf{1} \otimes D) \\
& \simeq \operatorname{Hom}_{\mathcal{C}}(X \otimes C, D)
\end{aligned}
\]
is a bijection.
(2) For every pair of objects \(C, D \in \mathcal{C}\), the composite map
\[
\begin{aligned}
\operatorname{Hom}_{\mathcal{C}}(C, D \otimes X) & \rightarrow \operatorname{Hom}_{\mathcal{C}}(C \otimes Y,(D \otimes X) \otimes Y) \\
& \simeq \operatorname{Hom}_{\mathcal{C}}(C \otimes Y, D \otimes(X \otimes Y)) \\
& \xrightarrow{\mathrm{ev}} \operatorname{Hom}_{\mathcal{C}}(C \otimes Y, D \otimes \mathbf{1}) \\
& \simeq \operatorname{Hom}_{\mathcal{C}}(C \otimes Y, D)
\end{aligned}
\]
is a bijection.
(3) There exists a morphism coev : \(\mathbf{1} \rightarrow Y \otimes X\) for which the pair (coev, ev) is a duality datum, in the sense of Definition 6.1.6.1.

Moreover, if these conditions are satisfied, then the morphism coev : \(\mathbf{1} \rightarrow Y \otimes X\) is unique.
Proof. Apply Proposition 6.1.2.13 to the 2-category BC of Example 2.2.2.5.
02E4 Definition 6.1.6.6. Let \(\mathcal{C}\) be a monoidal category. We will say that a morphism ev : \(X \otimes Y \rightarrow \mathbf{1}\) in \(\mathcal{C}\) is a duality datum if it satisfies the equivalent conditions of Proposition 6.1.6.5 that is, if there exists a morphism coev : \(\mathbf{1} \rightarrow Y \otimes X\) for which the pair (coev, ev) is a duality datum in the sense of Definition 6.1.6.1.

Applying Proposition 6.1.6.5 to the opposite monoidal category \(\mathcal{C}^{\text {op }}\), we obtain the following:

02E5 Variant 6.1.6.7. Let \(\mathcal{C}\) be a monoidal category and let coev: \(\mathbf{1} \rightarrow Y \otimes X\) be a morphism of \(\mathcal{C}\). The following conditions are equivalent:
(1) For every pair of objects \(C, D \in \mathcal{C}\), the composite map
\[
\begin{aligned}
\operatorname{Hom}_{\mathcal{C}}(X \otimes C, D) & \rightarrow \operatorname{Hom}_{\mathcal{C}}(Y \otimes(X \otimes C), Y \otimes D) \\
& \left.\simeq \operatorname{Hom}_{\mathcal{C}}(Y \otimes X) \otimes C, Y \otimes D\right) \\
& \xrightarrow{\text { coev }} \operatorname{Hom}_{\mathcal{C}}(\mathbf{1} \otimes C, Y \otimes D) \\
& \simeq \operatorname{Hom}_{\mathcal{C}}(C, Y \otimes D)
\end{aligned}
\]
is a bijection.
(2) For every pair of objects \(C, D \in \mathcal{C}\), the composite map
\[
\begin{aligned}
\operatorname{Hom}_{\mathcal{C}}(C \otimes Y, D) & \rightarrow \operatorname{Hom}_{\mathcal{C}}((C \otimes Y) \otimes X, D \otimes X) \\
& \simeq \operatorname{Hom}_{\mathcal{C}}(C \otimes(Y \otimes X), D \otimes X) \\
& \xrightarrow{\text { coev }} \operatorname{Hom}_{\mathcal{C}}(C \otimes \mathbf{1}, D \otimes X) \\
& \simeq \operatorname{Hom}_{\mathcal{C}}(C, D \otimes X)
\end{aligned}
\]
is a bijection.
(3) There exists a morphism ev : \(X \otimes Y \rightarrow \mathbf{1}\) for which the pair (coev, ev) is a duality datum, in the sense of Definition 6.1.6.1.

Moreover, if these conditions are satisfied, then the morphism ev : \(X \otimes Y \rightarrow \mathbf{1}\) is unique.
Definition 6.1.6.8. Let \(\mathcal{C}\) be a monoidal category. We will say that a morphism coev : \(\mathbf{1} \rightarrow Y \otimes X\) in \(\mathcal{C}\) is a duality datum if it satisfies the equivalent conditions of Variant 6.1.6.7. that is, if there exists a morphism ev : \(X \otimes Y \rightarrow \mathbf{1}\) for which the pair (coev, ev) is a duality datum in the sense of Definition 6.1.6.1.

Definition 6.1.6.9. Let \(\mathcal{C}\) be a monoidal category. Then:
- We say that an object \(X \in \mathcal{C}\) is right dualizable if there exists an object \(Y \in \mathcal{C}\) and a duality datum ev : \(X \otimes Y \rightarrow \mathbf{1}\). In this case, we will also say that \(Y\) is a right dual of \(X\), or that the morphism ev exhibits \(Y\) as a right dual of \(X\).
- We say that an object \(Y \in \mathcal{C}\) is left dualizable if there exists an object \(X \in \mathcal{C}\) and a duality datum ev : \(X \otimes Y \rightarrow \mathbf{1}\). In this case, we will also say that \(X\) is a left dual of \(Y\), or that the morphism ev exhibits \(X\) as a left dual of \(Y\).

Example 6.1.6.10. Let \(\mathcal{C}\) be a monoidal category. We say that an object \(X \in \mathcal{C}\) is invertible if there exists an object \(Y \in \mathcal{C}\) such that the tensor products \(Y \otimes X\) and \(X \otimes Y\) are isomorphic to the unit object 1. If this condition is satisfied, then any choice of isomorphism \(\mathbf{1} \simeq Y \otimes X\) is a duality datum (this is a special case of Proposition 6.1.4.1). In particular, the object \(Y\) is a right dual of \(X\). Similarly, \(Y\) is a left dual of \(X\).
Exercise 6.1.6.11. Let \(\mathcal{C}\) be a category which admits finite products, and regard \(\mathcal{C}\) as equipped with the monoidal structure given by cartesian products (Example 2.1.3.2). Show that an object \(X \in \mathcal{C}\) is left (or right) dualizable if and only if it is isomorphic to the final object 1.

Exercise 6.1.6.12. Let \(k\) be a field and let Vect \({ }_{k}\) denote the category of vector spaces over
```

02E8

```
\(k\), equipped with the monoidal structure described in Example 2.1.3.1. Show that an object \(V \in \operatorname{Vect}_{k}\) is left (or right) dualizable if and only if it is finite-dimensional as a vector space over \(k\).

It is instructive to contrast Definition 6.1.6.6 with a slightly more general notion of duality.

02EB Definition 6.1.6.13. Let \(\mathcal{C}\) be a monoidal category containing objects \(X\) and \(Y\). We will say that a morphism ev : \(X \otimes Y \rightarrow \mathbf{1}\) exhibits \(Y\) as a weak right dual of \(X\) if, for every object \(W \in \mathcal{C}\), the composite map
\[
\operatorname{Hom}_{\mathcal{C}}(W, Y) \rightarrow \operatorname{Hom}_{\mathcal{C}}(X \otimes W, X \otimes Y) \xrightarrow{\text { ev }} \operatorname{Hom}_{\mathcal{C}}(X \otimes W, \mathbf{1})
\]
is bijective. We say that ev exhibits \(X\) as a weak left dual of \(Y\) if, for every object \(Z \in \mathcal{C}\), the composite map
\[
\operatorname{Hom}_{\mathcal{C}}(Z, X) \rightarrow \operatorname{Hom}_{\mathcal{C}}(Z \otimes Y, X \otimes Y) \xrightarrow{\text { ev }} \operatorname{Hom}_{\mathcal{C}}(Z \otimes Y, \mathbf{1})
\]
is bijective.
02EC Remark 6.1.6.14. Let \(\mathcal{C}\) be a monoidal category and let \(X\) be an object of \(\mathcal{C}\). It follows immediately from the definition that if there exists a morphism ev : \(X \otimes Y \rightarrow \mathbf{1}\) which exhibits \(Y\) as a weak right dual of \(X\), then the pair \((Y, \mathrm{ev})\) is unique up to isomorphism and depends functorially on \(X\). To emphasize this dependence we will sometimes denote the object \(Y\) by \(X^{\vee}\) and abuse terminology by referring to it as the weak right dual of \(X\).

Similarly, if \(Y\) is a fixed object of \(\mathcal{C}\) and there exists a morphism ev : \(X \otimes Y \rightarrow \mathbf{1}\) which exhibits \(X\) as a weak left dual of \(Y\), then the pair ( \(X, \mathrm{ev}\) ) is uniquely determined up to isomorphism and depends functorially on \(Y\). We will emphasize this dependence by denoting the object \(X\) by \({ }^{\vee} Y\) and referring to it as the weak left dual of \(Y\).

O2ED Proposition 6.1.6.15. Let \(\mathcal{C}\) be a monoidal category and let \(\mathrm{ev}: X \otimes Y \rightarrow \mathbf{1}\) be a morphism of \(\mathcal{C}\). Then:
(1) If the morphism ev exhibits \(Y\) as a right dual of \(X\) (Definition 6.1.6.6), then it exhibits \(Y\) as a weak right dual of \(X\) (Definition 6.1.6.13). The converse holds if \(X\) is right dualizable.
(2) If the morphism ev exhibits \(X\) as a left dual of \(Y\), then it exhibits \(X\) as a weak left dual of \(Y\). The converse holds if \(Y\) is left dualizable.

Proof. We will prove (1); the proof of (2) is similar. If ev : \(X \otimes Y \rightarrow \mathbf{1}\) is a duality datum, then it exhibits \(Y\) as a weak right dual of \(X\) by virtue of Variant 6.1.3.2 (applied to the 2-category \(B \mathcal{C}\) ). Conversely, suppose that ev exhibits \(Y\) as a weak right dual of \(X\). If there exists another object \(Y^{\prime} \in \mathcal{C}\) and a duality datum \(\mathrm{ev}^{\prime}: X \otimes Y^{\prime} \rightarrow \mathbf{1}\), then the universal property of \(Y\) guarantees that there is a unique morphism \(u: Y^{\prime} \rightarrow Y\) for which ev' is equal to the composite map \(X \otimes Y^{\prime} \xrightarrow{\operatorname{id}_{X} \otimes u} X \otimes Y \xrightarrow{\text { ev }} \mathbf{1}\). Since ev \({ }^{\prime}\) exhibits \(Y^{\prime}\) as a weak right dual of \(X\), the morphism \(u\) must be an isomorphism, so that the morphism ev is also a duality datum.

Warning 6.1.6.16. In the situation of Proposition 6.1.6.15, it is possible for an object
02EE \(X \in \mathcal{C}\) to admit a weak right dual which is not a right dual. For example, let \(\mathcal{C}=\operatorname{Vect}_{k}\) be the category of vector spaces over a field \(k\), equipped with the monoidal structure of Example 2.1.3.1. Let \(V\) be a vector space over \(k\) and let \(V^{*}=\operatorname{Hom}_{k}(V, k)\) be its dual space. Then the evaluation map
\[
\text { ev : } V \otimes_{k} V^{*} \rightarrow k \quad v \otimes \lambda \mapsto \lambda(v)
\]
exhibits \(V^{*}\) as a weak (right) dual of \(V\) (in the sense of Definition 6.1.6.13). However, it is a duality datum only when \(V\) is finite-dimensional over \(k\) (Exercise 6.1.6.12).

Remark 6.1.6.17. Let \(\mathcal{C}\) be a monoidal category containing objects \(X\) and \(Y\). If both \(X\) and \(Y\) are right dualizable, then the tensor product \(X \otimes Y\) is also right dualizable; moreover we have a canonical isomorphism \((X \otimes Y)^{\vee} \simeq Y^{\vee} \otimes X^{\vee}\) (see Corollary 6.1.5.4 for a more precise statement). Similarly, if both \(X\) and \(Y\) are left dualizable, then the tensor product \(X \otimes Y\) is left dualizable, and there is a canonical isomorphism \({ }^{\vee}(X \otimes Y) \simeq{ }^{\vee} Y \otimes{ }^{\vee} X\).

Exercise 6.1.6.18. Let \(\mathcal{C}\) be a monoidal category containing objects \(X\) and \(Y\). Show that, 02EG if \(X\) is weakly right dualizable and \(Y\) is right dualizable, then the tensor product \(X \otimes Y\) is weakly right dualizable (and that there is a canonical isomorphism \(\left.(X \otimes Y)^{\vee} \simeq Y^{\vee} \otimes X^{\vee}\right)\).

\subsection*{6.2 Adjoint Functors Between \(\infty\)-Categories}

\subsection*{6.2.1 Adjunctions of \(\infty\)-Categories}

We now adapt Definition 6.1.0.2 to the setting of \(\infty\)-categories.
Definition 6.2.1.1. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) be functors of \(\infty\)-categories. We will say 02EK that a pair of natural transformations \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) and \(\epsilon: F \circ G \rightarrow \mathrm{id}_{\mathcal{D}}\) are compatible up to homotopy if the following conditions are satisfied:
(Z1) The identity isomorphism \(\operatorname{id}_{F}: F \rightarrow F\) is a composition of the natural transformations
\[
F=F \circ \mathrm{id}_{\mathcal{C}} \xrightarrow{\mathrm{id}_{F} \circ \eta} F \circ G \circ F \quad F \circ G \circ F \xrightarrow{\epsilon \mathrm{id}_{F}} \operatorname{id}_{\mathcal{D}} \circ F=F
\]
in the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\), in the sense of Definition 1.4.4.1.
(Z2) The identity isomorphism \(\operatorname{id}_{G}: G \rightarrow G\) is a composition of the natural transformations
\[
G=\operatorname{id}_{\mathcal{D}} \circ G \xrightarrow{\eta \circ \mathrm{oid}_{G}} G \circ F \circ G \quad G \circ F \circ G \xrightarrow{\mathrm{id}_{G} \circ \epsilon} G \circ \operatorname{id}_{\mathcal{D}}=G
\]
in the \(\infty\)-category \(\operatorname{Fun}(\mathcal{D}, \mathcal{C})\).

We say that a natural transformation \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) is the unit of an adjunction if there exists a natural transformation \(\epsilon: F \circ G \rightarrow \operatorname{id}_{\mathcal{D}}\) which is compatible with \(\eta\) up to homotopy. We say that a natural transformation \(\epsilon: F \circ G \rightarrow \mathrm{id}_{\mathcal{D}}\) is the counit of an adjunction if there exists a natural transformation \(\eta: \operatorname{id}_{\mathcal{C}} \rightarrow G \circ F\) which is compatible with \(\epsilon\) up to homotopy.

02EL Definition 6.2.1.2. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) be functors of \(\infty\)-categories. We say that \(F\) is a left adjoint of \(G\), or that \(G\) is a right adjoint of \(F\), if there exists a natural transformation \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) which is the unit of an adjunction between \(F\) and \(G\). In this case, we say that \(\eta\) exhibits \(F\) as a left adjoint of \(G\) and also that it exhibits \(G\) as a right adjoint of \(F\). Equivalently, \(F\) is a left adjoint of \(G\) if there exists a natural transformation \(\epsilon: F \circ G \rightarrow \mathrm{id}_{\mathcal{D}}\) which is the counit of an adjunction between \(F\) and \(G\); in this case, we say that \(\epsilon\) exhibits \(F\) as a left adjoint of \(G\) and also that it exhibits \(G\) as a right adjoint of \(F\).

02EM Notation 6.2.1.3. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between \(\infty\)-categories. We say that \(F\) is a left adjoint, or that \(F\) admits a right adjoint, if there exists a functor \(G: \mathcal{D} \rightarrow \mathcal{C}\) which is right adjoint to \(F\). We let \(\operatorname{LFun}(\mathcal{C}, \mathcal{D})\) denote the full subcategory of \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\) spanned by those functors \(F: \mathcal{C} \rightarrow \mathcal{D}\) which are left adjoints.

Let \(G: \mathcal{D} \rightarrow \mathcal{C}\) be a functor between \(\infty\)-categories. We say that \(G\) is a right adjoint, or that \(G\) admits a left adjoint, if there exists a functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) which is left adjoint to \(G\). We let \(\operatorname{RFun}(\mathcal{D}, \mathcal{C})\) denote the full subcategory of \(\operatorname{Fun}(\mathcal{D}, \mathcal{C})\) spanned by those functors \(G: \mathcal{D} \rightarrow \mathcal{C}\) which are right adjoints.

02EN Remark 6.2.1.4. Let \(\mathrm{h}_{2} \mathrm{QCat}\) be the homotopy 2-category of \(\infty\)-categories (see Construction 4.5.1.23). Suppose we are given functors of \(\infty\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\), which we regard as 1 -morphisms in the 2 -category \(\mathrm{h}_{2}\) QCat. Let \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) and \(\epsilon: F \circ G \rightarrow \mathrm{id}_{\mathcal{D}}\) be natural transformations and let \([\eta]\) and \([\epsilon]\) denote their homotopy classes, which we regard as 2 -morphisms in \(\mathrm{h}_{2} \mathbf{Q C a t}\). Then \(\eta\) and \(\epsilon\) are compatible up to homotopy (in the sense of Definition 6.2.1.1) if and only if the pair \(([\eta],[\epsilon])\) is an adjunction in the 2-category \(\mathrm{h}_{2}\) QCat (in the sense of Definition 6.1.1.1).

02EP Remark 6.2.1.5. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) be functors of \(\infty\)-categories, and let \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) and \(\epsilon: F \circ G \rightarrow \mathrm{id}_{\mathcal{D}}\) be natural transformations. Axioms (Z1) and (Z2) of Definition 6.2.1.1 can be restated as follows:
(Z1) There exists a 2 -simplex \(\sigma\) of the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\) with boundary as indicated in the diagram

(Z2) There exists a 2 -simplex \(\tau\) of the \(\infty\)-category \(\operatorname{Fun}(\mathcal{D}, \mathcal{C})\) with boundary as indicated in the diagram

In this case, we will say that the 2 -simplices \(\sigma\) and \(\tau\) witness the axioms (Z1) and (Z2), respectively.

Remark 6.2.1.6. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) be functors of \(\infty\)-categories, and let \(\eta: \operatorname{id}_{\mathcal{C}} \rightarrow G \circ F\) be a natural transformation. It follows from Remark 6.2.1.4 that the condition that \(\eta\) is the unit of an adjunction (in the sense of Definition 6.2.1.1) depends only on the homotopy class \([\eta]\), regarded as a morphism in the category hFun \((\mathcal{C}, \mathcal{C})\). Moreover, if \(\epsilon: F \circ G \rightarrow \operatorname{id}_{\mathcal{D}}\) is a counit which is compatible with \(\eta\) up to homotopy, then the homotopy class \([\epsilon]\) is uniquely determined (see Proposition 6.1.2.9). Beware that it is only the homotopy class of \(\epsilon\) that is uniquely determined: if \(\epsilon^{\prime}: F \circ G \rightarrow \operatorname{id}_{\mathcal{D}}\) is homotopic to \(\epsilon\), then it is also compatible with \(\eta\) up to homotopy.

Remark 6.2.1.7. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) be functors of \(\infty\)-categories and let \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) be a natural tranformation. Then \(\eta\) is the unit of an adjunction between \(F\) and \(G\) if and only if the opposite natural transformation \(\eta^{\mathrm{op}}: G^{\mathrm{op}} \circ F^{\mathrm{op}} \rightarrow \mathrm{id}_{\mathcal{C}^{\mathrm{op}}}\) is the counit of an adjunction between the functors \(G^{\mathrm{op}}: \mathcal{D}^{\mathrm{op}} \rightarrow \mathcal{C}^{\mathrm{op}}\) and \(F^{\mathrm{op}}: \mathcal{C}^{\mathrm{op}} \rightarrow \mathcal{D}^{\mathrm{op}}\). Note that in this case, \(\eta^{\mathrm{op}}\) exhibits \(G^{\mathrm{op}}\) as the left adjoint of \(F^{\mathrm{op}}\).

Remark 6.2.1.8 (Composition of Adjoints). Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(F^{\prime}: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories which admit right adjoints. Then the composite functor \(\left(F^{\prime} \circ F\right): \mathcal{C} \rightarrow \mathcal{E}\) also admits a right adjoint. More precisely, if \(G: \mathcal{D} \rightarrow \mathcal{C}\) and \(G^{\prime}: \mathcal{E} \rightarrow \mathcal{D}\) are right adjoints of \(F\) and \(F^{\prime}\), respectively, then the composite functor \(\left(G \circ G^{\prime}\right): \mathcal{E} \rightarrow \mathcal{C}\) is right adjoint to \(\left(F^{\prime} \circ F\right): \mathcal{C} \rightarrow \mathcal{E}\) (see Corollary 6.1.5.5).

Example 6.2.1.9. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) be functors between ordinary categories, 02ET and suppose we are given natural transformations \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) and \(\epsilon: F \circ G \rightarrow \mathrm{id}_{\mathcal{D}}\). Then the pair \((\eta, \epsilon)\) is an adjunction between \(F\) and \(G\) (in the sense of Definition 6.1.0.2) if and only if the induced maps
\[
\mathrm{N}_{\bullet}(\eta): \operatorname{id}_{\mathrm{N}_{\bullet}(\mathcal{C})} \rightarrow \mathrm{N}_{\bullet}(G) \circ \mathrm{N}_{\bullet}(F) \quad \mathrm{N}_{\bullet}(\epsilon): \mathrm{N}_{\bullet}(F) \circ \mathrm{N}_{\bullet}(G) \rightarrow \operatorname{id}_{\mathrm{N}_{\bullet}(\mathcal{D})}
\]
are compatible up to homotopy, in the sense of Definition 6.2.1.1. In particular:
- A natural transformation \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) is the unit of an adjunction between functors of ordinary categories \(F\) and \(G\) if and only if \(\mathrm{N}_{\bullet}(\eta): \operatorname{id}_{\mathrm{N}_{\bullet}(\mathcal{C})} \rightarrow \mathrm{N}_{\bullet}(G) \circ \mathrm{N}_{\bullet}(F)\) is the unit of an adjunction between functors of \(\infty\)-categories \(\mathrm{N}_{\bullet}(F)\) and \(\mathrm{N}_{\bullet}(G)\).
- A natural transformation \(\epsilon: F \circ G \rightarrow \mathrm{id}_{\mathcal{C}}\) is the counit of an adjunction between functors of ordinary categories \(F\) and \(G\) if and only if \(\mathrm{N}_{\bullet}(\epsilon): \mathrm{N}_{\bullet}(F) \circ \mathrm{N}_{\bullet}(G) \rightarrow \mathrm{id}_{\mathrm{N}_{\bullet}}(\mathcal{D})\) is the unit of an adjunction between functors of \(\infty\)-categories \(\mathrm{N}_{\bullet}(F)\) and \(\mathrm{N}_{\bullet}(G)\).
- A functor of ordinary categories \(F: \mathcal{C} \rightarrow \mathcal{D}\) admits a right adjoint \(G\) if and only if the induced functor of \(\infty\)-categories \(\mathrm{N}_{\bullet}(F): \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{D})\) admits a right adjoint (in which case \(\mathrm{N}_{\bullet}(G)\) is a right adjoint of \(\left.\mathrm{N}_{\bullet}(F)\right)\).
- A functor of ordinary categories \(G: \mathcal{D} \rightarrow \mathcal{C}\) admits a left adjoint \(F\) if and only if the induced functor of \(\infty\)-categories \(\mathrm{N}_{\bullet}(G): \mathrm{N}_{\bullet}(\mathcal{D}) \rightarrow \mathrm{N}_{\bullet}(\mathcal{C})\) admits a left adjoint (in which case \(\mathrm{N}_{\bullet}(F)\) is a left adjoint of \(\left.\mathrm{N}_{\bullet}(G)\right)\).

Proposition 3.1.6.9 generalizes to the setting of \(\infty\)-categories:
02EU Remark 6.2.1.10. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories which admits a right adjoint \(G: \mathcal{D} \rightarrow \mathcal{C}\). The existence of natural transformations
\[
\eta: \operatorname{id}_{\mathcal{C}} \rightarrow G \circ F \quad \epsilon: F \circ G \rightarrow \operatorname{id}_{\mathcal{D}}
\]
guarantees that \(F\) and \(G\) are simplicial homotopy inverses of one another, in the sense of Definition 3.1.6.1. In particular, \(F\) and \(G\) are homotopy equivalences of simplicial sets.
02EV Example 6.2.1.11. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an equivalence of \(\infty\)-categories, and let \(G: \mathcal{D} \rightarrow \mathcal{C}\) be a homotopy inverse of \(F\). Then \(G\) is also a right adjoint of \(F\). More precisely, any isomorphism \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) in the functor \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{C})\) is the unit of an adjunction between \(F\) and \(G\) (Proposition 6.1.4.1). Similarly, \(G\) is a left adjoint of \(F\).

02EW Remark 6.2.1.12. Let \(F: X \rightarrow Y\) be a morphism of Kan complexes. Then \(F\) admits a right adjoint (in the sense of Notation 6.2.1.3) if and only if \(F\) is a homotopy equivalence. This follows by combining Remark 6.2.1.10 with Example 6.2.1.11.

Remark 6.2.1.12 can be regarded as a special case of the following more general assertion:
02EX Proposition 6.2.1.13. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) be functors of \(\infty\)-categories and let
\[
\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F \quad \epsilon: F \circ G \rightarrow \operatorname{id}_{\mathcal{D}}
\]
be natural transformations which are compatible up to homotopy. Let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be the full subcategory spanned by those objects \(C \in \mathcal{C}\) for which the unit \(\eta_{C}: C \rightarrow(G \circ F)(C)\) is an isomorphism, and let \(\mathcal{D}^{\prime} \subseteq \mathcal{D}\) be the full subcategory spanned by those objects \(D \in \mathcal{D}\) for which the counit \(\epsilon_{D}:(F \circ G)(D) \rightarrow D\) is an isomorphism. Then \(F\) and \(G\) restrict to functors \(F^{\prime}: \mathcal{C}^{\prime} \rightarrow \mathcal{D}^{\prime}\) and \(G^{\prime}: \mathcal{D}^{\prime} \rightarrow \mathcal{C}^{\prime}\) which are homotopy inverse to one another.

Proof. Let \(C\) be an object of \(\mathcal{C}^{\prime}\), so that \(\eta_{C}: C \rightarrow(G \circ F)(C)\) is an isomorphism. Since \(\eta\) and \(\epsilon\) are compatible up to homotopy, the identity morphism \(\operatorname{id}_{F(C)}\) is a composition of \(F\left(\eta_{C}\right): F(C) \rightarrow(F \circ G \circ F)(C)\) with \(\epsilon_{F(C)}:(F \circ G \circ F)(C) \rightarrow F(C)\) in the \(\infty\)-category \(\mathcal{D}\). It follows that \(\epsilon_{F(C)}\) is an isomorphism in \(\mathcal{D}\) (Remark 1.4.6.3), so that \(F(C)\) belongs to the full subcategory \(\mathcal{D}^{\prime} \subseteq \mathcal{D}\). Setting \(F^{\prime}=\left.F\right|_{\mathcal{C}^{\prime}}\), we obtain a functor \(F^{\prime}: \mathcal{C}^{\prime} \rightarrow \mathcal{D}^{\prime}\). A similar argument shows that we can regard \(G^{\prime}=\left.G\right|_{\mathcal{D}^{\prime}}\) as a functor from \(\mathcal{D}^{\prime}\) to \(\mathcal{C}^{\prime}\). The unit morphism \(\eta\) restricts to a natural transformation of functors \(\eta^{\prime}: \mathrm{id}_{\mathcal{C}^{\prime}} \rightarrow G^{\prime} \circ F^{\prime}\). By construction, \(\eta^{\prime}\) carries each object \(C \in \mathcal{C}^{\prime}\) to an isomorphism, and is therefore an isomorphism in the functor \(\infty\)-category \(\operatorname{Fun}\left(\mathcal{C}^{\prime}, \mathcal{C}^{\prime}\right)\) (Theorem 4.4.4.4). Similarly, the counit \(\epsilon\) restricts to a natural isomorphism \(\epsilon^{\prime}: F^{\prime} \circ G^{\prime} \rightarrow \operatorname{id}_{\mathcal{D}^{\prime}}\), so that \(F^{\prime}\) and \(G^{\prime}\) are homotopy inverse to one another.

Proposition 6.2.1.14. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories which admits a right 02EY adjoint. Let \(G: \mathcal{D} \rightarrow \mathcal{C}\) be another functor of \(\infty\)-categories and let \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) be \(a\) natural transformation. The following conditions are equivalent:
(1) The natural transformation \(\eta\) is the unit of an adjunction between the \(\infty\)-categories \(\mathcal{C}\) and \(\mathcal{D}\).
(2) The induced map \(\operatorname{id}_{\mathrm{h} \mathcal{C}} \rightarrow \mathrm{h} G \circ \mathrm{~h} F\) is the unit of an adjunction between the homotopy categories hC and hD .

Proof. The implication (1) \(\Rightarrow(2)\) follows from the observation that the formation of homotopy categories defines a (strict) functor of 2-categories
\[
\mathrm{h}_{2} \mathrm{QCat} \rightarrow \text { Cat } \quad \mathcal{C} \mapsto \mathrm{hC},
\]
and therefore carries adjunctions to adjunctions (see Exercise 6.1.1.6). We will show that (2) implies (1). By assumption, the functor \(F\) admits a right adjoint \(G^{\prime}: \mathcal{D} \rightarrow \mathcal{C}\). Let \(\eta^{\prime}: \operatorname{id}_{\mathcal{C}} \rightarrow F \circ G^{\prime}\) be the unit of an adjunction. Applying Corollary 6.1.3.3, we deduce that there exists a natural transformation \(\gamma: G^{\prime} \rightarrow G\) such that \(\eta\) is a composition of the natural transformations
\[
\eta^{\prime}: \operatorname{id}_{\mathcal{C}} \rightarrow F \circ G^{\prime} \quad\left(\mathrm{id}_{F} \circ \gamma\right): F \circ G^{\prime} \rightarrow F \circ G
\]
in the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{C})\). If assumption (2) is satisfied, then the image of \(\gamma\) in the functor category \(\operatorname{Fun}(\mathrm{h} \mathcal{D}, \mathrm{h} \mathcal{C})\) is an isomorphism: that is, \(\gamma\) carries each object \(D \in \mathcal{D}\) to an isomorphism \(\gamma_{D}: G^{\prime}(D) \rightarrow G(D)\) in the \(\infty\)-category \(\mathcal{C}\). Applying Theorem 4.4.4.4 we conclude that \(\gamma\) is an isomorphism in the \(\infty\)-category \(\operatorname{Fun}(\mathcal{D}, \mathcal{C})\), so that the criterion of Corollary 6.1.3.3 guarantees that \(\eta\) is also the unit of an adjunction.

Corollary 6.2.1.15. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(\mathrm{h} F: \mathrm{hC} \rightarrow \mathrm{h} \mathcal{D}\) be the induced functor of homotopy categories. If \(F\) admits a right adjoint \(G\), then \(\mathrm{h} F\) also admits a right adjoint, which can be identified with the functor \(\mathrm{h} G\).

02FO Warning 6.2.1.16. The implication \((2) \Rightarrow(1)\) of Proposition 6.2 .1 .14 generally fails if the functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) does not have a right adjoint. For example, let \(X\) be a simply connected Kan complex, let \(F: \Delta^{0} \rightarrow X\) be the map corresponding to a vertex \(x \in X\), and let \(G: X \rightarrow \Delta^{0}\) be the projection map. Since \(X\) is simply connected, the functors \(\mathrm{h} F\) and \(\mathrm{h} G\) are equivalences of ordinary categories. In particular, the identity transformation from \(\mathrm{id}_{\Delta^{0}}=G \circ F\) to itself determines the unit of an adjunction between \(\mathrm{h} F\) and \(\mathrm{h} G\). However, the functors \(F\) and \(G\) cannot be adjoint unless the Kan complex \(X\) is contractible (see Remark 6.2.1.10

Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) be functors between \(\infty\)-categories and let \(\eta:\) id \(_{\mathcal{C}} \rightarrow G \circ F\) be a natural transformation. By virtue of Variant 6.1.2.11, the natural transformation \(\eta\) exhibits \(\mathrm{h} G\) as a right adjoint to \(\mathrm{h} F\) if and only if, for every pair of objects \(C \in \mathcal{C}\) and \(D \in \mathcal{D}\), the composite map
\[
\begin{array}{rll}
\operatorname{Hom}_{\mathrm{h} \mathcal{D}}(F(C), D) & \begin{array}{l}
= \\
\xrightarrow{G}
\end{array} & \pi_{0}\left(\operatorname{Hom}_{\mathcal{D}}(F(C), D)\right) \\
\xrightarrow{\circ\left[\eta_{\mathcal{C}}\right]} & \pi_{0}\left(\operatorname{Hom}_{\mathcal{C}}((G \circ F)(C), G(D))\right) \\
= & \pi_{0}\left(\operatorname{Hom}_{\mathcal{C}}(C, G(D))\right. \\
= & \operatorname{Hom}_{\mathrm{hC}}(C, G(D))
\end{array}
\]
is a bijection. If \(\eta\) exhibits \(G\) as a right adjoint to \(F\), then we can say more:
02F1 Proposition 6.2.1.17. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) be functors between \(\infty\)-categories and let \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) be the unit of an adjunction. Then, for every pair of objects \(C \in \mathcal{C}\) and \(D \in \mathcal{D}\), the composite map
\[
\operatorname{Hom}_{\mathcal{D}}(F(C), D) \xrightarrow{G} \operatorname{Hom}_{\mathcal{C}}((G \circ F)(C), G(D)) \xrightarrow{\circ\left[\eta_{C}\right]} \operatorname{Hom}_{\mathcal{C}}(C, G(D))
\]
is an isomorphism in the homotopy category hKan; here the second map is given by the composition law of Construction 4.6.9.9.

Proof. It will suffice to show that, for every Kan complex \(T\), the induced map
\[
\begin{aligned}
\pi_{0}\left(\operatorname{Fun}\left(T, \operatorname{Hom}_{\mathcal{D}}(F(C), D)\right)\right) & =\operatorname{Hom}_{\mathrm{hKan}}\left(T, \operatorname{Hom}_{\mathcal{D}}(F(C), D)\right) \\
& \xrightarrow{\theta} \operatorname{Hom}_{\mathrm{hKan}}\left(T, \operatorname{Hom}_{\mathcal{C}}(C, G(D))\right) \\
& =\pi_{0}\left(\operatorname{Fun}^{\left.\left(T, \operatorname{Hom}_{\mathcal{C}}(C, G(D))\right)\right)}\right.
\end{aligned}
\]
is bijective. Let \(\underline{C} \in \operatorname{Fun}(T, \mathcal{C})\) and \(\underline{D} \in \operatorname{Fun}(T, \mathcal{D})\) be the constant morphisms taking the values \(C\) and \(D\), respectively. Unwinding the definitions, we see that \(\theta\) can be identified with the map
\[
\operatorname{Hom}_{\mathrm{hFun}(T, \mathcal{D})}(F \circ \underline{C}, \underline{D}) \rightarrow \operatorname{Hom}_{\mathrm{hFun}(T, \mathcal{C})}(\underline{C}, G \circ \underline{D})
\]
given by the formation of right adjuncts with respect to the homotopy class [ \(\eta\) ] (regarded as a 2 -morphism in the category \(\mathrm{h}_{2} \mathbf{Q C a t}\) ). The bijectivity of \(\theta\) now follows from the criterion of Proposition 6.1.2.9.

Remark 6.2.1.18. We will see later that the converse of Proposition 6.2.1.17 also holds: if \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) are functors of \(\infty\)-categories and \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) is a natural transformation which induces a homotopy equivalence \(\operatorname{Hom}_{\mathcal{D}}(F(C), D) \simeq \operatorname{Hom}_{\mathcal{C}}(C, G(D))\) for every pair of objects \((C, D) \in \mathcal{C} \times \mathcal{D}\), then \(\eta\) is the unit of an adjunction between \(F\) and \(G\) (Corollary 6.2.4.5).

Remark 6.2.1.19. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. It follows from Proposition 6.1.3.4 that if \(F\) admits a right adjoint \(G\), then \(G\) is well-defined up to isomorphism as an object of the functor \(\infty\)-category \(\operatorname{Fun}(\mathcal{D}, \mathcal{C})\). We will sometimes emphasize this by referring to \(G\) as the right adjoint of \(F\) and denoting it by \(F^{R}\). By virtue of Notation 6.1.3.8, the construction \(F \mapsto F^{R}\) determines an equivalence of homotopy categories hLFun \((\mathcal{C}, \mathcal{D}) \rightarrow\) \(\operatorname{hRFun}(\mathcal{D}, \mathcal{C})^{\mathrm{op}}\). We will see later that this construction can be upgraded to an equivalence of \(\infty\)-categories \(\operatorname{LFun}(\mathcal{C}, \mathcal{D}) \simeq \operatorname{RFun}(\mathcal{D}, \mathcal{C})^{\mathrm{op}}\) (see Corollary 8.3.4.10).

Warning 6.2.1.20. Let \(\mathcal{C}\) and \(\mathcal{D}\) be \(\infty\)-categories. The following data are essentially 02F4 equivalent to one another:
- The datum of a functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) which admits a right adjoint.
- The datum of a functor \(G: \mathcal{D} \rightarrow \mathcal{C}\) which admits a left adjoint.
- The datum of a triple \((F, G, \eta)\), where \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) are functors and \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) is the unit of an adjunction between \(F\) and \(G\).
- The datum of a triple \((F, G, \epsilon)\), where \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) are functors and \(\epsilon: F \circ G \rightarrow \mathrm{id}_{\mathcal{D}}\) is the counit of an adjunction between \(F\) and \(G\).
- The datum of a quintuple \((F, G, \eta, \epsilon, \sigma)\), where \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) are functors, \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) and \(\epsilon: F \circ G \rightarrow \mathrm{id}_{\mathcal{D}}\) are natural transformations which are compatible up to homotopy, and \(\sigma: \Delta^{2} \rightarrow \operatorname{Fun}(\mathcal{C}, \mathcal{D})\) is a 2 -simplex witnessing axiom \((Z 1)\) of Definition 6.2.1.1 (see Remark 6.2.1.5).
- The datum of a quintuple \((F, G, \eta, \epsilon, \tau)\), where \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) are functors, \(\eta: \operatorname{id}_{\mathcal{C}} \rightarrow G \circ F\) and \(\epsilon: F \circ G \rightarrow \operatorname{id}_{\mathcal{D}}\) are natural transformations which are compatible up to homotopy, and \(\tau: \Delta^{2} \rightarrow \operatorname{Fun}(\mathcal{D}, \mathcal{C})\) is a 2 -simplex witnessing axiom \((Z 2)\) of Definition 6.2.1.1.

The following data are not equivalent to the above (or to each other):
- The datum of a pair \((F, G)\), where \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) are functors which are adjoint to one another.
- The datum of a quadruple ( \(F, G, \eta, \epsilon\) ), where \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) are functors, \(\eta: \operatorname{id}_{\mathcal{C}} \rightarrow G \circ F\) and \(\epsilon: F \circ G \rightarrow \operatorname{id}_{\mathcal{D}}\) are natural transformations which are compatible up to homotopy,
- The datum of a sextuple \((F, G, \eta, \epsilon, \sigma, \tau)\), where \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) are functors, \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) and \(\epsilon: F \circ G \rightarrow \mathrm{id}_{\mathcal{D}}\) are natural transformations, and \(\sigma: \Delta^{2} \rightarrow \operatorname{Fun}(\mathcal{C}, \mathcal{D})\) and \(\tau: \Delta^{2} \rightarrow \operatorname{Fun}(\mathcal{D}, \mathcal{C})\) are 2-simplices witnessing axioms (Z1) and (Z2) of Definition 6.2.1.1.

To say that a functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) is left adjoint to a functor \(G: \mathcal{D} \rightarrow \mathcal{C}\) is somewhat imprecise: one should really specify a witness to the adjointness of \(F\) and \(G\), which can take the form of either a unit \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) or a counit \(\epsilon: F \circ G \rightarrow \mathrm{id}_{\mathcal{D}}\). Given both a unit \(\eta\) and a counit \(\epsilon\), one can further demand evidence of their compatibility, which can take the form of a 2-simplex \(\sigma: \Delta^{2} \rightarrow \operatorname{Fun}(\mathcal{C}, \mathcal{D})\) witnessing axiom \((Z 1)\) or a 2-simplex \(\tau: \Delta^{2} \rightarrow \operatorname{Fun}(\mathcal{D}, \mathcal{C})\) witnessing axiom (Z2). If one specifies both of the witnesses \(\sigma\) and \(\tau\), then one can further demand a witness to the compatibility of \(\sigma\) with \(\tau\); we will return to this point in §[?].

\subsection*{6.2.2 Reflective Subcategories}

Let \(\mathcal{C}\) be an \(\infty\)-category. Our goal in this section is to characterize those full subcategories \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) for which the inclusion functor \(\mathcal{C}^{\prime} \hookrightarrow \mathcal{C}\) admits a left or right adjoint.

02F6 Definition 6.2.2.1. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a full subcategory. We say that a morphism \(u: X \rightarrow Y\) in \(\mathcal{C}\) exhibits \(Y\) as a \(\mathcal{C}^{\prime}\)-reflection of \(X\) if \(Y\) belongs to \(\mathcal{C}^{\prime}\) and, for every object \(Z \in \mathcal{C}^{\prime}\), the precomposition map \(\operatorname{Hom}_{\mathcal{C}}(Y, Z) \xrightarrow{\circ[u]} \operatorname{Hom}_{\mathcal{C}}(X, Z)\) is an isomorphism in the homotopy category hKan. We say that \(u\) exhibits \(X\) as a \(\mathcal{C}^{\prime}\) coreflection of \(Y\) if \(X\) belongs to \(\mathcal{C}^{\prime}\) and, for every object \(W \in \mathcal{C}^{\prime}\), the postcomposition map \(\operatorname{Hom}_{\mathcal{C}}(W, X) \xrightarrow{[u] \circ} \operatorname{Hom}_{\mathcal{C}}(W, Y)\) is an isomorphism in the homotopy category hKan.

We say that a subcategory \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) is reflective if it is full and, for every object \(X \in \mathcal{C}\), there exists a morphism \(u: X \rightarrow Y\) which exhibits \(Y\) as a \(\mathcal{C}^{\prime}\)-reflection of \(X\). We say that the subcategory \(\mathcal{C}^{\prime}\) is coreflective if it is full and, for every object \(Y \in \mathcal{C}\), there exists a morphism \(u: X \rightarrow Y\) which exhibits \(X\) as a \(\mathcal{C}^{\prime}\)-coreflection of \(Y\).

02F7 Remark 6.2.2.2. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a full subcategory, so that we can identify \(\mathcal{C}^{\prime \mathrm{op}}\) with a full subcategory of the opposite \(\infty\)-category \(\mathcal{C}^{\mathrm{op}}\). Then:
- A morphism \(u: X \rightarrow Y\) in \(\mathcal{C}\) exhibits \(Y\) as a \(\mathcal{C}^{\prime}\)-reflection of \(X\) if and only if \(u^{\mathrm{op}}: Y^{\mathrm{op}} \rightarrow X^{\mathrm{op}}\) exhibits \(Y^{\mathrm{op}}\) as a \(\mathcal{C}^{\prime \mathrm{op}}\)-coreflection of \(X^{\mathrm{op}}\).
- The subcategory \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) is reflective if and only if the subcategory \(\mathcal{C}^{\prime \mathrm{op}} \subseteq \mathcal{C}^{\mathrm{op}}\) is coreflective.

Remark 6.2.2.3. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a full subcategory, and suppose we are given a pair of morphisms \(u: X \rightarrow Y\) and \(w: X \rightarrow Z\) of \(\mathcal{C}\), where \(Y\) and \(Z\) belong to the subcategory \(\mathcal{C}^{\prime}\). If \(u\) exhibits \(Y\) as a \(\mathcal{C}^{\prime}\)-reflection of \(X\), then we can realize \(w\) as a composition of \(u\) with another morphism \(v: Y \rightarrow Z\) of \(\mathcal{C}^{\prime}\), which is uniquely determined up to homotopy. Moreover, \(v\) is an isomorphism if and only if \(w\) exhibits \(Z\) as a \(\mathcal{C}^{\prime}\)-reflection of \(X\). Stated more informally: a \(\mathcal{C}^{\prime}\)-reflection of \(X\), if it exists, is unique up to isomorphism.

Example 6.2.2.4. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a full subcategory, and let \(u: X \rightarrow Y\) be a morphism of \(\mathcal{C}\). If \(X\) belongs to the subcategory \(\mathcal{C}^{\prime}\), then \(u\) exhibits \(Y\) as a \(\mathcal{C}^{\prime}\)-reflection of \(X\) if and only if it is an isomorphism. Similarly, if \(Y\) belongs to \(\mathcal{C}^{\prime}\), then \(u\) exhibits \(X\) as a \(\mathcal{C}^{\prime}\)-coreflection of \(Y\) if and only if it is an isomorphism.
Example 6.2.2.5. Let \(\mathcal{C}\) be an \(\infty\)-category which contains a final object, and let \(\mathcal{C}^{\text {fin }}\) denote the full subcategory of \(\mathcal{C}\) spanned by its final objects (so that \(\mathcal{C}^{\mathrm{fin}}\) is a contractible Kan complex: see Corollary 4.6.7.14. Then \(\mathcal{C}^{\text {fin }}\) is a reflective subcategory of \(\mathcal{C}\).
Example 6.2.2.6. Let \(\mathcal{S}\) denote the \(\infty\)-category of spaces (Construction 5.5.1.1) and let \(\mathcal{Q C}\) denote the \(\infty\)-category of (small) \(\infty\)-categories (Construction 5.5.4.1). Then \(\mathcal{S}\) is a reflective and coreflective subcategory of \(\mathcal{Q C}\). If \(\mathcal{C}\) is a small \(\infty\)-category, then the inclusion map \(\mathcal{C}^{\simeq} \hookrightarrow \mathcal{C}\) exhibits the core \(\mathcal{C}^{\simeq}\) as a \(\mathcal{S}\)-coreflection of \(\mathcal{C}\) (this follows by combining Proposition 4.4.3.17 with Remark 5.5.4.6, and the comparison map \(\mathcal{C} \rightarrow \operatorname{Ex}^{\infty}(\mathcal{C})\) exhibits the Kan complex \(\mathrm{Ex}^{\infty}(\mathcal{C})\) as a \(\mathcal{S}\)-reflection of \(\mathcal{C}\) (this follows by combining Proposition 3.3.6.7 with Remark 5.5.4.6.

Example 6.2.2.7. Let Top denote the category whose objects are topological spaces and 04JC whose morphisms are continuous functions Let us regard Top as a simplicial category (Example 2.4.1.5, and let \(\mathcal{T}=\mathrm{N}_{\bullet}^{\mathrm{nc}}(\mathrm{Top})\) denote its homotopy coherent nerve. Let \(\mathcal{T}_{0} \subseteq \mathcal{T}\) be the full subcategory spanned by those topological spaces which have the homotopy type of a CW complex. Then:
- A continuous function between topological spaces \(f: X \rightarrow Y\) is a weak homotopy equivalence (in the sense of Definition 3.6.3.1) if and only if it exhibits \(X\) as a \(\mathcal{T}_{0^{-}}\) colocalization of \(Y\). This is restatement of Corollary 3.6.5.4
- The full subcategory \(\mathcal{T}_{0} \subseteq \mathcal{T}\) is coreflective. That is, for every topological space \(Y\), there exists a weak homotopy equivalence \(f: X \rightarrow Y\), where \(X\) has the homotopy type of a CW complex. For example, we can take \(f\) to be the counit map \(|\operatorname{Sing} .(Y)| \rightarrow Y\) (see Corollary 3.6.4.2).

Definition 6.2.2.1 can be rephrased as a lifting property:

03XA Proposition 6.2.2.8. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a full subcategory, and let \(f: X \rightarrow Y\) be a morphism in \(\mathcal{C}\), where \(Y \in \mathcal{C}^{\prime}\). The following conditions are equivalent:
(1) The morphism \(f\) exhibits \(Y\) as a \(\mathcal{C}^{\prime}\)-reflection of \(X\), in the sense of Definition 6.2.2.1.
(2) For every object \(Z \in \mathcal{C}^{\prime}\), the restriction \(\operatorname{map} \mathcal{C}_{f /} \times_{\mathcal{C}}\{Z\} \rightarrow \mathcal{C}_{X /} \times_{\mathcal{C}}\{Z\}\) is a homotopy equivalence of Kan complexes.
(3) The restriction map \(u: \mathcal{C}_{f /} \times{ }_{\mathcal{C}} \mathcal{C}^{\prime} \rightarrow \mathcal{C}_{X /} \times{ }_{\mathcal{C}} \mathcal{C}^{\prime}\) is an equivalence of \(\infty\)-categories.
(4) The restriction map \(u\) is a trivial Kan fibration.
(5) For \(n \geq 2\), every morphism of simplicial sets \(\sigma_{0}: \Lambda_{0}^{n} \rightarrow \mathcal{C}\) can be extended to an n-simplex of \(\mathcal{C}\), provided that \(\sigma_{0}\) carries the initial edge \(\Delta^{1}=\mathrm{N}_{\bullet}(\{0<1\})\) to the morphism \(f\) and satisfies \(\sigma_{0}(i) \in \mathcal{C}^{\prime}\) for \(i \geq 2\).

Proof. The equivalence (1) \(\Leftrightarrow(2)\) follows from Proposition 4.6.9.16, the equivalence (2) \(\Leftrightarrow\) (3) from Corollary 5.1.7.15 (and Proposition 5.1.7.5. Corollary 4.3.6.11 guarantees that \(u\) is a left fibration. In particular, it is an isofibration, so the equivalence \((3) \Leftrightarrow(4)\) is a special case of Proposition 4.5.5.20. The equivalence (4) \(\Leftrightarrow(5)\) follows by unwinding definitions.

04JD Corollary 6.2.2.9. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a full subcategory, and let \(q: K \rightarrow \mathcal{C}^{\prime}\) be a morphism of simplicial sets. Let \(\bar{f}: \bar{X} \rightarrow \bar{Y}\) be a morphism in the \(\infty\)-category \(\mathcal{C}_{/ q}\), having image \(f: X \rightarrow Y\) in \(\mathcal{C}\). If \(f\) exhibits \(Y\) as a \(\mathcal{C}^{\prime}\)-reflection of \(X\), then \(\bar{f}\) exhibits \(\bar{Y}\) as a \(\mathcal{C}_{/ q}^{\prime}\)-reflection of \(\bar{X}\).

Proof. Set \(\mathcal{D}=\mathcal{C}_{f /} \times_{\mathcal{C}} \mathcal{C}^{\prime}\) and \(\mathcal{E}=\mathcal{C}_{X /} \times{ }_{\mathcal{C}} \mathcal{C}^{\prime}\). Our assumption that \(f\) exhibits \(Y\) as a \(\mathcal{C}^{\prime}\)-reflection of \(X\) guarantees that the restriction map \(u: \mathcal{D} \rightarrow \mathcal{E}\) is a trivial Kan fibration (Proposition 6.2.2.8). We wish to show that the analogous restriction map
\[
\bar{u}:\left(\mathcal{C}_{/ q}\right)_{\bar{f} /} \times_{\mathcal{C}_{/ q}} \mathcal{C}_{/ q}^{\prime} \rightarrow\left(\mathcal{C}_{/ q}\right)_{\bar{X} /} \times_{\mathcal{C}_{/ q}} \mathcal{C}_{/ q}^{\prime}
\]
is also trivial Kan fibration. Let us regard \(\bar{f}\) as a morphism of simplicial sets \(\Delta^{1} \star K \rightarrow \mathcal{C}\), which we can identify with a diagram \(\bar{q}: K \rightarrow \mathcal{D}\). Under this identification, \(\bar{u}\) corresponds to the map \(\mathcal{D}_{/ \bar{q}} \rightarrow \mathcal{E}_{/ u \circ \bar{q}}\) induced by \(u\), which is a trivial Kan fibration by virtue of Corollary 4.3.7.17

04JE Corollary 6.2.2.10. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a full subcategory, and let \(q: K \rightarrow \mathcal{C}^{\prime}\) be a diagram. If \(\mathcal{C}^{\prime}\) is a reflective subcategory of \(\mathcal{C}\), then \(\mathcal{C}^{\prime}{ }_{/ q}\) is a reflective subcategory of \(\mathcal{C}_{/ q}\).

Proof. Let \(\bar{X}\) be an object of the slice \(\infty\)-category \(\mathcal{C}_{/ q}\); we wish to show that there exists a morphism \(\bar{f}: \bar{X} \rightarrow \bar{Y}\) which exhibits \(\bar{Y}\) as a \(\mathcal{C}_{/ q}^{\prime}\)-reflection of \(\bar{X}\). Let \(X\) denote the image of
\(\bar{X}\) in the \(\infty\)-category \(\mathcal{C}\). Since \(\mathcal{C}^{\prime}\) is a reflective subcategory of \(\mathcal{C}\), we can choose a morphism \(f: X \rightarrow Y\) in \(\mathcal{C}\) which exhibits \(Y\) as a \(\mathcal{C}^{\prime}\)-reflection of \(X\). By virtue of Corollary 6.2.2.9, it will suffice to show that \(f\) can be lifted to a morphism \(\bar{f}: \bar{X} \rightarrow \bar{Y}\) in \(\mathcal{C}_{/ q}\). Unwinding the definitions, we can rewrite this as a lifting problem

which admits a solution by virtue of the fact that the right vertical map is a trivial Kan fibration (Proposition 6.2.2.8).

Our next goal is to prove the following:
Proposition 6.2.2.11. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a full subcategory, and let \(\iota: \mathcal{C}^{\prime} \hookrightarrow \mathcal{C}\) be the inclusion map. Then \(\iota\) admits a left adjoint if and only if \(\mathcal{C}^{\prime}\) is a reflective subcategory of \(\mathcal{C}\). Similarly, \(\iota\) admits a right adjoint if and only if \(\mathcal{C}^{\prime}\) is a coreflective subcategory of \(\mathcal{C}\).

The first step toward proving Proposition 6.2.2.11 is to show that if \(X \in \mathcal{C}\) is an object which admits a \(\mathcal{C}^{\prime}\)-reflection \(u: X \rightarrow Y\), then the pair \((u, Y)\) can be chosen to depend functorially on \(X\).

Definition 6.2.2.12. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a full subcategory, and let \(L: \mathcal{C} \rightarrow \mathcal{C}\) be a functor. We will say that a natural transformation \(\eta: \operatorname{id}_{\mathcal{C}} \rightarrow L\) exhibits \(L\) as a \(\mathcal{C}^{\prime}\)-reflection functor if, for every object \(X \in \mathcal{C}\), the morphism \(\eta_{X}: X \rightarrow L(X)\) exhibits \(L(X)\) as a \(\mathcal{C}^{\prime}\)-reflection of \(\mathcal{C}\), in the sense of Definition 6.2.2.1. We say that a natural transformation \(\epsilon: L \rightarrow \operatorname{id}_{\mathcal{C}}\) exhibits \(L\) as a \(\mathcal{C}^{\prime}\)-coreflection functor if, for every object \(Y \in \mathcal{C}\), the morphism \(\epsilon_{Y}: L(Y) \rightarrow Y\) exhibits \(L(Y)\) as a \(\mathcal{C}^{\prime}\)-coreflection of \(Y\).

Remark 6.2.2.13. In the situation of Definition 6.2.2.12 the assumption that \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow L\) 02FC exhibits \(L\) as a \(\mathcal{C}^{\prime}\)-reflection functor guarantees in particular that for every object \(X \in \mathcal{C}\), the image \(L(X)\) belongs to the full subcategory \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\). Consequently, we can also view \(L\) as a functor from \(\mathcal{C}\) to \(\mathcal{C}^{\prime}\).

Lemma 6.2.2.14. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a full subcategory. Then \(\mathcal{C}^{\prime}\) 02FD is reflective if and only if there exists a functor \(L: \mathcal{C} \rightarrow \mathcal{C}^{\prime}\) and a natural transformation \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow L\) which exhibits \(L\) as a \(\mathcal{C}^{\prime}\)-reflection functor.

Proof. Assume that \(\mathcal{C}^{\prime}\) is a reflective subcategory of \(\mathcal{C}\); we will show that there exists a functor \(L: \mathcal{C} \rightarrow \mathcal{C}^{\prime}\) and a natural transformation \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow L\) which exhibits \(L\) as a
\(\mathcal{C}^{\prime}\)-reflection functor (the reverse implication is immediate from the definitions). Let \(\mathcal{E}\) be the full subcategory of \(\mathcal{C} \times \Delta^{1}\) spanned by those objects ( \(X, i\) ) having the property that if \(i=1\), then \(X\) belongs to the full subcategory \(\mathcal{C}^{\prime}\). Let \(\pi: \mathcal{E} \rightarrow \Delta^{1}\) denote the projection map. Let \(\widetilde{u}:(X, 0) \rightarrow(Y, 1)\) be a morphism in \(\mathcal{E}\), corresponding to a morphism \(u: X \rightarrow Y\) in \(\mathcal{C}\) for which the target \(Y\) belongs to \(\mathcal{C}^{\prime}\). By virtue of Corollary 5.1.2.3, the morphism \(\widetilde{u}\) is \(\pi\)-cocartesian if and only if \(u\) exhibits \(Y\) as a \(\mathcal{C}^{\prime}\)-localization of \(X\). Consequently, our assumption that \(\mathcal{C}^{\prime}\) is a reflective subcategory of \(\mathcal{C}\) guarantees that \(\pi\) is a cocartesian fibration of \(\infty\)-categories. Applying Proposition 5.2.2.8, we deduce that there exists a functor
\[
L: \mathcal{C} \simeq\{0\} \times_{\Delta^{1}} \mathcal{E} \rightarrow\{1\} \times_{\Delta^{1}} \mathcal{E} \simeq \mathcal{C}^{\prime}
\]
and a morphism \(\widetilde{\eta}\) : id \(\mathcal{C}_{\mathcal{C}} \rightarrow L\) in the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{E})\) which carries each object \(X \in \mathcal{C}\) to a \(\pi\)-cocartesian morphism \((X, 0) \rightarrow(L(X), 1)\) in \(\mathcal{E}\). Composing with the projection map \(\pi: \mathcal{E} \rightarrow \Delta^{1}\), we obtain a natural transformation \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow L\) in \(\operatorname{Fun}(\mathcal{C}, \mathcal{C})\) which exhibits \(L\) as a \(\mathcal{C}^{\prime}\)-reflection functor.

02FE Proposition 6.2.2.15. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a full subcategory, and let \(\iota: \mathcal{C}^{\prime} \hookrightarrow \mathcal{C}\) be the inclusion map. Let \(L: \mathcal{C} \rightarrow \mathcal{C}^{\prime}\) be a functor of \(\infty\)-categories and let \(\eta: \operatorname{id}_{\mathcal{C}} \rightarrow \iota \circ L\) be a natural transformation. The following conditions are equivalent:
(1) The natural transformation \(\eta\) is the unit of an adjunction: that is, it exhibits \(L\) as a left adjoint to the inclusion functor \(\mathcal{C}^{\prime} \hookrightarrow \mathcal{C}\).
(2) The natural transformation \(\eta\) exhibits \(L\) as a \(\mathcal{C}^{\prime}\)-reflection functor: that is, for every object \(X \in \mathcal{C}\), the morphism \(\eta_{X}: X \rightarrow L(X)\) exhibits \(L(X)\) as a \(\mathcal{C}^{\prime}\)-reflection of \(X\).
(3) For every object \(X \in \mathcal{C}\), the morphism \(L\left(\eta_{X}\right): L(X) \rightarrow L(L(X))\) is an isomorphism in \(\mathcal{C}^{\prime}\). Moreover, if \(X\) belongs to \(\mathcal{C}^{\prime}\), then \(\eta_{X}: X \rightarrow L(X)\) is an isomorphism.

Moreover, if these conditions are satisfied, then any natural transformation \(\epsilon: L \circ \iota \rightarrow\) \(\mathrm{id}_{\mathcal{C}^{\prime}}\) which is compatible with \(\eta\) up to homotopy (in the sense of Definition 6.2.1.1) is an isomorphism in the functor \(\infty\)-category \(\operatorname{Fun}\left(\mathcal{C}^{\prime}, \mathcal{C}^{\prime}\right)\).

Proof. We first show that (1) implies (2). Let \(X\) be an object of \(\mathcal{C}\), so that \(\eta\) determines a morphism \(\eta_{X}: X \rightarrow L(X)\). For every object \(Y \in \mathcal{C}^{\prime}\), Proposition 6.2.1.17 guarantees that composition with the homotopy class \(\left[\eta_{X}\right]\) induces an isomorphism
\[
\operatorname{Hom}_{\mathcal{C}^{\prime}}(L(X), Y)=\operatorname{Hom}_{\mathcal{C}}(L(X), Y) \xrightarrow{\circ\left[\eta_{X}\right]} \operatorname{Hom}_{\mathcal{C}}(X, Y)
\]
in the homotopy category hKan. It follows that \(\eta_{X}\) exhibits \(L(X)\) as a \(\mathcal{C}^{\prime}\)-reflection of \(X\). Allowing \(X\) to vary, we conclude that \(\eta\) exhibits \(L\) as a \(\mathcal{C}^{\prime}\)-reflection functor.

We now show that (2) implies (3). Assume that, for every object \(X \in \mathcal{C}\), the morphism \(\eta_{X}: X \rightarrow L(X)\) exhibits \(L(X)\) as a \(\mathcal{C}^{\prime}\)-reflection of \(X\). Note that we have a commutative diagram

in the \(\infty\)-category \(\mathcal{C}\), obtained by applying the natural transformation \(\eta\) to the morphism \(\eta_{X}: X \rightarrow L(X)\). For each object \(Y \in \mathcal{C}\), we obtain a commutative diagram of sets

If \(Y\) belongs to the subcategory \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\), then the vertical maps and the upper horizontal map in this diagram are bijective. It follows that the lower horizontal map is bijective as well. Allowing \(Y\) to vary, we deduce that the homotopy class \(\left[L\left(\eta_{X}\right)\right]\) is an isomorphism in the homotopy category \(\mathrm{h} \mathcal{C}^{\prime}\), so that \(L\left(\eta_{X}\right)\) is an isomorphism in the \(\infty\)-category \(\mathcal{C}^{\prime}\). In the special case where \(X\) belongs to \(\mathcal{C}^{\prime}\), Example 6.2 .2 .4 guarantees that \(\eta_{X}\) is already an isomorphism before applying the functor \(L\).

We now show that (3) implies (1). Note that \(\eta\) determines natural transformations
\[
\begin{gathered}
\eta^{\prime}: L \rightarrow L \circ \iota \circ L \quad(X \in \mathcal{C}) \mapsto\left(L\left(\eta_{X}\right) \in \operatorname{Hom}_{\mathcal{C}^{\prime}}(L(X), L(L(X)))\right) \\
\eta^{\prime \prime}: \iota \rightarrow \iota \circ L \circ \iota \quad\left(Y \in \mathcal{C}^{\prime}\right) \mapsto\left(\eta_{Y} \in \operatorname{Hom}_{\mathcal{C}}(Y, L(Y))\right) .
\end{gathered}
\]

If condition (3) is satisfied, then Theorem 4.4.4.4 guarantees that \(\eta^{\prime}\) and \(\eta^{\prime \prime}\) are isomorphisms in the \(\infty\)-categories \(\operatorname{Fun}\left(\mathcal{C}, \mathcal{C}^{\prime}\right)\) and \(\operatorname{Fun}\left(\mathcal{C}^{\prime}, \mathcal{C}\right)\), respectively. Invoking the criterion of Proposition 6.1.4.6, we conclude that \(\eta\) is the unit of an adjunction.

Proof of Proposition 6.2.2.11. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a full subcategory. It follows from Proposition 6.2.2.15 that the inclusion functor \(\mathcal{C}^{\prime} \hookrightarrow \mathcal{C}\) admits a left adjoint if and only if there exists a functor \(L: \mathcal{C} \rightarrow \mathcal{C}^{\prime}\) and a natural transformation \(\eta:\) id \(_{\mathcal{C}} \rightarrow L\) which exhibits \(L\) as a \(\mathcal{C}^{\prime}\)-reflection functor. By virtue of Lemma 6.2.2.14, this is equivalent to the requirement that \(\mathcal{C}^{\prime}\) is a reflective subcategory of \(\mathcal{C}\). The analogous characterization of coreflective subcategories follows by a similar argument.

02SU Example 6.2.2.16. Combining Example 6.2.2.6 with Proposition 6.2.2.11 we see that the inclusion functor \(\mathcal{S} \hookrightarrow \mathcal{Q C}\) admits both a right adjoint (given on objects by the construction \(\mathcal{C} \mapsto \mathcal{C}^{\sim}\) ) and a left adjoint (given on objects by the construction \(\mathcal{C} \mapsto \operatorname{Ex}^{\infty}(\mathcal{C})\) ).

02FF Corollary 6.2.2.17. Let \(G: \mathcal{D} \rightarrow \mathcal{C}\) be a functor of \(\infty\)-categories. The following conditions are equivalent:
(1) The functor \(G\) is fully faithful and the essential image of \(G\) is a reflective subcategory of \(\mathcal{C}\).
(2) The functor \(G\) is fully faithful and admits a left adjoint \(F: \mathcal{C} \rightarrow \mathcal{D}\).
(3) There exist a functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) and a natural isomorphism \(\epsilon: F \circ G \xrightarrow{\sim} \mathrm{id}_{\mathcal{D}}\) which is the counit of an adjunction between \(F\) and \(G\).
(4) The functor \(G\) admits a left adjoint \(F: \mathcal{C} \rightarrow \mathcal{D}\) for which the composition \((F \circ G): \mathcal{D} \rightarrow \mathcal{D}\) is an equivalence of \(\infty\)-categories.

Proof. Let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be the essential image of \(G\). If \(G\) is fully faithful, then it induces an equivalence \(\mathcal{D} \rightarrow \mathcal{C}^{\prime}\) (Corollary 4.6.2.22). The equivalence (1) \(\Leftrightarrow(2)\) follows by applying Proposition 6.2.2.11 to the subcategory \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\), and the implication (2) \(\Rightarrow\) (3) follows by applying Proposition \(6 \cdot 2.2 .15\) to the subcategory \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\). To show that \((3) \Rightarrow(2)\), we observe that if a natural isomorphism \(\epsilon: F \circ G \xrightarrow{\sim} \mathrm{id}_{\mathcal{D}}\) is the counit of an adjunction, then \(G\) restricts to an equivalence of \(\mathcal{D}\) with a full subcategory of \(\mathcal{C}\) (Proposition 6.2.1.13), and is therefore fully faithful. The equivalence \((3) \Leftrightarrow(4)\) is a special case of Proposition 6.1.4.7.

04JF Remark 6.2.2.18. In the situation of Corollary 6.2.2.17, suppose that \(\eta: \operatorname{id}_{\mathcal{C}} \rightarrow G \circ F\) is the unit of an adjunction between \(F\) and \(G\). Then an object \(C \in \mathcal{C}\) belongs to the essential image of \(G\) if and only if the unit map \(\eta_{C}: C \rightarrow(G \circ F)(C)\) is an isomorphism. The "if" direction is obvious. To prove the converse, we may assume without loss of generality that \(C=G(D)\), for some object \(D \in \mathcal{D}\). In this case, the morphism \(\eta_{C}=\eta_{G(D)}\) fits into a commutative diagram

where \(\epsilon: F \circ G \rightarrow \operatorname{id}_{\mathcal{D}}\) is compatible with \(\epsilon\) up to homotopy. Since \(\epsilon\) is an isomorphism, it follows that \(\eta_{C}=\eta_{G(D)}\) is also an isomorphism.

03UZ Corollary 6.2.2.19. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Then \(F\) is an equivalence if and only if it satisfies the following pair of conditions:
(1) The functor \(F\) is conservative. That is, a morphism \(u\) of \(\mathcal{C}\) is an isomorphism if and only if \(F(u)\) is an isomorphism in \(\mathcal{D}\).
(2) The functor \(F\) admits a fully faithful right adjoint \(G: \mathcal{D} \rightarrow \mathcal{C}\).

Proof. Suppose that conditions (1) and (2) are satisfied; we will show that \(F\) is an equivalence of \(\infty\)-categories (the converse is immediate from the definitions). Combining assumption (2) with Corollary 6.2.2.17, we can choose a functor \(G: \mathcal{D} \rightarrow \mathcal{C}\) and a natural isomorphism \(\epsilon: F \circ G \xrightarrow{\sim} \mathrm{id}_{\mathcal{D}}\) which is the counit of an adjunction between \(F\) and \(G\). Let \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) be a natural transformation which is compatible up to homotopy with \(\epsilon\), in the sense of Definition 6.2.1.1. For each object \(C \in \mathcal{C}\), the morphism \(\eta_{C}\) fits into a commutative diagram

in the \(\infty\)-category \(\mathcal{D}\), where \(\epsilon_{F(C)}\) and \(\operatorname{id}_{F(C)}\) are isomorphisms. It follows that \(F\left(\eta_{C}\right)\) is also an isomorphism in \(\mathcal{D}\). Applying assumption (1), we deduce that \(\eta_{C}\) is an isomorphism in \(\mathcal{C}\). Allowing the object \(C\) to vary (and invoking the criterion of Theorem 4.4.4.4), we deduce that \(\eta\) is also a natural isomorphism, so that \(F\) and \(G\) are homotopy inverse to one another.

Corollary 6.2.2.20. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(L\) be a functor from \(\mathcal{C}\) to itself, and let 02FG \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow L\) be a natural transformation. The following conditions are equivalent:
(1) For every object \(X \in \mathcal{C}\), the morphisms \(L\left(\eta_{X}\right): L(X) \rightarrow L(L(X))\) and \(\eta_{L(X)}: L(X) \rightarrow\) \(L(L(X))\) are isomorphisms.
(2) There exists a full subcategory \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) for which \(\eta\) exhibits \(L\) as a \(\mathcal{C}^{\prime}\)-reflection functor, in the sense of Definition 6.2.2.12.

Proof. The implication (2) \(\Rightarrow(1)\) follows from Proposition 6.2.2.15. Conversely, suppose that condition (1) is satisfied, and let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be the full subcategory spanned by those objects of the form \(L(X)\) for \(X \in \mathcal{C}\). Assumption (1) guarantees that \(\eta_{Y}\) is an isomorphism for each \(Y \in \mathcal{C}^{\prime}\), so that \(\eta\) exhibits \(L\) as a \(\mathcal{C}^{\prime}\)-reflection functor by virtue of Proposition 6.2.2.15.

Exercise 6.2.2.21. Suppose that the conditions of Corollary 6.2.2.20 are satisfied and let 02FH \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a full subcategory of \(\mathcal{C}\). Show that \(\eta\) exhibits \(L\) as a \(\mathcal{C}^{\prime}\)-reflection functor if and only if the following conditions are satisfied:
- For each object \(X \in \mathcal{C}\), the object \(L(X)\) is contained in \(\mathcal{C}^{\prime}\).
- For each object \(Y \in \mathcal{C}^{\prime}\), there exists an isomorphism \(Y \rightarrow L(X)\) for some object \(X \in \mathcal{C}\).

If the subcategory \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) is replete (Example 4.4.1.12), then it is uniquely determined by these conditions.

Reflective subcategories are stable under pullback along cocartesian fibrations:
02SV Proposition 6.2.2.22. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of \(\infty\)-categories and let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a reflective subcategory. Then the pullback \(\mathcal{E}^{\prime}=\mathcal{C}^{\prime} \times_{\mathcal{C}} \mathcal{E}\) is a reflective subcategory of \(\mathcal{E}\). Moreover, a morphism \(f: X \rightarrow Y\) in \(\mathcal{E}\) exhibits \(Y\) as a \(\mathcal{E}^{\prime}\)-reflection of \(X\) if and only if it satisfies the following pair of conditions:
(1) The morphism \(f\) is \(U\)-cocartesian.
(2) The morphism \(U(f): U(X) \rightarrow U(Y)\) exhibits \(U(Y)\) as a \(\mathcal{C}^{\prime}\)-reflection of \(U(X)\) in the \(\infty\)-category \(\mathcal{C}\).

Proof. We first show that, if \(f: X \rightarrow Y\) is a morphism of \(\mathcal{E}\) satisfying conditions (1) and (2), then \(f\) exhibits \(Y\) as a \(\mathcal{E}^{\prime}\)-reflection of \(X\). It follows from condition (2) that \(U(Y)\) belongs to \(\mathcal{C}^{\prime}\), so that \(Y\) belongs to \(\mathcal{E}^{\prime}\). It will therefore suffice to show that for each object \(Z \in \mathcal{E}\), precomposition with \(f\) induces a homotopy equivalence \(\theta: \operatorname{Hom}_{\mathcal{E}}(Y, Z) \rightarrow \operatorname{Hom}_{\mathcal{E}}(X, Z)\). Let us abuse notation by identifying \(\theta\) with the restriction map \(\{f\} \times_{\operatorname{Hom}_{\mathcal{E}}(X, Y)} \operatorname{Hom}_{\mathcal{E}}(X, Y, Z) \rightarrow\) \(\operatorname{Hom}_{\mathcal{E}}(X, Z)\), so that we have a commutative diagram of Kan complexes

Assumption (1) guarantees that this diagram is a homotopy pullback square (Proposition 5.1.2.1, and assumption (2) guarantees that \(\bar{\theta}\) is a homotopy equivalence of Kan complexes. Applying Corollary 3.4.1.5, we conclude that \(\theta\) is also a homotopy equivalence.

We now show that \(\mathcal{E}^{\prime}\) is a reflective subcategory of \(\mathcal{E}\). Fix an object \(X \in \mathcal{E}\). Since \(\mathcal{C}^{\prime}\) is a reflective subcategory of \(\mathcal{C}\), there exists a morphism \(\bar{f}: U(X) \rightarrow \bar{Y}\) in \(\mathcal{C}\) which exhibits \(\bar{Y}\) as a \(\mathcal{C}^{\prime}\)-reflection of \(U(X)\). Since \(U\) is a cocartesian fibration, we can write \(\bar{f}=U(f)\) for some \(U\)-cocartesian morphism \(f: X \rightarrow Y\) of \(\mathcal{E}\). By construction, the morphism \(f\) satisfies conditions (1) and (2), and therefore exhibits \(Y\) as an \(\mathcal{E}^{\prime}\)-reflection of \(X\).

To complete the proof, it will suffice to show that if \(h: X \rightarrow Z\) is another morphism which exhibits \(Z\) as a \(\mathcal{E}^{\prime}\)-reflection of \(X\), then \(h\) also satisfies conditions (1) and (2). By
virtue of Remark 6.2.2.3, there exists a 2 -simplex

of \(\mathcal{E}\), where \(g: Y \rightarrow Z\) is an isomorphism of \(\mathcal{E}^{\prime}\). In particular, \(g\) is \(U\)-cocartesian (Proposition 5.1.1.8, so that \(h\) satisfies (1) by virtue of Corollary 5.1.2.4 Since \(U(g)\) is an isomorphism in \(\mathcal{C}^{\prime}\), condition (2) follows from Remark 6.2.2.3.

\subsection*{6.2.3 Correspondences}

Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of \(\infty\)-categories. To every morphism \(e: C \rightarrow D\) 02FJ of \(\mathcal{C}\), Proposition 5.2.2.8 supplies a covariant transport functor
\[
e_{!}: \mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E} \rightarrow\{D\} \times_{\mathcal{C}} \mathcal{E}=\mathcal{E}_{D},
\]
which is well-defined up to isomorphism. Our goal in this section is to show that \(U\) is a cartesian fibration if and only if each of the functors \(e_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) admits a right adjoint (Proposition 6.2.3.5). Moreover, if this condition is satisfied, then the right adjoint to \(e_{\text {! }}\) is given by the contravariant transport functor \(e^{*}: \mathcal{E}_{D} \rightarrow \mathcal{E}_{C}\) of Proposition 5.2.2.16. We begin by analyzing the special case \(\mathcal{C}=\Delta^{1}\).

Lemma 6.2.3.1. Let \(\mathcal{E}\) be an \(\infty\)-category equipped with a functor \(U: \mathcal{E} \rightarrow \Delta^{1}\), having fibers 02FK \(\mathcal{E}_{0}=\{0\} \times_{\Delta^{1}} \mathcal{E}\) and \(\mathcal{E}_{1}=\{1\} \times_{\Delta^{1}} \mathcal{E}\). Let \(f: X \rightarrow Y\) be a morphism of \(\mathcal{E}\). Then:
- The morphism \(f\) exhibits \(X\) as a \(\mathcal{E}_{0}\)-coreflection of \(Y\) (in the sense of Definition 6.2.2.1) if and only if \(X\) belongs to \(\mathcal{E}_{0}\) and \(f\) is \(\pi\)-cartesian.
- The morphism \(f\) exhibits \(Y\) as a \(\mathcal{E}_{1}\)-reflection of \(X\) if and only if \(Y\) belongs to \(\mathcal{E}_{1}\) and \(f\) is \(\pi\)-cocartesian.

Proof. This is a special case of Corollary 5.1.2.3.
Corollary 6.2.3.2. Let \(\mathcal{E}\) be an \(\infty\)-category equipped with a functor \(U: \mathcal{E} \rightarrow \Delta^{1}\). Then: 02FL
- The functor \(U\) is a cartesian fibration if and only if the full subcategory \(\{0\} \times_{\Delta^{1}} \mathcal{E} \subseteq \mathcal{E}\) is coreflective.
- The functor \(U\) is a cocartesian fibration if and only if the full subcategory \(\{1\} \times{ }_{\Delta^{1}} \mathcal{E} \subseteq \mathcal{E}\) is reflective.

02 FM Remark 6.2.3.3. Let \(U: \mathcal{E} \rightarrow \Delta^{1}\) be a functor of \(\infty\)-categories having fibers \(\mathcal{E}_{0}=\{0\} \times{ }_{\Delta^{1}} \mathcal{E}\) and \(\mathcal{E}_{1}=\{1\} \times_{\Delta^{1}} \mathcal{E}\). Suppose that \(U\) is a cocartesian fibration, so that the full subcategory \(\mathcal{E}_{1} \subseteq \mathcal{E}\) is reflective (Corollary 6.2.3.2). By virtue of Lemma 6.2.2.14 there exists a \(\mathcal{E}_{1^{-}}\) reflection functor \(L: \mathcal{E} \rightarrow \mathcal{E}_{1}\). Then the restriction \(\left.L\right|_{\mathcal{E}_{0}}: \mathcal{E}_{0} \rightarrow \mathcal{E}_{1}\) is given by covariant transport along the unique nondegenerate edge \(e\) of \(\Delta^{1}\) (in the sense of Definition 5.2.2.4. More precisely, if \(\eta: \mathrm{id}_{\mathcal{E}} \rightarrow L\) is a natural transformation which exhibits \(L\) as a \(\mathcal{E}_{1}\)-reflection functor, then \(\eta\) carries each object \(X \in \mathcal{E}\) to a \(U\)-cocartesian morphism \(\eta_{X}: X \rightarrow L(X)\), so that \(\eta\) restricts to a natural transformation \(\operatorname{id}_{\mathcal{E}_{0}} \rightarrow L \mid \mathcal{E}_{0}\) which witnesses \(\left.L\right|_{\mathcal{E}_{0}}\) as given by covariant transport along \(e\).

Similarly, if \(U\) is a cartesian fibration, then the full subcategory \(\mathcal{E}_{0} \subseteq \mathcal{E}\) is coreflective; if \(L^{\prime}: \mathcal{E} \rightarrow \mathcal{E}_{0}\) is a \(\mathcal{E}_{0}\)-coreflection functor, then the restriction \(\left.L^{\prime}\right|_{\mathcal{E}_{1}}: \mathcal{E}_{1} \rightarrow \mathcal{E}_{0}\) is given by contravariant transport along \(e\), in the sense of Definition 5.2.2.14.

02FN Proposition 6.2.3.4. Let \(\mathcal{E}\) be an \(\infty\)-category equipped with a cocartesian fibration \(U: \mathcal{E} \rightarrow\) \(\Delta^{1}\), having fibers \(\mathcal{E}_{0}=\{0\} \times_{\Delta^{1}} \mathcal{E}\) and \(\mathcal{E}_{1}=\{1\} \times_{\Delta^{1}} \mathcal{E}\). Let \(F: \mathcal{E}_{0} \rightarrow \mathcal{E}_{1}\) be a functor given by covariant transport along the nondegenerate edge e of \(\Delta^{1}\). Then the functor \(F\) admits a right adjoint if and only if \(U\) is a cartesian fibration. In this case, the right adjoint to \(F\) is given by contravariant transport along \(e\).

Proof. Let \(\iota_{0}: \mathcal{E}_{0} \hookrightarrow \mathcal{E}\) and \(\iota_{1}: \mathcal{E}_{1} \hookrightarrow \mathcal{E}\) denote the inclusion maps. Since \(U\) is a cocartesian fibration, \(\mathcal{E}_{1}\) is a reflective subcategory of \(\mathcal{E}\) (Corollary 6.2.3.2). Let \(L: \mathcal{E} \rightarrow \mathcal{E}_{1}\) be a \(\mathcal{E}_{1}\)-reflection functor (Lemma 6.2.2.14). Without loss of generality, we may assume that the functor \(F: \mathcal{E}_{0} \rightarrow \mathcal{E}_{1}\) factors as a composition \(\mathcal{E}_{0} \xrightarrow{\iota_{0}} \mathcal{E} \xrightarrow{L} \mathcal{E}_{1}\) (Remark 6.2.3.3). Note that \(L\) is a left adjoint to the inclusion \(\iota_{1}: \mathcal{E}_{1} \hookrightarrow \mathcal{E}\) (Proposition 6.2.2.15).

Suppose that \(U\) is also a cartesian fibration, so that the subcategory \(\mathcal{E}_{0} \subseteq \mathcal{E}\) is coreflective (Corollary 6.2.3.2). Let \(L^{\prime}: \mathcal{E} \rightarrow \mathcal{E}_{0}\) be a \(\mathcal{E}_{0}\)-coreflection functor (Corollary 6.2.3.2, so that \(L^{\prime}\) can be regarded as a right adjoint to \(\iota_{0}\) (Proposition 6.2.2.15). Invoking Remark 6.2.1.8, we conclude that the composite functor \(F=L \circ \iota_{0}\) has a right adjoint \(G\), given by the composition \(L^{\prime} \circ \iota_{1}=L^{\prime} \mid \mathcal{E}_{1}\). Moreover, Remark 6.2.3.3 guarantees that \(G: \mathcal{E}_{1} \rightarrow \mathcal{E}_{0}\) is given by contravariant transport along \(e\).

We now prove the converse. Suppose that the functor \(F: \mathcal{E}_{0} \rightarrow \mathcal{E}_{1}\) admits a right adjoint \(G: \mathcal{E}_{1} \rightarrow \mathcal{E}_{0}\). Fix an object \(Z \in \mathcal{E}_{1}\); we wish to show that there exists an object \(Y \in \mathcal{E}_{0}\) and a \(U\)-cartesian morphism \(f: Y \rightarrow Z\). Let \(\epsilon: F \circ G \rightarrow \mathrm{id}_{\mathcal{E}_{1}}\) be the counit of an adjunction between \(F\) and \(G\). Set \(Y=G(Z)\), so that \(\epsilon\) determines a morphism \(\epsilon_{Z}: F(Y) \rightarrow Z\) in the \(\infty\)-category \(\mathcal{E}_{1}\). Let \(\eta: \mathrm{id}_{\mathcal{E}} \rightarrow L\) be a natural transformation which exhibits \(L\) as a \(\mathcal{E}_{1}\)-reflection functor, so that \(\eta\) determines a morphism \(\eta_{Y}: Y \rightarrow F(Y)\). Let \(f: Y \rightarrow Z\) be a composition of \(\eta_{Y}\) with \(\epsilon_{Z}\). We will complete the proof by showing that \(f\) is \(U\)-cartesian. To prove this, it will suffice to show that for every object \(X \in \mathcal{E}_{0}\), the composite map
\[
\operatorname{Hom}_{\mathcal{E}_{0}}(X, Y) \xrightarrow{\left[\eta_{Y}\right] 0} \operatorname{Hom}_{\mathcal{E}}(X, F(Y))=\operatorname{Hom}_{\mathcal{E}}(X,(F \circ G)(Z)) \xrightarrow{\left[\epsilon_{Z}\right] \circ} \operatorname{Map}_{\mathcal{E}}(X, Z)
\]
is an isomorphism in the homotopy category hKan (see Corollary 5.1.2.3). Unwinding the definitions, we see that this map factors as a composition
\(\operatorname{Hom}_{\mathcal{E}_{0}}(X, G(Z)) \xrightarrow{F} \operatorname{Hom}_{\mathcal{E}_{1}}(F(X),(F \circ G)(Z)) \xrightarrow{\left[\epsilon_{Z}\right] \circ} \operatorname{Hom}_{\mathcal{E}_{1}}(F(X), Z) \xrightarrow{\circ[\eta X]} \operatorname{Hom}_{\mathcal{E}}(X, Z)\),
where the composition of the first two maps is an isomorphism in hKan because \(\epsilon\) is the counit of an adjunction (see Proposition 6.2.1.17), and third is an isomorphism because \(\eta_{X}\) exhibits \(F(X)\) as a \(\mathcal{E}_{1}\)-reflection of \(X\).

Proposition 6.2.3.5. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets. The 02FP following conditions are equivalent:
(1) The morphism \(U\) is a cartesian fibration of simplicial sets.
(2) For every edge \(e: C \rightarrow D\) of the simplicial set \(\mathcal{C}\), the covariant transport functor \(e_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) of Notation 5.2.2.9 admits a right adjoint.

Moreover, if these conditions are satisfied and \(e: C \rightarrow D\) is an edge of \(\mathcal{C}\), then the contravariant transport functor \(e^{*}: \mathcal{E}_{D} \rightarrow \mathcal{E}_{C}\) of Notation 5.2.2.17 is right adjoint to e!.

Proof. Assume first that condition (1) is satisfied and let \(e: C \rightarrow D\) be an edge of the simplicial set \(\mathcal{C}\), which we identify with a morphism \(\Delta^{1} \rightarrow \mathcal{C}\). Applying Proposition 6.2.3.4 to the projection map \(\Delta^{1} \times_{\mathcal{C}} \mathcal{E} \rightarrow \Delta^{1}\), we deduce that the covariant transport functor \(e_{!}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{D}\) is right adjoint to the contravariant transport functor \(e^{*} \mathcal{E}_{D} \rightarrow \mathcal{E}_{C}\), which proves (2).

We now show that (2) implies (1). By virtue of Proposition 5.1.4.7, we may assume without loss of generality that \(\mathcal{C}=\Delta^{n}\) is a standard simplex. For \(0 \leq i \leq n\), let \(\mathcal{E}_{i}\) denote the fiber \(\{i\} \times_{\Delta^{n}} \mathcal{E}\), which we regard as a full subcategory of \(\mathcal{E}\). We wish to show that, for every pair of integers \(0 \leq j<k \leq n\) and every object \(Z \in \mathcal{E}_{k}\), there exists an object \(Y \in \mathcal{E}_{j}\) and a \(U\)-cartesian morphism \(g: Y \rightarrow Z\) in \(\mathcal{E}\). Proposition 6.2.3.4 implies that the projection map \(\mathrm{N}_{\bullet}(\{j<k\}) \times_{\Delta^{n}} \mathcal{E} \rightarrow \mathrm{~N}_{\bullet}(\{j<k\})\) is a cartesian fibration, so we can choose an object \(Y \in \mathcal{E}_{j}\) and a morphism \(g: Y \rightarrow Z\) which is locally \(U\)-cartesian. We will complete the proof by showing that \(g\) is \(U\)-cartesian. To prove this, we must show that for each integer \(0 \leq i \leq j\) and each object \(W \in \mathcal{E}_{i}\), composition with the homotopy class [g] induces an isomorphism \(\operatorname{Hom}_{\mathcal{E}}(W, Y) \xrightarrow{[g] 0} \operatorname{Hom}_{\mathcal{E}}(W, Z)\) in the homotopy category of Kan complexes hKan (see Corollary 5.1.2.3). Since \(U\) is a cocartesian fibration, we can choose a \(U\)-cocartesian morphism \(f: W \rightarrow X\), where \(X\) belongs to \(\mathcal{E}_{j}\). We conclude by observing
that there is a commutative diagram

in the homotopy category hKan, where the upper horizontal map is an isomorphism by virtue of our assumption that \(g\) is locally \(U\)-cartesian, and the vertical maps are isomorphisms by virtue of our assumption that \(f\) is \(U\)-cocartesian (Corollary 5.1.2.3).

\subsection*{6.2.4 Local Existence Criterion}

02FQ Let \(G: \mathcal{D} \rightarrow \mathcal{C}\) be a functor between categories. Suppose that \(G\) admits a left adjoint \(F: \mathcal{C} \rightarrow \mathcal{D}\). For each object \(X \in \mathcal{C}\), the value \(F(X) \in \mathcal{D}\) is determined, up to canonical isomorphism, by the property that it corepresents the functor \(Z \mapsto \operatorname{Hom}_{\mathcal{D}}(X, G(Z))\) : that is, there exists a bijection \(\operatorname{Hom}_{\mathcal{D}}(F(X), Z) \simeq \operatorname{Hom}_{\mathcal{C}}(X, G(Z))\) which depends functorially on \(Z\). This observation has a converse: if, for every object \(X \in \mathcal{C}\), the functor
\[
\mathcal{D} \rightarrow \text { Set } \quad Z \mapsto \operatorname{Hom}_{\mathcal{C}}(X, G(Z))
\]
is corepresentable by an object of \(\mathcal{D}\), then the functor \(G\) admits a left adjoint \(F: \mathcal{C} \rightarrow \mathcal{D}\) (Corollary 6.2.4.4). Our goal in this section is to establish a counterpart of this criterion in the \(\infty\)-categorical setting. We begin with a simple observation.

02FV Proposition 6.2.4.1. Let \(G: \mathcal{D} \rightarrow \mathcal{C}\) be a functor of \(\infty\)-categories. Then \(G\) admits a left adjoint if and only if, for every object \(X \in \mathcal{C}\), the following condition is satisfied:
\(\left(*_{X}\right)\) There exists an object \(Y \in \mathcal{D}\) and a morphism \(u: X \rightarrow G(Y)\) in \(\mathcal{C}\) such that, for every object \(Z \in \mathcal{D}\), the composite map
\[
\operatorname{Hom}_{\mathcal{D}}(Y, Z) \xrightarrow{G} \operatorname{Hom}_{\mathcal{C}}(G(Y), G(Z)) \xrightarrow{\circ} \xrightarrow{\circ[u]} \operatorname{Hom}_{\mathcal{C}}(X, G(Z))
\]
is a homotopy equivalence of Kan complexes.
Proof. We first prove necessity. Suppose that there exists a functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) and a natural transformation \(\eta: \operatorname{id}_{\mathcal{C}} \rightarrow G \circ F\) which exhibits \(F\) as a left adjoint of \(G\). Fix an object \(X \in \mathcal{C}\) and set \(Y=F(X)\). Then \(\eta\) determines a morphism \(\eta_{X}: X \rightarrow G(Y)\) which satisfies the requirement of condition \(\left(*_{X}\right)\) (Proposition 6.2.1.17).

We now prove sufficiency. Let \(\mathcal{E}\) denote the relative join \(\mathcal{C} \not \star \mathcal{C} \mathcal{D}\) and let \(U: \mathcal{E} \rightarrow \Delta^{1}\) be the cartesian fibration of Proposition 5.2.3.15. Let us abuse notation by identifying the fibers
\(\{0\} \times_{\Delta^{1}} \mathcal{E}\) and \(\{1\} \times_{\Delta^{1}} \mathcal{E}\) with \(\mathcal{C}\) and \(\mathcal{D}\), respectively. Fix an object \(X \in \mathcal{C}\), and suppose that there exists an object \(Y \in \mathcal{D}\) together with a morphism \(u: X \rightarrow G(Y)\) satisfying the requirement of condition \(\left(*_{X}\right)\). Then we can identify \(u\) with a morphism \(f: X \rightarrow Y\) in the \(\infty\)-category \(\mathcal{E}\). Our assumption on \(u\) guarantees that the morphism \(f\) is \(U\)-cocartesian (see Corollary 5.1.2.3). Consequently, if condition \(\left(*_{X}\right)\) is satisfied for every object \(X \in \mathcal{C}\), then \(U\) is a cocartesian fibration. Applying Proposition 6.2.3.4, we conclude that \(G\) admits a left adjoint.

Corollary 6.2.4.2. Let \(G: \mathcal{D} \rightarrow \mathcal{C}\) be a functor of \(\infty\)-categories. The following conditions 02J9 are equivalent:
(1) The functor \(G\) admits a left adjoint \(F: \mathcal{C} \rightarrow \mathcal{D}\).
(2) For every left fibration \(\widetilde{\mathcal{C}} \rightarrow \mathcal{C}\), if the \(\infty\)-category \(\widetilde{\mathcal{C}}\) has an initial object, then the \(\infty\)-category \(\mathcal{D} \times \mathcal{C} \widetilde{\mathcal{C}}\) also has an initial object.
(3) For every object \(X \in \mathcal{C}\), the \(\infty\)-category \(\mathcal{D} \times_{\mathcal{C}} \mathcal{C}_{X /}\) has an initial object.
(4) For every corepresentable hKan-enriched functor \(\lambda: \mathrm{hC} \rightarrow \mathrm{hKan}\), the composite functor
\[
\mathrm{hD} \xrightarrow{\mathrm{~h} G} \mathrm{hC} \xrightarrow{\lambda} \mathrm{hKan}
\]
is also corepresentable (in the sense of Definition 5.6.6.10).
(5) For every corepresentable functor \(\lambda: \mathcal{C} \rightarrow \mathcal{S}\) of \(\infty\)-categories, the composite functor
\[
\mathcal{D} \xrightarrow{G} \mathcal{C} \xrightarrow{\lambda} \mathcal{S}
\]
is also corepresentable (in the sense of Definition 5.6.6.1).
Proof. The equivalence (1) \(\Leftrightarrow(4)\) is a reformulation of Proposition 6.2.4.1. The implication \((2) \Rightarrow(3)\) is immediate. To see that (3) implies (4), we observe that if \(\lambda: \mathrm{hC} \rightarrow \mathrm{hKan}\) is an hKan-enriched functor which is corepresentable by an object \(X \in \mathcal{C}\), then \(\lambda \circ \mathrm{h} G\) is isomorphic to the enriched homotopy transport representation of the left fibration \(\mathcal{D} \times{ }_{\mathcal{C}} \mathcal{C}_{X /} \rightarrow \mathcal{D}\). If \(\mathcal{D} \times_{\mathcal{C}} \mathcal{C}_{X /}\) has an initial object, then this functor is corepresentable by virtue of Proposition 5.6.6.21.

The implication \((4) \Rightarrow(5)\) follows from Remark 5.6.6.11. We will complete the proof by showing that (5) implies (2). Let \(U: \widetilde{\mathcal{C}} \rightarrow \mathcal{C}\) be a left fibration, and let \(\operatorname{Tr}_{\widetilde{\mathcal{C}} / \mathcal{C}}: \mathcal{C} \rightarrow \mathcal{S}\) be a covariant transport representation for \(U\) (see Definition 5.6.5.1. If \(\widetilde{\mathcal{C}}\) has an initial object, then the functor \(\operatorname{Tr}_{\widetilde{\mathcal{C}} / \mathcal{C}}\) is corepresentable (Proposition 5.6.6.21). Assumption (5) then guarantees that the functor \(\operatorname{Tr}_{\widetilde{\mathcal{C}} / \mathcal{C}} \circ G\) is also corepresentable. Identifying \(\operatorname{Tr}_{\widetilde{\mathcal{C}} / \mathcal{C}} \circ G\) with the covariant transport representation of the left fibration \(\mathcal{D} \times{ }_{\mathcal{C}} \widetilde{\mathcal{C}} \rightarrow \mathcal{D}\), we see that the \(\infty\)-category \(\mathcal{D} \times \widetilde{\mathcal{C}}\) also has an initial object (Proposition 5.6.6.21.

038 S Remark 6.2.4.3. Let \(G: \mathcal{D} \rightarrow \mathcal{C}\) be a functor of \(\infty\)-categories which satisfies the equivalent conditions of Corollary 6.2.4.2, so that \(G\) admits a left adjoint \(F: \mathcal{C} \rightarrow \mathcal{D}\). For each object \(X \in \mathcal{C}\), the value \(F(X) \in \mathcal{D}\) admits several characterizations:
- The object \(F(X)\) corepresents the hKan-enriched functor
\[
\mathrm{hD} \xrightarrow{\mathrm{~h} G} \mathrm{hC} \xrightarrow{\mathrm{Hom}_{\mathrm{hC}}(X, \bullet)} \mathrm{hKan} .
\]
- The object \(F(X)\) corepresents the functor of \(\infty\)-categories
\[
\mathcal{D} \xrightarrow{G} \mathcal{C} \xrightarrow{h^{X}} \mathcal{S},
\]
where \(h^{X}\) is the functor corepresented by \(X\).
- The object \(F(X)\) is the image in \(\mathcal{D}\) of an initial object of the \(\infty\)-category \(\mathcal{D} \times{ }_{\mathcal{C}} \mathcal{C}_{X /}\).

02FW Corollary 6.2.4.4. Let \(G: \mathcal{D} \rightarrow \mathcal{C}\) be a functor between ordinary categories. The following conditions are equivalent:
(1) The functor \(G\) admits a left adjoint \(F: \mathcal{C} \rightarrow \mathcal{D}\).
(2) For every object \(X \in \mathcal{C}\), the set-valued functor
\[
\mathcal{D} \rightarrow \text { Set } \quad Z \mapsto \operatorname{Hom}_{\mathcal{C}}(X, G(Z))
\]
is corepresentable.
02FX Corollary 6.2.4.5. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{C}\) be functors between \(\infty\)-categories, and let \(\eta: \operatorname{id}_{\mathcal{C}} \rightarrow G \circ F\) be a natural transformation. The following conditions are equivalent:
(1) The natural transformation \(\eta\) is the unit of an adjunction between \(F\) and \(G\).
(2) For every pair of objects \(X \in \mathcal{C}\) and \(Y \in \mathcal{D}\), the composite map
\[
\operatorname{Hom}_{\mathcal{D}}(F(X), Y) \xrightarrow{G} \operatorname{Hom}_{\mathcal{C}}((G \circ F)(X), G(Y)) \xrightarrow{\circ\left[\eta_{X}\right]} \operatorname{Hom}_{\mathcal{C}}(X, G(Y))
\]
is a homotopy equivalence of Kan complexes.
(3) The functor \(F\) admits a right adjoint. Moreover, for every pair of objects \(X \in \mathcal{C}\) and \(Y \in \mathcal{D}\), the composite map
\[
\operatorname{Hom}_{\mathrm{hD}}(F(X), Y) \xrightarrow{G} \operatorname{Hom}_{\mathrm{h} \mathcal{C}}((G \circ F)(X), G(Y)) \xrightarrow{\circ\left[\eta_{x}\right]} \operatorname{Hom}_{\mathrm{h} \mathcal{C}}(X, G(Y))
\] is a bijection of sets.

Proof. The implication (1) \(\Rightarrow(2)\) follows from Proposition 6.2.1.17, the implication \((2) \Rightarrow(3)\) follows from Proposition 6.2.4.1. We will complete the proof by showing that \((3) \Rightarrow(1)\). Note that, if condition (3) is satisfied, then the natural transformation \(\eta\) exhibits \(\mathrm{h} G: \mathrm{h} \mathrm{\mathcal{D}} \rightarrow \mathrm{hC}\) as a right adjoint of the functor \(\mathrm{h} F: \mathrm{h} \mathrm{\mathcal{C}} \rightarrow \mathrm{hD}\) (see Variant 6.1.2.11). Invoking Proposition 6.2.1.14 we deduce that \(\eta\) is the unit of an adjunction between \(F\) and \(G\).

Corollary 6.2.4.6. Let \(G: \mathcal{D} \rightarrow \mathcal{C}\) be a functor of \(\infty\)-categories and let \(u: K \rightarrow \mathcal{D} 02 \mathrm{KD}\) be a morphism of simplicial sets, so that \(G\) induces a functor of coslice \(\infty\)-categories \(G^{\prime}: \mathcal{D}_{/ u} \rightarrow \mathcal{C}_{/(G \circ u)}\). If the functor \(G\) admits a left adjoint, then the functor \(G^{\prime}\) also admits a left adjoint.

Proof. We will use the criterion of Corollary 6.2.4.2. Fix an object \(\bar{X} \in \mathcal{C}_{/(G o u)}\); we wish to show that the \(\infty\)-category
\[
\mathcal{E}=\mathcal{D}_{/ u} \times_{\mathcal{C}_{/ G \circ u}}\left(\mathcal{C}_{/(\text {Gou })}\right)_{\bar{X} /}
\]
has an initial object. Let \(X\) denote the image of \(\bar{X}\) in the \(\infty\)-category \(\mathcal{C}\). Unwinding the definitions, we can identify \(\bar{X}\) with a morphism of simplicial sets \(\bar{u}: K \rightarrow\left(\mathcal{D} \times_{\mathcal{C}} \mathcal{C}_{X /}\right)\), and \(\mathcal{E}\) with the slice \(\infty\)-category \(\left(\mathcal{D} \times_{\mathcal{C}} \mathcal{C}_{X /}\right)_{/ \bar{u}}\). Since \(G\) admits a left adjoint, the \(\infty\)-category \(\mathcal{D} \times{ }_{\mathcal{C}} \mathcal{C}_{X /}\) has an initial object (Corollary 6.2.4.2). Applying Corollary 7.1.3.20, we conclude that \(\mathcal{E}\) also has an initial object.

\subsection*{6.2.5 Digression: \(\infty\)-Categories with Short Morphisms}

Let \(\mathcal{C}\) be a category. Recall that \(\mathcal{C}\) is free if every morphism \(f: X \rightarrow Y\) of \(\mathcal{C}\) factors 03XB uniquely as a composition
\[
X=X_{0} \xrightarrow{f_{1}} X_{1} \xrightarrow{f_{2}} X_{2} \rightarrow \cdots \xrightarrow{f_{n}} X_{n}=Y,
\]
where each \(f_{i}\) is an indecomposable morphism of \(\mathcal{C}\) (see Proposition 1.3.7.11). In this case, Proposition 1.5.7.3 asserts that the inclusion map \(G \hookrightarrow \mathrm{~N}_{\bullet}(\mathcal{C})\) is inner anodyne, where \(G\) is the 1-dimensional simplicial set whose vertices are the objects of \(\mathcal{C}\) and whose nondegenerate edges are the indecomposable morphisms of \(\mathcal{C}\). Our goal in this section is to prove a more general result, where we relax the assumption that \(\mathcal{C}\) is free. First, we need a definition.

Definition 6.2.5.1. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(S\) be a collection of morphisms of \(\mathcal{C}\). 03XC An \(S\)-optimal factorization of \(f\) is a 2 -simplex

of \(\mathcal{C}\), corresponding to a morphism \(\widetilde{g}: \widetilde{X} \rightarrow \widetilde{Y}\) in the \(\infty\)-category \(\mathcal{C}_{/ Z}\) with the following properties:
- The morphism \(s: Y \rightarrow Z\) belongs to \(S\).
- Let \(\tilde{Y}^{\prime}\) be an object of \(\mathcal{C} / Z\) corresponding to a morphism \(s^{\prime}: Y^{\prime} \rightarrow Z\) which belongs to \(S\). Then composition with \(\widetilde{g}\) induces a homotopy equivalence of Kan complexes
\[
\operatorname{Hom}_{\mathcal{C}_{/ Z}}\left(\tilde{Y}, \tilde{Y}^{\prime}\right) \rightarrow \operatorname{Hom}_{\mathcal{C}_{/ Z}}\left(\tilde{X}, \tilde{Y}^{\prime}\right)
\]

If these conditions are satisfied, we say that the diagram 6.2 is an \(S\)-optimal factorization of \(f\).

03XE Example 6.2.5.2. In the situation of Definition 6.2.5.1 assume that \(\mathcal{C}\) is (the nerve of) an ordinary category. Then an \(S\)-optimal factorization of a morphism \(f: X \rightarrow Z\) is a pair of morphisms \(X \xrightarrow{g} Y \xrightarrow{s} Z\), where \(s \in S\) and \(s \circ g=f\), which has the following universal property: for every other pair of morphisms \(X \xrightarrow{g^{\prime}} Y^{\prime} \xrightarrow{s^{\prime}} Z\) with \(s^{\prime} \in S\) and \(s^{\prime} \circ g^{\prime}=f\), there is a unique morphism \(h: Y \rightarrow Y^{\prime}\) satisfying \(h \circ g=g^{\prime}\) and \(s^{\prime} \circ h=s\), as indicated in the diagram

Stated more informally, the pair \((g, s)\) is universal among all factorizations of \(f\) through a morphism which belongs to \(S\).

03XF Example 6.2.5.3. Let \(G\) be a directed graph, let \(\mathcal{C}=\operatorname{Path}[G]\) denote its path category (Construction 1.3.7.1), and let \(S\) be the collection of morphisms of \(\mathcal{C}\) which are either identity morphisms or are indecomposable. Then every morphism \(f: X \rightarrow Z\) in \(\mathcal{C}\) admits a (unique) \(S\)-optimal factorization:
- If \(f=\operatorname{id}_{X}\) is an identity morphism, then its \(S\)-optimal factorization is given by the diagram \(X \xrightarrow{\mathrm{id}_{X}} X \xrightarrow{\mathrm{id}_{X}} X\).
- If \(f\) is not an identity morphism, then it admits a unique factorization \(X \xrightarrow{g} Y \xrightarrow{s} Z\), where \(s\) is an indecomposable morphism of \(\mathcal{C}\) (that is, a morphism which corresponds to an edge of the graph \(G\) ); this factorization is \(S\)-optimal.

Definition 6.2.5.4. Let \(\mathcal{C}\) be an \(\infty\)-category. A class of short morphisms for \(\mathcal{C}\) is a collection 03XG \(S\) of morphisms of \(\mathcal{C}\) with the following properties:
(1) Every identity morphism of \(\mathcal{C}\) belongs to \(S\).
(2) For every 2 -simplex

of the \(\infty\)-category \(\mathcal{C}\), if \(f\) and \(f^{\prime}\) belong to \(S\), then \(f^{\prime \prime}\) also belongs to \(S\).
(3) Every morphism \(f: X \rightarrow Z\) of \(\mathcal{C}\) admits an \(S\)-optimal factorization (Definition 6.2.5.1).
(4) Every morphism of \(\mathcal{C}\) can be obtained as a composition of morphisms which belong to \(S\).

Remark 6.2.5.5. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(S\) be a class of short morphisms for \(\mathcal{C}\). Let \(f: X \rightarrow Y\) and \(g: X \rightarrow Y\) be morphisms of \(\mathcal{C}\) which are homotopic. If \(f\) belongs to \(S\), then \(g\) also belongs to \(S\). This follows by applying property (2) of Definition 6.2.5.4 to a 2-simplex

Notation 6.2.5.6. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(S\) be a class of short morphisms for 03XJ \(\mathcal{C}\). We let \(\mathcal{C}^{\text {short }} \subseteq \mathcal{C}\) denote the simplicial subset consisting of those simplices \(\sigma: \Delta^{n} \rightarrow \mathcal{C}\) having the following property:
(*) For every pair of integers \(0 \leq i \leq j \leq n\), the induced morphism \(\sigma(i) \rightarrow \sigma(j)\) belongs to \(S\).

Note that, since \(S\) contains all identity morphisms of \(\mathcal{C}\), condition (*) is automatically satisfied in the case \(i=j\). In particular, every vertex of \(\mathcal{C}\) is contained in \(\mathcal{C}^{\text {short }}\), and an edge of \(\mathcal{C}\) is contained in \(\mathcal{C}^{\text {short }}\) if and only if belongs to \(S\).

Remark 6.2.5.7. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(S\) be a class of short morphisms for \(\mathcal{C}\). 03XK Then a simplex \(\sigma: \Delta^{n} \rightarrow \mathcal{C}\) belongs to \(\mathcal{C}^{\text {short }}\) if and only if, for every integer \(0 \leq i<n\), the morphism \(\sigma(i) \rightarrow \sigma(n)\) belongs to \(S\). Condition (*) of Notation 6.2.5.6 can be deduced
from this a priori weaker assumption by applying assumption (2) of Definition 6.2.5.4 to the diagrams

for \(i \leq j \leq n\).
03XL Remark 6.2.5.8. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(S\) be a class of short morphisms of \(\mathcal{C}\). Then the simplicial set \(\mathcal{C}^{\text {short }}\) is never an \(\infty\)-category, except in the trivial situation where \(S\) is the class of all morphisms of \(\mathcal{C}\) (in which case we have \(\mathcal{C}^{\text {short }}=\mathcal{C}\) ). However, for every object \(Z \in \mathcal{C}\), the simplicial set \(\mathcal{C}_{/ Z}^{\text {short }}=\left(\mathcal{C}^{\text {short }}\right)_{/ Z}\) is an \(\infty\)-category, since it can be identified with the full subcategory of \(\mathcal{C}_{/ Z}\) spanned by those morphisms \(s: Y \rightarrow Z\) which belong to \(S\).

03XM Remark 6.2.5.9. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(S\) be a class of short morphisms of \(\mathcal{C}\), and let \(f: X \rightarrow Z\) be a morphism of \(\mathcal{C}\), which we identify with an object \(\widetilde{X}\) of the slice \(\infty\)-category \(\mathcal{C}_{/ Z}\). Then an \(S\)-optimal factorization of \(f\) can be viewed as a morphism \(\widetilde{X} \rightarrow \widetilde{Y}\) in \(\mathcal{C}_{/ Z}\) which exhibits \(\tilde{Y}\) as a \(\mathcal{C}_{/ Z}^{\text {short }}\)-reflection of \(\tilde{X}\), in the sense of Definition 6.2.2.1. Consequently, condition (3) of Definition 6.2.5.4 is equivalent to the requirement that the full subcategory \(\mathcal{C}_{/ Z}^{\text {short }} \subseteq \mathcal{C}_{/ Z}\) is reflective, for each object \(Z \in \mathcal{C}\).

We can now state our main result.
03XN Theorem 6.2.5.10. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(S\) be a class of short morphisms for \(\mathcal{C}\). Then the inclusion map \(\mathcal{C}^{\text {short }} \hookrightarrow \mathcal{C}\) is an inner anodyne morphism of simplicial sets.

03XP Example 6.2.5.11. Let \(G\) be a directed graph and let \(\mathcal{C}=\operatorname{Path}[G]\) denote its path category (Construction 1.3.7.1). Let \(S\) be the collection of morphisms of \(\mathcal{C}\) which are either identity morphisms or are indecomposable. Then \(S\) is a class of short morphisms for the \(\infty\)-category \(\mathrm{N} .(\mathcal{C})\) (the existence of \(S\)-optimal factorizations follows from Example 6.2.5.3, and the remaining requirements are immediate from the definitions). Moreover, the simplicial set \(\mathrm{N} .(\mathcal{C})^{\text {short }}\) can be identified with the directed graph \(G\) (regarded as a 1-dimensional simplicial set; see \begin{tabular}{|c|}
1.1 .6
\end{tabular} . Applying Theorem 6.2.5.10 in this case, we recover the statement that the inclusion map \(G \hookrightarrow \mathrm{~N}_{\bullet}(\mathcal{C})\) is inner anodyne (Proposition 1.5.7.3).

Our proof of Theorem 6.2.5.10 will require some auxiliary constructions.
03XQ Notation 6.2.5.12. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(S\) be a class of short morphisms for \(\mathcal{C}\), and let \(f: X \rightarrow Y\) be a morphism of \(\mathcal{C}\). We let \(\ell(f)\) denote the smallest integer \(n\) such that \(f\)
can be written as the composition of \(n\) morphisms of \(S\) : that is, there exists an \(n\)-simplex \(\sigma: \Delta^{n} \rightarrow \mathcal{C}\) which carries the spine Spine \([n]\) into \(\mathcal{C}^{\text {short }}\), for which the composition
\[
\Delta^{1} \rightarrow \mathrm{~N}_{\bullet}(\{0, n\}) \hookrightarrow \Delta^{n} \xrightarrow{\sigma} \mathcal{C}
\]
coincides with \(f\). Note that condition (4) of Definition 6.2.5.4 guarantees that \(\ell(f)<\infty\). We will refer to \(\ell(f)\) as the \(S\)-length of \(f\). Note that \(\ell(f)=0\) if and only if \(f\) is an identity morphism of \(\mathcal{C}\), and \(\ell(f) \leq 1\) if and only if \(f\) belongs to \(S\).

Lemma 6.2.5.13. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(S\) be a class of short morphisms of \(\mathcal{C}\), and 03XR suppose we are given a 2-simplex

of \(\mathcal{C}\), where \(s\) belongs to \(S\). Then:
(a) If \(\ell(f) \geq 1\), then \(\ell(g) \leq \ell(f)\).
(b) If \(\ell(f) \geq 2\) and the factorization (6.3) is \(S\)-optimal, then \(\ell(g)=\ell(f)-1\).

Proof. We prove ( \(a\) ) and (b) by simultaneous induction on the length \(n=\ell(f)\). If \(n=1\), then assertion (a) follows from condition (2) of Definition 6.2.5.4 and assertion (b) is vacuous. We therefore assume that \(n \geq 2\). We first prove (b). Choose a factorization

where \(s^{\prime} \in S\) and \(\ell\left(g^{\prime}\right)=n-1\). If the factorization (6.3) is \(S\)-optimal, then we can choose a

3 -simplex

Condition (2) of Definition 6.2.5.4 guarantees that \(h\) belongs to \(S\). Our inductive hypothesis guarantees that the left half of the diagram satisfies assertion \((a)\); so that \(\ell(g) \leq \ell\left(g^{\prime}\right)=\) \(\ell(f)-1\). The reverse inequality follows immediately from the definition.

We now prove ( \(a\) ). Choose an \(S\)-optimal factorization

It follows from the preceding argument that \(\ell\left(g^{\prime \prime}\right)=n-1\). We then have a commutative diagram

and condition (2) of Definition 6.2.5.4 guarantees that \(j\) belongs to \(S\). We therefore obtain \(\ell(g) \leq \ell\left(g^{\prime \prime}\right)+\ell(j) \leq(n-1)+1=n\), as desired.

03XT Notation 6.2.5.14. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(S\) be a class of short morphisms of \(\mathcal{C}\). For every \(n\)-simplex \(\sigma\) of \(\mathcal{C}\), we let \(\operatorname{pr}(\sigma)\) denote the smallest nonnegative integer \(p\) such that, for \(p \leq q \leq n\), the morphism \(\sigma(q) \rightarrow \sigma(n)\) belongs to \(S\). We will refer to \(\operatorname{pr}(\sigma)\) as the priority of \(\sigma\). This definition has the following properties:
- The simplex \(\sigma\) has priority 0 if and only if it belongs to the simplicial subset \(\mathcal{C}^{\text {short }}\) of Notation 6.2.5.6 (see Remark 6.2.5.7).
- For each \(0 \leq i \leq n\), the face \(\tau=d_{i}^{n}(\sigma)\) satisfies \(\operatorname{pr}(\tau) \leq \operatorname{pr}(\sigma)\). The inequality is strict if \(i<\operatorname{pr}(\sigma)\), and equality holds if \(\operatorname{pr}(\sigma) \leq i<n\).
- For each \(0 \leq i \leq n\), the degenerate simplex \(\tau=s_{i}^{n}(\sigma)\) satisfies
\[
\operatorname{pr}(\tau)= \begin{cases}\operatorname{pr}(\sigma)+1 & \text { if } 0 \leq i<\operatorname{pr}(\sigma) \\ \operatorname{pr}(\sigma) & \text { if } \operatorname{pr}(\sigma) \leq i \leq n\end{cases}
\]

In the situation of Notation 6.2.5.14 suppose that \(\mathcal{C}\) is (the nerve of) an ordinary category. An \(n\)-simplex of \(\mathcal{C}\) can then be viewed as a diagram
\[
X_{0} \rightarrow X_{1} \rightarrow \cdots \rightarrow X_{n},
\]
whose transition maps we denote by \(f_{j, i}: X_{i} \rightarrow X_{j}\). If \(\sigma\) does not belong to \(\mathcal{C}^{\text {short }}\), then the priority of \(\sigma\) is the smallest integer \(p\) for which the morphism \(f_{n, p-1}: X_{p-1} \rightarrow X_{n}\) does not belong to \(S\). Then \(f_{n, p-1}\) admits an \(S\)-optimal factorization \(X_{p-1} \xrightarrow{g} Y \xrightarrow{s} X_{n}\). Since the morphism \(f_{n, p}: X_{p} \rightarrow X_{n}\) belongs to \(S\), there is a unique morphism \(h: Y \rightarrow X_{p}\) for which the diagram

is commutative. The diagram
\[
X_{0} \rightarrow \cdots \rightarrow X_{p-1} \xrightarrow{g} Y \xrightarrow{h} X_{p} \rightarrow \cdots \rightarrow X_{n}
\]
then determines an \((n+1)\)-simplex \(\sigma^{+}\)of \(\mathcal{C}\) having priority \(p\), which satisfies \(d_{p}^{n+1}\left(\sigma^{+}\right)=\sigma\). To prove Theorem 6.2.5.10 we will extend the construction \(\sigma \mapsto \sigma^{+}\)to the case where \(\mathcal{C}\) is an \(\infty\)-category.

Lemma 6.2.5.15. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(S\) be a class of short morphisms of \(\mathcal{C}\).
```

03XU

``` Then there is a function which associates to each n-simplex \(\sigma\) of \(\mathcal{C}\) which does not belong to \(\mathcal{C}^{\text {short }}\) an \((n+1)\)-simplex \(\sigma^{+}\)of \(\mathcal{C}\), which has the following properties:
(1) The face operators satisfy
\[
d_{i}^{n+1}\left(\sigma^{+}\right)= \begin{cases}\sigma & \text { if } i=\operatorname{pr}(\sigma) \\ d_{i-1}^{n}(\sigma)^{+} & \text {if } \operatorname{pr}(\sigma)<i \leq n\end{cases}
\]
(2) Let \(\sigma=s_{j}^{n-1}(\tau)\) be a degenerate \(n\)-simplex of \(\mathcal{C}\). Then
\[
\sigma^{+}= \begin{cases}s_{j}^{n}\left(\tau^{+}\right) & \text {if } 0 \leq j<\operatorname{pr}(\tau) \\ s_{j+1}^{n}\left(\tau^{+}\right) & \text {if } \operatorname{pr}(\tau) \leq j<n\end{cases}
\]
(3) If \(\sigma=\tau^{+}\)for some \((n-1)\)-simplex \(\tau\) of \(\mathcal{C}\) having priority \(p>0\), then \(\sigma^{+}=s_{p}^{n}(\sigma)\).
(4) If \(\operatorname{pr}(\sigma)=n\), then the 2-simplex
\[
\Delta^{2} \simeq \mathrm{~N}_{\bullet}(\{n-1<n<n+1\}) \hookrightarrow \Delta^{n+1} \xrightarrow{\sigma^{+}} \mathcal{C}
\]
is an \(S\)-optimal factorization.
03XV Exercise 6.2.5.16. Prove Lemma 6.2.5.15 in the special case where \(\mathcal{C}\) is (the nerve of) an ordinary category.

We defer the (somewhat tedious) proof of Lemma 6.2.5.15 until the end of this section.
Proof of Theorem 6.2.5.10. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(S\) be a class of short morphisms for \(\mathcal{C}\). For every nonnegative integer \(p\), let \(\mathcal{C} \leq p\) denote the smallest simplicial subset of \(\mathcal{C}\) which contains all simplices of priority \(\leq p\) (so that a nondegenerate simplex of \(\mathcal{C}\) belongs to \(\mathcal{C} \leq p\) if and only if it has priority \(\leq p)\). Then \(\mathcal{C}\) is the colimit of the sequence of inclusion maps
\[
\mathcal{C}^{\text {short }}=\mathcal{C}^{\leq 0} \hookrightarrow \mathcal{C}^{\leq 1} \hookrightarrow \mathcal{C}^{\leq 2} \hookrightarrow \cdots
\]

We will complete the proof by showing that each of these inclusion maps is inner anodyne. For the remainder of the proof, we fix a positive integer \(p\); our goal is to show that the inclusion map \(\mathcal{C}{ }^{\leq p-1} \hookrightarrow \mathcal{C} \leq p\) is inner anodyne.

Choose a function \(\sigma \mapsto \sigma^{+}\)satisfying the requirements of Lemma 6.2.5.15. For each integer \(n \geq 0\), let \(\mathcal{C} \leq p(n)\) denote the simplicial subset of \(\mathcal{C} \leq p\) generated by \(\mathcal{C} \leq p-1\) together with all simplices of the form \(\sigma^{+}\), where \(\sigma\) is a simplex of \(\mathcal{C}\) having priority \(p\) and dimension \(\leq n\). By virtue of requirement (2) of Lemma 6.2.5.15, it suffices to allow \(\sigma\) to range over nondegenerate simplices which satisfy these conditions. Note that each \(\mathcal{C} \leq p(n)\) contains the \(n\)-skeleton of \(\mathcal{C}{ }^{\leq p}\), so that \(\mathcal{C} \leq p\) can be realized as the colimit of the sequence
\[
\mathcal{C}^{\leq p-1}=\mathcal{C}^{\leq p}(0) \hookrightarrow \mathcal{C}^{\leq p}(1) \hookrightarrow \mathcal{C}^{\leq p}(2) \hookrightarrow \mathcal{C}^{\leq p}(3) \hookrightarrow \cdots
\]

It will therefore suffice to show that each of these inclusions is inner anodyne. For the remainder of the proof, we fix an integer \(n>0\); our goal is to show that the inclusion map \(\mathcal{C}^{\leq p}(n-1) \hookrightarrow \mathcal{C}^{\leq p}(n)\) is inner anodyne.

Let \(\left\{\sigma_{t}\right\}_{t \in T}\) denote the collection of \(n\)-simplices of \(\mathcal{C}\) which have priority \(p\) but are not contained in \(\mathcal{C}^{\leq p}(n-1)\). We first claim that \(\mathcal{C}{ }^{\leq p}(n)\) is generated by \(\mathcal{C} \leq p(n-1)\) together with the collection of \((n+1)\)-simplices \(\left\{\sigma_{t}^{+}\right\}_{t \in T}\). To prove this, it suffices to show that if \(\sigma\) is an \(n\)-simplex of \(\mathcal{C}\) which belongs to \(\mathcal{C}^{\leq p}(n-1)\), then \(\sigma^{+}\)also belongs to \(\mathcal{C}^{\leq p}(n-1)\). If \(\sigma\) is degenerate, then we can write \(\sigma^{+}=s_{i}^{n}\left(\sigma_{0}^{+}\right)\)when \(\sigma_{0}\) is an \((n-1)\)-simplex of \(\mathcal{C}\) having priority \(\leq p\) (Lemma 6.2.5.15), and the desired conclusion follows from the observation that \(\sigma_{0}^{+}\)is contained in \(\mathcal{C}^{\leq p}(n-1)\). We may therefore assume that \(\sigma\) is a nondegenerate \(n\)-simplex of \(\mathcal{C}\). If \(\sigma\) has priority \(<p\), then \(\sigma^{+}\)also has priority \(<p\) and is therefore contained in \(\mathcal{C}^{\leq p-1}\). We may therefore assume that \(\sigma\) has priority \(p\), and must therefore be of the form \(\tau^{+}\)where \(\tau\) is an \((n-1)\)-simplex of \(\mathcal{C}\) having priority \(p\). Condition (3) of Lemma 6.2.5.15 then guarantees that \(\sigma^{+}\)can be obtained from \(\sigma\) by applying a degeneracy operator, and is therefore contained in \(\mathcal{C}^{\leq p}(n-1)\) as desired.

For each \(t \in T\), we define the complexity of \(t\) to be the integer \(c(t)=\sum_{q=p}^{n} \ell\left(\sigma_{t}(p-1) \rightarrow\right.\) \(\left.\sigma_{t}(q)\right)\). Using Proposition 4.7.1.35, we can choose a well-ordering on \(T\) for which the complexity function
\[
c: T \rightarrow \mathbf{Z}_{\geq 0} \quad t \mapsto c(t)
\]
is nondecreasing. For each \(t \in T\), let \(\mathcal{C} \leq t(n)\) denote the simplicial subset of \(\mathcal{C} \leq p(n)\) generated by \(\mathcal{C}^{\leq p}(n-1)\) together with the simplices \(\sigma_{s}^{+}\)for \(s \leq t\), and define \(\mathcal{C}_{<t}^{\leq p}(n)\) similarly. Then the inclusion map \(\mathcal{C}^{\leq p}(n-1) \hookrightarrow \mathcal{C}^{\leq p}(n)\) can be realized as a transfinite composition of inclusion maps \(\left\{\mathcal{C}_{<t}^{\leq p}(n) \hookrightarrow \mathcal{C}_{\leq t}^{\leq p}(n)\right\}_{t \in T}\). It will therefore suffice to show that each of these inclusion maps is inner anodyne.

Fix an element \(t \in T\) and let \(L_{t} \subseteq \Delta^{n+1}\) be the inverse image of \(\mathcal{C}{ }_{<t}^{\leq p}(n)\) under the map \(\sigma_{t}^{+}: \Delta^{n+1} \rightarrow \mathcal{C}\), so that we have a pullback diagram of simplicial sets

03XW

We will complete the proof by showing that \(L_{t}\) coincides with the inner horn \(\Lambda_{p}^{n+1} \subseteq \Delta^{n+1}\), so that the diagram (6.4) is also a pushout square (Lemma 3.1.2.11). This is equivalent to the following more concrete assertion:
\(\left(*_{t}\right)\) For \(0 \leq i \leq n+1\), the \(n\)-simplex \(d_{i}^{n+1}\left(\sigma_{t}^{+}\right)\)belongs to \(\mathcal{C}_{<t}^{\leq p}(n)\) if and only if \(i \neq p\).
Our proof proceeds by induction on \(t\). We consider several cases:
- For \(0 \leq i<p\), the \(n\)-simplex \(d_{i}^{n+1}\left(\sigma_{t}^{+}\right)\)has priority \(<p\), and is therefore contained in \(\mathcal{C}^{<p} \subseteq \mathcal{C}^{\leq p}(n-1) \subseteq \mathcal{C}_{<t}^{\leq p}(n)\).
- For \(i=p\), the \(n\)-simplex \(d_{i}^{n+1}\left(\sigma_{t}^{+}\right)\)coincides with \(\sigma_{t}\) (Lemma 6.2.5.15), which is not contained in \(\mathcal{C}^{\leq p}(n-1)\). Consequently, if \(\sigma_{t}\) is contained in \(\mathcal{C}_{<t}^{\leq p}(n-1)\), then there exists some \(t^{\prime}<t\) such that \(\sigma_{t}\) is contained in \(\mathcal{C}_{\leq t^{\prime}}^{\leq p}(n-1)\) but not in \(\mathcal{C}_{<t^{\prime}}^{\leq p}(n-1)\). Applying our inductive hypothesis, we deduce that \(\sigma_{t}=\sigma_{t^{\prime}}\), which contradicts the inequality \(t^{\prime}<t\).
- For \(p<i \leq n\), condition (1) of Lemma 6.2.5.15 implies that \(d_{i}^{n+1}\left(\sigma_{t}^{+}\right)\)coincides with \(d_{i-1}^{n}\left(\sigma_{t}\right)^{+}\), and therefore belongs to \(\mathcal{C}^{\leq p}(n-1) \subseteq \mathcal{C}_{<t}^{\leq p}(n)\).
- Suppose that \(i=n+1\) and set \(\tau=d_{i}^{n+1}\left(\sigma_{t}^{+}\right)\); we wish to show that \(\tau\) is contained in \(\mathcal{C}<t(n)\). Note that \(\tau\) has priority \(\leq p\). If \(\tau\) is contained in \(\mathcal{C}{ }^{\leq p}(n-1)\), there is nothing to prove. We may therefore assume without loss of generality that \(\tau\) is contained in \(T\) : that is, we have \(\tau=\sigma_{t^{\prime}}\) for some \(t^{\prime} \in T\). Set \(X=\sigma_{t}(p-1)=\sigma_{t^{\prime}}(p-1)\). For \(p \leq q \leq n\), let \(f_{q}: X \rightarrow \sigma_{t}(q)\) be the morphism determined by \(\sigma_{t}\), and define \(f_{q}^{\prime}: X \rightarrow \sigma_{t^{\prime}}(q)\) similarly. By construction, the morphism \(f_{q}\) coincides with \(f_{q+1}^{\prime}\) for \(p \leq q<n\). Moreover, the restriction of \(\sigma_{t}^{+}\)to the 2-simplex \(\mathrm{N}_{\bullet}(\{p-1<p<n+1\}\) determines a diagram

which is an \(S\)-optimal factorization of \(f_{n}\), so that \(\ell\left(f_{p}^{\prime}\right)=\ell\left(f_{n}\right)-1\) by virtue of Lemma 6.2.5.13. It follows that the complexity \(c\left(\sigma_{t^{\prime}}\right)\) is given by
\[
\begin{aligned}
c\left(\sigma_{t^{\prime}}\right) & =\sum_{q=p}^{n} \ell\left(f_{q}^{\prime}\right) \\
& =\ell\left(f_{p}^{\prime}\right)+\sum_{q=p+1}^{n} \ell\left(f_{q}^{\prime}\right) \\
& =\ell\left(f_{n}\right)-1+\sum_{q=p}^{n-1} \ell\left(f_{q}\right) \\
& =\left(\sum_{q=p}^{n} \ell\left(f_{q}\right)\right)-1 \\
& =c\left(\sigma_{t}\right)-1 .
\end{aligned}
\]

We therefore have \(t^{\prime}<t\), so that \(\tau=\sigma_{t^{\prime}}=d_{p}^{n+1}\left(\sigma_{t^{\prime}}^{+}\right)\)is contained in \(\mathcal{C}_{\leq t^{\prime}}^{\leq p}(n) \subseteq \mathcal{C}_{<t}^{\leq p}(n)\).

Proof of Lemma 6.2.5.15. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(S\) be a class of short morphisms for \(\mathcal{C}\). Our construction proceeds by recursion. Fix an integer \(n \geq 0\). Assume that we have constructed a function \(\tau \mapsto \tau^{+}\)on simplices of \(\mathcal{C}\) having dimension \(<n\) and priority \(>0\), satisfying conditions (1) through (4) of Lemma 6.2.5.15. Let \(\sigma\) be an \(n\)-simplex of \(\mathcal{C}\) having priority \(>0\); we wish to show that there is an ( \(n+1\) )-simplex \(\sigma^{+}\)which also satisfies conditions (1) through (4). Let us say that \(\sigma\) of \(\mathcal{C}\) is free if it is not of the form \(\tau^{+}\), where \(\tau\) is an \((n-1)\)-simplex of priority \(>0\). We divide the construction into three cases:
(a) The \(n\)-simplex \(\sigma\) is not free.
(b) The \(n\)-simplex \(\sigma\) is free and degenerate.
(c) The \(n\)-simplex \(\sigma\) is free and nondegenerate.

We begin with case (a). Assume that \(\sigma=\tau^{+}\), where \(\tau\) is an \((n-1)\)-simplex of \(\mathcal{C}\) having priority \(p>0\). It follows from our inductive hypothesis that \(\sigma\) has the same priority \(p\), and that \(\tau=d_{p}^{n}(\sigma)\). In particular, \(\tau\) is uniquely determined by \(\sigma\). In this case, we define \(\sigma^{+}=s_{p}^{n}(\sigma)\), so that condition (3) is satisfied by construction. Since \(p \leq n-1<n\), condition \((4)\) is vacuous. Note that the faces \(d_{p}^{n+1}\left(\sigma^{+}\right)\)and \(d_{p+1}^{n+1}\left(\sigma^{+}\right)\)coincide with \(\sigma=\tau^{+}=d_{p}^{n}(\sigma)^{+}\), so that condition (1) is satisfied for \(i=p\) and \(i=p+1\). For \(p+1<i \leq n\), we compute
\[
\begin{aligned}
d_{i}^{n+1}\left(\sigma^{+}\right) & =d_{i}^{n+1}\left(s_{p}^{n}\left(\tau^{+}\right)\right) \\
& =s_{p}^{n-1}\left(d_{i-1}^{n}\left(\tau^{+}\right)\right) \\
& =s_{p}^{n-1}\left(d_{i-2}^{n-1}(\tau)^{+}\right) \\
& =\left(d_{i-2}^{n-1}(\tau)^{+}\right)^{+} \\
& =d_{i-1}^{n}\left(\tau^{+}\right)^{+} \\
& =d_{i-1}^{n}(\sigma)^{+} .
\end{aligned}
\]

It remains to verify condition (2). Suppose that \(\sigma=s_{j}^{n-1}\left(\sigma^{\prime}\right)\) for some ( \(n-1\) )-simplex \(\sigma^{\prime}\) of \(\mathcal{C}\). Note that, since \(\sigma\) has priority \(p\), we must have \(j \neq p-1\) (see Notation 6.2.5.14). We first consider the case \(j<p-1\), so that \(\sigma^{\prime}\) has priority \(p-1\). In this case, we wish to show that \(\sigma^{+}=s_{j}^{n}\left(\sigma^{\prime+}\right)\). Set \(\tau^{\prime}=d_{p-1}^{n-1}\left(\sigma^{\prime}\right)\). We then have
\[
\tau=d_{p}^{n}(\sigma)=d_{p}^{n}\left(s_{j}^{n-1}\left(\sigma^{\prime}\right)\right)=s_{j}^{n-2}\left(d_{p-1}^{n-1}\left(\sigma^{\prime}\right)\right)=s_{j}^{n-2}\left(\tau^{\prime}\right),
\]
so that \(\sigma=\tau^{+}=s_{j}^{n-1}\left(\tau^{\prime+}\right)\). Applying the face operator \(d_{j}^{n}\), we obtain \(\sigma^{\prime}=\tau^{\prime+}\), so that \(\sigma^{\prime+}=s_{p-1}^{n-1}\left(\sigma^{\prime}\right)\). The desired result now follows from the calculation
\[
\sigma^{+}=s_{p}^{n}(\sigma)=s_{p}^{n}\left(s_{j}^{n-1}\left(\sigma^{\prime}\right)\right)=s_{j}^{n}\left(s_{p-1}^{n-1}\left(\sigma^{\prime}\right)\right)=s_{j}^{n}\left(\sigma^{\prime+}\right) .
\]

We now treat the case \(j \geq p\), so that \(\sigma^{\prime}\) has priority \(p\). In this case, we wish to show that \(\sigma^{+}=s_{j+1}^{n}\left(\sigma^{++}\right)\). If \(j=p\), this follows from the calculation
\[
\begin{aligned}
\sigma^{+} & =s_{p}^{n}(\sigma) \\
& =s_{p}^{n}\left(s_{p}^{n-1}\left(\sigma^{\prime}\right)\right) \\
& =s_{p+1}^{n}\left(s_{p}^{n-1}\left(\sigma^{\prime}\right)\right) \\
& =s_{p+1}^{n}(\sigma) \\
& =s_{p+1}^{n}\left(\tau^{+}\right) .
\end{aligned}
\]

Let us therefore assume that \(j>p\), and set \(\tau^{\prime}=d_{p}^{n-1}\left(\sigma^{\prime}\right)\). We then have
\[
\tau=d_{p}^{n}(\sigma)=d_{p}^{n}\left(s_{j}^{n-1}\left(\sigma^{\prime}\right)\right)=s_{j-1}^{n-2}\left(d_{p}^{n-1}\left(\sigma^{\prime}\right)\right)=s_{j-1}^{n-2}\left(\tau^{\prime}\right),
\]
so that \(\sigma=\tau^{+}=s_{j}^{n-1}\left(\tau^{\prime+}\right)\). Applying the face operator \(d_{j}^{n}\), we deduce that \(\sigma^{\prime}=\tau^{\prime+}\), so that \(\sigma^{\prime+}=s_{p}^{n-1}\left(\sigma^{\prime}\right)\). The desired result now follows from the calculation
\[
\sigma^{+}=s_{p}^{n}(\sigma)=s_{p}^{n}\left(s_{j}^{n-1}\left(\sigma^{\prime}\right)\right)=s_{j+1}^{n}\left(s_{p}^{n-1}\left(\sigma^{\prime}\right)\right)=s_{j+1}^{n}\left(\sigma^{\prime+}\right) .
\]

This completes our treatment of case (a).
We now consider case (b). Assume that \(\sigma\) is a free simplex of \(\mathcal{C}\) of the form \(s_{j}^{n-1}(\tau)\). Choose \(j\) as small as possible and let \(p\) be the priority of \(\tau\). We first treat the case where \(j<p\), so that \(\sigma\) has priority \(p+1\) (see Notation 6.2.5.14). In this case, we define \(\sigma^{+}=s_{j}^{n}\left(\tau^{+}\right)\), so that
\[
d_{p+1}^{n+1}\left(\sigma^{+}\right)=d_{p+1}^{n+1}\left(s_{j}^{n}\left(\tau^{+}\right)\right)=s_{j}^{n-1}\left(d_{p}^{n}\left(\tau^{+}\right)\right)=s_{j}^{n-1}(\tau)=\sigma .
\]

For \(p+1<i \leq n\), a similar calculation gives
\[
\begin{aligned}
d_{i}^{n+1}\left(\sigma^{+}\right) & =d_{i}^{n+1}\left(s_{j}^{n}\left(\tau^{+}\right)\right) \\
& =s_{j}^{n-1}\left(d_{i-1}^{n}\left(\tau^{+}\right)\right) \\
& =s_{j}^{n-1}\left(d_{i-2}^{n-1}(\tau)^{+}\right) \\
& =s_{j}^{n-1}\left(d_{i-2}^{n-1}(\tau)\right)^{+} \\
& =d_{i-1}^{n}\left(s_{j}^{n-1}(\tau)\right)^{+} \\
& =d_{i-1}^{n}(\sigma)^{+},
\end{aligned}
\]
which proves (1).
To verify (2), suppose that \(\sigma=s_{j^{\prime}}^{n-1}\left(\tau^{\prime}\right)\), for some \((n-1)\)-simplex \(\tau^{\prime}\) of \(\mathcal{C}\). Note that we must have \(j^{\prime} \geq j\). Since \(\sigma\) has priority \(p+1\), we also have \(j^{\prime} \neq p\). Assume first that \(j^{\prime}<p\), so that \(\tau^{\prime}\) has priority \(p\). In this case, we wish to show that \(\sigma^{+}=s_{j^{\prime}}^{n}\left(\tau^{\prime+}\right)\). If \(j^{\prime}=j\), this is immediate. We may therefore assume that \(j^{\prime}>j\), so that we can write \(\tau^{\prime}=s_{j}^{n-2}\left(\tau^{\prime \prime}\right)\)
and \(\tau=s_{j^{\prime}-1}^{n-2}\left(\tau^{\prime \prime}\right)\) for some unique ( \(n-2\) )-simplex \(\tau^{\prime \prime}\) of \(\mathcal{C}\). In this case, the desired result follows from the calculation
\[
\begin{aligned}
\sigma^{+} & =s_{j}^{n}\left(\tau^{+}\right) \\
& =s_{j}^{n}\left(s_{j^{\prime}-1}^{n-2}\left(\tau^{\prime \prime}\right)^{+}\right) \\
& =s_{j}^{n}\left(s_{j^{\prime}-1}^{n-1}\left(\tau^{\prime \prime+}\right)\right) \\
& =s_{j^{\prime}}^{n} s_{j}^{n-1}\left(\tau^{\prime \prime+}\right) \\
& =s_{j^{\prime}}^{n}\left(s_{j}^{n-2}\left(\tau^{\prime \prime}\right)^{+}\right) \\
& =s_{j^{\prime}}^{n}\left(\tau^{\prime+}\right) .
\end{aligned}
\]

If \(j^{\prime}>p\), then \(\tau^{\prime}\) instead has priority \(p+1\), and the desired result follows instead from the calculation
\[
\begin{aligned}
\sigma^{+} & =s_{j}^{n}\left(\tau^{+}\right) \\
& =s_{j}^{n}\left(s_{j^{\prime}-1}^{n-2}\left(\tau^{\prime \prime}\right)^{+}\right) \\
& =s_{j}^{n}\left(s_{j^{\prime}}^{n-1}\left(\tau^{\prime \prime+}\right)\right) \\
& =s_{j^{\prime}+1}^{n} s_{j}^{n-1}\left(\tau^{\prime \prime+}\right) \\
& =s_{j^{\prime}+1}^{n}\left(s_{j}^{n-2}\left(\tau^{\prime \prime}\right)^{+}\right) \\
& =s_{j^{\prime}+1}^{n}\left(\tau^{\prime+}\right) .
\end{aligned}
\]

Condition (3) is vacuous (since we have assumed that \(\sigma\) is free). To prove (4), we note that if \(\sigma\) has priority \(n\), then \(\tau\) has priority \((n-1)\); the desired result now follows from the observation that the restriction of \(\sigma^{+}\)to \(\mathrm{N}_{\bullet}(\{n-1<n<n+1\})\) coincides with the restriction of \(\tau^{+}\)to \(\mathrm{N}_{\bullet}(\{n-2<n-1<n\})\), and is therefore an \(S\)-optimal factorization. This completes the construction in the case \(j<p\).

We now treat the case \(j \geq p\), so that the simplex \(\sigma=s_{j}^{n-1}(\tau)\) has priority \(p\). In this case, we set \(\sigma^{+}=s_{j+1}^{n}\left(\tau^{+}\right)\). Condition (3) again vacuous (since \(\sigma\) is assumed to be free), and condition (4) is vacuous since \(p<n\). We next prove (1). Note that we have
\[
d_{p}^{n+1}\left(\sigma^{+}\right)=d_{p}^{n+1}\left(s_{j+1}^{n}\left(\tau^{+}\right)\right)=s_{j}^{n-1}\left(d_{p}^{n}\left(\tau^{+}\right)\right)=s_{j}^{n-1}(\tau)=\sigma .
\]

To complete the proof of (1), we must show that \(d_{i}^{n+1}\left(\sigma^{+}\right)=d_{i-1}^{n}(\sigma)^{+}\)for \(p<i \leq n\). For \(i \leq j\), this follows from the calculation
\[
\begin{aligned}
d_{i}^{n+1}\left(\sigma^{+}\right) & =d_{i}^{n+1}\left(s_{j+1}^{n}\left(\tau^{+}\right)\right) \\
& =s_{j}^{n-1}\left(d_{i}^{n}\left(\tau^{+}\right)\right) \\
& =s_{j}^{n-1}\left(d_{i-1}^{n-1}(\tau)^{+}\right) \\
& =s_{j-1}^{n-2}\left(d_{i-1}^{n-1}(\tau)\right)^{+} \\
& =d_{i-1}^{n}\left(s_{j}^{n-1}(\tau)\right)^{+} \\
& =d_{i-1}^{n}(\sigma)^{+} .
\end{aligned}
\]

For \(j+2<i \leq n\), it follows instead from the calculation
\[
\begin{aligned}
d_{i}^{n+1}\left(\sigma^{+}\right) & =d_{i}^{n+1}\left(s_{j+1}^{n}\left(\tau^{+}\right)\right) \\
& =s_{j+1}^{n-1}\left(d_{i-1}^{n}\left(\tau^{+}\right)\right) \\
& =s_{j+1}^{n-1}\left(d_{i-2}^{n-1}(\tau)^{+}\right) \\
& =s_{j}^{n-2}\left(d_{i-2}^{n-1}(\tau)\right)^{+} \\
& =d_{i-1}^{n}\left(s_{j}^{n-1}(\tau)\right)^{+} \\
& =d_{i-1}^{n}(\sigma)^{+} .
\end{aligned}
\]

It will therefore suffice to treat the case \(i \in\{j+1, j+2\}\), in which case we have
\[
\begin{aligned}
d_{i}^{n+1}\left(\sigma^{+}\right) & =d_{i}^{n+1}\left(s_{j+1}^{n}\left(\tau^{+}\right)\right) \\
& =\tau^{+} \\
& =d_{i-1}^{n}\left(s_{j}^{n-1}(\tau)\right)^{+} \\
& =d_{i-1}^{n}(\sigma)^{+} .
\end{aligned}
\]

To verify condition (2), suppose that \(\sigma=s_{j^{\prime}}^{n-1}\left(\tau^{\prime}\right)\). By construction, we then have \(j^{\prime} \geq j \geq p\), so that the simplex \(\tau^{\prime}\) has priority \(p\). We wish to show that \(\sigma^{+}=s_{j^{\prime}+1}^{n}\left(\tau^{\prime+}\right)\). If \(j^{\prime}=j\), this is immediate. We may therefore assume that \(j^{\prime}>j\), so that we can write \(\tau^{\prime}=s_{j}^{n-2}\left(\tau^{\prime \prime}\right)\) and \(\tau=s_{j^{\prime}-1}^{n-2}\left(\tau^{\prime \prime}\right)\) as above. In this case, the desired result follows from the calculation
\[
\begin{aligned}
\sigma^{+} & =s_{j+1}^{n}\left(\tau^{+}\right) \\
& =s_{j+1}^{n}\left(s_{j^{\prime}-1}^{n-2}\left(\tau^{\prime \prime}\right)^{+}\right) \\
& =s_{j+1}^{n}\left(s_{j^{\prime}}^{n-1}\left(\tau^{\prime \prime+}\right)\right) \\
& =s_{j^{\prime}+1}^{n} s_{j+1}^{n-1}\left(\tau^{\prime \prime+}\right) \\
& =s_{j^{\prime}+1}^{n}\left(s_{j}^{n-2}\left(\tau^{\prime \prime}\right)^{+}\right) \\
& =s_{j^{\prime}+1}^{n}\left(\tau^{\prime+}\right)
\end{aligned}
\]

This completes the treatment of case (b).
We now consider case (c). For the remainder of the proof, we assume that the simplex \(\sigma\) is free and nondegenerate, of priority \(p>0\). Let us decompose \(\Delta^{n+1}\) as a join \(\Delta^{p-1} \star \Delta^{n-p} \star\{z\}\). In what follows, we write \(x\) for the final vertex of \(\Delta^{p-1}\) (corresponding to the element \(p-1 \in[n+1]\) ) and \(y\) for the initial vertex of \(\Delta^{n-p}\) (corresponding to the element \(p \in[n+1]\) ). Note that the \(n\)-simplices \(\sigma\) and \(\left\{d_{i}^{n+1}(\sigma)^{+}\right\}_{p \leq i<n}\) determine a morphism of simplicial sets \(\sigma^{\dagger}: \Delta^{p-1} \star \partial \Delta^{n-p} \star\{z\} \rightarrow \mathcal{C}\). Unwinding the definitions, we see that an \((n+1)\)-simplex \(\sigma^{+}\)of \(\mathcal{C}\) satisfying condition (1) can be identified with an extension of \(\sigma^{\dagger}\) to the join \(\Delta^{p-1} \star \Delta^{n-p} \star\{z\} \simeq \Delta^{n+1}\). We wish to show that such an extension can always be found,
which additionally satisfies condition (4) in the case \(p=n\) (note that conditions (2) and (3) are vacuous, by virtue of our assumption that \(\sigma\) is free and nondegenerate).

Let \(\bar{\sigma}^{\dagger}\) denote the restriction of \(\sigma^{\dagger}\) to \(\{x\} \star \partial \Delta^{n-p} \star\{z\}\). Since the inclusion \(\{x\} \hookrightarrow \Delta^{p-1}\) is right anodyne (Example 4.3.7.11), it will suffice to show that \(\bar{\sigma}^{\dagger}\) can be extended to an \((n+2-p)\)-simplex \(\bar{\sigma}^{+}\)of \(\mathcal{C}\), having the additional property that \(\bar{\sigma}^{+}\)is an \(S\)-optimal factorization in the case \(p=n\). If \(p=n\), the existence of \(\bar{\sigma}^{+}\)follows from our assumption that \(S\) is a class of short morphisms for \(\mathcal{C}\). We therefore assume that \(p<n\). Set \(Z=\sigma^{\dagger}(z)\), so that we can identify \(\bar{\sigma}^{\dagger}\) with a morphism of simplicial sets \(\rho_{0}: \Lambda_{0}^{n+1-p} \rightarrow \mathcal{C}_{/ Z}\); we wish to extend \(\rho_{0}\) to an \((n+1-p)\)-simplex of \(\mathcal{C}_{/ Z}\). For \(0<i \leq n+1-p\), the image \(\rho_{0}(i)\) belongs to the full subcategory \(\mathcal{C}_{/ Z}^{\text {short }} \subseteq \mathcal{C}_{/ Z}\). By virtue of Proposition 6.2.2.8. it will suffice to show that the restriction of \(\rho_{0}\) to \(\Delta^{1}\) exhibits \(\rho_{0}(1)\) as a \(\mathcal{C}_{/ Z}^{\text {short }}\)-reflection of \(\rho_{0}(0)\). This is equivalent to the assertion that the 2 -simplex

is an \(S\)-optimal factorization of the lower horizontal morphism (Remark 6.2.5.9), which follows from our inductive hypothesis.

\subsection*{6.3 Localization}

Let \(\mathcal{C}\) be a category and let \(W\) be a collection of morphisms in \(\mathcal{C}\). One can then construct a new category by formally adjoining an inverse to each morphism of \(W\).

Definition 6.3.0.1. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between categories and let \(W\) be a 01M5 collection of morphisms of \(\mathcal{C}\). We say that \(F\) exhibits \(\mathcal{D}\) as a strict localization of \(\mathcal{C}\) with respect to \(W\) if, for every category \(\mathcal{E}\), precomposition with \(F\) induces a bijection

\(\{\) Functors \(\mathcal{C} \rightarrow \mathcal{E}\) carrying each \(w \in W\) to an isomorphism in \(\mathcal{E}\}\).
Remark 6.3.0.2 (Existence and Uniqueness). Let \(\mathcal{C}\) be a category and let \(W\) be a collection 01M6 of morphisms in \(\mathcal{C}\). Then there exists a category \(W^{-1} \mathcal{C}\) and a functor \(F: \mathcal{C} \rightarrow W^{-1} \mathcal{C}\) which exhibits \(W^{-1} \mathcal{C}\) as a strict localization of \(\mathcal{C}\) with respect to \(W\). Moreover, the category \(W^{-1} \mathcal{C}\) is determined uniquely up to isomorphism. In what follows, we will sometimes
abuse terminology by referring to \(W^{-1} \mathcal{C}\) as the strict localization of \(\mathcal{C}\) with respect to \(W\). Explicitly, the category \(W^{-1} \mathcal{C}\) can be constructed from \(\mathcal{C}\) by adjoining a new morphism \(w^{-1}: Y \rightarrow X\) for each morphism \(w: X \rightarrow Y\) of \(W\), and imposing the relations \(w^{-1} \circ w=\operatorname{id}_{X}\) and \(w \circ w^{-1}=\operatorname{id}_{Y}\). From this description, we see that the functor \(F\) induces a bijection \(\mathrm{Ob}(\mathcal{C}) \simeq \mathrm{Ob}\left(W^{-1} \mathcal{C}\right)\).

01Q2 Example 6.3.0.3. Let Kan denote the category of Kan complexes and let hKan denote the homotopy category of Kan complexes (Construction 3.1.5.10). Then the quotient functor Kan \(\rightarrow\) hKan exhibits hKan as a strict localization of Kan with respect to the collection of all homotopy equivalences (see Corollary 3.1.7.7).

01 M7 Warning 6.3.0.4. Let \(\mathcal{C}\) be a category and let \(W\) be a collection of morphisms of \(\mathcal{C}\). If \(\mathcal{C}\) is small, then the strict localization \(W^{-1} \mathcal{C}\) is also small. Beware that if \(\mathcal{C}\) is only assumed to be locally small (Variant 4.7.8.6), then \(W^{-1} \mathcal{C}\) need not be locally small. However, one can often ensure that \(W^{-1} \mathcal{C}\) is locally small by imposing additional assumptions on the collection of morphisms \(W\).

01M8 Remark 6.3.0.5. Let \(\mathcal{C}\) be a category, let \(W\) be a collection of morphisms of \(\mathcal{C}\), and let \(F: \mathcal{C} \rightarrow W^{-1} \mathcal{C}\) be a functor which exhibits \(W^{-1} \mathcal{C}\) as a strict localization of \(\mathcal{C}\) with respect to \(W\). Then, for every category \(\mathcal{E}\), the precomposition functor \(\operatorname{Fun}\left(W^{-1} \mathcal{C}, \mathcal{E}\right) \xrightarrow{\circ \circ} \operatorname{Fun}(\mathcal{C}, \mathcal{E})\) induces an isomorphism from \(\operatorname{Fun}\left(W^{-1} \mathcal{C}, \mathcal{E}\right)\) to the full subcategory of \(\operatorname{Fun}(\mathcal{C}, \mathcal{E})\) spanned by those functors \(\mathcal{C} \rightarrow \mathcal{E}\) which carry each element \(w \in W\) to an isomorphism in \(\mathcal{E}\). Bijectivity at the level of objects follows immediately from the definition. At the level of morphisms, it follows from the bijectivity of the map

Beware that Definition 6.3.0.1 is not invariant under equivalence. If \(\mathcal{C}\) is a category, \(W\) is a collection of morphisms in \(\mathcal{C}\), and \(\mathcal{D}\) is a category which is equivalent but not isomorphic to the strict localization \(W^{-1} \mathcal{C}\), then \(\mathcal{D}\) is not a strict localization of \(\mathcal{C}\) with respect to \(W\). We can remedy the situation by introducing a more liberal notion of localization.
\(01 \mathrm{M9}\) Definition 6.3.0.6. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between categories and let \(W\) be a collection of morphisms of \(\mathcal{C}\). We will say that \(F\) exhibits \(\mathcal{D}\) as a 1-categorical localization of \(\mathcal{C}\) with respect to \(W\) if, for every category \(\mathcal{E}\), precomposition with \(F\) induces a fully faithful functor \(\operatorname{Fun}(\mathcal{D}, \mathcal{E}) \xrightarrow{\circ F} \operatorname{Fun}(\mathcal{C}, \mathcal{E})\), whose essential image consists of those functors \(\mathcal{C} \rightarrow \mathcal{E}\) which carry each \(w \in W\) to an isomorphism in \(\mathcal{E}\).

Example 6.3.0.7. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor between categories. If \(F\) exhibits \(\mathcal{D}\) as a strict localization of \(\mathcal{C}\) with respect to \(W\), then \(F\) exhibits \(\mathcal{D}\) as a 1-categorical localization of \(\mathcal{C}\) with respect to \(W\) (see Remark 6.3.0.5). The converse is false (except in the trivial case where \(\mathcal{C}\) is empty).

Example 6.3.0.8. Let \(\operatorname{Set}_{\Delta}\) denote the category of simplicial sets, and let hKan denote the
01MA
-
\(\qquad\)

0 homotopy category of Kan complexes (Construction 3.1.5.10). Then the fibrant replacement functor \(\mathrm{Ex}^{\infty}: \operatorname{Set}_{\Delta} \rightarrow\) hKan exhibits hKan as a 1-categorical localization of \(\operatorname{Set}_{\Delta}\) with respect to the collection \(W\) of weak homotopy equivalences (see Variant 3.1.7.8. However, it does not exhibit hKan as a strict localization of \(\operatorname{Set}_{\Delta}\) with respect to \(W\) (since it is not bijective on objects).

Remark 6.3.0.9. Let \(\mathcal{C}\) be a category, let \(W\) be a collection of morphisms in \(\mathcal{C}\), and let \(F: \mathcal{C} \rightarrow W^{-1} \mathcal{C}\) be a functor which exhibits \(W^{-1} \mathcal{C}\) as a strict localization of \(\mathcal{C}\) with respect to \(W\). Let \(G: \mathcal{C} \rightarrow \mathcal{D}\) be another functor. Then \(G\) exhibits \(\mathcal{D}\) as a 1-categorical localization of \(\mathcal{C}\) with respect to \(W\) if and only if the following conditions are satisfied:
- The functor \(G\) carries each \(w \in W\) to an isomorphism in \(\mathcal{D}\), and therefore factors uniquely as a composition \(\mathcal{C} \xrightarrow{F} W^{-1} \mathcal{C} \xrightarrow{G^{\prime}} \mathcal{D}\).
- The functor \(G^{\prime}: W^{-1} \mathcal{C} \rightarrow \mathcal{D}\) is an equivalence of categories.

Our goal in this section is to adapt the notion of localization to the setting of \(\infty\) categories. We begin in \(\S 6.3 .1\) by introducing an \(\infty\)-categorical counterpart of Definition 6.3.0.6. Given an \(\infty\)-category \(\mathcal{C}\) and a collection \(W\) of morphisms of \(\mathcal{C}\), we say that a functor of \(\infty\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\) exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\) if, for every \(\infty\)-category \(\mathcal{E}\), precomposition with \(F\) induces a fully faithful functor of \(\infty\)-categories \(\operatorname{Fun}(\mathcal{D}, \mathcal{E}) \xrightarrow{\circ{ }_{\mathrm{F}}} \operatorname{Fun}(\mathcal{C}, \mathcal{E})\), whose essential image consists of those functors which carry each element of \(W\) to an isomorphism in \(\mathcal{E}\) (Definition 6.3.1.9). In 6.3 .2 , we show that such a localization always exists (Proposition 6.3.2.1) and is uniquely determined up to equivalence (Remark 6.3.2.2) ; we will often emphasize this uniqueness by denoting the \(\infty\)-category \(\mathcal{D}\) by \(\mathcal{C}\left[W^{-1}\right]\).

Let \(\mathcal{C}\) be an ordinary category, and let \(W\) be a collection of morphisms of \(\mathcal{C}\). Then \(W\) can also be regarded as a collection of morphisms of the \(\infty\)-category \(\mathrm{N}_{\bullet}(\mathcal{C})\). By virtue of Proposition 6.3.2.1, there exists a functor of \(\infty\)-categories \(F: \mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow \mathcal{D}\) which exhibits \(\mathcal{D}\) as a localization of \(\mathrm{N}_{\bullet}(\mathcal{C})\) with respect to \(W\). In this case, it is not hard to see that the induced map \(\mathcal{C} \simeq \mathrm{hN} 。(\mathcal{C}) \xrightarrow{\mathrm{h} F} \mathrm{~h} \mathrm{\mathcal{D}}\) exhibits the homotopy category \(\mathrm{h} \mathcal{D}\) as a 1-categorical localization of \(\mathcal{C}\) with respect to \(W\), in the sense of Definition 6.3.0.6 (Example 6.3.1.18). Beware that, in this situation, the unit map \(\mathcal{D} \rightarrow \mathrm{N}_{\bullet}(\mathrm{hD})\) is generally not an equivalence. In other words, the formation of localizations (in the \(\infty\)-categorical setting) generally does not carry ordinary categories to ordinary categories, even up to equivalence. In fact, we prove
in \(\{6.3 .7\) that every \(\infty\)-category \(\mathcal{D}\) can be obtained by localizing (the nerve of) a partially ordered set (Theorem 6.3.7.1). The proof will make use of some basic stability properties for the class of localizations, which we establish in \(\S 6.3 .4\).

In general, it is very difficult to give an explicit description of the localization of an \(\infty\)-category \(\mathcal{C}\) with respect to a class of morphisms \(W\). In \(\S 6.3 .3\), we study a special case in which such a description is available. We will say that a localization functor \(F: \mathcal{C} \rightarrow \mathcal{C}\left[W^{-1}\right]\) is reflective if it admits a right adjoint. In this case, the right adjoint \(G: \mathcal{C}\left[W^{-1}\right] \rightarrow \mathcal{C}\) is automatically fully faithful, and its essential image is a reflective subcategory \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) (Proposition 6.3.3.6). Reflective localizations are extremely common in practice, and will play a central role in the theory of locally presentable \(\infty\)-categories which we develop in \(\S[?]\).
01MC Warning 6.3.0.10. It also is possible to contemplate a version of Definition 6.3.0.1 in the \(\infty\)-categorical setting. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(W\) be a collection of morphisms of \(\mathcal{C}\). Let us say that a functor of \(\infty\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\) exhibits \(\mathcal{D}\) as a strict localization of \(\mathcal{C}\) with respect to \(W\) if, for every \(\infty\)-category \(\mathcal{E}\), precomposition with \(F\) induces a bijection
\[
\{\text { Functors } \mathcal{D} \rightarrow \mathcal{E}\}
\]
\(\{\) Functors \(\mathcal{C} \rightarrow \mathcal{E}\) carrying each \(w \in W\) to an isomorphism in \(\mathcal{E}\}\)
However, this definition is useless. One can show that an \(\infty\)-category \(\mathcal{C}\) admits a strict localization with respect to \(W\) only in the trivial case where every element of \(W\) is already an isomorphism in \(\mathcal{C}\) (in which case we can take \(F\) to be the identity functor id \({ }_{\mathcal{C}}: \mathcal{C} \rightarrow \mathcal{C}\) ). Roughly speaking, the problem is that if \(w: X \rightarrow Y\) is an isomorphism in an \(\infty\)-category \(\mathcal{C}\), then the homotopy inverse isomorphism \(w^{-1}: Y \rightarrow X\) is only well-defined up to homotopy (or up to a contractible space of choices), in contrast with classical category theory where the inverse isomorphism \(w^{-1}\) is unique.

\subsection*{6.3.1 Localizations of \(\infty\)-Categories}

01ME We begin by introducing some terminology.
01 MF Notation 6.3.1.1. Let \(\mathcal{C}\) be a simplicial set, let \(W\) be a collection of edges of \(\mathcal{C}\), and let \(\mathcal{E}\) be an \(\infty\)-category. We let \(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)\) denote the full subcategory of \(\operatorname{Fun}(\mathcal{C}, \mathcal{E})\) spanned by those morphisms \(F: \mathcal{C} \rightarrow \mathcal{E}\) that carry each edge of \(W\) to an isomorphism in \(\mathcal{E}\).

01MG Remark 6.3.1.2. In the context of Notation 6.3.1.1, we will usually be interested in the situation where the simplicial set \(\mathcal{C}\) is an \(\infty\)-category (as suggested by the notation). However, it will be technically convenient to allow more general simplicial sets as well.

Example 6.3.1.3. Let \(\mathcal{C}\) be a simplicial set and let \(W\) be a collection of degenerate edges 01MH of \(\mathcal{C}\). Then, for every \(\infty\)-category \(\mathcal{E}\), we have \(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)=\operatorname{Fun}(\mathcal{C}, \mathcal{E})\).

Example 6.3.1.4. Let \(\mathcal{C}\) be a simplicial set and let \(W\) be a collection of edges of \(\mathcal{C}\). If \(\mathcal{E}\) is 01MJ a Kan complex, then \(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)=\operatorname{Fun}(\mathcal{C}, \mathcal{E})(\) see Proposition 1.4.6.10].

Example 6.3.1.5. Let \(W=\left\{\operatorname{id}_{\Delta^{1}}\right\}\) consist of the single nondegenerate edge of the standard 1 -simplex \(\Delta^{1}\). For every \(\infty\)-category \(\mathcal{E}, \operatorname{Fun}\left(\Delta^{1}\left[W^{-1}\right], \mathcal{E}\right)\) is the full subcategory \(\operatorname{Isom}(\mathcal{E}) \subseteq\) \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{E}\right)\) spanned by the isomorphisms in \(\mathcal{E}\) (Example 4.4.1.14).

Example 6.3.1.6. Let \(\mathcal{C}\) be a simplicial set and let \(h \mathcal{C}\) denote its homotopy category 01MK (Definition 1.3.6.1). Let \(W\) be a collection of edges of \(\mathcal{C}\), let [ \(W\) ] denote the collection of morphisms in hC which belong to the image of \(W\), and let \(F: \mathrm{h} \mathcal{C} \rightarrow \mathcal{D}\) be a functor of ordinary categories which exhibits \(\mathcal{D}\) as a strict localization of \(h \mathcal{C}\) with respect to [ \(W\) ] (Definition 6.3.0.1). If \(\mathcal{E}\) is an ordinary category, then we have a canonical isomorphism of simplicial sets
\[
\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], N_{\bullet}(\mathcal{E})\right) \simeq \mathrm{N}_{\bullet}(\operatorname{Fun}(\mathcal{D}, \mathcal{E}))
\]

Remark 6.3.1.7. Let \(\mathcal{C}\) and \(\mathcal{D}\) be simplicial sets and let \(W\) be a collection of edges of \(\mathcal{C}\). For every \(\infty\)-category \(\mathcal{E}\), the canonical isomorphism \(\operatorname{Fun}(\mathcal{C}, \operatorname{Fun}(\mathcal{D}, \mathcal{E})) \simeq \operatorname{Fun}(\mathcal{D}, \operatorname{Fun}(\mathcal{C}, \mathcal{E}))\) restricts to an isomorphism of full subcategories
\[
\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \operatorname{Fun}(\mathcal{D}, \mathcal{E})\right) \simeq \operatorname{Fun}\left(\mathcal{D}, \operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)\right)
\]

This follows immediately from the criterion of Theorem 4.4.4.4.
Remark 6.3.1.8. Let \(\mathcal{C}\) be a simplicial set, let \(W\) be a collection of edges of \(\mathcal{C}\), and let
01MN \(\mathcal{E}\) be an \(\infty\)-category. Then the full subcategory \(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right) \subseteq \operatorname{Fun}(\mathcal{C}, \mathcal{E})\) is replete. That is, if \(F, F^{\prime}: \mathcal{C} \rightarrow \mathcal{E}\) are isomorphic objects of \(\operatorname{Fun}(\mathcal{C}, \mathcal{E})\), then \(F\) carries edges of \(W\) to isomorphisms in \(\mathcal{E}\) if and only if \(F^{\prime}\) carries edges of \(W\) to isomorphisms in \(\mathcal{E}\) (see Example 4.4.1.14.

Definition 6.3.1.9. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets and let \(W\) be a collection of edges of \(\mathcal{C}\). We say that \(F\) exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\) if, for every \(\infty\)-category \(\mathcal{E}\), the precomposition \(\operatorname{map} \operatorname{Fun}(\mathcal{D}, \mathcal{E}) \xrightarrow{\circ} \operatorname{Fun}(\mathcal{C}, \mathcal{E})\) is fully faithful, and its essential image is the full subcategory \(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right) \subseteq \operatorname{Fun}(\mathcal{C}, \mathcal{E})\).

Remark 6.3.1.10. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets. If \(F\) exhibits \(\mathcal{D}\) as a 01MQ localization of \(\mathcal{C}\) with respect to a collection of edges \(W\), then, for every \(\infty\)-category \(\mathcal{E}\) and every morphism \(G: \mathcal{D} \rightarrow \mathcal{E}\), the composite map \((G \circ F): \mathcal{C} \rightarrow \mathcal{E}\) carries each element of \(W\) to an isomorphism in \(\mathcal{E}\). In particular, if \(\mathcal{D}\) itself is an \(\infty\)-category, then \(F\) carries each element of \(W\) to an isomorphism in \(\mathcal{D}\).

02SW Exercise 6.3.1.11. Let \(\mathcal{C}\) be a simplicial set, let \(W\) be a collection of edges of \(\mathcal{C}\), and let \(F, F^{\prime}: \mathcal{C} \rightarrow \mathcal{D}\) be a pair of diagrams taking values in an \(\infty\)-category \(\mathcal{D}\). Suppose that \(F\) and \(F^{\prime}\) are isomorphic when viewed as objects of the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\). Show that \(F\) exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\) if and only if \(F^{\prime}\) exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\).

01 MR Example 6.3.1.12. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets and let \(W\) be a collection of degenerate edges of \(\mathcal{C}\). Then \(F\) exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\) if and only if it is a categorical equivalence of simplicial sets (see Proposition 4.5.3.8).

01MS Proposition 6.3.1.13. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets and let \(W\) be \(a\) collection of edges of \(\mathcal{C}\). The following conditions are equivalent:
(1) The morphism \(F\) exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\) (Definition 6.3.1.9).
(2) For every \(\infty\)-category \(\mathcal{E}\), the functor \(\operatorname{Fun}(\mathcal{D}, \mathcal{E}) \xrightarrow{\circ} \operatorname{Fun}(\mathcal{C}, \mathcal{E})\) factors through the full subcategory \(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)\) and induces an equivalence of \(\infty\)-categories \(\operatorname{Fun}(\mathcal{D}, \mathcal{E}) \rightarrow\) \(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)\).
(3) For every \(\infty\)-category \(\mathcal{E}\), the functor \(\operatorname{Fun}(\mathcal{D}, \mathcal{E}) \xrightarrow{\circ} \operatorname{Fun}(\mathcal{C}, \mathcal{E})\) factors through the full subcategory \(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)\) and induces a homotopy equivalence of Kan complexes \(\operatorname{Fun}(\mathcal{D}, \mathcal{E})^{\simeq} \rightarrow \operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)^{\simeq}\).
(4) For every \(\infty\)-category \(\mathcal{E}\), the functor \(\operatorname{Fun}(\mathcal{D}, \mathcal{E}) \xrightarrow{\circ} \operatorname{Fun}(\mathcal{C}, \mathcal{E})\) factors through the full subcategory \(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)\) and induces a bijection of sets \(\pi_{0}\left(\operatorname{Fun}(\mathcal{D}, \mathcal{E})^{\sim}\right) \rightarrow\) \(\pi_{0}\left(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)^{\simeq}\right)\).

Proof. The equivalence (1) \(\Leftrightarrow(2)\) follows from Corollary 4.6.2.22 (and the repleteness of the full subcategory \(\left.\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right) \subseteq \operatorname{Fun}(\mathcal{C}, \mathcal{E})\right)\). The implication \((2) \Rightarrow(3)\) follows from Remark 4.5.1.19 and the implication (3) \(\Rightarrow(4)\) from Remark 3.1.6.5. We will complete the proof by showing that \((4) \Rightarrow(2)\). Assume that \(F: \mathcal{C} \rightarrow \mathcal{D}\) satisfies condition (4), and let \(\mathcal{E}\) be an \(\infty\)-category; we wish to show that the precomposition functor \(\operatorname{Fun}(\mathcal{D}, \mathcal{E}) \xrightarrow{\circ F}\) \(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)\) is an equivalence of \(\infty\)-categories. For this, it will suffice to show that for every simplicial set \(\mathcal{B}\), the induced map
\[
\theta: \pi_{0}\left(\operatorname{Fun}(\mathcal{B}, \operatorname{Fun}(\mathcal{D}, \mathcal{E}))^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}\left(\mathcal{B}, \operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)\right)^{\simeq}\right)
\]
is a bijection. Using Remark 6.3.1.7, we can identify \(\theta\) with the map
\[
\pi_{0}\left(\operatorname{Fun}(\mathcal{D}, \operatorname{Fun}(\mathcal{B}, \mathcal{E}))^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \operatorname{Fun}(\mathcal{B}, \mathcal{E})\right)^{\simeq}\right),
\]
which is bijective by virtue of assumption (4).

Example 6.3.1.14. Let \(W=\left\{\operatorname{id}_{\Delta^{1}}\right\}\) consist of the single nondegenerate edge of the 01MT standard 1 -simplex \(\Delta^{1}\). Then the projection map \(\Delta^{1} \rightarrow \Delta^{0}\) exhibits \(\Delta^{0}\) as a localization of \(\Delta^{1}\) with respect to \(W\). To prove this, it will suffice to show that for every \(\infty\)-category \(\mathcal{E}\), the construction \(X \mapsto \operatorname{id}_{X}\) induces an equivalence of \(\infty\)-categories \(\mathcal{E}=\operatorname{Fun}\left(\Delta^{0}, \mathcal{E}\right) \rightarrow\) \(\operatorname{Fun}\left(\Delta^{1}\left[W^{-1}\right], \mathcal{E}\right)=\operatorname{Isom}(\mathcal{E})\), which follows from Corollary 4.5.3.13.
Remark 6.3.1.15. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets which exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to a collection of edges \(W\), and let \(U: \overline{\mathcal{E}} \rightarrow \mathcal{E}\) be an isofibration of \(\infty\)-categories. Then, for every diagram \(\mathcal{D} \rightarrow \mathcal{E}\), precomposition with \(F\) induces a fully faithful functor
\[
\operatorname{Fun}_{/ \mathcal{E}}(\mathcal{D}, \overline{\mathcal{E}}) \rightarrow \operatorname{Fun}_{/ \mathcal{E}}(\mathcal{C}, \overline{\mathcal{E}}),
\]
whose essential image is spanned by those functors \(G: \mathcal{C} \rightarrow \overline{\mathcal{E}}\) which carry each edge of \(W\) to an isomorphism in the \(\infty\)-category \(\overline{\mathcal{E}}\). This follows by applying Corollary 4.5.2.32 to the diagram

Remark 6.3.1.16. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets which exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to a collection of edges \(W\). Then, for every Kan complex \(\mathcal{E}\), precomposition with \(F\) induces a homotopy equivalence of Kan complexes
\[
\operatorname{Fun}(\mathcal{D}, \mathcal{E}) \xrightarrow{\circ F} \operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)=\operatorname{Fun}(\mathcal{C}, \mathcal{E})
\]
(see Example 6.3.1.4). It follows that \(F\) is a weak homotopy equivalence of simplicial sets.
Remark 6.3.1.17. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets which exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to a collection of edges \(W\). Let \([W]\) denote the collection of morphisms in the homotopy category hC which belong to the image of \(W\). Then the induced functor \(\mathrm{h} F: \mathrm{h} \mathrm{\mathcal{C}} \rightarrow \mathrm{~h} \mathrm{\mathcal{D}}\) exhibits the homotopy category \(\mathrm{h} \mathcal{D}\) as a 1-categorical localization of \(h \mathcal{C}\) with respect to \([W]\), in the sense of Definition 6.3.0.6. This follows immediately from Example 6.3.1.6.

Example 6.3.1.18. Let \(\mathcal{C}\) be an ordinary category and let \(W\) be a collection of morphisms
\(\qquad\)
01MU
\(\qquad\)

01MX Remark 6.3.1.19. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be morphisms of simplicial sets, and let \(W\) be a collection of edges of \(\mathcal{C}\). If any two of the following three conditions is satisfied, then so is the third:
- The morphism \(F\) exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\).
- The morphism \(G \circ F\) exhibits \(\mathcal{E}\) as a localization of \(\mathcal{C}\) with respect to \(W\).
- The morphism \(G\) is a categorical equivalence of simplicial sets.

01MY Proposition 6.3.1.20. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets, where \(\mathcal{D}\) is an \(\infty\)-category, and let \(W\) be the collection of all edges of \(\mathcal{C}\). The following conditions are equivalent:
(1) The morphism \(F\) exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\).
(2) The \(\infty\)-category \(\mathcal{D}\) is a Kan complex and \(F\) is a weak homotopy equivalence of simplicial sets.

Proof. We first prove that (2) implies (1). Assume that \(\mathcal{D}\) is a Kan complex and that \(F: \mathcal{C} \rightarrow \mathcal{D}\) is a weak homotopy equivalence; we wish to show that \(F\) exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\). By virtue of Proposition 6.3.1.13, it will suffice to show that for every \(\infty\)-category \(\mathcal{E}\), composition with \(F\) induces a homotopy equivalence of Kan complexes \(\theta: \operatorname{Fun}(\mathcal{D}, \mathcal{E})^{\simeq} \rightarrow \operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)^{\simeq}\). Since \(\mathcal{D}\) is a Kan complex, Proposition 4.4.3.22 allows us to identify \(\theta\) with the canonical map
\[
\operatorname{Fun}\left(\mathcal{D}, \mathcal{E}^{\simeq}\right) \xrightarrow{\circ F} \operatorname{Fun}\left(\mathcal{C}, \mathcal{E}^{\simeq}\right),
\]
which is a homotopy equivalence by virtue of our assumption that \(F\) is a weak homotopy equivalence.

We now show that (1) implies (2). Assume that \(F\) exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\). Invoking Remark 6.3.1.16, we deduce that \(F\) is a weak homotopy equivalence. We wish to show that \(\mathcal{D}\) is a Kan complex. Choose a weak homotopy equivalence \(G: \mathcal{D} \rightarrow \mathcal{E}\), where \(\mathcal{E}\) is a Kan complex (Corollary 3.1.7.2). Then the composite map \((G \circ F): \mathcal{C} \rightarrow \mathcal{E}\) is also a weak homotopy equivalence (Remark 3.1.6.16). Invoking the implication (2) \(\Rightarrow\) (1), we conclude that \(G \circ F\) exhibits \(\mathcal{E}\) as a localization of \(\mathcal{C}\) with respect to \(W\). It follows from Remark 6.3.1.19 that \(G\) is an equivalence of \(\infty\)-categories. Since \(\mathcal{E}\) is a Kan complex, it follows that the \(\infty\)-category \(\mathcal{D}\) is also a Kan complex (Remark 4.5.1.21).

02LS Proposition 6.3.1.21 (Transitivity). Let \(F: \mathcal{C} \rightarrow \mathcal{C}^{\prime}\) and \(F^{\prime}: \mathcal{C}^{\prime} \rightarrow \mathcal{C}^{\prime \prime}\) be morphisms of simplicial sets. Let \(W\) and \(W^{\prime}\) be collections of edges of \(\mathcal{C}\) satisfying the following conditions:
- The morphism \(F\) exhibits \(\mathcal{C}^{\prime}\) as a localization of \(\mathcal{C}\) with respect to \(W\).
- The morphism \(F^{\prime}\) exhibits \(\mathcal{C}^{\prime \prime}\) as a localization of \(\mathcal{C}^{\prime}\) with respect to \(F\left(W^{\prime}\right)\).

Then the composite morphism \(\left(F^{\prime} \circ F\right): \mathcal{C} \rightarrow \mathcal{C}^{\prime \prime}\) exhibits \(\mathcal{C}^{\prime \prime}\) as a localization of \(\mathcal{C}\) with respect to \(W \cup W^{\prime}\).

Proof. Let \(\mathcal{E}\) be an \(\infty\)-category; we wish to prove that precomposition with \(F^{\prime} \circ F\) induces an equivalence from \(\operatorname{Fun}\left(\mathcal{C}^{\prime \prime}, \mathcal{E}\right)\) to the full subcategory \(\operatorname{Fun}\left(\mathcal{C}\left[\left(W \cup W^{\prime}\right)^{-1}\right], \mathcal{E}\right) \subseteq \operatorname{Fun}(\mathcal{C}, \mathcal{E})\). We have a commutative diagram

where the horizontal functors on the left and lower right are equivalences of \(\infty\)-categories. Since the square is a pullback and the vertical maps are isofibrations (Remark 6.3.1.8), it follows that the horizontal map on the upper right is also an equivalence of \(\infty\)-categories (Corollary 4.5.2.29).

Corollary 6.3.1.22. Let \(\mathcal{C}\) be a simplicial set, let \(W\) and \(W^{\prime}\) be collections of edges of \(\mathcal{C}\), 02LT and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets which exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\). Suppose that, for every edge \(w \in W^{\prime}\), the image \(F(w)\) is a degenerate edge of \(\mathcal{D}\). Then \(F\) also exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W \cup W^{\prime}\).

Proof. Combine Proposition 6.3.1.21 with Example 6.3.1.12

\subsection*{6.3.2 Existence of Localizations}

Our goal in this section is to prove the following:
Proposition 6.3.2.1 (Existence of Localizations). Let \(\mathcal{C}\) be a simplicial set and let \(W\) be a 01N0 collection of edges of \(\mathcal{C}\). Then there exists an \(\infty\)-category \(\mathcal{D}\) and a morphism of simplicial sets \(F: \mathcal{C} \rightarrow \mathcal{D}\) which exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\).

Remark 6.3.2.2 (Uniqueness of Localizations). Let \(\mathcal{C}\) be a simplicial set and let \(W\) be a 01N1 collection of edges of \(\mathcal{C}\). Proposition 6.3.2.1 asserts that there exists an \(\infty\)-category \(\mathcal{D}\) and a morphism \(F: \mathcal{C} \rightarrow \mathcal{D}\) which exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\). In this case, for every \(\infty\)-category \(\mathcal{E}\), composition with \(F\) induces a bijection
\[
\operatorname{Hom}_{\mathrm{hCat}_{\infty}}(\mathcal{D}, \mathcal{E})=\pi_{0}\left(\operatorname{Fun}(\mathcal{D}, \mathcal{E})^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)^{\simeq}\right)
\]
(Proposition 6.3.1.13). In other words, the \(\infty\)-category \(\mathcal{D}\) corepresents the functor
\[
\operatorname{hCat}_{\infty} \rightarrow \text { Set } \quad \mathcal{E} \mapsto \pi_{0}\left(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)^{\sim}\right) .
\]

It follows that \(\mathcal{D}\) is uniquely determined (up to canonical isomorphism) as an object of the homotopy category \(\mathrm{hCat}_{\infty}\). We will sometimes emphasize this uniqueness by referring to \(\mathcal{D}\) as the localization of \(\mathcal{C}\) with respect to \(W\), and denoting it by \(\mathcal{C}\left[W^{-1}\right]\). Beware that the localization \(\mathcal{C}\left[W^{-1}\right]\) is not well-defined up to isomorphism as a simplicial set: in fact, any equivalent \(\infty\)-category can also be regarded as a localization of \(\mathcal{C}\) with respect to \(W\) (Remark 6.3.1.19).

01N2 Warning 6.3.2.3. Let \(\mathcal{C}\) be a simplicial set, let \(W\) be a collection of edges of \(\mathcal{C}\), and let \(\mathcal{E}\) be an \(\infty\)-category. We have now given two different definitions for the \(\infty\)-category \(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)\) :
(1) According to Notation 6.3.1.1, \(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)\) denotes the full subcategory of \(\operatorname{Fun}(\mathcal{C}, \mathcal{E})\) spanned by those diagrams \(F: \mathcal{C} \rightarrow \mathcal{E}\) which carry each edge of \(W\) to an isomorphism in \(\mathcal{E}\).
(2) By the convention of Remark 6.3.2.2, \(\mathcal{C}\left[W^{-1}\right]\) denotes an \(\infty\)-category equipped with a diagram \(F: \mathcal{C} \rightarrow \mathcal{C}\left[W^{-1}\right]\) which exhibits \(\mathcal{C}\left[W^{-1}\right]\) as a localization of \(\mathcal{C}\) with respect to \(W\). We can then consider the \(\infty\)-category of functors from \(\mathcal{C}\left[W^{-1}\right]\) to \(\mathcal{E}\), which we will temporarily denote by \(\operatorname{Fun}^{\prime}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)\).

Beware that these \(\infty\)-categories are not identical. However, they are equivalent: if \(F: \mathcal{C} \rightarrow\) \(\mathcal{C}\left[W^{-1}\right]\) exhibits \(\mathcal{C}\left[W^{-1}\right]\) as a localization of \(\mathcal{C}\) with respect to \(W\), then composition with \(F\) induces an equivalence of \(\infty\)-categories \(\operatorname{Fun}^{\prime}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right) \rightarrow \operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)\) (Proposition 6.3.1.13). Note that the \(\infty\)-category \(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)\) does not depend on any auxiliary choices: it is well-defined up to equality as a simplicial subset of \(\operatorname{Fun}(\mathcal{C}, \mathcal{E})\). By contrast, the \(\infty\)-category \(\operatorname{Fun}^{\prime}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)\) depends on the choice of the functor \(F: \mathcal{C} \rightarrow \mathcal{C}\left[W^{-1}\right]\) (and is therefore well-defined up to equivalence, but not up to isomorphism).

Our proof of Proposition 6.3.2.1 will make use of the following:
01 N 3 Lemma 6.3.2.4. Let \(Q\) be a contractible Kan complex, let \(e: \Delta^{1} \hookrightarrow Q\) be a monomorphism of simplicial sets, and let \(W=\left\{\mathrm{id}_{\Delta^{1}}\right\}\) consist of the single nondegenerate edge of \(\Delta^{1}\). Then, for any \(\infty\)-category \(\mathcal{E}\), precomposition with \(e\) induces a trivial Kan fibration of simplicial sets
\[
\theta: \operatorname{Fun}(Q, \mathcal{E}) \rightarrow \operatorname{Fun}\left(\Delta^{1}\left[W^{-1}\right], \mathcal{E}\right)=\operatorname{Isom}(\mathcal{E})
\]

Proof. Since \(e\) is a monomorphism, Corollary 4.4.5.3 immediately implies that \(\theta\) is an isofibration when regarded as a functor from \(\operatorname{Fun}(Q, \mathcal{E})\) to \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{E}\right)\). Using the pullback
diagram

we deduce that \(\theta\) is also an isofibration when regarded as a functor from \(\operatorname{Fun}(Q, \mathcal{E})\) to \(\operatorname{Isom}(\mathcal{E})\). Consequently, to show that \(\theta\) is a trivial Kan fibration, it will suffice to show that it is an equivalence of \(\infty\)-categories (Proposition 4.5.5.20). In other words, we are reduced to proving that the morphism \(e\) exhibits \(Q\) as a localization of \(\Delta^{1}\) with respect to \(W\). Let \(q: Q \rightarrow \Delta^{0}\) denote the projection map. Since \(Q\) is contractible, the morphism \(q\) is an equivalence of \(\infty\)-categories. By virtue of Remark 6.3.1.19, we are reduced to proving that the composite map \(\Delta^{1} \xrightarrow{e} Q \xrightarrow{q} \Delta^{0}\) exhibits \(\Delta^{0}\) as a localization of \(\Delta^{1}\) with respect to \(W\), which follows from Example 6.3.1.14

We will deduce Proposition 6.3.2.1 from the following more precise result:
Proposition 6.3.2.5. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets, where \(\mathcal{D}\) is an 01N4 \(\infty\)-category. Let \(W\) be a collection of edges of \(\mathcal{C}\) such that, for each \(w \in W\), the image \(F(w)\) is an isomorphism in \(\mathcal{D}\). Then \(F\) factors as a composition
\[
\mathcal{C} \xrightarrow{G} \mathcal{C}\left[W^{-1}\right] \xrightarrow{H} \mathcal{D},
\]
where \(G\) exhibits \(\mathcal{C}\left[W^{-1}\right]\) as a localization of \(\mathcal{C}\) with respect to \(W\) and \(H\) is an inner fibration (so that \(\mathcal{C}\left[W^{-1}\right]\) is also an \(\infty\)-category). Moreover, this factorization can be chosen to depend functorially on the diagram \(F: \mathcal{C} \rightarrow \mathcal{D}\) and the collection of edges \(W\), in such a way that the construction \((F: \mathcal{C} \rightarrow \mathcal{D}, W) \mapsto \mathcal{C}\left[W^{-1}\right]\) commutes with filtered colimits.
Proof. For each element \(w \in W\), the image \(F(w)\) can be regarded as a morphism from \(\Delta^{1}\) to the core \(\mathcal{D}^{\simeq}\). By virtue of Proposition 3.1.7.1 we can (functorially) choose a factorization of this morphism as a composition
\[
\Delta^{1} \xrightarrow{i_{w}} Q_{w} \xrightarrow{q_{w}} \mathcal{D}^{\simeq},
\]
where \(i_{w}\) is anodyne and \(q_{w}\) is a Kan fibration. Since \(\mathcal{D}^{\simeq}\) is a Kan complex, \(Q_{w}\) is also a Kan complex, which is contractible by virtue of the fact that \(i_{w}\) is anodyne. Form a pushout diagram of simplicial sets

We first claim that \(i: \mathcal{C} \rightarrow \mathcal{C}^{\prime}\) exhibits \(\mathcal{C}^{\prime}\) as a localization of \(\mathcal{C}\) with respect to \(W\). Let \(\mathcal{E}\) be an \(\infty\)-category. Note that if \(G: \mathcal{C} \rightarrow \mathcal{E}\) is a morphism of simplicial sets which factors through \(\mathcal{C}^{\prime}\), then for each \(w \in W\) the morphism \(G(w)\) belongs to the image of a functor \(Q_{w} \rightarrow \mathcal{E}\), and is therefore an isomorphism in \(\mathcal{E}\). It follows that composition with \(i\) induces a functor \(\theta: \operatorname{Fun}\left(\mathcal{C}^{\prime}, \mathcal{E}\right) \rightarrow \operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)\), and we wish to show that \(\theta\) is an equivalence of \(\infty\)-categories. This follows by inspecting the commutative diagram

The outer rectangle is a pullback square by the definition of \(\mathcal{C}^{\prime}\), and the right square is a pullback by the definition of \(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)\). It follows that the left square is also a pullback. Lemma 6.3.2.4 implies that \(\theta^{\prime}\) is a trivial Kan fibration, so that \(\theta\) is also a trivial Kan fibration (hence an equivalence of \(\infty\)-categories by Proposition 4.5.3.11).

Note that the morphism \(F: \mathcal{C} \rightarrow \mathcal{D}\) and the collection of morphisms \(\left\{q_{w}: Q_{w} \rightarrow \mathcal{D}^{\simeq} \subseteq\right.\) \(\mathcal{D}\}_{w \in W}\) can be amalgamated to a single morphism of simplicial sets \(F^{\prime}: \mathcal{C}^{\prime} \rightarrow \mathcal{D}\). Applying Proposition 4.1.3.2, we can (functorially) factor \(F^{\prime}\) as a composition \(\mathcal{C}^{\prime} \xrightarrow{G^{\prime}} \mathcal{C}\left[W^{-1}\right] \xrightarrow{H} \mathcal{D}\), where \(G^{\prime}\) is inner anodyne and \(H\) is an inner fibration. We conclude by observing that the composite map \(G=\left(G^{\prime} \circ i\right): \mathcal{C} \rightarrow \mathcal{C}\left[W^{-1}\right]\) exhibits \(\mathcal{C}\left[W^{-1}\right]\) as a localization of \(\mathcal{C}\) with respect to \(W\), by virtue of Remark 6.3.1.19,

Proof of Proposition 6.3.2.1. Apply Proposition 6.3.2.5 in the special case \(\mathcal{D}=\Delta^{0}\).
03TZ Variant 6.3.2.6. Let \(\kappa\) be an uncountable cardinal, and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets which exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to some collection of edges \(W\) (Definition 6.3.1.9. If \(\mathcal{C}\) is essentially \(\kappa\)-small, then \(\mathcal{D}\) is essentially \(\kappa\)-small.

Proof. Without loss of generality, we may assume that \(F\) is a monomorphism of simplicial sets. Choose a categorical equivalence of simplicial sets \(u: \mathcal{C} \rightarrow \overline{\mathcal{C}}\), where \(\overline{\mathcal{C}}\) is \(\kappa\)-small, and form a pushout diagram of simplicial sets

Then (6.5) is a categorical pushout square (Example 4.5.4.12), so \(v\) is also a categorical equivalence (Proposition 4.5.4.10). Moreover, the morphism \(\bar{F}\) exhibits \(\bar{D}\) as a localization of
\(\overline{\mathcal{C}}\) with respect to \(u(W)\) (Corollary 6.3.4.3). We may therefore replace \(F\) by \(\bar{F}\), and thereby reduce to proving Variant 6.3 .2 .6 in the special case where \(\mathcal{C}\) is \(\kappa\)-small. In particular, the set of edges \(W\) is \(\kappa\)-small.

Let \(Q\) be a contractible Kan complex which is equipped with a monomorphism \(\Delta^{1} \hookrightarrow Q\) and has only countably many simplices. Form a pushout diagram of simplicial sets

so that \(\mathcal{C}^{\prime}\) is \(\kappa\)-small (Remark 4.7.4.6). It follows from Corollary 6.3.4.3 that the morphism \(G\) exhibits \(\mathcal{C}^{\prime}\) as a localization of \(\mathcal{C}\) with respect to \(W\). Using Proposition 4.7.5.5, we can choose an inner anodyne morphism \(\mathcal{C}^{\prime} \hookrightarrow \mathcal{C}^{\prime \prime}\), where \(\mathcal{C}^{\prime \prime}\) is a \(\kappa\)-small \(\infty\)-category. Then \(\mathcal{C}^{\prime \prime}\) is also a localization of \(\mathcal{C}\) with respect to \(W\), so Remark 6.3 .2 .2 supplies a categorical equivalence of simplicial sets \(\mathcal{D} \rightarrow \mathcal{C}^{\prime \prime}\). It follows that \(\mathcal{D}\) is essentially \(\kappa\)-small, as desired.

\subsection*{6.3.3 Reflective Localizations}

It will often be convenient to work with the following variant of Definition 6.3.1.9.
Definition 6.3.3.1. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. We will say that \(F\) is a localization functor if there exists a collection of morphisms \(W\) in \(\mathcal{C}\) such that \(F\) exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\).

In the situation of Definition 6.3.3.1 there is always a canonical choice for the collection of morphisms \(W\) :

Proposition 6.3.3.2. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(W\) be the 04 JH collection of all morphisms \(w\) of \(\mathcal{C}\) such that \(F(w)\) is an isomorphism in \(\mathcal{D}\). Then \(F\) is a localization functor if and only if it exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\).

Proof. Assume that \(F\) is a localization functor; we will show that it exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\) (the reverse implication follows immediately from the definitions). Let \(\mathcal{E}\) be an \(\infty\)-category; we wish to show that composition with \(F\) induces an equivalence of \(\infty\)-categories \(\operatorname{Fun}(\mathcal{D}, \mathcal{E}) \rightarrow \operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)\). Choose a collection of morphisms \(W^{\prime}\) of \(\mathcal{C}\) such that \(F\) exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W^{\prime}\). Note that \(W^{\prime}\) is contained in \(W\), so that we can regard \(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{D}\right)\) as a full subcategory of \(\operatorname{Fun}\left(\mathcal{C}\left[W^{\prime-1}\right], \mathcal{D}\right)\). It will therefore suffice to show that the composite functor
\[
\operatorname{Fun}(\mathcal{D}, \mathcal{E}) \xrightarrow{\circ \circ} \operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right) \hookrightarrow \operatorname{Fun}\left(\mathcal{C}\left[W^{\prime-1}\right], \mathcal{E}\right)
\]
is an equivalence of \(\infty\)-categories, which follows from our assumption on the functor \(F\).

We now use the ideas of \(\$ 6.2 .2\) to describe a large class of localization functors.
02G9 Definition 6.3.3.3. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. We say that \(F\) is a reflective localization functor if it admits a right adjoint \(G: \mathcal{D} \rightarrow \mathcal{C}\) which is fully faithful.

04JJ Remark 6.3.3.4. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Using Corollary 6.2.2.17 to the right adjoint of \(F\), we see that the following conditions are equivalent:
- The functor \(F\) is a reflective localization: that is, it admits a fully faithful right adjoint \(G: \mathcal{D} \rightarrow \mathcal{C}\).
- There exists a functor \(G: \mathcal{D} \rightarrow \mathcal{C}\) and a natural isomorphism \(\epsilon: F \circ G \xrightarrow{\sim} \mathrm{id}_{\mathcal{D}}\) which is the counit of an adjunction between \(F\) and \(G\).
- The functor \(F\) admits a right adjoint \(G: \mathcal{D} \rightarrow \mathcal{C}\) for which the composition \((F \circ G)\) : \(\mathcal{D} \rightarrow \mathcal{D}\) is an equivalence of \(\infty\)-categories.

Moreover, if these conditions are satisfied, then the essential image of \(G\) is a reflective subcategory of \(\mathcal{C}\).

04JK Remark 6.3.3.5. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a reflective localization of \(\infty\)-categories. Then there exists a functor \(G: \mathcal{D} \rightarrow \mathcal{C}\) and a natural transformation \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) which is the unit of an adjunction between \(F\) and \(G\). The natural transformation \(\eta\) is generally not an isomorphism (unless \(F\) is an equivalence of \(\infty\)-categories). However, our assumption that \(F\) is a reflective localization guarantees that there exists a natural isomorphism \(\epsilon: F \circ G \xrightarrow{\sim} \operatorname{id}_{\mathcal{D}}\) which is compatible with \(\eta\) up to homotopy. In particular, for every object \(X \in \mathcal{C}\), the composition
\[
F(X) \xrightarrow{F\left(\eta_{X}\right)}(F \circ G \circ F)(X) \xrightarrow{\epsilon_{F(X)}} F(X)
\]
is homotopic to the identity \(\operatorname{id}_{F(X)}\), which guarantees that \(F\left(\eta_{X}\right)\) is an isomorphism in \(\mathcal{D}\).
04JL Proposition 6.3.3.6. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. The following conditions are equivalent:
(1) The functor \(F\) is a reflective localization (in the sense of Definition 6.3.3.3): that is, it admits a fully faithful right adjoint.
(2) The functor \(F\) is a localization functor (in the sense of Definition 6.3.3.1) which admits a right adjoint \(G: \mathcal{D} \rightarrow \mathcal{C}\).

Proof. We first show that (2) implies (1). Let \(G: \mathcal{D} \rightarrow \mathcal{C}\) be a right adjoint to \(F\) and let \(\epsilon: F \circ G \rightarrow \mathrm{id}_{\mathcal{D}}\) be the counit of an adjunction. We wish to show that, if \(F\) is a localization functor, then \(\epsilon\) is an isomorphism (Remark 6.3.3.4). By virtue of Proposition 6.1.4.7 (applied
to the opposite of the 2-category \(\mathrm{h}_{2} \mathbf{Q C a t}\) ), it will suffice to show that for any \(\infty\)-category \(\mathcal{E}\), precomposition with the isomorphism class \([F] \in \pi_{0}\left(\operatorname{Fun}(\mathcal{C}, \mathcal{D})^{\sim}\right)\) induces a monomorphism
\[
\pi_{0}\left(\operatorname{Fun}(\mathcal{D}, \mathcal{E})^{\simeq}\right) \xrightarrow{\circ[F]} \pi_{0}\left(\operatorname{Fun}(\mathcal{C}, \mathcal{E})^{\simeq}\right),
\]
which follows immediately from our assumption on \(F\).
We now prove the converse. Assume that \(F\) is a reflective localization functor and let \(W\) be the collection of all morphisms \(w\) of \(\mathcal{C}\) such that \(F(w)\) is an isomorphism in \(\mathcal{D}\); we will show that \(F\) exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\). Fix an \(\infty\)-category \(\mathcal{E}\), so that precomposition with \(F\) induces a function
\[
\varphi: \pi_{0}\left(\operatorname{Fun}(\mathcal{D}, \mathcal{E})^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)^{\simeq}\right) .
\]

Let \(G: \mathcal{D} \rightarrow \mathcal{C}\) and \(\epsilon: F \circ G \rightarrow \operatorname{id}_{\mathcal{D}}\) be as above, so that precomposition with \(G\) induces a function
\[
\psi: \pi_{0}\left(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)^{\simeq}\right) \subseteq \pi_{0}\left(\operatorname{Fun}(\mathcal{C}, \mathcal{E})^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}(\mathcal{D}, \mathcal{E})^{\simeq}\right) .
\]

We will show that \(\psi\) is inverse to \(\varphi\). By assumption, the natural transformation \(\epsilon\) is an isomorphism. It follows that, for every functor \(E: \mathcal{D} \rightarrow \mathcal{E}, \epsilon\) induces an isomorphism \(E \circ F \circ G \xrightarrow{\sim} E\). Passing to isomorphism classes, we obtain an equality \([E]=[E \circ F \circ G]=\) \(\psi([E \circ F])=(\psi \circ \varphi)([E])\). Allowing \(E\) to vary, we conclude that \(\psi \circ \varphi\) is the identity on \(\pi_{0}(\operatorname{Fun}(\mathcal{D}, \mathcal{E}) \simeq)\).

We now complete the proof by showing that \(\varphi \circ \psi\) is the identity on \(\pi_{0}\left(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)^{\sim}\right)\). Let \(H: \mathcal{C} \rightarrow \mathcal{E}\) be a functor of \(\infty\)-categories which carries each morphism of \(W\) to an isomorphism in \(\mathcal{E}\); we wish to show that \(H\) is isomorphic to \(H \circ G \circ F\). Choose a unit map \(\eta: \mathrm{id}_{\mathcal{C}} \rightarrow G \circ F\) which is compatible with \(\epsilon\) up to homotopy. For every object \(C \in \mathcal{C}\), Remark 6.3.3.5 guarantees that the morphism \(\eta_{C}: C \rightarrow(G \circ F)(C)\) belongs to \(W\), so that \(H\left(\eta_{C}\right)\) is an isomorphism in the \(\infty\)-category \(\mathcal{E}\). Allowing the object \(C\) to vary (and invoking the criterion of Theorem 4.4.4.4), we conclude that \(\eta\) induces an isomorphism from \(H\) to \(H \circ G \circ F\) in the functor \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{E})\).

Example 6.3.3.7. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a reflective subcategory, and let \(L: \mathcal{C} \rightarrow \mathcal{C}^{\prime}\) be a \(\mathcal{C}^{\prime}\)-reflection functor (Definition 6.2.2.12). Then \(L\) is a reflective localization functor (since it is left adjoint to the inclusion map \(\mathcal{C}^{\prime} \hookrightarrow \mathcal{C}\); see Proposition 6.2.2.15). In particular, \(L\) exhibits \(\mathcal{C}^{\prime}\) as a localization of \(\mathcal{C}\) with respect to the collection of morphisms \(w\) such that \(L(w)\) is an isomorphism.
Remark 6.3.3.8. Let \(\mathcal{C}\) be an \(\infty\)-category. Up to equivalence, every reflective localization 04 JN functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) can be obtained from the construction of Example 6.3.3.7. More precisely, if \(G\) is a fully faithful right adjoint to \(F\), then it induces an equivalence of \(\mathcal{D}\) with a reflective subcategory \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) (carrying \(F\) to the \(\mathcal{C}^{\prime}\)-reflection functor \((G \circ F): \mathcal{C} \rightarrow \mathcal{C}^{\prime}\) ); see Corollary 6.2.2.17

04JP Remark 6.3.3.9. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories, where \(F\) is a reflective localization functor. Then \(G\) is a reflective localization functor if and only if ( \(G \circ F\) ) is a reflective localization functor. In particular, the collection of reflective localization functors is closed under composition. See Remarks 6.2.1.8 and 4.6.2.5.

04JQ Warning 6.3.3.10. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) and \(G: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories. If \(F\) and \(G\) are localization functors, the composition \(G \circ F\) need not be a localization functor. For example, let \(\mathcal{C}\) be the 1-dimensional simplicial set corresponding to the directed graph depicted in the diagram
\[
\bullet \xrightarrow{e} \bullet \stackrel{w}{\leftarrow} \bullet \stackrel{e^{\prime}}{\longrightarrow} \bullet .
\]

There is a functor \(F: \mathcal{C} \rightarrow \Delta^{2}\) which carries \(e\) and \(e^{\prime}\) to the edges \(0 \rightarrow 1\) and \(1 \rightarrow 2\), respectively. It is not difficult to show that \(F\) exhibits \(\Delta^{2}\) as a localization of \(\mathcal{C}\) with respect to \(w\). However, the localization of \(\Delta^{2}\) with respect to its "long edge" \(0 \rightarrow 2\) cannot be realized directly as a localization of \(\mathcal{C}\).

04JR Variant 6.3.3.11. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. We say that \(F\) is a coreflective localization functor if it admits a fully faithful left adjoint \(\mathcal{D} \rightarrow \mathcal{C}\). Equivalently, \(F\) is a coreflective localization functor if the opposite functor \(F^{\mathrm{op}}: \mathcal{C}^{\mathrm{op}} \rightarrow \mathcal{D}^{\mathrm{op}}\) is a reflective localization functor (see Remark 6.2.1.7). It follows from Proposition 6.3.3.6 that every coreflective localization functor is a localization functor (in the sense of Definition 6.3.3.1).

04JS Warning 6.3.3.12. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a localization functor of \(\infty\)-categories which is both reflective and coreflective. Then \(F\) admits both a left adjoint \(F^{L}: \mathcal{D} \rightarrow \mathcal{C}\) and a right adjoint \(F^{R}: \mathcal{D} \rightarrow \mathcal{C}\), which are automatically fully faithful (Proposition 6.3.3.6). Let \(\mathcal{C}^{L} \subseteq \mathcal{C}\) be the full subcategory spanned by the essential image of the functor \(F^{L}\), and define \(\mathcal{C}^{R} \subseteq \mathcal{C}\) similarly. When viewed as abstract \(\infty\)-categories, \(\mathcal{C}^{L}\) and \(\mathcal{C}^{R}\) are equivalent (since they are both equivalent to the \(\infty\)-category \(\mathcal{D}\) ). Beware that they generally do not coincide as subcategories of \(\mathcal{C}\). See Warning 9.1.1.23.

\subsection*{6.3.4 Stability Properties of Localizations}

01 N 5 Our goal in this section is to record some basic formal properties of the localization construction \(\mathcal{C} \mapsto \mathcal{C}\left[W^{-1}\right]\) introduced in \(\S 6.3 .2\). We first show that localization commutes with the formation of filtered colimits. More precisely, we have the following:

01 N6 Proposition 6.3.4.1. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets which is given as the colimit (in the arrow category Fun([1], \(\left.\operatorname{Set}_{\Delta}\right)\) ) of a filtered diagram of morphisms \(\left\{F_{\alpha}: \mathcal{C}_{\alpha} \rightarrow \mathcal{D}_{\alpha}\right\}\). Assume that:
- Each morphism \(F_{\alpha}\) exhibits \(\mathcal{D}_{\alpha}\) as a localization of \(\mathcal{C}_{\alpha}\) with respect to some collection of edges \(W_{\alpha}\).
- Each of the transition maps \(\mathcal{C}_{\alpha} \rightarrow \mathcal{C}_{\beta}\) of the diagram carries \(W_{\alpha}\) into \(W_{\beta}\).

Let us regard \(W=\underset{\rightarrow}{\lim } W_{\alpha}\) as a collection of edges of the simplicial set \(\mathcal{C}\). Then \(F\) exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\).

Proof. Using Corollary 4.1.3.3, we can choose a compatible family of inner anodyne morphisms \(G_{\alpha}: \mathcal{D}_{\alpha} \rightarrow \mathcal{E}_{\alpha}\), where each \(\mathcal{E}_{\alpha}\) is an \(\infty\)-category. Set \(\mathcal{E}=\underset{\longrightarrow}{\lim } \mathcal{E}_{\alpha}\), so that the morphisms \(G_{\alpha}\) determine a map of simplicial sets \(G: \mathcal{D} \rightarrow \mathcal{E}\). Since each \(\vec{G}_{\alpha}\) is a categorical equivalence of simplicial sets, each of the composite maps \(\left(G_{\alpha} \circ F_{\alpha}\right): \mathcal{C}_{\alpha} \rightarrow \mathcal{E}_{\alpha}\) exhibits \(\mathcal{E}_{\alpha}\) as a localization of \(\mathcal{C}_{\alpha}\) with respect to \(W_{\alpha}\). In particular, each of the morphisms \(G_{\alpha} \circ F_{\alpha}\) carries edges of \(W_{\alpha}\) to isomorphisms in the \(\infty\)-category \(\mathcal{E}_{\alpha}\) (Remark 6.3.1.10). Applying Proposition 6.3.2.5 we can (functorially) factor each of the morphisms \(G_{\alpha} \circ F_{\alpha}\) as a composition
\[
\mathcal{C}_{\alpha} \xrightarrow{G_{\alpha}^{\prime}} \mathcal{C}_{\alpha}\left[W_{\alpha}^{-1}\right] \xrightarrow{F_{\alpha}^{\prime}} \mathcal{E}_{\alpha}
\]
where each \(\mathcal{C}_{\alpha}\left[W_{\alpha}^{-1}\right]\) is an \(\infty\)-category, each of the morphisms \(G_{\alpha}^{\prime}\) exhibits \(\mathcal{C}_{\alpha}\left[W_{\alpha}^{-1}\right]\) as a localization of \(\mathcal{C}_{\alpha}\) with respect to \(W_{\alpha}\), and the colimit map \(G^{\prime}: \mathcal{C} \rightarrow \underline{\lim }_{\alpha} \mathcal{C}_{\alpha}\left[W_{\alpha}^{-1}\right]\) exhibits \(\mathcal{C}\left[W^{-1}\right]=\lim _{\rightarrow} \mathcal{C}_{\alpha}\left[W_{\alpha}^{-1}\right]\) as a localization of \(\mathcal{C}\) with respect to \(W\). We then have a filtered diagram of commutative squares

having colimit

Applying Remark 6.3.1.19, we deduce that each of the morphisms \(F_{\alpha}^{\prime}\) is a categorical equivalence of simplicial sets. Since the collection of categorical equivalences is stable under filtered colimits (Corollary 4.5.7.2), the morphism \(F^{\prime}\) is also a categorical equivalence of simplicial sets. Applying Remark 6.3.1.19 again, we deduce that \(F^{\prime} \circ G^{\prime}\) exhibits \(\mathcal{E}\) as a localization of \(\mathcal{C}\) with respect to \(W\). Since each \(G_{\alpha}\) is a categorical equivalence, Corollary 4.5.7.2 also guarantees that \(G\) is a categorical equivalence. Using the equality \(G \circ F=F^{\prime} \circ G^{\prime}\) and applying Remark 6.3.1.19 again, we conclude that \(F\) exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to \(W\), as desired.

We now show that localization is compatible with the formation of categorical pushout squares.

01N7 Proposition 6.3.4.2. Suppose we are given a commutative diagram of simplicial sets

with the following properties:
(a) The back face

is a categorical pushout square of simplicial sets.
(b) The morphism of simplicial sets \(F_{01}: \mathcal{C}_{01} \rightarrow \mathcal{D}_{01}\) exhibits \(\mathcal{D}_{01}\) as a localization of \(\mathcal{C}_{01}\) with respect to some collection of edges \(W_{01}\).
(c) The morphism of simplicial sets \(F_{0}: \mathcal{C}_{0} \rightarrow \mathcal{D}_{0}\) exhibits \(\mathcal{D}_{0}\) as a localization of \(\mathcal{C}_{0}\) with respect to some collection of edges \(W_{0}\) containing \(G\left(W_{01}\right)\).
(d) The morphism of simplicial sets \(F_{1}: \mathcal{C}_{1} \rightarrow \mathcal{D}_{1}\) exhibits \(\mathcal{D}_{1}\) as a localization of \(\mathcal{C}_{1}\) with respect to some collection of edges \(W_{1}\) containing \(H\left(W_{01}\right)\).

Then the following conditions are equivalent:
(1) The front face

is a categorical pushout square of simplicial sets.
(2) The morphism of simplicial sets \(F: \mathcal{C} \rightarrow \mathcal{D}\) exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to the collection of edges \(W=H^{\prime}\left(W_{0}\right) \cup G^{\prime}\left(W_{1}\right)\).

Proof. Let \(\mathcal{E}\) be an \(\infty\)-category. Assumption (a) guarantees that the diagram of Kan complexes

is a homotopy pullback square. Applying Proposition 3.4.1.14, we deduce that the diagram of summands

is also a homotopy pullback square. Invoking Corollary 3.4.1.12, we conclude that the following conditions are equivalent:
( \(1_{\mathcal{E}}\) ) The diagram of Kan complexes

is a homotopy pullback square.
\(\left(2_{\mathcal{E}}\right)\) Precomposition with \(F\) induces a homotopy equivalence of Kan complexes
\[
\operatorname{Fun}(\mathcal{D}, \mathcal{E})^{\simeq} \xrightarrow{\circ} \operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \mathcal{E}\right)^{\simeq} .
\]

We now observe that condition (1) is equivalent to the requirement that \(\left(1_{\mathcal{E}}\right)\) holds for every \(\infty\)-category \(\mathcal{E}\) (by definition), and condition (2) is equivalent to the requirement that ( \(2 \mathcal{E}\) ) holds for every \(\infty\)-category \(\mathcal{E}\) (Proposition 6.3.1.13).

03E3 Corollary 6.3.4.3. Suppose we are given a categorical pushout diagram of simplicial sets

where \(F\) exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to some collection of edges \(W\). Then \(F^{\prime}\) exhibits \(\mathcal{D}^{\prime}\) as a localization of \(\mathcal{C}^{\prime}\) with respect to \(G(W)\).

Proof. Apply Proposition 6.3.4.2 to the cubical diagram

03E4 Example 6.3.4.4 (Contracting an Edge). Let \(\mathcal{C}\) be a simplicial set and let \(e\) be an edge of \(\mathcal{C}\) which corresponds to a monomorphism of simplicial sets \(\Delta^{1} \hookrightarrow \mathcal{C}\) (that is, the source
and target of \(e\) are distinct when regarded as vertices of \(\mathcal{C}\) ). Let \(\mathcal{C}^{\prime}\) denote the simplicial set obtained from \(\mathcal{C}\) by collapsing the edge \(e\), so that we have a pushout square of simplicial sets

Since the horizontal maps in this diagram are monomorphisms, it is also a categorical pushout square (Example 4.5.4.12). Combining Corollary 6.3.4.3 with Example 6.3.1.14, we see that \(T\) exhibits \(\mathcal{C}^{\prime}\) as a localization of \(\mathcal{C}\) with respect to the singleton \(W=\{e\}\).

\subsection*{6.3.5 Fiberwise Localization}

Suppose we are given a commutative diagram of \(\infty\)-categories

where \(U\) and \(U^{\prime}\) are cocartesian fibrations and the functor \(F\) carries \(U\)-cocartesian morphisms of \(\mathcal{E}\) to \(U^{\prime}\)-cocartesian morphisms of \(\mathcal{E}^{\prime}\). For each object \(C \in \mathcal{C}\), write \(F_{C}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{G(C)}^{\prime}\) for the induced map of fibers. It follows from Theorem 5.1.6.1 that if the functors \(\left\{F_{C}\right\}_{C \in \mathcal{C}}\) and \(G\) are equivalences of \(\infty\)-categories, then \(F\) is also an equivalence of \(\infty\)-categories. Our goal in this section is to prove a generalization of this result, which gives a sufficient condition for \(F\) to exhibit \(\mathcal{E}^{\prime}\) as a localization of \(\mathcal{E}\).

Theorem 6.3.5.1. Suppose we are given a commutative diagram of simplicial sets

which satisfies the following conditions:
(1) The morphisms \(U\) and \(U^{\prime}\) are cocartesian fibrations.
(2) The morphism \(F\) carries \(U\)-cocartesian edges of \(\mathcal{E}\) to \(U^{\prime}\)-cocartesian edges of \(\mathcal{E}^{\prime}\).
(3) For every vertex \(C \in \mathcal{C}\) having image \(C^{\prime}=\bar{F}(C) \in \mathcal{C}^{\prime}\), the induced functor of \(\infty\) categories \(F_{C}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{C^{\prime}}^{\prime}\) exhibits \(\mathcal{E}_{C^{\prime}}^{\prime}\) as the localization of \(\mathcal{E}_{C}\) with respect to some collection of morphisms \(W_{C}\) of \(\mathcal{E}_{C}\).
(4) The morphism \(\bar{F}\) exhibits \(\mathcal{C}^{\prime}\) as a localization of \(\mathcal{C}\) with respect to some collection of morphisms \(\bar{W}\) of \(\mathcal{C}\).

Set \(W_{-}=\bigcup_{C \in \mathcal{C}} W_{C}\) and let \(W_{+}\)be the collection of all \(U\)-cocartesian edges e such that \(U(e)\) belongs to \(\bar{W}\). Then \(F\) exhibits \(\mathcal{E}^{\prime}\) as a localization of \(\mathcal{E}\) with respect to \(W_{-} \cup W_{+}\).

We begin by proving a special case of Theorem 6.3.5.1, where \(\bar{F}\) is assumed to be an isomorphism.

02LW Proposition 6.3.5.2. Suppose we are given a commutative diagram of simplicial sets

with the following properties:
(1) The morphisms \(U\) and \(U^{\prime}\) are cocartesian fibrations.
(2) The morphism \(F\) carries \(U\)-cocartesian edges of \(\mathcal{E}\) to \(U^{\prime}\)-cocartesian edges of \(\mathcal{E}^{\prime}\).
(3) For every vertex \(C \in \mathcal{C}\), the induced functor of \(\infty\)-categories \(F_{C}: \mathcal{E}_{C} \rightarrow \mathcal{E}_{C}^{\prime}\) exhibits \(\mathcal{E}_{C}^{\prime}\) as the localization of \(\mathcal{E}_{C}\) with respect to some collection of morphisms \(W_{C}\).

Set \(W=\bigcup_{C \in \mathcal{C}} W_{C}\), which we regard as a collection of edges of the simplicial set \(\mathcal{E}\). Then \(F\) exhibits \(\mathcal{E}^{\prime}\) as a localization of \(\mathcal{E}\) with respect to \(W\).

Proof. Let \(\mathcal{D}\) be an \(\infty\)-category, so that precomposition with \(F\) induces a functor \(F^{*}\) : \(\operatorname{Fun}\left(\mathcal{E}^{\prime}, \mathcal{D}\right) \rightarrow \operatorname{Fun}(\mathcal{E}, \mathcal{D})\). We wish to show that the functor \(F^{*}\) is fully faithful, and that its essential image is the full subcategory \(\operatorname{Fun}\left(\mathcal{E}\left[W^{-1}\right], \mathcal{D}\right) \subseteq \operatorname{Fun}(\mathcal{E}, \mathcal{D})\). Let \(\mathcal{B}=\operatorname{Fun}(\mathcal{E} / \mathcal{C}, \mathcal{D})\) and \(\mathcal{B}^{\prime}=\operatorname{Fun}\left(\mathcal{E}^{\prime} / \mathcal{C}, \mathcal{D}\right)\) be the relative exponentials of Construction 4.5.9.1, and let \(\pi: \mathcal{B} \rightarrow \mathcal{C}\) and \(\pi^{\prime}: \mathcal{B}^{\prime} \rightarrow \mathcal{C}\) denote the projection maps. Combining assumption (1) with Corollary 5.3.6.8, we see that \(\pi\) and \(\pi^{\prime}\) are cartesian fibrations.

For each vertex \(C \in \mathcal{C}\), let us identify the fibers \(\mathcal{B}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{B}\) and \(\mathcal{B}_{C}^{\prime}=\{C\} \times_{\mathcal{C}} \mathcal{B}^{\prime}\) with the \(\infty\)-categories \(\operatorname{Fun}\left(\mathcal{E}_{C}, \mathcal{D}\right)\) and \(\operatorname{Fun}\left(\mathcal{E}_{C}^{\prime}, \mathcal{D}\right)\), respectively. Precomposition with \(F\)
induces a morphism of simplicial sets \(G: \mathcal{B}^{\prime} \rightarrow \mathcal{B}\) satisfying \(\pi \circ G=\pi^{\prime}\), given on each fiber by the functor
\[
\mathcal{B}_{C}^{\prime}=\operatorname{Fun}\left(\mathcal{E}_{C}^{\prime}, \mathcal{D}\right) \xrightarrow{\circ F_{C}} \operatorname{Fun}\left(\mathcal{E}_{C}, \mathcal{D}\right)=\mathcal{B}_{C} .
\]

Combining assumption (2) with Corollary 5.3.6.8, we see that \(G\) carries \(\pi^{\prime}\)-cartesian edges of \(\mathcal{B}^{\prime}\) to \(\pi\)-cartesian edges of \(\mathcal{B}\). In particular, for every edge \(e: X \rightarrow Y\) of \(\mathcal{C}\), the diagram of \(\infty\)-categories

commutes up to isomorphism, where the horizontal functors are given by contravariant transport along \(e\) (see Remark 5.2.8.5).

Let us identify the vertices of \(\mathcal{B}\) with pairs \((C, \rho)\), where \(C\) is a vertex of \(\mathcal{C}\) and \(\rho: \mathcal{E}_{C} \rightarrow \mathcal{D}\) is a functor of \(\infty\)-categories. Let \(\mathcal{B}^{0} \subseteq \mathcal{B}\) denote the full simplicial subset spanned by those vertices \((C, \rho)\) for which the functor \(\rho\) carries each edge of \(W_{C}\) to an isomorphism in the \(\infty\)-category \(\mathcal{D}\). It follows from assumption (3) that for every vertex \(C\), the functor \(G_{C}: \mathcal{B}_{C}^{\prime} \rightarrow \mathcal{B}_{C}\) is fully faithful, and its essential image can be identified with the full subcategory \(\mathcal{B}_{C}^{0}=\{C\} \times_{\mathcal{C}} \mathcal{B}^{0} \subseteq \mathcal{B}_{C}\). Combining this observation with the homotopy commutativity of the diagram (6.7), we see that for every edge \(e: X \rightarrow Y\) in \(\mathcal{E}\), the contravariant transport functor \(e^{*}: \mathcal{B}_{Y} \rightarrow \mathcal{B}_{X}\) carries \(\mathcal{B}_{Y}^{0}\) into \(\mathcal{B}_{X}^{0}\). It follows that \(\pi\) restricts to a cartesian fibration of simplicial sets \(\pi^{0}: \mathcal{B}^{0} \rightarrow \mathcal{C}\), and that an edge of \(\mathcal{B}^{0}\) is \(\pi^{0}\)-cartesian if and only if it is \(\pi\)-cartesian when viewed as an edge of \(\mathcal{B}\) (Proposition 5.1.4.16). In particular, the morphism \(G: \mathcal{B}^{\prime} \rightarrow \mathcal{B}^{0} \subseteq \mathcal{B}\) carries \(\pi^{\prime}\)-cartesian edges of \(\mathcal{B}^{\prime}\) to \(\pi^{0}\)-cartesian edges of \(\mathcal{B}^{0}\), and therefore induces an equivalence \(\mathcal{B}^{\prime} \rightarrow \mathcal{B}^{0}\) of cartesian fibrations over \(\mathcal{C}\) (Proposition 5.1.7.14). We complete the proof by observing that \(F^{*}: \operatorname{Fun}\left(\mathcal{E}^{\prime}, \mathcal{D}\right) \rightarrow \operatorname{Fun}\left(\mathcal{E}\left[W^{-1}\right], \mathcal{D}\right)\) can be identified with the functor
\[
\operatorname{Fun}_{/ \mathcal{C}}\left(\mathcal{C}, \mathcal{B}^{\prime}\right) \rightarrow \operatorname{Fun}_{/ \mathcal{C}}\left(\mathcal{C}, \mathcal{B}^{0}\right)
\]
given by precomposition with \(G\), and is therefore an equivalence of \(\infty\)-categories.
Corollary 6.3.5.3. Let \(U: \mathcal{E} \rightarrow \mathcal{C}\) be a cocartesian fibration of simplicial sets. Suppose that, for every vertex \(C \in \mathcal{C}\), the \(\infty\)-category \(\mathcal{E}_{C}=\{C\} \times_{\mathcal{C}} \mathcal{E}\) is weakly contractible. Let \(W\) be the collection of all edges \(e\) of \(\mathcal{E}\) having the property that \(U(e)\) is a degenerate edge of \(\mathcal{C}\). Then \(U\) exhibits \(\mathcal{C}\) as a localization of \(\mathcal{E}\) with respect to \(W\).

Proof. For each vertex \(C \in \mathcal{C}\), let \(W_{C}\) be the collection of all morphisms in the \(\infty\)-category \(\mathcal{E}_{C}\). Since \(\mathcal{E}_{C}\) is weakly contractible, the projection map \(\mathcal{E}_{C} \rightarrow\{C\}\) exhibits \(\{C\}\) as a
localization of \(\mathcal{E}_{C}\) with respect to \(W_{C}\) (Proposition 6.3.1.20). The desired result now follows by applying Proposition 6.3.5.2 to the commutative diagram

We now consider another special case of Theorem 6.3.5.1.
038W Proposition 6.3.5.4. Suppose we are given a pullback diagram of simplicial sets

where \(U\) and \(U^{\prime}\) are cocartesian fibrations. Suppose that \(\bar{F}\) exhibits \(\mathcal{C}^{\prime}\) as a localization of \(\mathcal{C}\) with respect to some collection of edges \(\bar{W}\), and let \(W\) denote the collection of \(U\)-cocartesian edges e of \(\mathcal{E}\) which satisfy \(U(e) \in \bar{W}\). Then \(F\) exhibits \(\mathcal{E}^{\prime}\) as a localization of \(\mathcal{E}\) with respect to \(W\).

Proof. Using Corollary 4.1.3.3, we can choose an inner anodyne map \(\mathcal{C}^{\prime} \hookrightarrow \mathcal{C}^{\prime \prime}\), where \(\mathcal{C}^{\prime \prime}\) is an \(\infty\)-category. By virtue of Proposition 5.6.7.2, we can assume that \(U^{\prime}\) is the pullback of a cocartesian fibration of simplicial sets \(U^{\prime \prime}: \mathcal{E}^{\prime \prime} \rightarrow \mathcal{C}^{\prime \prime}\). Applying Proposition 5.3.6.1, we deduce that the inclusion map \(\mathcal{E}^{\prime} \hookrightarrow \mathcal{E}^{\prime \prime}\) is a categorical equivalence of simplicial sets. We may therefore replace \(U^{\prime}\) by \(U^{\prime \prime}\), and thereby reduce to proving Proposition 6.3.5.4 in the special case where \(\mathcal{C}^{\prime}\) is an \(\infty\)-category.

Fix an \(\infty\)-category \(\mathcal{D}\). We wish to show that the functor \(F^{*}: \operatorname{Fun}\left(\mathcal{E}^{\prime}, \mathcal{D}\right) \rightarrow \operatorname{Fun}(\mathcal{E}, \mathcal{D})\) is fully faithful and that its essential image is the full subcategory \(\operatorname{Fun}\left(\mathcal{E}\left[W^{-1}\right], \mathcal{D}\right) \subseteq \operatorname{Fun}(\mathcal{E}, \mathcal{D})\). Let \(\mathcal{B}^{\prime}=\operatorname{Fun}\left(\mathcal{E}^{\prime} / \mathcal{C}, \mathcal{D}\right)\) and \(\pi^{\prime}: \mathcal{B}^{\prime} \rightarrow \mathcal{C}\) be as in the proof of Proposition 6.3.5.2, so that we have canonical isomorphisms
\[
\operatorname{Fun}\left(\mathcal{E}^{\prime}, \mathcal{D}\right) \simeq \operatorname{Fun}_{/ \mathcal{C}^{\prime}}\left(\mathcal{C}^{\prime}, \mathcal{B}^{\prime}\right) \quad \operatorname{Fun}(\mathcal{E}, \mathcal{D}) \simeq \operatorname{Fun}_{/ \mathcal{C}^{\prime}}\left(\mathcal{C}, \mathcal{B}^{\prime}\right)
\]

Note that a morphism \(G: \mathcal{E} \rightarrow \mathcal{D}\) carries each edge of \(W\) to an isomorphism in \(\mathcal{D}\) if and only if the corresponding object \(g \in \operatorname{Fun}_{/ \mathcal{C}^{\prime}}\left(\mathcal{C}, \mathcal{B}^{\prime}\right)\) carries each element \(\bar{e} \in \bar{W}\) to a \(\pi^{\prime}\)-cartesian
edge of \(\mathcal{B}^{\prime}\) (see Corollary 5.3.6.8). Since \(\bar{F}\) carries each edge \(\bar{e} \in \bar{W}\) to an isomorphism in \(\mathcal{C}^{\prime}\), this is equivalent to the requirement that \(g(\bar{e})\) is an isomorphism in \(\mathcal{B}^{\prime}\) (Proposition 5.1 .1 .8 . We are therefore reduced to showing that composition with \(\bar{F}\) induces a fully faithful functor Fun \(/ \mathcal{C}^{\prime}\left(\mathcal{C}^{\prime}, \mathcal{B}^{\prime}\right) \rightarrow \operatorname{Fun}_{/ \mathcal{C}^{\prime}}\left(\mathcal{C}, \mathcal{B}^{\prime}\right)\), whose essential image is spanned by those functors \(g \in \operatorname{Fun}_{/ \mathcal{C}^{\prime}}\left(\mathcal{C}, \mathcal{B}^{\prime}\right)\) which carry each edge of \(\bar{W}\) to an isomorphism in \(\mathcal{B}^{\prime}\). This is a special case of Remark 6.3.1.15.

Corollary 6.3.5.5. Suppose we are given a pullback diagram of simplicial sets

where \(U\) and \(U^{\prime}\) are left fibrations. Suppose that \(\bar{F}\) exhibits \(\mathcal{C}^{\prime}\) as a localization of \(\mathcal{C}\) with respect to some collection of edges \(\bar{W}\). Then \(F\) exhibits \(\mathcal{E}^{\prime}\) as a localization of \(\mathcal{E}\) with respect to \(W=U^{-1}(\bar{W})\).

Proof. Combine Proposition 6.3.5.4 with Proposition 5.1.4.14
Proof of Theorem 6.3.5.1. Suppose we are given a commutative diagram of simplicial sets

which satisfies the hypotheses of Theorem 6.3.5.1. Fix an \(\infty\)-category \(\mathcal{D}\). We wish to show that precomposition with \(F\) induces a fully faithful functor \(F^{*}: \operatorname{Fun}\left(\mathcal{E}^{\prime}, \mathcal{D}\right) \rightarrow \operatorname{Fun}(\mathcal{E}, \mathcal{D})\), whose essential image consists of those morphisms \(G: \mathcal{E} \rightarrow \mathcal{D}\) which carry each edge of \(W_{-} \cup W_{+}\)to an isomorphism in \(\mathcal{D}\). Let \(\pi: \mathcal{C} \times \times_{\mathcal{C}^{\prime}} \mathcal{E}^{\prime} \rightarrow \mathcal{E}^{\prime}\) be given by projection onto the second factor. Note that the pair \((U, F)\) determines a morphism of simplicial sets \(\widetilde{F}: \mathcal{E} \rightarrow \mathcal{C} \times{ }_{\mathcal{C}^{\prime}} \mathcal{E}^{\prime}\) satisfying \(\pi \circ \widetilde{F}=F\), so that \(F^{*}\) factors as a composition
\[
\operatorname{Fun}\left(\mathcal{E}^{\prime}, \mathcal{D}\right) \xrightarrow{\pi^{*}} \operatorname{Fun}\left(\mathcal{C} \times{ }_{\mathcal{C}^{\prime}} \mathcal{E}^{\prime}, \mathcal{D}\right) \xrightarrow{\widetilde{F}^{*}} \operatorname{Fun}(\mathcal{E}, \mathcal{D}) .
\]

Let \(W^{\prime}\) be the collection of all edges of \(\mathcal{C} \times{ }_{\mathcal{C}^{\prime}} \mathcal{E}^{\prime}\) of the form \((\bar{e}, f)\), where \(\bar{e}\) belongs to \(\bar{W}\) and \(f\) is a \(U^{\prime}\)-cocartesian edge of \(\mathcal{E}^{\prime}\). It follows from Proposition 6.3.5.4 that the functor \(\pi^{*}\)
is fully faithful, and that its essential image consists of those morphisms \(G^{\prime}: \mathcal{C} \times{ }_{\mathcal{C}^{\prime}} \mathcal{E}^{\prime} \rightarrow \mathcal{D}\) which carry each edge of \(W^{\prime}\) to an isomorphism in \(\mathcal{D}\). Applying Proposition 6.3.5.2, we see that the functor \(\widetilde{F}^{*}\) is also fully faithful, and that its essential image consists of those morphisms \(G: \mathcal{E} \rightarrow \mathcal{D}\) which carry each edge of \(W_{-}\)to an isomorphism in \(\mathcal{D}\). To complete the proof, it will suffice to show the following:
(*) A morphism of simplicial sets \(G^{\prime}: \mathcal{C} \times{ }_{\mathcal{C}^{\prime}} \mathcal{E}^{\prime} \rightarrow \mathcal{D}\) carries each edge of \(W^{\prime}\) to an isomorphism in \(\mathcal{D}\) if and only if \(G^{\prime} \circ \widetilde{F}\) carries each edge of \(W_{+}\)to an isomorphism in \(\mathcal{D}\).

The "only if" assertion is immediate (since \(\widetilde{F}\left(W_{+}\right)\)is contained in \(W^{\prime}\) ). The converse follows from the observation that every edge ( \(\bar{e}, f\) ) is isomorphic, when viewed as an object of the \(\infty\)-category Fun \(/ \mathcal{C}\left(\Delta^{1}, \mathcal{C} \times_{\mathcal{C}^{\prime}} \mathcal{E}^{\prime}\right)\), to \(\widetilde{F}(e)\), where \(e: X \rightarrow Y\) is any \(U\)-cocartesian edge of \(\mathcal{E}\) for which \(U(e)=\bar{e}\) and \(F(X)\) is isomorphic to the domain of \(f\) as an object of the \(\infty\)-category \(\{X\} \times{ }_{\mathcal{C}^{\prime}} \mathcal{E}^{\prime}\).

We now record a few other thematically related results which will be useful later.
02LV Proposition 6.3.5.6. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a morphism of simplicial sets which exhibits \(\mathcal{D}\) as a localization of \(\mathcal{C}\) with respect to a collection of edges \(W\). Let \(K\) be any simplicial set, and let \(W_{K}\) denote the collection of edges \(e=\left(e^{\prime}, e^{\prime \prime}\right)\) of the product \(K \times \mathcal{C}\) for which \(e^{\prime}\) is a degenerate edge of \(K\) and \(e^{\prime \prime}\) belongs to \(W\). Then the induced map \(F_{K}: K \times \mathcal{C} \rightarrow K \times \mathcal{D}\) exhibits \(K \times \mathcal{D}\) as the localization of \(K \times \mathcal{C}\) with respect to \(W_{K}\).

Proof. Let \(\mathcal{E}\) be an \(\infty\)-category, and let
\[
\theta: \operatorname{Fun}(K \times \mathcal{D}, \mathcal{E}) \rightarrow \operatorname{Fun}(K \times \mathcal{C}, \mathcal{E})
\]
be the functor given by precomposition with \(F_{K}\). We wish to show that \(F_{K}\) is fully faithful, and that its essential image is the full subcategory \(\operatorname{Fun}\left((K \times \mathcal{C})\left[W_{K}^{-1}\right], \mathcal{E}\right)\) of Notation 6.3.1.1. Unwinding the definitions, we can identify \(\theta\) with the functor
\[
\theta^{\prime}: \operatorname{Fun}(\mathcal{D}, \operatorname{Fun}(K, \mathcal{E})) \rightarrow \operatorname{Fun}(\mathcal{C}, \operatorname{Fun}(K, \mathcal{E}))
\]
given by precomposition with \(F\). Under this identification \(\operatorname{Fun}\left((K \times \mathcal{C})\left[W_{K}^{-1}\right], \mathcal{E}\right)\) corresponds to the full subcategory \(\operatorname{Fun}\left(\mathcal{C}\left[W^{-1}\right], \operatorname{Fun}(K, \mathcal{E})\right) \subseteq \operatorname{Fun}(\mathcal{C}, \operatorname{Fun}(K, \mathcal{E}))\) (see Theorem 4.4.4.4, so that the desired result follows from our assumption on the functor \(F\).

\subsection*{6.3.6 Universal Localizations}

The formation of localizations is generally not compatible with fiber products. If

is a pullback diagram of simplicial sets where the morphism \(f\) exhibits \(S\) as a localization of \(X\) (with respect to some collection of edges of \(X\) ), then the morphism \(f^{\prime}\) need not have the same property. To address this point, it will be convenient to introduce a more restrictive notion of localization.

Definition 6.3.6.1. Let \(f: X \rightarrow S\) be a morphism of simplicial sets. We will say that \(f\) is universally localizing if, for every morphism of simplicial sets \(S^{\prime} \rightarrow S\), the projection map \(S^{\prime} \times{ }_{S} X \rightarrow S^{\prime}\) exhibits \(S^{\prime}\) as a localization of \(S^{\prime} \times{ }_{S} X\) with respect to some collection of edges \(W\).

Example 6.3.6.2. Let \(f: X \rightarrow S\) be a cocartesian fibration of simplicial sets. If each fiber 047 T \(X_{s}=\{s\} \times_{S} X\) is weakly contractible, then \(f\) is universally localizing. See Corollary 6.3.5.3

If \(f: X \rightarrow S\) is a universally localizing morphism of simplicial sets, then it exhibits \(S\) as a localization of \(X\) with respect to some collection of edges \(W\). It is possible to be more precise: we can take \(W\) to be the collection of edges of \(X\) having degenerate image in \(S\).

Proposition 6.3.6.3. Let \(f: X \rightarrow S\) be a morphism of simplicial sets. For every morphism 02M1 \(T \rightarrow S\), let \(W_{T}\) denote the collection of all edges \(w=\left(w_{T}, w_{X}\right)\) of the fiber product \(T \times_{S} X\) for which \(w_{T}\) is a degenerate edge of \(T\). The following conditions are equivalent:
(1) For every morphism of simplicial sets \(T \rightarrow S\), the projection map \(T \times{ }_{S} X \rightarrow T\) exhibits \(T\) as a localization of \(T \times_{S} X\) with respect to \(W_{T}\).
(2) The morphism \(f\) is universally localizing, in the sense of Definition 6.3.6.1.
(3) For every simplex \(\sigma: \Delta^{n} \rightarrow S\), the projection map \(\Delta^{n} \times_{S} X \rightarrow \Delta^{n}\) exhibits \(\Delta^{n}\) as a localization of \(\Delta^{n} \times_{S} X\) with respect to some collection of edges of \(\Delta^{n} \times_{S} X\).
(4) For every simplex \(\sigma: \Delta^{n} \rightarrow S\), the projection map \(\Delta^{n} \times_{S} X \rightarrow \Delta^{n}\) exhibits \(\Delta^{n}\) as a localization of \(\Delta^{n} \times_{S} X\) with respect to \(W_{\Delta^{n}}\).

Proof. The implications \((1) \Rightarrow(2) \Rightarrow(3)\) are immediate. We next show that (3) implies (4). Let \(\sigma\) be an \(n\)-simplex of \(S\), and suppose that the projection map \(\pi: \Delta^{n} \times{ }_{S} X \rightarrow \Delta^{n}\) exhibits \(\Delta^{n}\) as a localization of \(\Delta^{n} \times_{S} X\) with respect to some collection of edges \(W\). Since
\(\Delta^{n}\) is an \(\infty\)-category in which every isomorphism is an identity morphism, the diagram \(\pi\) must carry each edge of \(W\) to a degenerate edge of \(\Delta^{n}\) : that is, we have \(W \subseteq W_{\Delta^{n}}\). Applying Corollary 6.3.1.22, we deduce that \(\pi\) also exhibits \(\Delta^{n}\) as a localization of \(\Delta^{n} \times_{S} X\) with respect to \(W_{\Delta^{n}}\).

We now complete the proof by showing that (4) implies (1). Let us say that a simplicial set \(T\) is good if, for every morphism \(T \rightarrow S\), the projection map \(T \times{ }_{S} X \rightarrow T\) exhibits \(T\) as a localization of \(T \times{ }_{S} X\) with respect to \(W_{T}\). Assume that condition (4) is satisfied, so that every standard simplex \(\Delta^{m}\) is good. We wish to show that every simplicial set \(T\) is good. Using Proposition 6.3.4.1, we see that the collection of good simplicial sets is closed under filtered colimits; we may therefore assume without loss of generality that \(T\) is finite. If \(T=\emptyset\), the result is obvious. We may therefore assume that \(T\) has dimension \(n\) for some integer \(n \geq 0\). We proceed by induction on \(n\) and on the number of nondegenerate \(n\)-simplices of \(T\). Fix a nondegenerate \(n\)-simplex \(\sigma: \Delta^{n} \rightarrow T\). Using Proposition 1.1.4.12 we see that there is a pushout square of simplicial sets

where \(T^{\prime}\) is a simplicial set of dimension \(\leq n\) having fewer nondegenerate \(n\)-simplices than \(T\). By virtue of Proposition 6.3.4.2, to show that \(T\) is good, it will suffice to show that the simplicial sets \(\Delta^{n}, \partial \Delta^{n}\), and \(T^{\prime}\) are good. In the first case this follows from assumption (4), and in the remaining cases it follows from our inductive hypothesis.

02M2 Corollary 6.3.6.4. Let \(f: X \rightarrow S\) be a universally localizing morphism of simplicial sets, and let \(W\) be the collection of edges \(w\) of \(X\) for which \(f(w)\) is a degenerate edge of \(S\). Then \(f\) exhibits \(S\) as a localization of \(X\) with respect to \(W\).

02M3
Remark 6.3.6.5. Let \(f: X \rightarrow S\) be a universally localizing morphism of simplicial sets. Then \(f\) is a weak homotopy equivalence (see Remark 6.3.1.16).

02M4 Remark 6.3.6.6. Let \(X\) be a simplicial set. Then the projection map \(X \rightarrow \Delta^{0}\) is universally localizing if and only if \(X\) is weakly contractible. This follows by combining Propositions 6 6.3.1.20 and 6.3.5.6

Remark 6.3.6.7. Suppose we are given a pullback diagram of simplicial sets

If \(f\) is universally localizing, then \(f^{\prime}\) is universally localizing.
Proposition 6.3.6.8. Let \(f: X \rightarrow S\) be a morphism of simplicial sets which admits a 04JT section \(u: S \hookrightarrow X\). Suppose that \(u \circ f\) and \(\operatorname{id}_{X}\) belong to the same connected component of the simplicial set \(\operatorname{Fun}_{/ S}(X, X)\). Then \(f\) is universally localizing.
Proof. Let \(W\) be the collection of all edges \(w\) of \(X\) such that \(f(w)\) is degenerate in \(S\). Since our hypothesis is stable under the formation of pullbacks, it will suffice to show that \(f\) exhibits \(S\) as a localization of \(X\) with respect to \(W\). Fix an \(\infty\)-category \(\mathcal{C}\); we wish to show that composition with \(f\) induces a bijection
\[
\alpha: \pi_{0}\left(\operatorname{Fun}(S, \mathcal{C})^{\simeq}\right) \rightarrow \pi_{0}\left(\operatorname{Fun}\left(X\left[W^{-1}\right], \mathcal{C}\right)^{\simeq}\right) .
\]

The injectivity of \(\alpha\) follows immediately from the existence of the section \(u\). To prove surjectivity, it will suffice to show that for every object \(g \in \operatorname{Fun}\left(X\left[W^{-1}\right], \mathcal{C}\right)\) is isomorphic to \(g \circ u \circ f\). Since \(u \circ f\) and \(\operatorname{id}_{X}\) belong to the same connected component of Fun \(/ S(X, X)\), it suffices to observe that postcomposition with \(g\) carries every edge of \(\operatorname{Fun}_{/ S}(X, X)\) to an isomorphism in the \(\infty\)-category \(\operatorname{Fun}(X, \mathcal{C})\).
Proposition 6.3.6.9. Let \(f: X \rightarrow S\) be a universally localizing morphism of simplicial sets. 02M6 Then \(f\) is surjective.
Proof. Let \(\sigma: \Delta^{n} \rightarrow S\) be an \(n\)-simplex of \(S\); we wish to show that \(\sigma\) can be lifted to an \(n\)-simplex of \(X\). Assume otherwise, so that the inclusion map \(\partial \Delta^{n} \times_{S} X \hookrightarrow \Delta^{n} \times_{S} X\) is an isomorphism. We have a commutative diagram of simplicial sets

where the vertical maps are weak homotopy equivalences (see Remarks 6.3.6.7 and 6.3.6.5). It follows that the inclusion \(\partial \Delta^{n} \hookrightarrow \Delta^{n}\) is also a weak homotopy equivalence, which is a contradiction (since the relative homology group \(\mathrm{H}_{n}\left(\Delta^{n}, \partial \Delta^{n} ; \mathbf{Z}\right) \simeq \mathbf{Z}\) is nonzero).

02M7 Proposition 6.3.6.10. Let \(f: X \rightarrow Y\) and \(g: Y \rightarrow Z\) be universally localizing morphisms of simplicial sets. Then the composition \((g \circ f): X \rightarrow Z\) is universally localizing.

Proof. Suppose we are given a morphism of simplicial sets \(Z^{\prime} \rightarrow Z\). Set \(X^{\prime}=Z^{\prime} \times{ }_{Z} X\), and let \(W\) be the collection of those edges \(w\) of \(X^{\prime}\) having degenerate image in \(Z^{\prime}\). We will show that the projection map \(\pi: X^{\prime} \rightarrow Z^{\prime}\) exhibits \(Z^{\prime}\) as a localization of \(X^{\prime}\) with respect to \(W\). Set \(Y^{\prime}=Z^{\prime} \times{ }_{Z} Y\), so that \(\pi\) factors as a composition \(X^{\prime} \xrightarrow{f^{\prime}} Y^{\prime} \xrightarrow{g^{\prime}} Z^{\prime}\). It follows from Proposition 6.3.6.9 (and Remark 6.3.6.7) that \(f^{\prime}\) is a surjection of simplicial sets. In particular, the image \(f^{\prime}(W)\) is the collection of all edges \(u\) of \(Y^{\prime}\) having the property that \(g^{\prime}(u)\) is a degenerate edge of \(Z^{\prime}\).

Let \(W_{0} \subseteq W\) be the collection of those edges \(w\) of \(X^{\prime}\) for which \(f^{\prime}(w)\) is a degenerate edge of \(Y^{\prime}\). Applying Proposition 6.3.6.3, we conclude that \(f^{\prime}\) exhibits \(Y^{\prime}\) as a localization of \(X^{\prime}\) with respect to \(W_{0}\), and that \(g^{\prime}\) exhibits \(Z^{\prime}\) as a localization of \(Y^{\prime}\) with respect to \(f^{\prime}(W)\). Applying Proposition 6.3.1.21, we conclude that \(\pi=g^{\prime} \circ f^{\prime}\) exhibits \(Z^{\prime}\) as the localization of \(X^{\prime}\) with respect to \(W_{0} \cup W=W\), as desired.

02M8 Corollary 6.3.6.11. Let \(f: X \rightarrow S\) be a universally localizing morphism of simplicial sets, and let \(K\) be a weakly contractible simplicial set. Then the composite map \(X \times K \rightarrow X \xrightarrow{f} S\) is universally localizing.

Proof. By virtue of Proposition 6.3.6.10, it will suffice to show that the projection map \(X \times K \rightarrow X\) is universally localizing. Using Remark 6.3.6.7, we can reduce to the case \(X=\Delta^{0}\), in which case the desired result follows from Remark 6.3.6.6.

02M9
Proposition 6.3.6.12. The collection of universally localizing morphisms is closed under the formation of filtered colimits (when regarded as a full subcategory of the arrow category \(\left.\operatorname{Fun}\left([1], \operatorname{Set}_{\Delta}\right)\right)\).

Proof. Suppose that \(f: X \rightarrow S\) is a morphism of simplicial sets which can be realized as the colimit of a filtered diagram \(\left\{f_{\alpha}: X_{\alpha} \rightarrow S_{\alpha}\right\}\) in the category Fun( \(\left.[1], \operatorname{Set}_{\Delta}\right)\), where each \(f_{\alpha}\) is universally localizing. We wish to show that \(f\) is universally localizing. Fix a morphism of simplicial sets \(T \rightarrow S\) and let \(W\) be the collection of all edges \(w=\left(w_{T}, w_{X}\right)\) of \(T \times_{S} X\) for which \(w_{T}\) is a degenerate edge of \(T\). Note that the projection map \(f_{T}: T \times_{S} X \rightarrow T\) can be realized as a filtered colimit of morphisms \(f_{T, \alpha}: T \times_{S} X_{\alpha} \rightarrow T \times_{S} S_{\alpha}\). For each index \(\alpha\), let \(W_{\alpha}\) denote the collection of edges of \(T \times_{S} X_{\alpha}\) having degenerate image in \(T\). Since \(f_{\alpha}\) is universally localizing, Proposition 6.3.6.3 guarantees that \(f_{T, \alpha}\) exhibits \(T \times{ }_{S} S_{\alpha}\) as a localization of \(T \times_{S} X_{\alpha}\) with respect to \(W_{\alpha}\). Applying Proposition 6.3.4.1 we conclude that \(f_{T}\) exhibits \(T\) as a localization of \(T \times_{S} X\) with respect to \(W\).

Proposition 6.3.6.13. Suppose we are given a commutative diagram of simplicial sets

with the following properties:
(a) The front and back faces

are pushout squares.
(b) The morphisms \(S_{01} \rightarrow S_{0}\) and \(X_{01} \rightarrow X_{0}\) are monomorphisms.
(c) The morphisms \(f_{01}, f_{0}\), and \(f_{1}\) are universally localizing.

Then the morphism \(f\) is universally localizing.
Proof. Fix a morphism of simplicial sets \(T \rightarrow S\); we wish to show that the projection map \(f_{T}: T \times{ }_{S} X \rightarrow T\) exhibits \(T\) as a localization of \(T \times_{S} X\) with respect to some collection of morphisms \(W\). Since the hypotheses of Proposition 6.3.6.13 are stable with respect to pullback, we may assume without loss of generality that \(T=S\). Let \(W_{0}\) be the collection of edges \(w\) of \(X_{0}\) having the property that \(f_{0}(w)\) is a degenerate edge of \(S_{0}\), and define \(W_{1}\) and \(W_{01}\) similarly. Combining assumption (c) with Proposition 6.3.6.3, we conclude that the morphism \(f_{0}\) (respectively \(f_{1}, f_{01}\) ) exhibits the simplicial set \(S_{0}\) (respectively \(S_{1}, S_{01}\) ) as a
localization of \(X_{0}\) (respectively \(X_{1}, X_{01}\) ) with respect to \(W_{0}\) (respectively \(W_{1}, W_{01}\) ). Let \(W\) be the collection of edges of \(X\) given by the union of the images of \(W_{0}\) and \(W_{1}\). Note that conditions \((a)\) and \((b)\) guarantee that the front and back faces of the diagram (6.9) are categorical pushout squares (Proposition 4.5.4.11). Applying Proposition 6.3.4.2 we conclude that \(f\) exhibits \(S\) as a localization of \(X\) with respect to \(W\).

\subsection*{6.3.7 Subdivision and Localization}

02MC Our goal in this section is to prove the following:
02MD Theorem 6.3.7.1. Let \(S\) be a simplicial set. Then there exists a partially ordered set \((A, \leq)\) and a universally localizing morphism \(\mathrm{N}_{\bullet}(A) \rightarrow S\).

We begin by proving a weaker version of Theorem 6.3.7.1, which asserts that every simplicial set \(S\) admits a universally localizing morphism \(\mathrm{N}_{\bullet}(\mathcal{C}) \rightarrow S\), for some category \(\mathcal{C}\). Here it is possible to be completely explicit: we can take \(\mathcal{C}\) to be the category of simplices \(\boldsymbol{\Delta}_{S}\) introduced in Construction 1.1.3.9 (Corollary 6.3.7.5).

02ME Proposition 6.3.7.2. Let \(S\) be a simplicial set, let \(\operatorname{Sd}(S)\) denote the subdivision of \(S\) (Definition 3.3.3.1), and let \(\lambda_{S}: \operatorname{Sd}(S) \rightarrow S\) denote the last vertex map (Construction 3.3.4.3). Then \(\lambda_{S}\) is universally localizing.

02MF Remark 6.3.7.3. Let \(S\) be a simplicial set. Combining Proposition 6.3.7.2 with Remark 6.3.6.5, we recover the assertion that the last vertex map \(\lambda_{S}: \operatorname{Sd}(S) \rightarrow S\) is a weak homotopy equivalence. In other words, we can regard Proposition 6.3.7.2 as a refinement of Proposition 3.3.4.8

Proof of Proposition 6.3.7.2. By virtue of Proposition 6.3.6.12, we may assume without loss of generality that the simplicial set \(S\) is finite. If \(S\) is empty, there is nothing to prove. We may therefore assume that \(S\) has dimension \(n\) for some integer \(n \geq 0\). We proceed by induction on \(n\) and on the number of nondegenerate \(n\)-simplices of \(S\). Fix a nondegenerate \(n\)-simplex \(\sigma: \Delta^{n} \rightarrow S\). Using Proposition 1.1.4.12, we see that there is a pushout square of simplicial sets

where \(S^{\prime}\) is a simplicial set of dimension \(\leq n\) having fewer nondegenerate \(n\)-simplices than
\(S\). Applying Proposition 6.3.6.13 to the commutative diagram

we are reduced to showing that the morphisms \(\lambda_{S^{\prime}}, \lambda_{\partial \Delta^{n}}\), and \(\lambda_{\Delta^{n}}\) are universally localizing. In the first two cases, this follows from our inductive hypothesis. We are therefore reduced to proving Proposition 6.3.7.2 in the special case where \(S=\Delta^{n}\) is a standard simplex. Using Example 3.3.3.5, we can identify the subdivision \(\operatorname{Sd}(S)=\operatorname{Sd}\left(\Delta^{n}\right)\) with the nerve of the partially ordered set Chain \([n]\) of nonempty subsets \(P \subseteq[n]\). Under this identification, \(\lambda_{S}\) is obtained from the map of partially ordered sets
\[
\text { Chain }[n] \rightarrow[n] \quad(S \subseteq[n]) \mapsto \max (S)
\]

We now observe that this map admits section \(\mu:[n] \rightarrow\) Chain \([n]\), given by the construction \(i \mapsto\{0<1<\cdots<i\}\), and there is a (unique) natural transformation \(\operatorname{id}_{\operatorname{Sd}(S)} \rightarrow \mu \circ \lambda_{S}\) which belongs to Fun \(/ S(\operatorname{Sd}(S), \operatorname{Sd}(S))\). The desired result now follows from the criterion of Proposition 6.3.6.8

Variant 6.3.7.4. Let \(S\) be a simplicial set and let \(\psi_{S}: \mathrm{N}_{\bullet}\left(\boldsymbol{\Delta}_{S}\right) \rightarrow \operatorname{Sd}(S)\) be the comparison map of Construction 3.3.3.9. Then \(\psi_{S}\) is universally localizing.

Proof. Note that the functor \(S \mapsto \mathrm{~N}_{\bullet}\left(\boldsymbol{\Delta}_{S}\right)\) preserves small colimits (Variant 3.3.3.19). Proceeding as in the proof of Proposition 6.3.7.2, we can reduce to the case where \(S=\Delta^{n}\) is a standard simplex. In this case, we can identify \(\psi_{S}\) with (the nerve of) the functor
\[
\boldsymbol{\Delta}_{S} \rightarrow \text { Chain }[n] \quad(\alpha:[m] \rightarrow[n] \mapsto \operatorname{im}(\alpha) \subseteq[n])
\]

This functor admits a section \(\phi\), which identifies Chain \([n]\) with the subcategory \(\boldsymbol{\Delta}_{S}^{\text {nd }} \subseteq \boldsymbol{\Delta}_{S}\) of nondegenerate simplices of \(S\). Note that there is a (unique) natural transformation from
the identity functor \(\mathrm{id}_{\boldsymbol{\Delta}_{S}}\) to \(\phi \circ \psi_{S}\) which belongs to \(\mathrm{Fun}_{/ \mathrm{Sd}(S)}\left(\mathrm{N}_{\bullet}\left(\boldsymbol{\Delta}_{S}\right), \mathrm{N}_{\bullet}\left(\boldsymbol{\Delta}_{S}\right)\right)\), so the desired result follows from the criterion of Proposition 6.3.6.8.

04 JV Corollary 6.3.7.5. Let \(S\) be a simplicial set. Then the composite morphism
\[
\mathrm{N}_{\bullet}\left(\boldsymbol{\Delta}_{S}\right) \xrightarrow{\psi_{S}} \operatorname{Sd}(S) \xrightarrow{\lambda_{S}} S
\]
is universally localizing.
Proof. By virtue of Proposition 6.3.6.10, this follows from the observation that the morphisms \(\lambda_{S}\) and \(\psi_{S}\) are universally localizing (Proposition 6.3.7.2 and Variant 6.3.7.4).

We now study some additional assumptions on the simplicial set \(S\) which will allow us to replace the category \(\boldsymbol{\Delta}_{S}\) of Corollary 6.3.7.5 by a partially ordered set.

02MG Definition 6.3.7.6. Let \(S\) be a simplicial set. We say that \(S\) is nonsingular if, for every every nondegenerate \(n\)-simplex \(\sigma\) of \(S\), the corresponding map \(\sigma: \Delta^{n} \rightarrow S\) is a monomorphism of simplicial sets.

02MH Remark 6.3.7.7. Recall that a simplicial set \(S\) is braced if the collection of nondegenerate simplices of \(S\) is closed under the face operators (Definition 3.3.1.1). Every nonsingular simplicial set is braced. However, the converse is false. For example, the quotient \(\Delta^{1} / \partial \Delta^{1}\) is braced, but is not nonsingular.

02 MJ Example 6.3.7.8. Let \((A, \leq)\) be a partially ordered set. Then the nerve \(\mathrm{N}_{\bullet}(A)\) is a nonsingular simplicial set. In particular, for every integer \(n \geq 0\), the standard simplex \(\Delta^{n}\) is nonsingular.

Remark 6.3.7.9. Let \(S\) be a nonsingular simplicial set. Then every simplicial subset \(S^{\prime} \subseteq S\) is also nonsingular.

02ML Remark 6.3.7.10. Let \(S\) be a simplicial set which can be written as a union of a collection of simplicial subsets \(\left\{S_{\alpha} \subseteq S\right\}\). If each \(S_{\alpha}\) is nonsingular, then \(S\) is nonsingular.

02MM Remark 6.3.7.11. Let \(S\) and \(T\) be nonsingular simplicial sets. Then the join \(S \star T\) is nonsingular. In particular, if \(S\) is nonsingular, then the cone \(S^{\triangleright}\) is also nonsingular.

02MN Remark 6.3.7.12. Let \(S\) be a simplicial set and \(A\) denote the collection of simplicial subsets \(S^{\prime} \subseteq S\) which are isomorphic to a standard simplex. We regard \(\operatorname{Sub}_{\boldsymbol{\Delta}}(S)\) as a partially ordered set with respect to inclusion. If \(S\) is nonsingular, the construction
\[
\left(\sigma: \Delta^{n} \rightarrow S\right) \mapsto(\operatorname{im}(\sigma) \subseteq S)
\]
determines an isomorphism of categories \(\boldsymbol{\Delta}_{S}^{\text {nd }} \simeq A\), where \(\boldsymbol{\Delta}_{S}^{\text {nd }}\) denotes category of nondegenerate simplices of \(S\) (Notation 3.3.3.11). Combining this observation with Proposition 3.3.3.16, we obtain an isomorphism of simplicial sets \(\mathrm{N}_{\bullet}(A) \rightarrow \operatorname{Sd}(S)\).

Corollary 6.3.7.13. Let \(S\) be a nonsingular simplicial set. Then there exists a partially 02MP ordered set \(A\) and a universally localizing morphism \(\mathrm{N}_{\bullet}(A) \rightarrow S\).

Proof. Combine Proposition 6.3.7.2 with Remark 6.3.7.12.
For our purposes, Corollary 6.3.7.13 is a poor replacement for Theorem 6.3.7.1 an \(\infty\)-category \(\mathcal{C}\) is rarely nonsingular when regarded as a simplicial set (see Exercise 3.3.1.2). We will deduce the general form of Theorem 6.3.7.1 by combining Corollary 6.3.7.13 with the following result:

Proposition 6.3.7.14. Let \(S\) be a simplicial set. Then there exists a universally localizing 02MQ morphism \(\varphi: \widetilde{S} \rightarrow S\), where \(\widetilde{S}\) is nonsingular.

The proof of Proposition 6.3.7.14 will make use of the following:
Lemma 6.3.7.15. Let \(\left\{S_{\alpha}\right\}\) be a diagram of nonsingular simplicial sets. Then the limit 02MR \(\varliminf_{\leftrightarrows} \lim _{\alpha}\) is also nonsingular.

Proof. By virtue of Remark 6.3.7.9, it will suffice to show that the product \(S=\prod_{\alpha} S_{\alpha}\) is nonsingular. Let \(\sigma: \Delta^{n} \rightarrow S\) be a nondegenerate simplex of \(S\); we wish to show that \(\sigma\) is a monomorphism of simplicial sets. For each index \(\alpha\), Proposition 1.1.3.8 guarantees that there exists a commutative diagram

where \(\sigma_{\alpha}\) is a nondegenerate simplex \(S_{\alpha}\). Our assumption that \(S_{\alpha}\) is nondegenerate guarantees that \(\sigma_{\alpha}\) is a monomorphism of simplicial sets, so that the product map
\[
\prod_{\alpha} \Delta^{n_{\alpha}} \xrightarrow{\prod_{\alpha} \sigma_{\alpha}} \prod_{\alpha} S_{\alpha}=S
\]
is also a monomorphism. It will therefore suffice to show that \(\tau=\left\{\tau_{\alpha}\right\}\) determines a monomorphism of simplicial sets \(\Delta^{n} \rightarrow \prod_{\alpha} \Delta^{n_{\alpha}}\). Since \(\prod_{\alpha} \Delta^{n_{\alpha}}\) can be identified with the nerve of the partially ordered set \(\prod_{\alpha}\left[n_{\alpha}\right]\), it is a nonsingular simplicial set (Example 6.3.7.8). It will therefore suffice to show that \(\tau\) is nondegenerate, which follows immediately from our assumption that \(\sigma\) is nondegenerate.

Proof of Proposition 6.3.7.14, Let \(S\) be a simplicial set. For each integer \(k \geq 0\), let \(\operatorname{sk}_{k}(S)\) denote the \(k\)-skeleton of \(S\) (Construction 1.1.4.1). We will construct a commutative diagram

where each of the horizontal maps is a monomorphism, each of the vertical maps is universally localizing, and each of the simplicial sets \(\widetilde{\mathrm{sk}}_{k}(S)\) is nonsingular. It then follows from Remark 6.3.7.10 that the colimit \(\widetilde{S}=\lim _{\longrightarrow} \widetilde{\mathrm{sk}}_{k}(S)\) is nonsingular. Applying Proposition 6.3.6.12, we conclude that the morphisms \(\varphi_{k}\) determine a universally localizing morphism \(\varphi: S \rightarrow S\).

The construction of the morphisms \(\varphi_{k}: \widetilde{\operatorname{sk}}_{k}(S) \rightarrow \operatorname{sk}_{k}(S)\) proceeds by induction. If \(k=0\), we can take \(\widetilde{\mathrm{sk}}_{k}(S)=\operatorname{sk}_{k}(S)\) and \(\varphi_{k}\) to be the identity morphism. Let us therefore assume that \(k>0\), and that the morphism \(\varphi_{k-1}: \widetilde{\operatorname{sk}}_{k-1}(S) \rightarrow \mathrm{sk}_{k-1}(S)\) has already been constructed. Let \(S_{k}^{\text {nd }}\) denote the set of nondegenerate \(k\)-simplices of \(S\), let \(T\) denote the coproduct \(\amalg_{\sigma \in S_{k}^{\text {nd }}} \Delta^{k}\), and let \(T_{0} \subseteq T\) denote the coproduct \(\amalg_{\sigma \in S_{k}^{\text {nd }}} \partial \Delta^{k}\), so that Proposition 1.1.4.12 supplies a pushout diagram

Note that \(T\) is nonsingular (Example 6.3.7.8), so the simplicial subset \(T_{0} \subseteq T\) is also nonsingular (Remark 6.3.7.9). Let \(\widetilde{T}_{0}\) denote the fiber product \(T_{0} \times_{\mathrm{sk}_{k-1}(S)} \widetilde{\mathrm{sk}_{k-1}}(S)\), and we define \(\widetilde{\operatorname{sk}}_{k}(S)\) to be the pushout of the diagram
\[
\left(\widetilde{\operatorname{sk}}_{k-1}(S) \times \widetilde{T}_{0}^{\triangleright}\right) \hookleftarrow \widetilde{T}_{0} \hookrightarrow\left(T \times \widetilde{T}_{0}^{\triangleright}\right) .
\]

Note that the cone point of \(\widetilde{T}_{0}^{\triangleright}\) determines an embedding \(\widetilde{\operatorname{sk}}_{k-1}(S) \rightarrow \widetilde{\operatorname{sk}}_{k}(S)\). Moreover, we have a commutative diagram

which determines an extension of \(\varphi_{k-1}\) to a map
\[
\varphi_{k}: \widetilde{\operatorname{sk}}_{k}(S) \rightarrow \operatorname{sk}_{k-1}(S) \coprod_{T_{0}} T \simeq \operatorname{sk}_{k}(S) .
\]

Since the cone \(\widetilde{T}_{0}^{\triangleright}\) is weakly contractible, it follows from Corollary 6.3.6.11 that the vertical maps in the diagram (6.10) are universally localizing. Applying Proposition 6.3.6.13, we deduce that \(\varphi_{k}\) is also universally localizing.

To complete the proof, it will suffice to show that the simplicial set \(\widetilde{\mathrm{sk}}_{k}(S)\) is nonsingular. By virtue of Remark 6.3.7.10, it will suffice to show that the simplicial subsets \(\widetilde{s k}_{k-1}(S) \times \widetilde{T}_{0}^{\triangleright}\) and \(T \times \widetilde{T}_{0}^{\triangleright}\) are nonsingular. Since \(\widetilde{\mathrm{sk}}_{k-1}(S)\) is nonsingular (by our inductive hypothesis) and \(T\) is nonsingular (Example 6.3.7.8, we are reduced to proving that the cone \(\widetilde{T}_{0}^{\triangleright}\) is nonsingular (Lemma 6.3.7.15). By virtue of Remark 6.3.7.11 we can reduce further to showing that \(\widetilde{T}_{0}\) is nonsingular. This follows from Remark 6.3.7.9 and Lemma 6.3.7.15 since \(\widetilde{T}_{0}\) can be identified with a simplicial subset of the product \(T \times \widetilde{\operatorname{sk}}_{k-1}(S)\).

Remark 6.3.7.16. Let \(S\) be a finite simplicial set. In this case, each of the simplicial sets \(\widetilde{\mathrm{sk}}_{k}(S)\) constructed in the proof of Proposition 6.3.7.14 will also be finite. Specializing to the case \(k \geq \operatorname{dim}(S)\), we obtain a universally localizing morphism
\[
\widetilde{\mathrm{sk}}_{k}(S) \rightarrow \mathrm{sk}_{k}(S)=S
\]
where the simplicial set \(\widetilde{\mathrm{sk}}_{k}(S)\) is both finite and nonsingular.
Proof of Theorem 6.3.7.1. Let \(S\) be a simplicial set. Applying Proposition 6.3.7.14, we can choose a universally localizing morphism \(\varphi: \widetilde{S} \rightarrow S\), where \(\widetilde{S}\) is a nonsingular simplicial set. Let \(A=\operatorname{Sub}_{\Delta}(\widetilde{S})\) denote the partially ordered set of simplicial subsets of \(\widetilde{S}\) which are isomorphic to a standard simplex, so that Corollary 6.3 .7 .13 supplies a universally localizing morphism \(\lambda_{\widetilde{S}}: \mathrm{N}_{\bullet}(A) \rightarrow \widetilde{S}\). Applying Proposition 6.3.6.10, we deduce that the composite morphism
\[
\mathrm{N}_{\bullet}(A) \xrightarrow{\lambda_{\widetilde{S}}} \widetilde{S} \xrightarrow{\varphi} S
\]
is also universally localizing.
Combining the preceding argument with Remark 6.3.7.16, we also obtain the following:
Variant 6.3.7.17. Let \(S\) be a finite simplicial set. Then there exists a finite partially
```

02MU

``` ordered set \((A, \leq)\) and a universally localizing morphism \(\mathrm{N}_{\bullet}(A) \rightarrow S\).
Exercise 6.3.7.18. Let \(S\) be a simplicial set and let \(\widetilde{S}\) be the smallest simplicial subset of \(S \times \mathrm{N}_{\bullet}\left(\mathbf{Z}_{\geq 0}\right)\) which contains all simplices of the form \((\sigma, \tau)\), where \(\tau\) is a nondegenerate simplicial subset of \(\mathrm{N}_{\bullet}\left(\mathbf{Z}_{\geq 0}\right)\) (that is, it corresponds to a strictly increasing sequence of nonnegative integers). Show that \(\widetilde{S}\) is nonsingular, and that projection onto the first factor determines a universally localizing morphism \(\widetilde{S} \rightarrow S\).

\section*{Chapter 7}

\section*{Limits and Colimits}

In this chapter, we extend the classical theory of limits and colimits to the setting of higher category theory. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. We say that an object \(Y \in \mathcal{D}\) is a limit of \(F\) if there exists a natural transformation \(\alpha: \underline{Y} \rightarrow F\) having the following universal property: for every object \(X \in \mathcal{C}\), composition with \(\alpha\) induces a homotopy equivalence of Kan complexes
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\operatorname{Fun}(\mathcal{C}, \mathcal{D})}(\underline{X}, F) ;
\]
here \(\underline{X}, \underline{Y} \in \operatorname{Fun}(\mathcal{C}, \mathcal{D})\) denote the constant functors taking the values \(X\) and \(Y\), respectively. In this case, the object \(Y\) is uniquely determined up to isomorphism; to emphasize this, we often denote \(Y\) by \(\varliminf_{亡} \lim ^{( }(F)\), or by \(\lim _{C \in \mathcal{C}}(F(C))\). In \(\S 7.1\), we summarize the formal properties of this notion (as well as the dual notion of colimit, which plays an equally essential role in the theory).

Throughout this book, we will often be faced with the problem of computing (or describing) the limit of a diagram \(F: \mathcal{C} \rightarrow \mathcal{D}\). In such situations, it is useful to have some flexibility to modify the \(\infty\)-category \(\mathcal{C}\). In \(\S 7.2\), we introduce the notion of a left cofinal morphism of simplicial sets \(e: \mathcal{C}^{\prime} \rightarrow \mathcal{C}\) (Definition 7.2.1.1). If \(e: \mathcal{C}^{\prime} \rightarrow \mathcal{C}\) is left cofinal, then an object of \(\mathcal{D}\) is a limit of \(F\) if and only if it is a limit of the composite map \(F^{\prime}=F \circ e\) (see Corollary 7.2.2.11, and Corollary 7.4.5.14 for a converse). When \(\mathcal{C}\) is an \(\infty\)-category, cofinality admits a simple characterization: a morphism \(e: \mathcal{C}^{\prime} \rightarrow \mathcal{C}\) is left cofinal if and only if, for each object \(C \in \mathcal{C}\), the simplicial set \(\mathcal{C}^{\prime} \times_{\mathcal{C}} \mathcal{C}_{/ C}\) is weakly contractible (Theorem 7.2.3.1). We will encounter many situations where this criterion is easy to verify. In such cases, it is harmless to replace \(\mathcal{C}\) by \(\mathcal{C}^{\prime}\) for the purpose of calculating the limit of a diagram \(F: \mathcal{C} \rightarrow \mathcal{D}\).

In \(\$ 7.3\), we consider another important technique for computing limits. Suppose we are given a cartesian fibration of \(\infty\)-categories \(U: \mathcal{E} \rightarrow \mathcal{C}\). Under some mild assumptions, one can show that the limit of a diagram \(F: \mathcal{E} \rightarrow \mathcal{D}\) obeys a transitivity formula, which we can
write informally as
\[
\lim _{\underset{X}{ } \in \mathcal{E}}(F(X)) \simeq \lim _{C \in \mathcal{C}}\left(\lim _{X \in \mathcal{E}_{C}} F(X)\right) .
\]

More precisely, suppose that for every object \(C \in \mathcal{C}\), the diagram \(F_{C}=F \mid \mathcal{E}_{C}\) admits a limit in the \(\infty\)-category \(\mathcal{D}\). Then one can construct a new functor \(G: \mathcal{C} \rightarrow \mathcal{D}\), given on objects by the formula \(G(C)=\lim \left(F_{C}\right)\); we refer to \(G\) as a right Kan extension of \(F\) along \(U\) (see Definition 7.3 .1 .2 and Proposition 7.3.4.4). Moreover, an object of the \(\infty\)-category \(\mathcal{D}\) is a limit of the functor \(F\) if and only if it is a limit of the functor \(G\) (Corollary 7.3.8.20).

The remainder of this chapter is devoted to studying limits and colimits in special situations. Let \(\mathcal{S}\) denote the \(\infty\)-category of spaces (Construction 5.5.1.1). For any \(\infty\) category \(\mathcal{C}\), Corollary 5.6.0.6 supplies a bijection from the set of isomorphism classes of functors \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}\) and the set of equivalence classes of essentially small left fibrations \(U: \mathcal{E} \rightarrow \mathcal{C}\). In \(\S \boxed{7.4}\), we use this identification to give an explicit description of limits and colimits in \(\mathcal{S}\) :
(1) The Kan complex \(\operatorname{Fun}_{/ \mathcal{C}}(\mathcal{C}, \mathcal{E})\) parametrizing sections of \(U\) is a limit of the diagram \(\mathscr{F}\).
(2) A Kan complex \(X\) is a colimit of \(\mathscr{F}\) if and only if there exists a weak homotopy equivalence \(\mathcal{E} \rightarrow X\) (Corollary 7.4.5.4).

These assertions are special cases of more general results which apply to diagrams taking values in the \(\infty\)-category \(\mathcal{Q C} \supset \mathcal{S}\); see Theorems 7.4.1.1 and7.4.3.6.

Recall that the \(\infty\)-category \(\mathcal{S}\) is defined as the homotopy coherent nerve of the ordinary category of Kan complexes Kan. In particular, if \(\mathscr{F}_{0}: \mathcal{C}_{0} \rightarrow\) Kan is a functor between ordinary categories, then passing to the homotopy coherent nerve gives a functor of \(\infty\) categories \(\mathscr{F}: \mathcal{C} \rightarrow \mathcal{S}\), where \(\mathcal{C}=\mathrm{N}_{\bullet}\left(\mathcal{C}_{0}\right)\). In this case, there is a natural candidate for the corresponding left fibration \(U: \mathcal{E} \rightarrow \mathcal{C}\), obtained by taking \(\mathcal{E}\) to be the weighted nerve \(\mathrm{N}_{\bullet}^{\mathscr{F}_{0}}\left(\mathcal{C}_{0}\right)\) of Definition 5.3.3.1. In \(\S 7.5\), we combine this observation with assertions (1) and (2) to compare limits and colimits in the \(\infty\)-category \(\mathcal{S}\) with the classical theory of homotopy limits and colimits introduced by Bousfield and Kan in [6].

In \(\S 7.6\), we provide a detailed discussion of some special classes of limits which arise frequently in practice, such as products (Definition 7.6.1.3), powers (Definition 7.6.2.1), pullbacks (Definition 7.6.3.1), equalizers (Definition 7.6.5.4), and sequential limits (Definition 7.6.6.1). From these primitives, many other examples can be constructed: for example, arbitrary limits in an \(\infty\)-category \(\mathcal{D}\) can be built by combining products and equalizers (see Corollary 7.6.5.25 and Proposition 7.6.7.9.

\subsection*{7.1 Limits and Colimits}

Let \(\mathcal{K}\) and \(\mathcal{C}\) be categories. For every object \(X \in \mathcal{C}\), let \(\underline{X}\) denote the constant functor from \(\mathcal{K}\) to \(\mathcal{C}\), carrying each object of \(\mathcal{K}\) to \(X\) and each morphism of \(\mathcal{K}\) to the identity morphism \(\operatorname{id}_{X}\). If \(U: \mathcal{K} \rightarrow \mathcal{C}\) is an arbitrary functor, then a limit of \(U\) is an object of \(\mathcal{C}\) which represents the functor \(X \mapsto \operatorname{Hom}_{\operatorname{Fun}(\mathcal{K}, \mathcal{C})}(\underline{X}, U)\). This can be formulated more precisely as follows:

02H2 Definition 7.1.0.1. Let \(F: \mathcal{K} \rightarrow \mathcal{C}\) be a functor between categories. Let \(Y\) be an object of \(\mathcal{C}\) and let \(\alpha: \underline{Y} \rightarrow F\) be a natural transformation of functors. We say that the natural transformation \(\alpha\) exhibits \(Y\) as a limit of \(F\) if the following condition is satisfied:
(*) For every object \(X \in \mathcal{C}\), composition with \(\alpha\) induces a bijection from \(\operatorname{Hom}_{\mathcal{C}}(X, Y)\) to the set \(\operatorname{Hom}_{\operatorname{Fun}(\mathcal{K}, \mathcal{C})}(\underline{X}, F)\) of natural transformations from \(\underline{X}\) to \(F\).

Our goal in this section is to introduce an \(\infty\)-categorical counterpart of Definition 7.1.0.1. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(F: \mathcal{K} \rightarrow \mathcal{C}\) be a diagram, let \(\alpha: \underline{Y} \rightarrow F\) be a natural transformation. For every object \(X \in \mathcal{C}\), composition with \(\alpha\) induces a map of Kan complexes
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\operatorname{Fun}(K, \mathcal{C})}(\underline{X}, F),
\]
which is well-defined up to homotopy. We will say that \(\alpha\) exhibits \(Y\) as a limit of \(F\) if this map is a homotopy equivalence for each \(X \in \mathcal{C}\) (Definition 7.1.1.1). In \(\S 7.1 .1\), we provide a detailed analysis of this notion and its formal properties (as well as the dual notion of colimit, which is defined in a similar way).

In \(\S 4.6 .7\), we introduced the notion of a final object of an \(\infty\)-category \(\mathcal{C}\) (Definition 4.6.7.1). This can be regarded as a special case of the general theory of limits: an object \(Y \in \mathcal{C}\) is final if and only if it is a limit of the empty diagram (Example 7.1.1.6). Conversely, if \(K\) is an arbitrary simplicial set equipped with a diagram \(F: K \rightarrow \mathcal{C}\), we will see that a natural transformation \(\alpha: \underline{Y} \rightarrow F\) exhibits \(Y\) as a limit of \(F\) if and only if it is final when viewed as an object of the \(\infty\)-category \(\mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{F\}\) (Proposition 7.1.2.1). Recall that \(\mathcal{C} \tilde{\times}_{\text {Fun }(K, \mathcal{C})}\{F\}\) is equivalent (but not isomorphic) to the slice \(\infty\)-category \(\mathcal{C}_{/ F}\) (Theorem 4.6.4.17). In \(\S 7.1 .2\), we use this observation to reformulate the notion of limit: an object \(Y\) is a limit of a diagram \(F: K \rightarrow \mathcal{C}\) if there exists a diagram \(\bar{F}: K^{\triangleleft} \rightarrow \mathcal{C}\) which carries the cone point of \(K^{\triangleleft}\) to the object \(Y\) and which is final when viewed as an object of the slice \(\infty\)-category \(\mathcal{C}_{/ F}\) (Corollary 7.1.2.2. In this situation, we will refer to \(\bar{F}\) as a limit diagram in the \(\infty\)-category \(\mathcal{C}\) (Definintion 7.1.2.4).

In \(\$ 7.1 .3\), we study the dependence of \(K\)-indexed limits on the ambient \(\infty\)-category in which they are formed. We say that a functor of \(\infty\)-categories \(G: \mathcal{C} \rightarrow \mathcal{D}\) preserves \(K\)-indexed limits if, for every diagram \(F: K \rightarrow \mathcal{C}\), the induced functor \(\mathcal{C}_{/ F} \rightarrow \mathcal{D}_{/(G \circ F)}\) carries final objects of \(\mathcal{C}_{/ F}\) to final objects of \(\mathcal{D}_{/(G \circ F)}\) (Definition 7.1.3.4). We illustrate the concept in this section with a few elementary examples (and will encounter many others later in this book):
- If \(G: \mathcal{C} \rightarrow \mathcal{D}\) is an equivalence of \(\infty\)-categories, then it preserves \(K\)-indexed limits for every simplicial set \(K\) (Proposition 7.1.3.9).
- Let \(\mathcal{C}\) be an \(\infty\)-category which admits \(K\)-indexed limits, and let \(f: A \rightarrow \mathcal{C}\) be any morphism of simplicial sets. Then the coslice \(\infty\)-category \(\mathcal{C}_{f /}\) also admits \(K\)-indexed limits, and the projection map \(\mathcal{C}_{f /} \rightarrow \mathcal{C}\) preserves \(K\)-indexed limits (Corollary 7.1.3.20).
- Let \(G: \mathcal{C} \rightarrow \mathcal{D}\) be a right fibration of \(\infty\)-categories, and suppose that \(\mathcal{D}\) admits \(K\)-indexed limits. If \(K\) is weakly contractible, then the \(\infty\)-category \(\mathcal{C}\) also admits \(K\)-indexed limits, and the right fibration \(F\) preserves \(K\)-indexed limits (Corollary 7.1.5.18.

For many applications, it will be useful to consider a relative version of the theory of limit diagrams. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. We say that an object \(Y \in \mathcal{C}\) is \(U\)-final if, for every object \(X \in \mathcal{C}\), the functor \(U\) induces a homotopy equivalence \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(U(X), U(Y))\) (Definition 7.1.4.1. We say that a diagram \(\bar{F}: K^{\triangleleft} \rightarrow \mathcal{C}\) with restriction \(F=\left.\bar{F}\right|_{K}\) is a \(U\)-limit diagram if it is \(U_{/ F}\)-final when regarded as an object of the \(\infty\)-category \(\mathcal{C}_{/ F}\), where \(U_{/ F}: \mathcal{C}_{/ F} \rightarrow \mathcal{D}_{/(U \circ F)}\) is the projection map (Definition 7.1.5.1). In the special case \(\mathcal{D}=\Delta^{0}\), we recover the usual notions of final object and limit diagram, respectively (Examples 7.1.4.2 and 7.1.5.3). Moreover, most of the basic features of final objects and limit diagrams have counterparts in the relative setting, which we summarize in \(\$ 7.1 .4\) and \(\$ 7.1 .5\). Even if one is ultimately interested in the "absolute" theory, the language of relative limits is a useful tool: we illustrate this point in \(\$ 7.1 .6\) by using the relative language to study limits in an \(\infty\)-category of the form \(\operatorname{Fun}(B, \mathcal{C})\) (our main result is that, under mild assumptions, such limits can be computed pointwise: see Proposition 7.1.6.1)
Remark 7.1.0.2. The preceding discussion has centered around the theory of limits. There 02VX is also a dual theory of colimits in the \(\infty\)-categorical setting, which can be obtained by passing to opposite \(\infty\)-categories. Every assertion concerning limits has a counterpart for colimits (and vice versa). We will often use this implicitly (for example, by stating a result only for colimits but later using the dual assertion for limits).

\subsection*{7.1.1 Limits and Colimits in \(\infty\)-Categories}

Let \(\mathcal{C}\) be an \(\infty\)-category and let \(K\) be a simplicial set. For each object \(X \in \mathcal{C}\), we let 02VY \(\underline{X} \in \operatorname{Fun}(K, \mathcal{C})\) denote the constant diagram \(K \rightarrow\{X\} \hookrightarrow \mathcal{C}\). Note that the construction \(X \mapsto \underline{X}\) determines a functor of \(\infty\)-categories \(\mathcal{C} \rightarrow \operatorname{Fun}(K, \mathcal{C})\), carrying each morphism \(f: X \rightarrow Y\) to a natural transformation \(\underline{f}: \underline{X} \rightarrow \underline{Y}\).
Definition 7.1.1.1. Let \(\mathcal{C}\) be an \(\infty\)-category containing an object \(Y\), let \(K\) be a simplicial set, and let \(u: K \rightarrow \mathcal{C}\) be a diagram. We say that a natural transformation \(\alpha: \underline{Y} \rightarrow u\) exhibits \(Y\) as a limit of \(u\) if the following condition is satisfied:
(*) For each object \(X \in \mathcal{C}\), the composition
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\operatorname{Fun}(K, \mathcal{C})}(\underline{X}, \underline{Y}) \xrightarrow{[\alpha] \circ} \operatorname{Hom}_{\operatorname{Fun}(K, \mathcal{C})}(\underline{X}, u)
\]
is an isomorphism in the homotopy category hKan, where the second map is described in Notation 4.6.9.15

We will say that a natural transformation \(\beta: u \rightarrow \underline{Y}\) exhibits \(Y\) as a colimit of \(u\) if the following dual condition is satisfied:
(*') For each object \(Z \in \mathcal{C}\), the composition
\[
\operatorname{Hom}_{\mathcal{C}}(Y, Z) \rightarrow \operatorname{Hom}_{\operatorname{Fun}(K, \mathcal{C})}(\underline{Y}, \underline{Z}) \xrightarrow{\circ[\beta]} \operatorname{Hom}_{\operatorname{Fun}(K, \mathcal{C})}(u, \underline{Z})
\]
is an isomorphism in the homotopy category hKan.
02W0 Remark 7.1.1.2. Stated more informally, a natural transformation \(\alpha: \underline{Y} \rightarrow u\) exhibits \(Y\) as a limit of \(u\) if and only if postcomposition with \(\alpha\) induces a homotopy equivalence \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\operatorname{Fun}(K, \mathcal{C})}(\underline{X}, u)\) for each object \(X \in \mathcal{C}\). Similarly, a natural transformation \(\beta: u \rightarrow \underline{Y}\) exhibits \(Y\) as a colimit of \(u\) if and only if precomposition with \(\beta\) induces a homotopy equivalence \(\operatorname{Hom}_{\mathcal{C}}(Y, Z) \rightarrow \operatorname{Hom}_{\operatorname{Fun}(K, \mathcal{C})}(u, \underline{Z})\) for each object \(Z \in \mathcal{C}\).

02JC Remark 7.1.1.3. Let \(\mathcal{C}\) be an \(\infty\)-category containing an object \(Y\) and let \(u: K \rightarrow \mathcal{C}\) be a diagram. Then a natural transformation \(\alpha: \underline{Y} \rightarrow u\) exhibits \(Y\) as a limit of \(u\) if and only if it exhibits \(Y\) as a colimit of the induced diagram \(u^{\mathrm{op}}: K^{\mathrm{op}} \rightarrow \mathcal{C}^{\mathrm{op}}\), when regarded as a morphism in the \(\infty\)-category \(\operatorname{Fun}\left(K^{\mathrm{op}}, \mathcal{C}^{\mathrm{op}}\right) \simeq \operatorname{Fun}(K, \mathcal{C})^{\mathrm{op}}\).

02JD Example 7.1.1.4. Let \(\mathcal{C}\) be an ordinary category, let \(K\) be a simplicial set, and suppose we are given a diagram \(u: K \rightarrow \mathrm{~N}_{\bullet}(\mathcal{C})\), which we can identify with a functor of ordinary categories \(U: \mathrm{h} K \rightarrow \mathcal{C}\) (see Proposition 1.4.5.7). If \(Y\) is an object of \(\mathcal{C}\), then we can use Corollary 1.5.3.5 to identify natural transformations \(\underline{Y} \rightarrow u\) (of diagrams in the \(\infty\)-category \(\mathrm{N}_{\bullet}(\mathcal{C})\) ) with natural transformations \(\underline{Y} \rightarrow U\) (of diagrams in the ordinary category \(\mathcal{C}\) ). Under this identification, a natural transformation \(\underline{Y} \rightarrow u\) exhibits \(Y\) as a limit of \(u\) (in the \(\infty\)-categorical sense of Definition 7.1.1.1) if and only if it exhibits \(Y\) as a limit of \(U\) (in the classical sense of Definition 7.1.0.1).

02JR Example 7.1.1.5. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(f: X \rightarrow Y\) be a morphism in \(\mathcal{C}\). The following conditions are equivalent:
- The morphism \(f\) is an isomorphism from \(X\) to \(Y\) in the \(\infty\)-category \(\mathcal{C}\) (Definition 1.4.6.1.
- The morphism \(f\) exhibits \(X\) as a limit of the diagram \(\{Y\} \hookrightarrow \mathcal{C}\).
- The morphism \(f\) exhibits \(Y\) as a colimit of the diagram \(\{X\} \hookrightarrow \mathcal{C}\).

Example 7.1.1.6. Let \(\mathcal{C}\) be an \(\infty\)-category. Then an object \(Y \in \mathcal{C}\) is initial (in the sense of Definition 4.6.7.1) if and only if it is a colimit of the empty diagram \(\emptyset \hookrightarrow \mathcal{C}\). Similarly, \(Y\) is final if and only if it is a limit of the empty diagram.

Remark 7.1.1.7. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(u: K \rightarrow \mathcal{C}\) be a diagram, and let \(Y \in \mathcal{C}\) be an object. If \(\alpha: \underline{Y} \rightarrow u\) is a natural transformation, then the condition that \(\alpha\) exhibits \(Y\) as a limit of \(u\) depends only on its homotopy class \([\alpha]\) (as a morphism in the \(\infty\)-category Fun \((K, \mathcal{C})\) ). Similarly, if \(\beta: u \rightarrow \underline{Y}\) is a natural transformation, then the condition that \(\beta\) exhibits \(Y\) as a colimit of \(u\) depends only on its homotopy class \([\beta]\).

Remark 7.1.1.8. Let \(\mathcal{C}\) be an \(\infty\)-category containing an object \(Y\), let \(K\) be a simplicial set, and let \(\beta: u \rightarrow u^{\prime}\) be an isomorphism in the \(\infty\)-category \(\operatorname{Fun}(K, \mathcal{C})\). Suppose we are given a natural transformation \(\alpha: \underline{Y} \rightarrow u\), and let \(\alpha^{\prime}: \underline{Y} \rightarrow u^{\prime}\) be any composition of \(\alpha\) with \(\beta\). Then \(\alpha\) exhibits \(Y\) as a limit of \(u\) if and only if \(\alpha^{\prime}\) exhibits \(Y\) as a limit of \(u^{\prime}\). Similarly, if \(\gamma^{\prime}: u^{\prime} \rightarrow \underline{Y}\) is a natural transformation and \(\gamma: u \rightarrow \underline{Y}\) is a composition of \(\beta\) with \(\gamma^{\prime}\), then \(\gamma\) exhibits \(Y\) as a colimit of \(u\) if and only if \(\gamma^{\prime}\) exhibits \(Y\) as a colimit of \(u^{\prime}\).

Remark 7.1.1.9. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(u: K \rightarrow \mathcal{C}\) be a diagram, and let \(f: X \rightarrow Y\) be a morphism in \(\mathcal{C}\). Suppose we are given a natural transformation of diagrams \(\beta: \underline{Y} \rightarrow u\), and let \(\alpha: \underline{X} \rightarrow u\) be a composition of \(\beta\) with the constant natural transformation \(\underline{f}: \underline{X} \rightarrow \underline{Y}\). Then any two of the following three properties imply the third:
- The natural transformation \(\alpha\) exhibits \(X\) as a limit of the diagram \(u\).
- The natural transformation \(\beta\) exhibits \(Y\) as a limit of the diagram \(u\).
- The morphism \(f: X \rightarrow Y\) is an isomorphism in the \(\infty\)-category \(\mathcal{C}\).

Remark 7.1.1.10. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a fully faithful functor of \(\infty\)-categories, let \(u: K \rightarrow \mathcal{C}\)
02W4 be a diagram, and let \(Y \in \mathcal{C}\) be an object equipped with a natural transformation \(\alpha: \underline{Y} \rightarrow u\). If \(F(\alpha): F(Y) \rightarrow(F \circ u)\) exhibits \(F(Y)\) as a limit of the diagram \((F \circ u): K \rightarrow \mathcal{D}\), then \(\alpha\) exhibits \(Y\) as a limit of \(u\). The converse holds if \(F\) is an equivalence of \(\infty\)-categories.

Definition 7.1.1.11. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(u: K \rightarrow \mathcal{C}\) be a diagram. We say that an object \(Y \in \mathcal{C}\) is a limit of \(u\) if there exists a natural transformation \(\alpha: \underline{Y} \rightarrow u\) which exhibits \(Y\) as a limit of \(u\), in the sense of Definition 7.1.1.1. We say that \(Y\) is a colimit of \(u\) if there exists a natural transformation \(\beta: u \rightarrow \underline{Y}\) which exhibits \(Y\) as a colimit of \(u\).

Proposition 7.1.1.12. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(u: K \rightarrow \mathcal{C}\) be a diagram. Then: 02JH
- Suppose that the diagram \(u\) has limit \(Y \in \mathcal{C}\). Then an object \(X \in \mathcal{C}\) is a limit of \(u\) if and only if it is isomorphic to \(Y\).
- Suppose that the diagram \(u\) has colimit \(Y \in \mathcal{C}\). Then an object \(X \in \mathcal{C}\) is a colimit of \(u\) if and only if it is isomorphic to \(Y\).

Proof. Let \(\beta: \underline{Y} \rightarrow u\) be a natural transformation which exhibits \(Y\) as a limit of the diagram \(u\). For any object \(X\) and any natural transformation \(\alpha: \underline{X} \rightarrow u\), there exists a morphism \(f: X \rightarrow Y\) such that \(\alpha\) is a composition of \(\beta\) with the constant natural transformation \(\underline{f}: \underline{X} \rightarrow \underline{Y}\). If \(\alpha\) also exhibits \(X\) as a limit of the diagram \(u\), then \(f\) is an isomorphism (Remark 7.1.1.9); in particular, \(X\) is isomorphic to \(Y\). Conversely, if \(f: X \rightarrow Y\) is an isomorphism, then any composition of \(\underline{f}\) with \(\beta\) is a natural transformation \(\underline{X} \rightarrow u\) which exhibits \(X\) as a limit of \(u\) (Remark 7.1.1.9). This proves the first assertion; the proof of the second follows by applying the same argument to the opposite \(\infty\)-category \(\mathcal{C}^{\text {op }}\).

02JJ Notation 7.1.1.13. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(u: K \rightarrow \mathcal{C}\) be a diagram. It follows from Proposition 7.1.1.12 that, if the diagram \(u\) admits a limit \(Y\), then the isomorphism class of the object \(Y\) depends only on the diagram \(u\). To emphasize this dependence, we will often denote \(Y\) by \(\varliminf_{\longleftarrow}(u)\) and refer to it as the limit of the diagram \(u\). Similarly, if \(u\) admits a colimit \(X \in \mathcal{C}\), we will often denote \(X\) by \(\xrightarrow{\lim }(u)\) and refer to it as the colimit of the diagram \(u\). Beware that this terminology is somewhat abusive, since the objects \({\underset{L i m}{~}}_{\leftarrow}(u)\) and \(\underset{\longrightarrow}{\lim }(u)\) are only well-defined up to isomorphism.

In situations where the limit \(\underset{\leftrightarrows}{\lim }(u)\) and colimit \(\underset{\longrightarrow}{\lim }(u)\) are defined, they depend functorially on the diagram \(u: K \rightarrow \mathcal{C}\).

02JK Definition 7.1.1.14. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(K\) be a simplicial set. We will say that \(\mathcal{C}\) admits \(K\)-indexed limits if, for every diagram \(u: K \rightarrow \mathcal{C}\), there exists an object \(Y \in \mathcal{C}\) which is a limit of \(u\). We will say that \(\mathcal{C}\) admits \(K\)-indexed colimits if, for every diagram \(u: K \rightarrow \mathcal{C}\), there exists an object \(X \in \mathcal{C}\) which is a colimit of \(u\).

03U1 Remark 7.1.1.15. Let \(u: K \rightarrow K^{\prime}\) be a categorical equivalence of simplicial sets. Then an \(\infty\)-category \(\mathcal{C}\) admits \(K\)-indexed colimits if and only if it admits \(K^{\prime}\)-indexed colimits.

0390 Variant 7.1.1.16. It will often be useful to extend the terminology of Definition 7.1.1.14, replacing the individual simplicial set \(K\) by a collection of simplicial sets. For example:
- We say that an \(\infty\)-category \(\mathcal{C}\) admits finite limits if it admits \(K\)-indexed limits for every finite simplicial set \(K\) (Definition 3.6.1.1), every diagram \(f: K \rightarrow \mathcal{C}\) admits a limit.
- We say that an \(\infty\)-category \(\mathcal{C}\) admits finite colimits if it admits \(K\)-indexed colimits for every finiite simplicial set \(K\).
- We say that an \(\infty\)-category \(\mathcal{C}\) is complete if it admits \(K\)-indexed limits for every small simplicial set \(K\).
- We say that an \(\infty\)-category \(\mathcal{C}\) is cocomplete if it admits \(K\)-indexed colimits for every small simplicial set \(K\).

Let \(\mathcal{C}\) be an \(\infty\)-category. For every simplicial set \(K\), precomposition with the projection map \(K \rightarrow \Delta^{0}\) determines a functor
\[
\delta: \mathcal{C} \simeq \operatorname{Fun}\left(\Delta^{0}, \mathcal{C}\right) \rightarrow \operatorname{Fun}(K, \mathcal{C}) .
\]

We will refer to \(\delta\) as the diagonal functor: it carries each object \(X \in \mathcal{C}\) to the constant diagram \(\underline{X}: K \rightarrow \mathcal{C}\) taking the value \(X\).

Proposition 7.1.1.17. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(K\) be a simplicial set. Then:
- The \(\infty\)-category \(\mathcal{C}\) admits \(K\)-indexed limits if and only if the diagonal functor \(\delta: \mathcal{C} \rightarrow\) \(\operatorname{Fun}(K, \mathcal{C})\) admits a right adjoint \(G\). If this condition is satisfied, then the right adjoint \(G: \operatorname{Fun}(K, \mathcal{C}) \rightarrow \mathcal{C}\) carries each diagram \(u: K \rightarrow \mathcal{C}\) to a limit \(\underset{\leftrightarrows}{\lim }(u) \in \mathcal{C}\).
- The \(\infty\)-category \(\mathcal{C}\) admits \(K\)-indexed colimits if and only if the diagonal functor \(\delta: \mathcal{C} \rightarrow \operatorname{Fun}(K, \mathcal{C})\) admits a left adjoint \(F\). If this condition is satisfied, then the left adjoint \(F: \operatorname{Fun}(K, \mathcal{C}) \rightarrow \mathcal{C}\) carries each diagram \(u: K \rightarrow \mathcal{C}\) to a colimit \(\underset{\longrightarrow}{\lim }(u) \in \mathcal{C}\).

Proof. Apply Proposition 6.2.4.1.

\subsection*{7.1.2 Limit and Colimit Diagrams}

Let \(\mathcal{C}\) be an \(\infty\)-category, let \(u: K \rightarrow \mathcal{C}\) be a diagram, and let \(\mathcal{C} \tilde{x}_{\operatorname{Fun}(K, \mathcal{C})}\{u\}\) denote the oriented fiber product of Construction 4.6.4.1. By definition, we can identify objects of \(\mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{u\}\) with pairs \((Y, \alpha)\), where \(Y\) is an object of \(\mathcal{C}\) and \(\alpha: \underline{Y} \rightarrow u\) is a natural transformation (here \(\underline{Y}\) denotes the constant diagram \(K \rightarrow\{Y\} \hookrightarrow \mathcal{C}\) ). Using Proposition 5.6.6.21, we can reformulate Definition 7.1.1.1 as follows:

Proposition 7.1.2.1. Let \(\mathcal{C}\) be an \(\infty\)-category containing an object \(Y\) and let \(u: K \rightarrow \mathcal{C}\) be 02W7 a diagram. Then:
- A natural transformation \(\alpha: \underline{Y} \rightarrow u\) exhibits \(Y\) as a limit of the diagram \(u\) if and only if it is final when regarded as an object of the oriented fiber product \(\mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{u\}\).
- A natural transformation \(\beta: u \rightarrow \underline{Y}\) exhibits \(Y\) as a colimit of the diagram \(u\) if and only if it is initial when regarded as an object of the oriented fiber product \(\{u\} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})} \mathcal{C}\).

Proof. We will prove the first assertion; the second follows by a similar argument. Projection onto the first factor determines a right fibration \(\theta: \mathcal{C} \tilde{x}_{\operatorname{Fun}(K, \mathcal{C})}\{u\} \rightarrow \mathcal{C}\). For each object \(X \in \mathcal{C}\), we can identify \(\theta^{-1}(X)\) with the morphism space \(\operatorname{Hom}_{\operatorname{Fun}(K, \mathcal{C})}(\underline{X}, u)\). Let
\[
\rho_{X}: \operatorname{Hom}_{\operatorname{Fun}(K, \mathcal{C})}(\underline{Y}, u) \times \operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\operatorname{Fun}(K, \mathcal{C})}(\underline{X}, u)
\]
be the parametrized contravariant transport map of Variant 5.2.8.6. Using Remark 5.2.8.5 and Proposition 5.2.8.7, we see that \(\rho_{X}\) factors as a composition
\[
\begin{aligned}
\operatorname{Hom}_{\operatorname{Fun}(K, \mathcal{C})}(\underline{Y}, u) \times \operatorname{Hom}_{\mathcal{C}}(X, Y) & \rightarrow \operatorname{Hom}_{\operatorname{Fun}(K, \mathcal{C})}(\underline{Y}, u) \times \operatorname{Hom}_{\operatorname{Fun}(K, \mathcal{C})}(\underline{X}, \underline{Y}) \\
& \xrightarrow{\circ} \operatorname{Hom}_{\operatorname{Fun}(K, \mathcal{C})}(\underline{X}, u),
\end{aligned}
\]
given on objects by the construction \((\alpha, f) \mapsto \alpha \circ \underline{f}\). It follows that a natural transformation \(\alpha: \underline{Y} \rightarrow u\) exhibits \(Y\) as a limit of \(u\) if and only if, for every object \(X \in \mathcal{C}\), the restriction \(\left.\rho_{X}\right|_{\{\alpha\} \times \operatorname{Hom}_{\mathcal{C}}(X, Y)}\) is a homotopy equivalence of Kan complexes. By virtue of Proposition 5.6.6.21, this is equivalent to the requirement that \(\alpha\) is final when regarded as an object of the \(\infty\)-category \(\mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{u\}\).

02W8 Corollary 7.1.2.2. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(u: K \rightarrow \mathcal{C}\) be a diagram, and let \(Y \in \mathcal{C}\) be an object. The following conditions are equivalent:
(1) The object \(Y\) is a limit of the diagram \(u\).
(2) The object \(Y\) represents the right fibration \(\mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{u\} \rightarrow \mathcal{C}\) given by projection onto the first factor.
(3) The object \(Y\) represents the right fibration \(\mathcal{C}_{/ u} \rightarrow \mathcal{C}\) of Proposition 4.3.6.1.

Proof. The equivalence (1) \(\Leftrightarrow(2)\) follows immediately from Proposition 7.1.2.1, and the equivalence \((2) \Leftrightarrow(3)\) follows from the observation that the slice diagonal \(\mathcal{C}_{/ u} \hookrightarrow \mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{u\}\) of Construction 4.6.4.13 is an equivalence of \(\infty\)-categories (Theorem 4.6.4.17).

02W9 Corollary 7.1.2.3. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(u: K \rightarrow \mathcal{C}\) be a diagram. The following conditions are equivalent:
(1) The diagram \(u\) has a limit in \(\mathcal{C}\).
(2) The oriented fiber product \(\mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{u\} \rightarrow \mathcal{C}\) has a final object.
(3) The slice \(\infty\)-category \(\mathcal{C}_{/ u}\) has a final object.

Let \(u: K \rightarrow \mathcal{C}\) be a diagram in an \(\infty\)-category \(\mathcal{C}\). If \(Y\) is an object of \(\mathcal{C}\), then supplying a natural transformation of diagrams \(\alpha: \underline{Y} \rightarrow u\) is equivalent to giving a morphism of simplicial sets \(\bar{u}: \Delta^{0} \diamond K \rightarrow \mathcal{C}\) satisfying \(\left.\bar{u}\right|_{\Delta^{0}}=Y\) and \(\left.\bar{u}\right|_{K}=u\), where
\[
\Delta^{0} \diamond K=\Delta^{0} \coprod_{(\{0\} \times K)}\left(\Delta^{1} \times K\right)
\]
is the simplicial set introduced in Notation 4.5.8.3. In practice, a datum of this type can be somewhat cumbersome to work with. For example, if \(K\) is an \(\infty\)-category, then \(\Delta^{0} \diamond K\) need not be an \(\infty\)-category. It is therefore often convenient to work with the following variant of Definition 7.1.1.1:

Definition 7.1.2.4. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(K\) be a simplicial set, and let \(\bar{u}: K^{\triangleleft} \rightarrow \mathcal{C} 02 \mathrm{JM}\) be a morphism of simplicial sets carrying the cone point of \(K^{\triangleleft}\) to an object \(Y \in \mathcal{C}\). Set \(u=\left.\bar{u}\right|_{K}\), so that the diagram \(\bar{u}\) can be identified with an object of the slice \(\infty\)-category \(\mathcal{C}_{/ u}\). We will say that \(\bar{u}\) is a limit diagram if it is a final object of \(\mathcal{C}_{/ u}\). If this condition is satisfied, we say that \(\bar{u}\) exhibits \(Y\) as a limit of the diagram \(u\).

Variant 7.1.2.5. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(K\) be a simplicial set, and let \(\bar{u}: K^{\triangleright} \rightarrow \mathcal{C}\) 02JN be a morphism of simplicial sets carrying the cone point of \(K^{\triangleright}\) to an object \(Y \in \mathcal{C}\). Set \(u=\left.\bar{u}\right|_{K}\), so that the diagram \(\bar{u}\) can be identified with an object of the coslice \(\infty\)-category \(\mathcal{C}_{u /}\). We will say that \(\bar{u}\) is a colimit diagram if it is an initial object of \(\mathcal{C}_{u /}\). If this condition is satisfied, we say that \(\bar{u}\) exhibits \(Y\) as a colimit of the diagram \(u\).

Remark 7.1.2.6. Let \(\bar{u}: K^{\triangleleft} \rightarrow \mathcal{C}\) be as in Definition 7.1.2.4. Then \(\bar{u}\) is a limit diagram if 02WA and only if the composite map
\[
\Delta^{1} \times K \simeq K \star_{K} K \rightarrow \Delta^{0} \star_{\Delta^{0}} K=K^{\triangleleft} \xrightarrow{\bar{u}} \mathcal{C}
\]
corresponds to a natural transformation \(\alpha: \underline{Y} \rightarrow u\) which exhibits \(Y\) as a limit of \(u\), in the sense of Definition 7.1.1.1. This follows from the characterization of Proposition 7.1.2.1, together with the observation that the slice diagonal \(\mathcal{C} / u \hookrightarrow \mathcal{C} \tilde{\times}_{\operatorname{Fun}(K, \mathcal{C})}\{u\}\) of Construction 4.6.4.13 is an equivalence of \(\infty\)-categories (Theorem 4.6.4.17).

Remark 7.1.2.7. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(u: K \rightarrow \mathcal{C}\) be a diagram. Then an object 02JP \(Y \in \mathcal{C}\) is a limit of \(u\) (in the sense of Definition 7.1.1.11) if and only if there exists a diagram \(\bar{u}: K^{\triangleleft} \rightarrow \mathcal{C}\) which exhibits \(Y\) as a limit of \(u\). This is a reformulation of Corollary 7.1.2.2. Similarly, \(Y\) is a colimit of \(u\) if and only if there exists a diagram \(\bar{u}^{\prime}: K^{\triangleright} \rightarrow \mathcal{C}\) which exhibits \(Y\) as a colimit of \(u\).

Remark 7.1.2.8. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(f: K \rightarrow \mathcal{C}\) be a morphism of simplicial 02JS sets. An extension \(\bar{f}: K^{\triangleright} \rightarrow \mathcal{C}\) is a colimit diagram in \(\mathcal{C}\) if and only if the opposite map \(\bar{f}^{\mathrm{op}}:\left(K^{\mathrm{op}}\right)^{\triangleleft} \rightarrow \mathcal{C}^{\mathrm{op}}\) is a limit diagram in the \(\infty\)-category \(\mathcal{C}^{\mathrm{op}}\).

Example 7.1.2.9. Let \(\mathcal{C}\) be an \(\infty\)-category. Then an object \(Y \in \mathcal{C}\) is final (in the sense of 02JQ Definition 4.6.7.1) if and only if the map
\[
(\emptyset)^{\triangleleft} \simeq \Delta^{0} \xrightarrow{Y} \mathcal{C}
\]
is a limit diagram in \(\mathcal{C}\). Similarly, \(Y\) is initial if and only if the map
\[
(\emptyset)^{\triangleright} \simeq \Delta^{0} \xrightarrow{Y} \mathcal{C}
\]
is a colimit diagram in \(\mathcal{C}\).

02WB Example 7.1.2.10. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(f: X \rightarrow Y\) be a morphism of \(\mathcal{C}\). The following conditions are equivalent:
- The morphism \(f\) is an isomorphism.
- When regarded as a morphism \(\left(\Delta^{0}\right)^{\triangleleft} \rightarrow \mathcal{C}, f\) is a limit diagram.
- When regarded as a morphism \(\left(\Delta^{0}\right)^{\triangleright} \rightarrow \mathcal{C}, f\) is a colimit diagram.

This is a restatement of Proposition 4.6.7.22 (and also of Example 7.1.1.5, by virtue of Remark 7.1.2.6).

02JT Remark 7.1.2.11. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(g: B \rightarrow \mathcal{C}\) be a morphism of simplicial sets, and suppose we are given a diagram \(\bar{f}: A^{\triangleleft} \rightarrow \mathcal{C}_{/ g}\), which we can identify with a morphism of simplicial sets
\[
\bar{q}:(A \star B)^{\triangleleft} \simeq A^{\triangleleft} \star B \rightarrow \mathcal{C} .
\]

Then \(\bar{f}\) is a limit diagram in the slice \(\infty\)-category \(\mathcal{C}_{/ g}\) if and only if \(\bar{q}\) is a limit diagram in the \(\infty\)-category \(\mathcal{C}\).

02JU Proposition 7.1.2.12. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(K\) be a simplicial set, and let \(\bar{f}: K^{\triangleleft} \rightarrow \mathcal{C}\) be a morphism with restriction \(f=\left.\bar{f}\right|_{K}\). The following conditions are equivalent:
(1) The morphism \(\bar{f}\) is a limit diagram (Definition 7.1.2.4).
(2) The restriction map \(\mathcal{C}_{/ \bar{f}} \rightarrow \mathcal{C}_{/ f}\) is a trivial Kan fibration.
(3) The restriction map \(\mathcal{C}_{/ \bar{f}} \rightarrow \mathcal{C}_{/ f}\) is an equivalence of \(\infty\)-categories.
(4) For every object \(X \in \mathcal{C}\), the restriction map \(\{X\} \times_{\mathcal{C}} \mathcal{C}_{/ \bar{f}} \rightarrow\{X\} \times \times_{\mathcal{C}} \mathcal{C}_{/ f}\) is a homotopy equivalence of Kan complexes.

Proof. The equivalence (1) \(\Leftrightarrow(2)\) follows from Proposition 4.6.7.10. Note that the restriction \(\operatorname{map} \mathcal{C}_{/ \bar{f}} \rightarrow \mathcal{C}_{/ f}\) is a right fibration of \(\infty\)-categories (Corollary 4.3.6.11), and therefore an isofibration (Example 4.4.1.11). The equivalence \((2) \Leftrightarrow(3)\) now follows from Proposition 4.5.5.20, and the equivalence \((3) \Leftrightarrow(4)\) follows from Corollary 5.1.6.4.

0391 Proposition 7.1.2.13. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(K\) be a simplicial set, and let \(\bar{\rho}: \bar{F} \rightarrow \bar{G}\) be a natural transformation between diagrams \(\bar{F}, \bar{G}: K^{\triangleleft} \rightarrow \mathcal{C}\). Assume that, for every vertex \(x \in K\), the morphism \(\bar{\rho}_{x}: \bar{F}(x) \rightarrow \bar{G}(x)\) is an isomorphism in \(\mathcal{C}\). Then any two of the following conditions imply the third:
(1) The morphism of simplicial sets \(\bar{F}\) is a limit diagram in \(\mathcal{C}\).
(2) The morphism of simplicial sets \(\bar{G}\) is a limit diagram in \(\mathcal{C}\).
(3) The natural transformation \(\bar{\rho}\) carries the cone point \(\mathbf{0} \in K^{\triangleleft}\) to an isomorphism \(\bar{\rho}_{\mathbf{0}}\) : \(\bar{F}(\mathbf{0}) \rightarrow \bar{G}(\mathbf{0})\).

Proof. Set \(F=\left.\bar{F}\right|_{K}\) and \(G=\left.\bar{G}\right|_{K}\), so that \(\bar{\rho}\) restricts to an isomorphism \(\rho: F \rightarrow G\) in the \(\infty\)-category \(\operatorname{Fun}(K, \mathcal{C})\) (Theorem 4.4.4.4). Set \(X=\bar{F}(\mathbf{0})\) and \(Y=\bar{F}(\mathbf{0})\), and let \(\underline{X}, \underline{Y}: K \rightarrow \mathcal{C}\) be the constant maps taking the values \(X\) and \(Y\), respectively. Let \(c\) denote the composition \(\Delta^{1} \times K \simeq K \star_{K} K \rightarrow \Delta^{0} \star_{\Delta^{0}} K=K^{\triangleleft}\). Then the composition
\[
\Delta^{1} \times \Delta^{1} \times K \xrightarrow{\text { id } \times c} \Delta^{1} \times K^{\triangleleft} \xrightarrow{\bar{\rho}} \mathcal{C}
\]
can be identified with a commutative diagram

in the \(\infty\)-category \(\operatorname{Fun}(K, \mathcal{C})\). Using Remark 7.1.2.6, we can reformulate conditions (1) and (2) as follows:
(1') The natural transformation \(\alpha\) exhibits \(X\) as a limit of \(F\).
(2') The natural transformation \(\beta\) exhibits \(Y\) as a limit of \(G\).
Since \(\rho\) is an isomorphism, we can use Remark 7.1 .1 .8 to reformulate ( \(1^{\prime}\) ) as follows:
( \(1^{\prime \prime}\) ) The natural transformation \(\gamma\) exhibits \(X\) as a limit of \(G\).
It will therefore suffice to show that any two of the conditions \(\left(1^{\prime \prime}\right)\), \(\left(2^{\prime}\right)\), and (3) imply the third, which is a special case of Remark 7.1.1.9.

Corollary 7.1.2.14. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(K\) be a simplicial set. Then:
(1) Let \(\bar{u}, \bar{v}: K^{\triangleleft} \rightarrow \mathcal{C}\) be a pair of diagrams which are isomorphic when regarded as objects of the \(\infty\)-category \(\operatorname{Fun}\left(K^{\triangleleft}, \mathcal{C}\right)\). Then \(\bar{u}\) is a limit diagram if and only if \(\bar{v}\) is a limit diagram.
(2) Let \(\bar{u}, \bar{v}: K^{\triangleright} \rightarrow \mathcal{C}\) be a pair of diagrams which are isomorphic when regarded as objects of the \(\infty\)-category \(\operatorname{Fun}\left(K^{\triangleright}, \mathcal{C}\right)\). Then \(\bar{u}\) is a colimit diagram if and only if \(\bar{v}\) is a colimit diagram.

Corollary 7.1.2.15. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(K\) be a simplicial set, and suppose we are 02 K 2 given a pair of morphisms \(u, v: K \rightarrow \mathcal{C}\) which are isomorphic as objects of the \(\infty\)-category \(\operatorname{Fun}(K, \mathcal{C})\). Then:
(1) The morphism \(u\) can be extended to a limit diagram \(\bar{u}: K^{\triangleleft} \rightarrow \mathcal{C}\) if and only if \(v\) can be extended to a limit diagram \(\bar{v}: K^{\triangleleft} \rightarrow \mathcal{C}\).
(2) The morphism \(u\) can be extended to a colimit diagram \(\bar{u}: K^{\triangleright} \rightarrow \mathcal{C}\) if and only if \(v\) can be extended to a colimit diagram \(\bar{v}: K^{\triangleright} \rightarrow \mathcal{C}\).

Proof. We will prove (1); the proof of (2) is similar. Suppose that \(u\) can be extended to a limit diagram \(\bar{u}: K^{\triangleleft} \rightarrow \mathcal{C}\). Since the diagrams \(u\) and \(v\) are isomorphic, it follows from Corollary 4.4.5.3 that \(\bar{u}\) is isomorphic to a diagram \(\bar{v}: K^{\triangleleft} \rightarrow \mathcal{C}\) satisfying \(\left.\bar{v}\right|_{K}=v\). Applying Corollary 7.1.2.14, we conclude that \(\bar{v}\) is also a limit diagram.

\subsection*{7.1.3 Preservation of Limits and Colimits}

02JV Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Beware that, in general, \(F\) need not carry (co)limit diagrams in \(\mathcal{C}\) to (co)limit diagrams in \(\mathcal{D}\). This motivates the following:

0392 Definition 7.1.3.1. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, and let \(q: K \rightarrow \mathcal{C}\) be a diagram. Suppose that \(q\) can be extended to a limit diagram \(\bar{q}: K^{\triangleleft} \rightarrow \mathcal{C}\). We say that the limit of \(q\) is preserved by \(F\) if the composition \(F \circ \bar{q}\) is a limit diagram in the \(\infty\)-category \(\mathcal{D}\). Similarly, if \(q\) can be extended to a colimit diagram \(\bar{q}: K^{\triangleright} \rightarrow \mathcal{C}\), we say that the colimit of \(q\) is preserved by \(F\) if \(F \circ \bar{q}\) is a colimit diagram in the \(\infty\)-category \(\mathcal{D}\).

0393 Remark 7.1.3.2. In the situation of Definition 7.1.3.1, the condition that \(F\) preserves the (co)limit of a diagram \(q: K \rightarrow \mathcal{C}\) depends only on the diagram \(q\), and not on the extension \(\bar{q}\) (see Corollary 7.1.2.14).

0394 Remark 7.1.3.3. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(q: K \rightarrow \mathcal{C}\) be a diagram which admits a limit in \(\mathcal{C}\). Choose an object \(X \in \mathcal{C}\) and a natural transformation \(\alpha: \underline{X} \rightarrow q\) which exhibits \(X\) as a limit of \(q\). Then \(F\) preserves the limit of \(q\) if and only if the natural transformation \(F(\alpha)\) exhibits the object \(F(X)\) as a limit of the diagram \(F \circ q\).

02JW Definition 7.1.3.4. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(K\) be a simplicial set. We will say that \(F\) preserves \(K\)-indexed limits if, for every limit diagram \(\bar{q}: K^{\triangleleft} \rightarrow \mathcal{C}\), the composite map \((F \circ \bar{q}): K^{\triangleleft} \rightarrow \mathcal{D}\) is a limit diagram in \(\mathcal{D}\). We will say that \(F\) preserves \(K-\) indexed colimits if, for every colimit diagram \(\bar{q}: K^{\triangleright} \rightarrow \mathcal{C}\), the composite map \((F \circ \bar{q}): K^{\triangleright} \rightarrow \mathcal{D}\) is a colimit diagram in \(\mathcal{D}\).

02JX Example 7.1.3.5. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be any functor of \(\infty\)-categories. Then \(F\) preserves \(\Delta^{0}\)-indexed limits and colimits. By virtue of Example 7.1.2.10, this is equivalent to the observation that \(F\) carries isomorphisms in \(\mathcal{C}\) to isomorphisms in \(\mathcal{D}\) (see Remark 1.5.1.6).

02JY Warning 7.1.3.6. In the formulation of Definition 7.1.3.4 it is not necessary to assume that the \(\infty\)-category \(\mathcal{C}\) admits \(K\)-indexed limits or colimits. For example, if \(\mathcal{C}\) is an \(\infty\)-category
which contains no limit diagrams \(\bar{q}: K^{\triangleleft} \rightarrow \mathcal{C}\), then every functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) preserves \(K\)-indexed limits. In practice, we will usually (but not always) apply the terminology of Definition 7.1.3.4 in cases where the \(\infty\)-category admits \(K\)-indexed limits or colimits, so that the conclusion of Definition 7.1.3.4 is non-vacuous.

Exercise 7.1.3.7. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(K\) be a simplicial set. 02WC Show that \(F\) preserves \(K\)-indexed limits if and only if it satisfies the following condition:
- For every diagram \(u: K \rightarrow \mathcal{C}\) and every natural transformation \(\alpha: \underline{Y} \rightarrow u\) which exhibits an object \(Y \in \mathcal{C}\) as a limit of \(u\) (in the sense of Definition 7.1.1.1), the image \(F(\alpha): F(Y) \rightarrow(F \circ u)\) exhibits the object \(F(Y) \in \mathcal{D}\) as a limit of the diagram \((F \circ u): \bar{K} \mathcal{D}\).

Variant 7.1.3.8. It will often be useful to extend the terminology of Definition 7.1.3.4, 0395 replacing the individual simplicial set \(K\) by a collection of simplicial sets.
- We say that a functor of \(\infty\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\) preserves finite limits if it preserves \(K\)-indexed limits, for every finite simplicial set \(K\).
- We say that a functor of \(\infty\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\) preserves finite colimits if it preserves \(K\)-indexed colimits, for every finite simplicial set \(K\).
- We say that a functor of \(\infty\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\) preserves small limits if it preserves \(K\)-indexed limits, for every small simplicial set \(K\).
- We say that a functor of \(\infty\)-categories \(F: \mathcal{C} \rightarrow \mathcal{D}\) preserves small colimits if it preserves \(K\)-indexed colimits, for every small simplicial set \(K\).

Let us begin with a trivial example.
Proposition 7.1.3.9. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an equivalence of \(\infty\)-categories and let \(K\) be a 02JZ simplicial set. Then:
(1) A morphism \(\bar{u}: K^{\triangleleft} \rightarrow \mathcal{C}\) is a limit diagram if and only if the composition \(F \circ \bar{u}\) is a limit diagram in \(\mathcal{D}\).
(2) A morphism \(\bar{u}: K^{\triangleright} \rightarrow \mathcal{C}\) is a colimit diagram if and only if the composition \(F \circ \bar{u}\) is a colimit diagram in \(\mathcal{D}\).

In particular, the equivalence \(F\) preserves \(K\)-indexed limits and colimits.

Proof. We will prove (1); the proof of (2) is similar. Let \(\bar{u}: K^{\triangleleft} \rightarrow \mathcal{C}\) be a diagram and set \(u=\left.\bar{u}\right|_{K}\). We then have a commutative diagram of \(\infty\)-categories

Since \(F\) is an equivalence of \(\infty\)-categories, the horizontal maps in this diagram are also equivalences of \(\infty\)-categories (Corollary 4.6.4.19). It follows that the left vertical map is an equivalence of \(\infty\)-categories if and only if the right vertical map is an equivalence of \(\infty\)-categories. The desired result now follows from the criterion of Proposition 7.1.2.12.

02WD Variant 7.1.3.10. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a fully faithful functor of \(\infty\)-categories and let \(\bar{u}: K^{\triangleleft} \rightarrow \mathcal{C}\) be a morphism of simplicial sets. If \(F \circ \bar{u}\) is a limit diagram in the \(\infty\)-category \(\mathcal{D}\), then \(\bar{u}\) is a limit diagram in the \(\infty\)-category \(\mathcal{C}\).

Proof. Combine Remark 7.1.1.10 with Exercise 7.1.3.7.
02K3 Corollary 7.1.3.11. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be an equivalence of \(\infty\)-categories and let \(u: K \rightarrow \mathcal{C}\) be a morphism of simplicial sets. Then:
(1) The morphism \(u\) can be extended to a limit diagram \(\bar{u}: K^{\triangleleft} \rightarrow \mathcal{C}\) if and only if the composite map \((F \circ u): K \rightarrow \mathcal{D}\) can be extended to a limit diagram \(K^{\triangleleft} \rightarrow \mathcal{D}\).
(2) The morphism \(u\) can be extended to a colimit diagram \(\bar{u}: K^{\triangleright} \rightarrow \mathcal{C}\) if and only if the composite map \((F \circ u): K \rightarrow \mathcal{D}\) can be extended to a colimit diagram \(K^{\triangleright} \rightarrow \mathcal{D}\).

Proof. We will prove (1); the proof of (2) is similar. If \(u\) can be extended to a limit diagram \(\bar{u}: K^{\triangleleft} \rightarrow \mathcal{C}\), then Proposition 7.1.3.9 guarantees that \(F \circ \bar{u}\) is a limit diagram in \(\mathcal{D}\) extending \(F \circ u\). Conversely, suppose that \(F \circ u\) can be extended to a limit diagram \(\bar{v}: K^{\triangleleft} \rightarrow \mathcal{D}\). Let \(G: \mathcal{D} \rightarrow \mathcal{C}\) be an equivalence of \(\infty\)-categories which is homotopy inverse to \(F\), so that \(G \circ F\) is isomorphic to the identity functor \(\mathrm{id}_{\mathcal{C}}\). Then \((G \circ \bar{v}): K^{\triangleleft} \rightarrow \mathcal{C}\) is a limit diagram in \(\mathcal{C}\) (Proposition 7.1.3.9), and the restriction \(\left.(G \circ \bar{v})\right|_{K}=(G \circ F \circ u)\) is isomorphic to \(u\) as an object of the \(\infty\)-category \(\operatorname{Fun}(K, \mathcal{C})\). Applying Corollary 7.1.2.15, we deduce that \(u\) can be extended to a limit diagram \(\bar{p}: K^{\triangleleft} \rightarrow \mathcal{C}\).

02K4 Corollary 7.1.3.12. Let \(\mathcal{C}\) and \(\mathcal{D}\) be \(\infty\)-categories which are equivalent to one another, and let \(K\) be a simplicial set. Then \(\mathcal{C}\) admits \(K\)-indexed (co)limits if and only if \(\mathcal{D}\) admits \(K\)-indexed (co)limits.

Remark 7.1.3.13. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, let \(K\) be a simplicial set, 02 K 5 and let \(\bar{u}: K^{\triangleleft} \rightarrow \mathcal{C}\) be a limit diagram with restriction \(u=\left.\bar{u}\right|_{K}\). The following conditions are equivalent:
(1) The composition \((F \circ \bar{u}): K^{\triangleleft} \rightarrow \mathcal{D}\) is a limit diagram.
(2) For every limit diagram \(\bar{u}^{\prime}: K^{\triangleleft} \rightarrow \mathcal{C}\) with \(\left.\bar{u}^{\prime}\right|_{K}=u\), the composition \(\left(F \circ \bar{u}^{\prime}\right): K^{\triangleleft} \rightarrow \mathcal{D}\) is a limit diagram.

The implication \((2) \Rightarrow(1)\) is immediate. For the converse, we observe that if \(\bar{u}^{\prime}: K^{\triangleleft} \rightarrow \mathcal{C}\) is another limit diagram with \(\left.\bar{u}^{\prime}\right|_{K}=u\), then \(\bar{u}\) and \(\bar{u}^{\prime}\) are isomorphic when viewed as objects of the slice \(\infty\)-category \(\mathcal{C}_{/ u}\), so that \(F \circ \bar{u}\) and \(F \circ \bar{u}^{\prime}\) are isomorphic when viewed as objects of the \(\infty\)-category \(\mathcal{D}_{/(F \circ u)}\). Since \(F \circ \bar{u}\) is a final object of \(\mathcal{D}_{/(F \circ u)}\), it follows that \(F \circ \bar{u}^{\prime}\) is also a final object of \(\mathcal{D}_{/(F \circ u)}\) (Corollary 4.6.7.15).

A conservative functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) which preserves \(K\)-indexed limits also reflects them:
Proposition 7.1.3.14. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a conservative functor of \(\infty\)-categories and let \(K\) be a simplicial set.
- Suppose that \(\mathcal{C}\) admits \(K\)-indexed limits and the functor \(F\) preserves \(K\)-indexed limits. Then a morphism \(\bar{u}: K^{\triangleleft} \rightarrow \mathcal{C}\) is a limit diagram in \(\mathcal{C}\) if and only if \((F \circ \bar{u}): K^{\triangleleft} \rightarrow \mathcal{D}\) is a limit diagram in \(\mathcal{D}\).
- Suppose that \(\mathcal{C}\) admits \(K\)-indexed colimits and the functor \(F\) preserves \(K\)-indexed colimits. Then a morphism \(\bar{u}: K^{\triangleright} \rightarrow \mathcal{C}\) is a colimit diagram in \(\mathcal{C}\) if and only if \((F \circ \bar{u}): K^{\triangleright} \rightarrow \mathcal{D}\) is a colimit diagram in \(\mathcal{D}\).

Proposition 7.1.3.14 is an immediate consequence of the following more precise assertion:
Lemma 7.1.3.15. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a conservative functor of \(\infty\)-categories and let \(02 \mathrm{K7}\) \(u: K \rightarrow \mathcal{C}\) be a diagram. Suppose that \(u\) can be extended to a limit diagram \(\bar{u}: K^{\triangleleft} \rightarrow \mathcal{C}\) for which the composition \((F \circ \bar{u}): K^{\triangleleft} \rightarrow \mathcal{D}\) is also a limit diagram. Let \(\bar{u}^{\prime}: K^{\triangleleft} \rightarrow \mathcal{C}\) be an arbitrary extension of \(u\). Then \(\bar{u}^{\prime}\) is a limit diagram in \(\mathcal{C}\) if and only if \(F \circ \bar{u}^{\prime}\) is a limit diagram in \(\mathcal{D}\).

Proof. Let us identify \(\bar{u}\) and \(\bar{u}^{\prime}\) with objects \(C\) and \(C^{\prime}\) of the slice \(\infty\)-category \(\mathcal{C}_{/ u}\). Our assumption that \(\bar{u}\) is a limit diagram guarantees that \(C\) is a final object of \(\mathcal{C}_{/ u}\), so there exists a morphism \(f: C^{\prime} \rightarrow C\) in \(\mathcal{C}_{/ u}\). Note that \(\bar{u}^{\prime}\) is a limit diagram if and only if the object \(C^{\prime}\) is also final: that is, if and only if the morphism \(f\) is an isomorphism.

Let \(g: D^{\prime} \rightarrow D\) be the image of \(f\) under the functor \(F_{/ u}: \mathcal{C}_{/ u} \rightarrow \mathcal{D}_{/(F \circ u)}\). Our assumption that \(F \circ \bar{u}\) is a limit diagram guarantees that \(D\) is a final object of \(\mathcal{D}_{/(F \circ u)}\). Consequently, \(g\)
is an isomorphism if and only if the object \(D^{\prime}\) is also final: that is, if and only if \(\left(F \circ \bar{u}^{\prime}\right)\) is a limit diagram in \(\mathcal{D}\).

To complete the proof, it will suffice to show that \(f\) is an isomorphism in \(\mathcal{C}_{/ u}\) if and only if \(g=F_{/ u}(f)\) is an isomorphism in \(\mathcal{D}_{/(F \circ u)}\). In fact, the functor \(F_{/ u}\) is conservative: this follows from our assumption that \(F\) is conservative, by virtue of Corollary 4.4.2.12.

02K8 Definition 7.1.3.16. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a conservative functor of \(\infty\)-categories and let \(K\) be a simplicial set. We will say that the functor \(F\) creates \(K\)-indexed limits if the following condition is satisfied:
- Let \(u: K \rightarrow \mathcal{C}\) be a diagram for which the induced map \((F \circ u): K \rightarrow \mathcal{D}\) admits a limit in \(\mathcal{D}\). Then \(u\) can be extended to a limit diagram \(\bar{u}: K^{\triangleleft} \rightarrow \mathcal{C}\) for which the composition \((F \circ \bar{u}): K^{\triangleleft} \rightarrow \mathcal{D}\) is a limit diagram in \(\mathcal{D}\).

We say that the functor \(F\) creates \(K\)-indexed colimits if it satisfies the following dual condition:
- Let \(u: K \rightarrow \mathcal{C}\) be a diagram for which the induced map \((F \circ u): K \rightarrow \mathcal{D}\) admits a colimit in \(\mathcal{D}\). Then \(u\) can be extended to a colimit diagram \(\bar{q}: K^{\triangleright} \rightarrow \mathcal{C}\) for which the composition \((F \circ \bar{u}): K^{\triangleright} \rightarrow \mathcal{D}\) is a colimit diagram in \(\mathcal{D}\).

02K9 Remark 7.1.3.17. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a conservative functor of \(\infty\)-categories and let \(u: K \rightarrow \mathcal{C}\) be a diagram. Suppose that \(F\) creates \(K\)-indexed limits and that \(F \circ u\) can be extended to a limit diagram \(K^{\triangleleft} \rightarrow \mathcal{D}\). Then an extension \(\bar{u}: K^{\triangleleft} \rightarrow \mathcal{C}\) of \(u\) is a limit diagram if and only if \(F \circ \bar{u}\) is a limit diagram in \(\mathcal{D}\) (see Lemma 7.1.3.15).

02KA Proposition 7.1.3.18. Let \(K\) be a simplicial set, let \(\mathcal{D}\) be an \(\infty\)-category which admits \(K\)-indexed limits, and let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a conservative functor of \(\infty\)-categories. The following conditions are equivalent:
(1) The \(\infty\)-category \(\mathcal{C}\) admits \(K\)-indexed limits and the functor \(F\) preserves \(K\)-indexed limits.
(2) The functor \(F\) creates \(K\)-indexed limits.

Proof. The implication (1) \(\Rightarrow(2)\) is immediate. Conversely, suppose that (2) is satisfied and let \(u: K \rightarrow \mathcal{C}\) be a diagram. Since \(\mathcal{D}\) admits \(K\)-indexed limits, \(F \circ u\) can be extended to a limit diagram in \(\mathcal{D}\). Since \(F\) creates \(K\)-indexed limits, it follows that there exists a limit diagram \(\bar{u}: K^{\triangleleft} \rightarrow \mathcal{C}\) with \(\left.\bar{u}\right|_{K}=u\) such that \(F \circ \bar{u}\) is a limit diagram in \(\mathcal{D}\). Applying Remark 7.1.3.13, we see that this holds for every limit diagram \(\bar{u}: K^{\triangleleft} \rightarrow \mathcal{C}\) satisfying \(\left.\bar{u}\right|_{K}=u\), which proves (1).

The following is an important example of Definition 7.1.3.16

Proposition 7.1.3.19. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(A\) be a simplicial set, and let \(f: A \rightarrow \mathcal{C} 02 \mathrm{~KB}\) be a diagram. Then:
(1) The projection map \(\mathcal{C}_{f /} \rightarrow \mathcal{C}\) creates \(K\)-indexed limits, for every simplicial set \(K\).
(2) The projection map \(\mathcal{C}_{/ f} \rightarrow \mathcal{C}\) creates \(K\)-indexed colimits, for every simplicial set \(K\).

Proof. We will prove (1); the proof of (2) is similar. Let \(K\) be a simplicial set and let \(p: K \rightarrow \mathcal{C}_{f /}\) be a diagram, which we will identify with a morphism of simplicial sets \(q: A \star K \rightarrow \mathcal{C}\) satisfying \(\left.q\right|_{A}=f\). Set \(g=\left.q\right|_{K}\), so that \(q\) can also be identified with a diagram \(f^{\prime}: A \rightarrow \mathcal{C}_{/ g}\). Suppose that \(g\) can be extended to a limit diagram \(\bar{g}: K^{\triangleleft} \rightarrow \mathcal{C}\). Then the projection map \(\mathcal{C}_{/ \bar{g}} \rightarrow \mathcal{C}_{/ g}\) is a trivial Kan fibration (Proposition 7.1.2.12), so that \(f^{\prime}\) can be lifted to a diagram \(f^{\prime \prime}: A \rightarrow \mathcal{C}_{/ \bar{g}}\). We can then identify \(f^{\prime \prime}\) with a morphism of simplicial sets \(\bar{q}: A \star K^{\triangleleft} \rightarrow \mathcal{C}\) extending \(q\), or equivalently with a morphism \(\bar{p}: K^{\triangleleft} \rightarrow \mathcal{C}_{f /}\) extending \(p\). We will complete the proof by showing that \(\bar{p}\) is a limit diagram. To prove this, it will suffice to show that \(\bar{p}\) is final when regarded as an object of the slice \(\infty\)-category \(\left(\mathcal{C}_{f /}\right)_{/ p} \simeq\left(\mathcal{C}_{/ g}\right)_{f^{\prime} /}\). This follows from Proposition 4.6.7.12, since \(\bar{g}\) is a final object of \(\mathcal{C}_{/ g}\).

Corollary 7.1.3.20. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(f: A \rightarrow \mathcal{C}\) be a morphism of simplicial 02KC sets, and let \(K\) be an arbitrary simplicial set. Then:
(1) If \(\mathcal{C}\) admits \(K\)-indexed limits, then the coslice \(\infty\)-category \(\mathcal{C}_{f /}\) admits \(K\)-indexed limits. Moreover, a morphism \(K^{\triangleleft} \rightarrow \mathcal{C}_{f /}\) is a limit diagram if and only if its image in \(\mathcal{C}\) is a limit diagram.
(2) If \(\mathcal{C}\) admits \(K\)-indexed colimits, then the slice \(\infty\)-category \(\mathcal{C}_{/ f}\) admits \(K\)-indexed colimits. Moreover, a morphism \(K^{\triangleright} \rightarrow \mathcal{C}_{/ f}\) is a colimit diagram if and only if its image in \(\mathcal{C}\) is a colimit diagram.

Proof. Combine Propositions 7.1.3.19 and 7.1.3.18 with Remark 7.1.3.17
Corollary 7.1.3.21. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories which admits a right 02KE adjoint \(G: \mathcal{D} \rightarrow \mathcal{C}\). For every simplicial set \(K\), the functor \(F\) preserves \(K\)-indexed colimits and the functor \(G\) preserves \(K\)-indexed limits.

Proof. We will show that \(F\) preserves \(K\)-indexed colimits; the assertion that \(G\) preserves \(K\)-indexed limits can be proved by a similar argument. Let \(u: K \rightarrow \mathcal{C}\) be a morphism of simplicial sets, so that \(F\) induces a functor \(F^{\prime}: \mathcal{C}_{u /} \rightarrow \mathcal{D}_{(F \circ u) /}\). We wish to show that the functor \(F^{\prime}\) carries initial objects of \(\mathcal{C}_{u /}\) to initial objects of \(\mathcal{D}_{(F \circ u) /}\). It follows from Corollary 6.2.4.6 that the functor \(F^{\prime}\) also admits a right adjoint. We may therefore replace \(F\) by \(F^{\prime}\) and thereby reduce to the case where \(K=\emptyset\). In this case, we must show that if \(X\) is an initial object of \(\mathcal{C}\), then \(F(X)\) is an initial object of \(\mathcal{D}\). Choose an object \(Y \in \mathcal{D}\); we wish to show that
the morphism space \(\operatorname{Hom}_{\mathcal{D}}(F(X), Y)\) is a contractible Kan complex. Proposition 6.2.1.17 supplies a homotopy equivalence of \(\operatorname{Kan}\) complexes \(\operatorname{Hom}_{\mathcal{D}}(F(X), Y) \simeq \operatorname{Hom}_{\mathcal{C}}(X, G(Y))\). We conclude by observing that the Kan complex \(\operatorname{Hom}_{\mathcal{C}}(X, G(Y))\) is contractible, by virtue of our assumption that the object \(X \in \mathcal{C}\) is initial.

04JW Corollary 7.1.3.22 (Colimits in a Reflective Localization). Let \(\mathcal{C}\) be an \(\infty\)-category, let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a reflective subcategory (Definition 6.2.2.1), and let \(u: K \rightarrow \mathcal{C}^{\prime}\) be a diagram. If \(u\) admits a colimit in \(\mathcal{C}\), then it also admits a colimit in \(\mathcal{C}^{\prime}\).

Proof. By virtue of Proposition 6.2.2.11, the inclusion functor \(\mathcal{C}^{\prime} \hookrightarrow \mathcal{C}\) admits a left adjoint \(L: \mathcal{C} \rightarrow \mathcal{C}^{\prime}\). If \(u\) admits a colimit in \(\mathcal{C}\), then \(L \circ u\) admits a colimit in \(\mathcal{C}^{\prime}\) (Corollary 7.1.3.21). Since \(u\) factors through \(\mathcal{C}^{\prime}\), it is isomorphic to \(L \circ u\) and therefore also admits a colimit in \(\mathcal{C}^{\prime}\) (Remark 7.1.1.8).
\(03 \mathrm{Y0}\) Warning 7.1.3.23. In the situation of Corollary 7.1.3.22 the inclusion functor \(\mathcal{C}^{\prime} \hookrightarrow \mathcal{C}\) generally does not preserve the colimit of the diagram \(u\). If \(C=\underline{\longrightarrow}(u)\) is a colimit of \(u\) in the \(\infty\)-category \(\mathcal{C}\), then \(C\) usually does not belong to \(\mathcal{C}^{\prime}\). The colimit of \(u\) in the \(\infty\)-category \(\mathcal{C}^{\prime}\) is instead given by the localization \(L(C)\).

04JX Variant 7.1.3.24 (Limits in a Reflective Localization). Let \(\mathcal{C}\) be an \(\infty\)-category and let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a reflective subcategory. Then a diagram \(u: K \rightarrow \mathcal{C}^{\prime}\) admits a limit in \(\mathcal{C}^{\prime}\) if and only if it admits a limit in \(\mathcal{C}\). In this case, the limit of \(u\) is preserved by the inclusion functor \(\mathcal{C}^{\prime} \hookrightarrow \mathcal{C}\).

We will deduce Variant 7.1.3.24 from the following special case:
04 JY Lemma 7.1.3.25. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a reflective subcategory. If \(\mathcal{C}\) contains a final object \(X\), then \(\mathcal{C}^{\prime}\) contains an object which is isomorphic to \(X\). In particular, if \(\mathcal{C}^{\prime}\) is replete, then it contains every final object of \(\mathcal{C}\).

Proof. Choose a morphism \(f: X \rightarrow Y\) in \(\mathcal{C}\) which exhibits \(Y\) as a \(\mathcal{C}^{\prime}\)-reflection of \(X\) (see Definition 6.2.2.1. Since \(X\) is a final object of \(\mathcal{C}\), we can choose a morphism \(g: Y \rightarrow X\). We will complete the proof by showing that \(g\) is a homotopy inverse to \(f\) : that is, the homotopy classes \([f]\) and \([g]\) are inverses of one another in the homotopy category hC . Since \(X\) is a final object of \(\mathcal{C}\), the equality \([g] \circ[f]=\left[\mathrm{id}_{X}\right]\) is automatic. We wish to prove the equality \([f] \circ[g]=\left[\mathrm{id}_{Y}\right]\). Since \(f\) exhibits \(Y\) as a \(\mathcal{C}^{\prime}\)-reflection of \(X\), precomposition with \([f]\) induces a bijection \(\operatorname{Hom}_{\mathrm{h} \mathcal{C}}(Y, Y) \rightarrow \operatorname{Hom}_{\mathrm{h} \mathcal{C}}(X, Y)\). The desired result now follows from the calculation
\[
([f] \circ[g]) \circ[f]=[f] \circ([g] \circ[f])=[f] \circ\left[\mathrm{id}_{X}\right]=[f]=\left[\mathrm{id}_{Y}\right] \circ[f] .
\]

Proof of Variant 7.1.3.2舛 Let \(\mathcal{C}\) be an \(\infty\)-category, let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a reflective subcategory, and let \(u: K \rightarrow \mathcal{C}^{\prime}\) be a diagram. Applying Corollary 6.2.2.10, we deduce that \(\mathcal{C}^{\prime} / u\) is a reflective subcategory of \(\mathcal{C}_{/ u}\). If the diagram \(u\) admits a limit in \(\mathcal{C}\), then the slice \(\infty\)-category \(\mathcal{C}_{/ u}\) has a final object \(X\). Applying Lemma 7.1.3.25 we deduce that \(X\) is isomorphic to an object of \(\mathcal{C}_{/ u}^{\prime}\), which is also a final object of \(\mathcal{C}_{/ u}\) and therefore also of \(\mathcal{C}_{/ u}^{\prime}\). In particular, the diagram \(u\) has a limit in \(\mathcal{C}^{\prime}\) (which is preserved by the inclusion functor \(\mathcal{C}^{\prime} \hookrightarrow \mathcal{C}\) ).

Proposition 7.1.3.26. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(\mathcal{C}^{\prime} \subseteq \mathcal{C}\) be a reflective subcategory. 04JZ If \(\mathcal{C}\) has a final object \(X\), then \(\mathcal{C}^{\prime}\) contains an object which is isomorphic to \(X\). In particular, if \(\mathcal{C}^{\prime}\) is replete, then it contains every final object of \(\mathcal{C}\).

Proof. Choose a morphism \(f: X \rightarrow Y\) which exhibits \(Y\) as a \(\mathcal{C}^{\prime}\)-reflection of \(X\).

Corollary 7.1.3.27. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(\mathcal{C}_{0} \subseteq \mathcal{C}\) be a reflective subcategory of \(\mathcal{C}, 03 Y 1\) and let \(K\) be a simplicial set. If \(\mathcal{C}\) admits \(K\)-indexed limits, then \(\mathcal{C}_{0}\) also admits \(K\)-indexed limits. If \(\mathcal{C}\) admits \(K\)-indexed colimits, then \(\mathcal{C}_{0}\) also admits \(K\)-indexed colimits.

Proof. Combine Variant 7.1.3.24 with Corollary 7.1.3.22.

\subsection*{7.1.4 Relative Initial and Final Objects}

In \(\$ 4.6 .7\), we introduced the notions of initial and final object of an \(\infty\)-category \(\mathcal{C}\) 02WE (Definition 4.6.7.1). In this section, we study the more general notions of \(U\)-initial and \(U\)-final objects, where \(U: \mathcal{C} \rightarrow \mathcal{D}\) is a functor of \(\infty\)-categories.

Definition 7.1.4.1. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. We say that an object 02KU \(Y \in \mathcal{C}\) is \(U\)-final if, for every object \(X \in \mathcal{C}\), the functor \(U\) induces a homotopy equivalence
\[
\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(U(X), U(Y)) .
\]

We say that \(Y\) is \(U\)-initial if, for every object \(Z \in \mathcal{C}\), the functor \(U\) induces a homotopy equivalence
\[
\operatorname{Hom}_{\mathcal{C}}(Y, Z) \rightarrow \operatorname{Hom}_{\mathcal{D}}(U(Y), U(Z)) .
\]

Example 7.1.4.2. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(U: \mathcal{C} \rightarrow \Delta^{0}\) be the projection map. 02WF Then an object \(Y \in \mathcal{C}\) is \(U\)-initial if and only if it is initial, and \(U\)-final if and only if it is final.

Remark 7.1.4.3. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, and let \(\mathcal{C}_{0} \subseteq \mathcal{C}\) be the full 0396 subcategory of \(\mathcal{C}\) spanned by the \(U\)-initial objects. Then the restriction \(\left.U\right|_{\mathcal{C}_{0}}: \mathcal{C}_{0} \rightarrow \mathcal{D}\) is fully faithful. Similarly, \(U\) is fully faithful when restricted to the full subcategory of \(U\)-final objects of \(\mathcal{C}\).

02WG Example 7.1.4.4. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. The following conditions are equivalent:
- The functor \(U\) is fully faithful.
- Every object of \(\mathcal{C}\) is \(U\)-initial.
- Every object of \(\mathcal{C}\) is \(U\)-final.

02WH Remark 7.1.4.5. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories. Then an object \(Y \in \mathcal{C}\) is \(U\)-initial if and only if it is \(U^{\text {op }}\)-final, when regarded as an object of the opposite \(\infty\)-category \(\mathcal{C}^{\mathrm{op}}\).

02WJ Remark 7.1.4.6 (Transitivity). Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) and \(V: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories, and let \(Y \in \mathcal{C}\) be an object for which \(U(Y)\) is \(V\)-final. Then \(Y\) is \(U\)-final if and only if it is \((V \circ U)\)-final.

02WK Remark 7.1.4.7. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(Y \in \mathcal{C}\) be an object. Suppose that \(U(Y)\) is a final object of \(\mathcal{D}\). Then \(Y\) is a final object of \(\mathcal{C}\) if and only if it is a \(U\)-final object of \(\mathcal{C}\) (apply Remark 7.1.4.6 in the special case \(\mathcal{E}=\Delta^{0}\) ).

02WL Remark 7.1.4.8. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, and let \(V: \mathcal{C} \rightarrow \mathcal{D}\) be another functor which is isomorphic to \(U\) (as an object of the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\) ). Then an object \(Y \in \mathcal{C}\) is \(U\)-initial if and only if it is \(V\)-initial. To prove this, let \(Z\) be an object of \(\mathcal{C}\) and let \(\alpha: U \rightarrow V\) be an isomorphism of functors, so that we have a commutative diagram

in the homotopy category hKan, where the bottom horizontal and right vertical maps are homotopy equivalences. It follows that the upper horizontal map is a homotopy equivalence if and only if the left vertical map is a homotopy equivalence. Similarly, the object \(Y\) is \(U\)-final if and only if it is \(V\)-final.

02WM Remark 7.1.4.9. Suppose we are given a commutative diagram of \(\infty\)-categories

where the horizontal maps are equivalences of \(\infty\)-categories. Then an object \(X \in \mathcal{C}\) is \(U\)-initial if and only if \(F(X) \in \mathcal{C}^{\prime}\) is \(U^{\prime}\)-initial, and \(U\)-final if and only if \(F(X)\) is \(U^{\prime}\)-final.

Proposition 7.1.4.10. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(f: X \rightarrow Y\) 02WN be a morphism in \(\mathcal{C}\) with the property that \(U(f)\) is an isomorphism. Then any two of the following three conditions imply the third:
(1) The object \(X\) is \(U\)-initial.
(2) The object \(Y\) is \(U\)-initial.
(3) The morphism \(f\) is an isomorphism.

Proof. Fix an object \(Z \in \mathcal{C}\). We claim that any two of the following three conditions imply the third:
\(\left(1_{Z}\right)\) The functor \(U\) induces a homotopy equivalence \(\operatorname{Hom}_{\mathcal{C}}(X, Z) \rightarrow \operatorname{Hom}_{\mathcal{C}}(U(X), U(Z))\).
\(\left(2_{Z}\right)\) The functor \(U\) induces a homotopy equivalence \(\operatorname{Hom}_{\mathcal{C}}(Y, Z) \rightarrow \operatorname{Hom}_{\mathcal{C}}(U(Y), U(Z))\).
\(\left(3_{Z}\right)\) Precomposition \([f]\) induces a homotopy equivalence \(\operatorname{Hom}_{\mathcal{C}}(Y, Z) \rightarrow \operatorname{Hom}_{\mathcal{C}}(X, Z)\) (see Notation 4.6.9.15.

This follows from the commutativity of the diagram

in the homotopy category hKan, since the bottom horizontal map is a homotopy equivalence (by virtue of our assumption that \(U(f)\) is an isomorphism). Proposition 7.1.4.10 follows by allowing the object \(Z\) to vary.

Corollary 7.1.4.11. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, and let \(f: X \rightarrow Y\) be 02WP an isomorphism in \(\mathcal{C}\). Then the object \(X\) is \(U\)-initial if and only if \(Y\) is \(U\)-initial, and the object \(X\) is \(U\)-final if and only if \(Y\) is \(U\)-final.

Corollary 7.1.4.12 (Uniqueness). Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(X\) and \(Y\) be \(U\)-initial objects of \(\mathcal{C}\). Then \(X\) and \(Y\) are isomorphic if and only if \(U(X)\) and \(U(Y)\) are isomorphic as objects of \(\mathcal{D}\).

Proof. Assume that there exists an isomorphism \(\bar{f}: U(X) \rightarrow U(Y)\) in the \(\infty\)-category \(\mathcal{D}\). Since \(X\) is \(U\)-initial, the functor \(U\) induces a homotopy equivalence \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow\) \(\operatorname{Hom}_{\mathcal{D}}(U(X), U(Y))\). It follows that there exists a morphism \(f: X \rightarrow Y\) in \(\mathcal{C}\) such that \(U(f)\) is homotopic to \(\bar{f}\). In particular, \(U(f): U(X) \rightarrow U(Y)\) is also an isomorphism in \(\mathcal{D}\). Applying Proposition 7.1.4.10, we deduce that \(f\) is an isomorphism. In particular, the objects \(X\) and \(Y\) are isomorphic.

Recall that a functor of \(\infty\)-categories \(U: \mathcal{C} \rightarrow \mathcal{D}\) is a coreflective localization if it admits a fully faithful left adjoint \(\mathcal{D} \rightarrow \mathcal{C}\) (Proposition 6.3.3.6). This condition has a simple formulation in terms of relatively final objects:

0397 Proposition 7.1.4.13. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Then \(U\) is a coreflective localization functor if and only if, for every object \(D \in \mathcal{D}\), there exists a \(U\)-initial object \(C \in \mathcal{C}\) and an isomorphism \(D \rightarrow U(C)\) in the \(\infty\)-category \(\mathcal{D}\).

We will deduce Proposition 7.1.4.13 from a slightly more precise result.
0398 Lemma 7.1.4.14. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, let \(\mathcal{C}_{0}\) denote the full subcategory of \(\mathcal{C}\) spanned by the \(U\)-initial objects, and suppose that the restriction \(U_{0}=\left.U\right|_{\mathcal{C}_{0}}\) is essentially surjective. Then:
(1) The functor \(U_{0}: \mathcal{C}_{0} \rightarrow \mathcal{D}\) is an equivalence of \(\infty\)-categories.
(2) Let \(e: X \rightarrow Y\) be a morphism in \(\mathcal{C}\), where \(X\) is \(U\)-initial. Then \(e\) exhibits \(X\) as a \(\mathcal{C}_{0}\)-coreflection of \(Y\) (in the sense of Definition 6.2.2.1) if and only if \(U(e)\) is an isomorphism in the \(\infty\)-category \(\mathcal{D}\).
(3) The full subcategory \(\mathcal{C}_{0} \subseteq \mathcal{C}\) is coreflective.
(4) Let \(F_{0}: \mathcal{D} \rightarrow \mathcal{C}_{0}\) be a homotopy inverse of the functor \(U_{0}\), and let \(F: \mathcal{D} \rightarrow \mathcal{C}\) be a composition of \(F_{0}\) with the inclusion map \(\iota: \mathcal{C}_{0} \hookrightarrow \mathcal{C}\). Then \(F\) is a left adjoint of \(U\).
(5) The functor \(U\) is a coreflective localization.

Proof. Note that the functor \(U_{0}: \mathcal{C}_{0} \rightarrow \mathcal{D}\) is automatically fully faithful (Remark 7.1.4.3). Our assumption that \(U_{0}\) is essentially surjective then guarantees that it is an equivalence of \(\infty\)-categories, which proves (1).

We next prove the following:
(*) For every object \(Y \in \mathcal{C}\), there exists a morphism \(e: X \rightarrow Y\) in \(\mathcal{C}\), where \(X\) is \(U\)-initial and \(U(e)\) is an isomorphism in \(\mathcal{D}\).

To prove (*), we observe that the essential surjectivity of \(U_{0}\) guarantees that there exists a \(U\) initial object \(X \in \mathcal{C}\) and an isomorphism \(\bar{e}: U(X) \rightarrow U(Y)\) in the \(\infty\)-category \(\mathcal{D}\). Since \(X\) is \(U\)-initial, the functor \(U\) induces a homotopy equivalence \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}}(U(X), U(Y))\). Modifying \(\bar{e}\) by a homotopy, we can assume without loss of generality that \(\bar{e}=U(e)\) for some morphism \(X \rightarrow Y\) of \(\mathcal{C}\).

We now prove (2). Let \(e: X \rightarrow Y\) be a morphism in \(\mathcal{C}\), where the object \(X\) is \(U\)-initial. Assume first that \(U(e)\) is an isomorphism in \(\mathcal{D}\). We wish to show that, for every \(U\)-initial object \(C \in \mathcal{C}\), postcomposition with \(e\) induces a homotopy equivalence of Kan complexes \(\operatorname{Hom}_{\mathcal{C}}(C, X) \rightarrow \operatorname{Hom}_{\mathcal{C}}(C, Y)\). This follows by inspecting the commutative diagram

in the homotopy category of Kan complexes hKan; here the vertical maps are homotopy equivalences by virtue of our assumption that \(C\) is \(U\)-initial, and the bottom horizontal map is a homotopy equivalence by virtue of our assumption that \(U(e)\) is an isomorphism.

We now prove the converse. Assume that \(e: X \rightarrow Y\) exhibits \(X\) as a \(\mathcal{C}_{0}\)-coreflection of \(Y\); we wish to show that \(U(e)\) is an isomorphism. Using (*), we can choose a \(U\)-initial object \(X^{\prime} \in \mathcal{C}\) and a morphism \(e^{\prime}: X^{\prime} \rightarrow Y\) such that \(U\left(e^{\prime}\right)\) is an isomorphism in \(\mathcal{D}\). It follows from the previous step that \(e^{\prime}\) exhibits \(X^{\prime}\) as a \(\mathcal{C}_{0}\)-coreflection of \(Y\). It follows that \(e\) can be realized as the composition of \(e^{\prime}\) with an isomorphism \(v: X \rightarrow X^{\prime}\) in the \(\infty\)-category \(\mathcal{C}\) (Remark 6.2.2.3). Then \(U(e)\) is a composition of the isomorphisms \(U(v)\) and \(U\left(e^{\prime}\right)\) in the \(\infty\)-category \(\mathcal{D}\), and is therefore also an isomorphism.

Assertion (3) follows immediately from (2) and (*). Combining (3) with Proposition 6.2.2.11, we see that there exists a functor \(L: \mathcal{C} \rightarrow \mathcal{C}_{0}\) and a natural transformation \(\eta: L \rightarrow \mathrm{id}_{\mathcal{C}}\) which exhibits \(L\) as a \(\mathcal{C}_{0}\)-colocalization functor: that is, it carries each object \(Y \in \mathcal{C}\) to a morphism \(\eta_{Y}: L(Y) \rightarrow Y\) where \(L(Y)\) is \(U\)-initial and \(U\left(\eta_{Y}\right)\) is an isomorphism. In particular, \(\eta\) induces an isomorphism \(U_{0} \circ L \rightarrow U\) in the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\) (Theorem 4.4.4.4). It follows from assumption (1) that the functor \(U_{0}\) admits a homotopy inverse \(F_{0}: \mathcal{D} \rightarrow \mathcal{C}_{0}\), which is also a left adjoint of \(U_{0}\) (Example 6.2.1.11). Moreover, the inclusion functor \(\iota: \mathcal{C}_{0} \hookrightarrow \mathcal{C}\) is left adjoint to \(L\) (Proposition 6.2.2.15). It follows that the composition \(F=\iota \circ F_{0}\) is left adjoint to \(U_{0} \circ L\) (Remark 6.2.1.8), and therefore also to \(U\). This proves (4). Moreover, the functor \(F\) is fully faithful (since \(F_{0}\) is an equivalence of \(\infty\)-categories and \(\iota\) is the inclusion of a full subcategory), so assertion (5) follows from Proposition 6.3.3.6.

Proof of Proposition 7.1.4.13. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Assume that \(U\)
is a coreflective localization functor: we will show that, for every object \(D \in \mathcal{D}\), there exists a \(U\)-initial object \(C \in \mathcal{C}\) and an isomorphism \(D \rightarrow U(C)\) in \(\mathcal{D}\) (the converse follows from Lemma 7.1.4.14). Using Proposition 6.3.3.6, we see that there exists a functor \(F: \mathcal{D} \rightarrow \mathcal{C}\) and a natural isomorphism \(\eta: \operatorname{id}_{\mathcal{D}} \rightarrow U \circ F\) which is the unit of an adjunction between \(F\) and \(U\). In particular, for every object \(D \in \mathcal{D}\), we have an isomorphism \(\eta_{D}: D \rightarrow U(C)\) for \(C=F(D)\). We will complete the proof by showing that the object \(C\) is \(U\)-initial. Fix an object \(X \in \mathcal{C}\); we wish to show that the functor \(U\) induces a homotopy equivalence of Kan complexes \(\rho: \operatorname{Hom}_{\mathcal{C}}(F(D), X) \rightarrow \operatorname{Hom}_{\mathcal{D}}((U \circ F)(D), U(X))\). Since \(\eta_{D}: D \rightarrow(U \circ F)(D)\) is an isomorphism, this is equivalent to the requirement that the composite map
\[
\operatorname{Hom}_{\mathcal{C}}(F(D), X) \rightarrow \operatorname{Hom}_{\mathcal{D}}((U \circ F)(D), U(X)) \xrightarrow{\circ\left[\eta_{D}\right]} \operatorname{Hom}_{\mathcal{D}}(D, U(X))
\]
is a homotopy equivalence of Kan complexes, which follows from our assumption that \(\eta\) is the unit of an adjunction (Proposition 6.2.1.17).

0399 Corollary 7.1.4.15. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be an isofibration of \(\infty\)-categories. Then \(U\) is a coreflective localization functor if and only if, for every object \(Y \in \mathcal{D}\), the fiber \(\mathcal{C}_{Y}=\{Y\} \times{ }_{\mathcal{D}} \mathcal{C}\) contains a \(U\)-initial object of \(\mathcal{C}\).

Proof. Assume that \(U\) is a coreflective localization functor. We will show that, for each object \(Y \in \mathcal{D}\), the \(\infty\)-category \(\mathcal{C}_{Y}\) contains a \(U\)-initial object of \(\mathcal{C}\) (the converse follows immediately from Proposition 7.1.4.13). Using Proposition 7.1.4.13, we see that there exists a \(U\)-initial object \(X \in \mathcal{C}\) and an isomorphism \(e: Y \rightarrow U(X)\) in \(\mathcal{D}\). Since \(U\) is an isofibration, we can lift \(e\) to an isomorphism \(\tilde{e}: \widetilde{Y} \rightarrow X\) in the \(\infty\)-category \(\mathcal{C}\). Our assumption that \(X\) is \(U\)-initial then guarantees that \(\tilde{Y}\) is also \(U\)-initial (Corollary 7.1.4.11).

02 WR Proposition 7.1.4.16. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Then:
(1) An object \(Y \in \mathcal{C}\) is \(U\)-initial if and only if \(U\) induces an equivalence of \(\infty\)-categories \(U^{\prime}: \mathcal{C}_{Y /} \rightarrow \mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{U(Y) /}\).
(2) An object \(Y \in \mathcal{C}\) is \(U\)-final if and only if \(U\) induces an equivalence of \(\infty\)-categories \(U^{\prime \prime}: \mathcal{C}_{/ Y} \rightarrow \mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{/ U(Y)}\).

Proof. We will prove (2); the proof of (1) is similar. Fix an object \(Y \in \mathcal{C}\), so that the morphism \(U^{\prime \prime}\) of (1) fits into a commutative diagram

where the vertical maps are right fibrations (Proposition 4.3.6.1). Applying Corollary 5.1.7.15, we see that \(U^{\prime \prime}\) is an equivalence of \(\infty\)-categories if and only if, for every object \(X \in \mathcal{C}\), the induced map of fibers
\[
U_{X}^{\prime \prime}:\{X\} \times_{\mathcal{C}} \mathcal{C}_{/ Y} \rightarrow\{X\} \times_{\mathcal{D}} \mathcal{D}_{/ U(Y)}
\]
is a homotopy equivalence of Kan complexes. By virtue of Proposition 4.6.5.10, this is equivalent to the requirement that \(U\) induces a homotopy equivalence \(\operatorname{Hom}_{\mathcal{C}}(X, Y) \rightarrow\) \(\operatorname{Hom}_{\mathcal{D}}(U(X), U(Y))\).

Corollary 7.1.4.17. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories and let \(Y\) be an 02WS object of \(\mathcal{C}\). The following conditions are equivalent:
(1) The object \(Y\) is \(U\)-initial.
(2) The induced map \(U^{\prime}: \mathcal{C}_{Y /} \rightarrow \mathcal{C} \times{ }_{\mathcal{D}} \mathcal{D}_{U(Y) /}\) is a trivial Kan fibration.
(3) Every lifting problem

has a solution, provided that \(n>0\) and \(\sigma_{0}(0)=Y\).
Proof. Since \(U\) is an inner fibration, the morphism \(U^{\prime}\) is a left fibration (Corollary 4.3.6.9. . In particular, it is a trivial Kan fibration if and only if it is an equivalence of \(\infty\)-categories (Proposition 4.5.5.20). The equivalence (1) \(\Leftrightarrow(2)\) now follows from Proposition 7.1.4.16. The equivalence \((2) \Leftrightarrow(3)\) is immediate from the definitions.

Corollary 7.1.4.18. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories. Let \(\mathcal{C}_{0} \subseteq \mathcal{C}\) be a 02WT full subcategory of \(\mathcal{C}\) whose objects are \(U\)-initial, and let \(\mathcal{D}_{0} \subseteq \mathcal{D}\) be the full subcategory of \(\mathcal{D}\) spanned by objects of the form \(U(C)\) for \(C \in \mathcal{C}_{0}\). Then the functor \(\left.U\right|_{\mathcal{C}_{0}}: \mathcal{C}_{0} \rightarrow \mathcal{D}_{0}\) is a trivial Kan fibration.

Proof. Suppose we are given a lifting problem

If \(n=0\), this lifting problem admits a solution by the definition of the subcategory \(\mathcal{D}_{0} \subseteq \mathcal{D}\). If \(n>0\), then \(\sigma_{0}(0)\) is a \(U\)-initial object of \(\mathcal{C}\), so Corollary 7.1.4.17 guarantees that \(\sigma_{0}\) can be extended to an \(n\)-simplex \(\sigma: \Delta^{n} \rightarrow \mathcal{C}\) satisfying \(U(\sigma)=\bar{\sigma}\). We conclude by observing that \(\sigma\) automatically factors through the full subcategory \(\mathcal{C}_{0}\) (since every vertex of \(\Delta^{n}\) is contained in the boundary \(\partial \Delta^{n}\) ).

02WU Proposition 7.1.4.19. Suppose we are given a commutative diagram of \(\infty\)-categories

where \(U\) and \(V\) are inner fibrations. Let \(E \in \mathcal{E}\) be an object, and let \(F_{E}: \mathcal{C}_{E} \rightarrow \mathcal{D}_{E}\) denote the corresponding restriction of \(F\). Then:
(1) If \(X \in \mathcal{C}_{E}\) is \(F\)-initial when viewed as an object of the \(\infty\)-category \(\mathcal{C}\), then \(X\) is \(F_{E}\)-initial.
(2) Assume that \(U\) and \(V\) are cartesian fibrations, and that the functor \(F\) carries \(U\)-cartesian morphisms of \(\mathcal{C}\) to \(V\)-cartesian morphisms of \(\mathcal{D}\). If \(X\) is \(F_{E}\)-initial, then it is \(F\)-initial when viewed as an object of \(\mathcal{C}\).

Proof. We first prove (1). Assume that \(X\) is \(F\)-initial. For every object \(Y \in \mathcal{C}_{E}\), we have a commutative diagram of Kan complexes

Our assumption that \(X\) is \(F\)-initial guarantees that \(\rho\) is a homotopy equivalence. Since \(U\) and \(V\) are inner fibrations, the vertical maps are Kan fibrations (Proposition 4.6.1.21). Applying Corollary 3.3.7.5, we conclude that \(\rho\) restricts to a homotopy equivalence
\[
\begin{aligned}
\operatorname{Hom}_{\mathcal{C}_{E}}(X, Y) & =\operatorname{Hom}_{\mathcal{C}}(X, Y) \times_{\operatorname{Hom} \mathcal{E}(E, E)}\left\{\operatorname{id}_{E}\right\} \\
& \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Y)) \times_{\operatorname{Hom} \mathcal{E}(E, E)}\left\{\operatorname{id}_{E}\right\} \\
& =\operatorname{Hom}_{\mathcal{D}_{E}}(F(X), F(Y)) .
\end{aligned}
\]

Allowing \(Y\) to vary over objects of \(\mathcal{C}_{E}\), it follows that \(X\) is an \(F_{E}\)-initial object of \(\mathcal{C}\).

We now prove (2). Assume that \(U\) and \(V\) are cartesian fibrations, that the functor \(F\) carries \(U\)-cartesian morphisms of \(\mathcal{C}\) to \(V\)-cartesian morphisms of \(\mathcal{D}\), and that \(X\) is \(F_{E}\)-initial. We wish to show that \(X\) is \(F\)-initial. Fix an object \(Z \in \mathcal{C}\); we must show that the horizontal map in the diagram

is a homotopy equivalence. Since the vertical maps are Kan fibrations (Proposition 4.6.1.21), it will suffice to show that the induced map
\[
\theta_{\bar{f}}: \operatorname{Hom}_{\mathcal{C}}(X, Z) \times_{\operatorname{Hom}_{\mathcal{E}}(U(X), U(Z))}\{\bar{f}\} \rightarrow \operatorname{Hom}_{\mathcal{D}}(F(X), F(Z)) \times_{\operatorname{Hom}_{\mathcal{E}}(U(X), U(Z))}\{\bar{f}\}
\]
is a homotopy equivalence, for each morphism \(\bar{f}: U(X) \rightarrow U(Z)\) in the \(\infty\)-category \(\mathcal{E}\) (Corollary 3.3.7.5). Since \(U\) is a cartesian fibration, we can write \(\bar{f}=U(f)\), where \(f: Y \rightarrow Z\) is a \(U\)-cartesian morphism in \(\mathcal{C}\). By assumption, the image \(F(f): F(Y) \rightarrow F(Z)\) is a \(V\)-cartesian morphism in the \(\infty\)-category \(\mathcal{D}\). Using Proposition 5.1.3.11, we can replace \(\theta_{\bar{f}}\) with the morphism
\[
\operatorname{Hom}_{\mathcal{C}_{E}}(X, Y) \rightarrow \operatorname{Hom}_{\mathcal{D}_{E}}(F(X), F(Y)),
\]
which is a homotopy equivalence by virtue of our assumption that \(X\) is \(F_{E}\)-initial.
Exercise 7.1.4.20. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a cocartesian fibration of \(\infty\)-categories, and let \(C \in \mathcal{C} 02 \mathrm{WW}\) be an object having image \(D=U(C)\) in \(\mathcal{D}\). Show that \(C\) is \(U\)-initial if and only if the following condition is satisfied:
(*) For every morphism \(f: D \rightarrow D^{\prime}\) in \(\mathcal{D}\), the covariant transport functor \(f_{!}: \mathcal{C}_{D} \rightarrow \mathcal{C}_{D^{\prime}}\) carries \(C\) to an initial object of the \(\infty\)-category \(\mathcal{C}_{D^{\prime}}\).

For a more general statement, see Proposition 7.3.9.2.
Corollary 7.1.4.21. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories, and let \(C \in \mathcal{C}\) 02WV be an object having image \(D=U(C)\) in \(\mathcal{D}\). If the object \(C\) is \(U\)-initial, then it is initial when regarded as an object of the \(\infty\)-category \(\mathcal{C}_{D}=\{D\} \times_{\mathcal{D}} \mathcal{C}\). The converse holds if \(U\) is a cartesian fibration.

Proof. Apply Proposition 7.1.4.19 in the special case where \(\mathcal{E}=\mathcal{D}\) and \(\mathcal{E}^{\prime}=\{D\}\).
Corollary 7.1.4.22. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a cartesian fibration of \(\infty\)-categories. The following 039A conditions are equivalent:
(1) For each object \(D \in \mathcal{D}\), the \(\infty\)-category \(\mathcal{C}_{D}=\{D\} \times_{\mathcal{D}} \mathcal{C}\) has an initial object.
(2) The functor \(U\) is a coreflective localization: that is, it admits a fully faithful left adjoint \(F: \mathcal{D} \rightarrow \mathcal{C}\).

Proof. Combine Corollaries 7.1.4.15 and 7.1.4.21.

\subsection*{7.1.5 Relative Limits and Colimits}

02KF We now introduce a relative version of Definition 7.1.2.4,
02KG Definition 7.1.5.1. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(\bar{f}: K^{\triangleleft} \rightarrow \mathcal{C}\) be a morphism of simplicial sets with restriction \(f=\left.\bar{f}\right|_{K}\), so that \(U\) induces a functor \(U_{/ f}: \mathcal{C}_{/ f} \rightarrow \mathcal{D}_{/(U \circ f)}\). We will say that \(\bar{f}\) is a \(U\)-limit diagram if it is \(U_{/ f}\)-final when viewed as an object of the \(\infty\)-category \(\mathcal{C}_{/ f}\). Similarly, we say that a morphism \(\bar{g}: K^{\triangleright} \rightarrow \mathcal{C}\) with restriction \(g=\left.\bar{g}\right|_{K}\) is a \(U\)-colimit diagram if \(\bar{g}\) is \(U_{g / \text {-initial when viewed as an object of the }}\) \(\infty\)-category \(\mathcal{C}_{g /}\), where \(U_{/ g}: \mathcal{C}_{g /} \rightarrow \mathcal{D}_{(U \circ g) /}\) denotes the functor induced by \(U\).

02KH Remark 7.1.5.2. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories. Then a morphism \(\bar{f}: K^{\triangleleft} \rightarrow \mathcal{C}\) is a \(U\)-limit diagram if and only if the opposite map \(\bar{f}^{\mathrm{op}}:\left(K^{\mathrm{op}}\right)^{\triangleright} \rightarrow \mathcal{C}^{\mathrm{op}}\) is an \(U^{\text {op }}\)-colimit diagram.

02KK Example 7.1.5.3. Let \(\mathcal{C}\) be an \(\infty\)-category and \(U: \mathcal{C} \rightarrow \Delta^{0}\) be the projection map. Then a morphism \(\bar{f}: K^{\triangleleft} \rightarrow \mathcal{C}\) is a \(U\)-limit diagram (in the sense of Definition 7.1.5.1) if and only if it is a limit diagram (in the sense of Definition 7.1.2.4). Similarly, a morphism \(\bar{g}: K^{\triangleright} \rightarrow \mathcal{C}\) is a \(U\)-colimit diagram if and only if it is a colimit diagram.

02KM Example 7.1.5.4. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a fully faithful functor of \(\infty\)-categories. Then every morphism \(\bar{f}: K^{\triangleleft} \rightarrow \mathcal{C}\) is a \(U\)-limit diagram, and every morphism \(\bar{g}: K^{\triangleright} \rightarrow \mathcal{C}\) is a \(U\)-colimit diagram. This follows by combining Example 7.1.4.4 with Corollary 4.6.4.20.

02WX Example 7.1.5.5. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Then an object \(C \in \mathcal{C}\) is \(U\)-final if and only if it is a \(U\)-limit diagram when viewed as a morphism of simplicial sets \((\emptyset)^{\triangleleft} \simeq \Delta^{0} \rightarrow \mathcal{C}\). Similarly, \(C\) is \(U\)-initial if and only if it is a \(U\)-colimit diagram when viewed as a morphism of simplicial sets \((\emptyset)^{\triangleright} \simeq \Delta^{0} \rightarrow \mathcal{C}\).

02 WY Remark 7.1.5.6. Suppose we are given a commutative diagram of \(\infty\)-categories

where the horizontal maps are equivalences of \(\infty\)-categories. Then a morphism of simplicial sets \(\bar{f}: K^{\triangleleft} \rightarrow \mathcal{C}\) is a \(U\)-limit diagram if and only if \(F \circ \bar{f}\) is a \(U^{\prime}\)-limit diagram. Similarly, a morphism of simplicial sets \(\bar{g}: K^{\triangleright} \rightarrow \mathcal{C}\) is a \(U\)-colimit diagram if and only if \(F \circ \bar{g}\) is a \(U^{\prime}\)-colimit diagram. This follows by combining Remark 7.1.4.9 with Corollary 4.6.4.19.

Remark 7.1.5.7. Let \(U_{0}: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, and let \(U_{1}: \mathcal{C} \rightarrow \mathcal{D}\) be 02WZ a functor which is isomorphic to \(U_{0}\) (as an object of the \(\infty\)-category \(\operatorname{Fun}(\mathcal{C}, \mathcal{D})\) ). Then a diagram \(\bar{f}: K^{\triangleleft} \rightarrow \mathcal{C}\) is a \(U_{0}\)-limit diagram if and only if it is a \(U_{1}\)-limit diagram (see Remark 7.1.4.8. This follows by applying Remark 7.1.5.6 to each square of the diagram

where \(U: \mathcal{C} \rightarrow \operatorname{Isom}(\mathcal{D})\) classifies an isomorphism between \(U_{0}\) and \(U_{1}\); note that \(\mathrm{ev}_{0}\) and \(\mathrm{ev}_{1}\) are trivial Kan fibrations by virtue of Corollary 4.4.5.10.

Remark 7.1.5.8. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, let \(\bar{f}: K^{\triangleleft} \rightarrow \mathcal{C}\) be a 02 KJ morphism, and set \(f=\left.\bar{f}\right|_{K}\), so that \(U\) induces a functor
\[
U^{\prime}: \mathcal{C}_{/ \bar{f}} \rightarrow \mathcal{C}_{/ f} \times_{\mathcal{D}_{/(U \circ f)}} \mathcal{D}_{/(U \circ \bar{f})}
\]

By virtue of Proposition 7.1.4.16, the following conditions are equivalent:
(1) The morphism \(\bar{f}\) is a \(U\)-limit diagram.
(2) The functor \(U^{\prime}\) is an equivalence of \(\infty\)-categories.

If \(U\) is an inner fibration of \(\infty\)-categories, then the functor \(U^{\prime}\) is automatically a right fibration (Proposition 4.3.6.8). In this case, we can replace (1) and (2) by either of the following conditions:
(3) The functor \(U^{\prime}\) is a trivial Kan fibration.
(4) Each fiber of \(U^{\prime}\) is a contractible Kan complex.

The equivalence of \((2) \Leftrightarrow(3)\) follows from Proposition 4.5.5.20, and the equivalence (3) \(\Leftrightarrow\) (4) from Proposition 4.4.2.14.

Example 7.1.5.9. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories. Then:
- A morphism \(e\) of \(\mathcal{C}\) is \(U\)-cartesian (in the sense of Definition 5.1.1.1) if and only if it is a \(U\)-limit diagram when viewed as a morphism of simplicial sets \(\left(\Delta^{0}\right)^{\triangleleft} \rightarrow \mathcal{C}\).
- A morphism \(f\) of \(\mathcal{C}\) is \(U\)-cocartesian (in the sense of Definition 5.1.1.1) if and only if it is a \(U\)-colimit diagram when viewed as a morphism of simplicial sets \(\left(\Delta^{0}\right)^{\triangleright} \rightarrow \mathcal{C}\).

This follows by combining Remark 7.1.5.8 with Proposition 5.1.1.13
02KN Example 7.1.5.10. Let \(K\) be a weakly contractible simplicial set and let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a right fibration of \(\infty\)-categories. Then every morphism \(\bar{f}: K^{\triangleleft} \rightarrow \mathcal{C}\) is a \(U\)-limit diagram (see Proposition 4.3.7.6. Similarly, if \(U\) is a left fibration, then every morphism \(\bar{g}: K^{\triangleright} \rightarrow \mathcal{C}\) is a \(U\)-colimit diagram.

02X0 Remark 7.1.5.11. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories and let \(K\) be a simplicial set. Using Remark 7.1.5.8, we see that a morphism \(\bar{f}: K^{\triangleleft} \rightarrow \mathcal{C}\) is a \(U\)-limit diagram if and only if every lifting problem

admits a solution, provided that \(n \geq 1\) and the the restriction of \(\rho\) to \(\{n\} \star K \simeq K^{\triangleleft}\) coincides with \(\bar{f}\).

02 X 1 Proposition 7.1.5.12. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(\bar{f}: K^{\triangleleft} \rightarrow \mathcal{C}\). Then \(\bar{f}\) is a \(U\)-limit diagram if and only if, for every object \(C \in \mathcal{C}\), the diagram of morphism spaces

is a homotopy pullback square; here we let \(\underline{C} \in \operatorname{Fun}\left(K^{\triangleleft}, \mathcal{C}\right)\) denote the constant diagram taking the value \(C\).

Proof. Set \(f=\left.\bar{f}\right|_{K}\). Note that the restriction maps
\[
\mathcal{C}_{/ \bar{f}} \rightarrow \mathcal{C}_{/ f} \quad \mathcal{C}_{/ f} \rightarrow \mathcal{C} \quad \mathcal{D}_{/(U \circ \bar{f})} \rightarrow \mathcal{D}_{/(U \circ f)}
\]
are right fibrations of simplicial sets (Corollary 4.3.6.11). It follows that we can regard the map
\[
U^{\prime}: \mathcal{C}_{/ \bar{f}} \rightarrow \mathcal{C}_{/ f} \times_{\mathcal{D}_{/(U \circ f)}} \mathcal{D}_{/(U \circ \bar{f})}
\]
of Remark 7.1 .5 .8 as a functor between \(\infty\)-categories which are right-fibered over \(\mathcal{C}\). Combining Remark 7.1.5.8 with the criterion of Corollary 5.1.6.4, we see that \(\bar{f}\) is a \(U\)-colimit diagram if and only if, for every object \(C \in \mathcal{C}\), the induced map
\[
U_{C}^{\prime}:\{C\} \times_{\mathcal{C}} \mathcal{C}_{/ \bar{f}} \rightarrow\{C\} \times_{\mathcal{C}} \mathcal{C}_{/ f} \times_{\mathcal{D}_{/(U \circ f)}} \mathcal{D}_{/(U \circ \bar{f})}
\]
is a homotopy equivalence of Kan complexes.
To complete the proof, it will suffice to show that \(U_{C}^{\prime}\) is a homotopy equivalence if and only if the diagram (7.1) is a homotopy pullback square. To see this, we note that Proposition 4.6.5.10 supplies a levelwise homotopy equivalence of (7.1) with the diagram

It will therefore suffice to show that 7.2 is a homotopy pullback square if and only if \(U_{C}^{\prime}\) is a homotopy equivalence (Corollary 3.4.1.12). This is a special case of Example 3.4.1.3, since the horizontal maps in the diagram (7.2) are Kan fibrations (combine Corollaries 4.3.6.11 and 4.4.3.8.

Proposition 7.1.5.13. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(\bar{u}, \bar{v}^{\prime}: K^{\triangleleft} \rightarrow \mathcal{C}\)
```

02X4

``` be diagrams which are isomorphic when viewed as objects of the \(\infty\)-category \(\operatorname{Fun}\left(K^{\triangleleft}, \mathcal{C}\right)\). Then \(\bar{u}\) is a \(U\)-limit diagram if and only if \(\bar{v}\) is a \(U\)-limit diagram.

Proof. We proceed as in the proof of Corollary 7.1.2.14. Let \(\operatorname{Isom}(\mathcal{C})\) denote the full subcategory of \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{C}\right)\) spanned by the isomorphisms in \(\mathcal{C}\), and define \(\operatorname{Isom}(\mathcal{D}) \subseteq\) \(\operatorname{Fun}\left(\Delta^{1}, \mathcal{D}\right)\) similarly. For \(i \in\{0,1\}\), the evaluation functors
\[
\mathrm{ev}_{i}: \operatorname{Isom}(\mathcal{C}) \rightarrow \mathcal{C} \quad \mathrm{ev}_{i}: \operatorname{Isom}(\mathcal{D}) \rightarrow \mathcal{D}
\]
are trivial Kan fibrations (Corollary 4.4.5.10), and therefore equivalences of \(\infty\)-categories (Proposition 4.5.3.11). Our assumption that \(\bar{u}\) and \(\bar{v}\) are isomorphic guarantees that we can choose a diagram \(\bar{w}: K^{\triangleleft} \rightarrow \operatorname{Isom}(\mathcal{C})\) satisfying \(\mathrm{ev}_{0} \circ \bar{w}=\bar{u}\) and \(\mathrm{ev}_{1} \circ \bar{w}=\bar{v}\). Applying

Remark 7.1.5.6 to the commutative diagram

we see that \(\bar{u}\) is a \(U\)-limit diagram if and only if \(\bar{w}\) is a \(U^{\prime}\)-limit diagram. A similar argument shows that this is equivalent to the requirement that \(\bar{v}\) is a \(U\)-limit diagram.

02KQ Proposition 7.1.5.14 (Transitivity). Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) and \(V: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories.
(1) Let \(\bar{f}: K^{\triangleleft} \rightarrow \mathcal{C}\) be a morphism of simplicial sets such that \(U \circ \bar{f}\) is a \(V\)-limit diagram. Then \(\bar{f}\) is a \(U\)-limit diagram if and only if it is a \((V \circ U)\)-limit diagram.
(2) Let \(\bar{g}: K^{\triangleright} \rightarrow \mathcal{C}\) be a morphism of simplicial sets such that \(U \circ \bar{g}\) is a \(V\)-colimit diagram. Then \(\bar{g}\) is a \(U\)-colimit diagram if and only if it is a \((V \circ U)\)-colimit diagram.

Proof. Apply Remark 7.1.4.6.
02X5 Corollary 7.1.5.15. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) and \(V: \mathcal{D} \rightarrow \mathcal{E}\) be functors of \(\infty\)-categories, where \(V\) is fully faithful. Then:
(1) A morphism \(\bar{f}: K^{\triangleleft} \rightarrow \mathcal{C}\) is a \(U\)-limit diagram if and only if it is a \((V \circ U)\)-limit diagram.
(2) A morphism \(\bar{g}: K^{\triangleright} \rightarrow \mathcal{C}\) is a \(U\)-colimit diagram if and only if it is a \((V \circ U)\)-colimit diagram.

Proof. Combine Proposition 7.1.5.14 with Example 7.1.5.4.
02KR Corollary 7.1.5.16. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Then:
(1) Let \(\bar{f}: K^{\triangleleft} \rightarrow \mathcal{C}\) be a morphism of simplicial sets such that \(U \circ \bar{f}\) is a limit diagram in \(\mathcal{D}\). Then \(\bar{f}\) is a limit diagram in \(\mathcal{C}\) if and only if it is a \(U\)-limit diagram.
(2) Let \(\bar{g}: K^{\triangleright} \rightarrow \mathcal{C}\) be a morphism of simplicial sets such that \(U \circ \bar{g}\) is a colimit diagram in \(\mathcal{D}\). Then \(\bar{g}\) is a colimit diagram in \(\mathcal{C}\) if and only if it is a \(U\)-colimit diagram.

Proof. Apply Proposition 7.1.5.14 in the case \(\mathcal{E}=\Delta^{0}\) (and use Example 7.1.5.3).
02KS Corollary 7.1.5.17. Let \(K\) be a weakly contractible simplicial set and let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be \(a\) functor of \(\infty\)-categories. If \(U\) is a left fibration, then it creates \(K\)-indexed colimits. If \(U\) is a right fibration, then it creates \(K\)-indexed limits.

Proof. Assume \(U\) is a right fibration; we will show that it creates \(K\)-indexed limits (the analogous statement for left fibrations follows by a similar argument). Let \(f: K \rightarrow \mathcal{C}\) be a diagram and suppose that \(U \circ f\) can be extended to a limit diagram \(g: K^{\triangleleft} \rightarrow \mathcal{D}\). Since the inclusion \(K \hookrightarrow K^{\triangleleft}\) is right anodyne (Example 4.3.7.10), our assumption that \(U\) is a right fibration guarantees that the lifting problem

has a solution. Since \(K\) is weakly contractible, the morphism \(\bar{f}\) is automatically a \(U\) limit diagram (Example 7.1.5.10). Applying Corollary 7.1.5.16, we see that \(\bar{f}\) is a limit diagram.

Corollary 7.1.5.18. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(K\) be a weakly 02KT contractible simplicial set. Then:
- If \(U\) is a right fibration and the \(\infty\)-category \(\mathcal{D}\) admits \(K\)-indexed limits, then \(\mathcal{C}\) also admits \(K\)-indexed limits and \(U\) preserves \(K\)-indexed limits.
- If \(U\) is a left fibration and the \(\infty\)-category \(\mathcal{D}\) admits \(K\)-indexed colimits, then \(\mathcal{C}\) also admits \(K\)-indexed colimits and \(U\) preserves \(K\)-indexed colimits.

Proof. Combine Corollary 7.1.5.17 with Proposition 7.1.3.18

02x6 Proposition 7.1.5.19 (Base Change). Suppose we are given a commutative diagram of \(\infty\)-categories

where each square is a pullback and the diagonal maps are inner fibrations. Let \(\bar{f}: K^{\triangleright} \rightarrow \mathcal{C}^{\prime}\) be a morphism of simplicial sets. Then:
(1) If \(G \circ \bar{f}\) is an \(F\)-colimit diagram in the \(\infty\)-category \(\mathcal{C}\), then \(\bar{f}\) is an \(F^{\prime}\)-colimit diagram in the \(\infty\)-category \(\mathcal{C}^{\prime}\).
(2) Assume that \(U\) and \(V\) are cartesian fibrations, and that the functor \(F\) carries \(U\)-cartesian morphisms of \(\mathcal{C}\) to \(V\)-cartesian morphisms of \(\mathcal{D}\). If \(\bar{f}\) is an \(F^{\prime}\)-colimit diagram in the \(\infty\)-category \(\mathcal{C}^{\prime}\), then \(G \circ \bar{f}\) is an \(F\)-colimit diagram in the \(\infty\)-category \(\mathcal{C}\).

Proof. Set \(f=\left.\bar{f}\right|_{K}\). By virtue of Corollary 4.3.6.10 and Proposition 5.1.4.19, we can replace
(7.3) by the commutative diagram

and thereby reduce to the special case \(K=\emptyset\). In this case, the desired result follows from Proposition 7.1.4.19.

Corollary 7.1.5.20. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories, let \(D \in \mathcal{D}\) be 02KY an object, and let
\[
\bar{f}: K^{\triangleright} \rightarrow \mathcal{C}_{D}=\{D\} \times_{\mathcal{D}} \mathcal{C}
\]
be a diagram. If \(\bar{f}\) is a \(U\)-colimit diagram in \(\mathcal{C}\), then it is a colimit diagram in the \(\infty\)-category \(\mathcal{C}_{D}\). The converse holds if \(U\) is a cartesian fibration.

Proof. Apply Proposition 7.1.5.19 in the special case \(\mathcal{E}=\mathcal{D}\) and \(\mathcal{E}^{\prime}=\{D\}\).
Remark 7.1.5.21. Corollary 7.1.5.20 has an obvious counterpart for \(U\)-limit diagrams 02 KZ under the assumption that \(U: \mathcal{C} \rightarrow \mathcal{D}\) is a cocartesian fibration, which can be proved in the same way. It also has a more subtle counterpart for \(U\)-colimit diagrams when \(U\) is a cocartesian fibration (or \(U\)-limit diagrams when \(U\) is a cartesian fibration), which we will discuss in \(\$ 7.3 .9\) (see Proposition 7.3.9.2).

\subsection*{7.1.6 Limits and Colimits of Functors}

Let \(\mathcal{C}\) be an \(\infty\)-category and let \(B\) be a simplicial set. For every vertex \(b \in B\), we let
\[
\mathrm{ev}_{b}: \operatorname{Fun}(B, \mathcal{C}) \rightarrow \operatorname{Fun}(\{b\}, \mathcal{C}) \simeq \mathcal{C}
\]
denote the functor given by evaluation at \(b\). Our goal in this section is to show that the collection of functors \(\left\{\operatorname{ev}_{b}\right\}_{b \in B}\) creates colimits in the following sense:

02X9 Proposition 7.1.6.1. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(B\) be a simplicial set, and let \(f: K \rightarrow\) \(\operatorname{Fun}(B, \mathcal{C})\) be a diagram. Assume that, for every vertex \(b \in B\), the composite diagram
\[
K \xrightarrow{f} \operatorname{Fun}(B, \mathcal{C}) \xrightarrow{\mathrm{ev}_{b}} \mathcal{C}
\]
admits a colimit in the \(\infty\)-category \(\mathcal{C}\). Then:
(1) The diagram \(f\) admits a colimit in \(\operatorname{Fun}(B, \mathcal{C})\).
(2) Let \(\bar{f}: K^{\triangleright} \rightarrow \operatorname{Fun}(B, \mathcal{C})\) be an extension of \(f\). Then \(\bar{f}\) is a colimit diagram if and only \(i f\), for every vertex \(b \in B\), the morphism
\[
K^{\triangleright} \xrightarrow{\bar{f}} \operatorname{Fun}(B, \mathcal{C}) \xrightarrow{\mathrm{ev}_{b}} \mathcal{C}
\]
is a colimit diagram in \(\mathcal{C}\).
02XA Corollary 7.1.6.2. Let \(K\) be a simplicial set and let \(\mathcal{C}\) be an \(\infty\)-category which admits \(K\)-indexed colimits. Then, for every simplicial set \(B\), the \(\infty\)-category \(\operatorname{Fun}(B, \mathcal{C})\) also admits \(K\)-indexed colimits. Moreover, a morphism of simplicial sets \(\bar{f}: K^{\triangleright} \rightarrow \operatorname{Fun}(B, \mathcal{C})\) is a colimit diagram if and only if, for every vertex \(b \in B\), the morphism
\[
K^{\triangleright} \xrightarrow{\bar{f}} \operatorname{Fun}(B, \mathcal{C}) \xrightarrow{\mathrm{ev}_{b}} \mathcal{C}
\]
is a colimit diagram in \(\mathcal{C}\).
We will give a proof of Proposition 7.1.6.1 at the end of this section. Our strategy is to deduce Proposition 7.1.6.1 from a pair of more general results which apply to relative colimit diagrams (Corollaries 7.1.6.7 and 7.1.6.11). The increased flexibility of the relative setting will allow us to reduce to the case \(K=\emptyset\), by virtue of the following:
02XB Proposition 7.1.6.3. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, let \(K\) be a simplicial set, and let
\[
U^{\prime}: \operatorname{Fun}\left(K^{\triangleright}, \mathcal{C}\right) \rightarrow \operatorname{Fun}(K, \mathcal{C}) \times_{\operatorname{Fun}(K, \mathcal{D})} \operatorname{Fun}\left(K^{\triangleright}, \mathcal{D}\right)
\]
be the restriction map. Then a morphism of simplicial sets \(\bar{f}: K^{\triangleright} \rightarrow \mathcal{C}\) is a \(U\)-colimit diagram if and only if it is \(U^{\prime}\)-initial when viewed as an object of the \(\infty\)-category \(\operatorname{Fun}\left(K^{\triangleright}, \mathcal{C}\right)\). Proof. Set \(f=\left.\bar{f}\right|_{K}\), so that \(U^{\prime}\) restricts to a functor
\[
U^{\prime \prime}:\{f\} \times_{\operatorname{Fun}(K, \mathcal{C})} \operatorname{Fun}\left(K^{\triangleright}, \mathcal{C}\right) \rightarrow\{U \circ f\} \times_{\operatorname{Fun}(K, \mathcal{D})} \operatorname{Fun}\left(K^{\triangleright}, \mathcal{D}\right) .
\]

We have a commutative diagram

where the horizontal maps are equivalences of \(\infty\)-categories (see Example 4.6.6.8. Applying Remark 7.1.4.9, we see that \(\bar{f}\) is an \(U\)-colimit diagram if and only if it is \(U^{\prime \prime}\)-initial when viewed as an object of the fiber \(\{f\} \times_{\operatorname{Fun}(K, \mathcal{C})} \operatorname{Fun}\left(K^{\triangleright}\right)\).

We have a commutative diagram of \(\infty\)-categories

Applying Corollary 5.3.7.5, we see that \(V\) and \(V^{\prime}\) are cartesian fibrations and that \(U^{\prime}\) carries \(V\)-cartesian morphisms of \(\operatorname{Fun}\left(K^{\triangleright}, \mathcal{C}\right)\) to \(V^{\prime}\)-cartesian morphisms of \(\operatorname{Fun}(K, \mathcal{C}) \times{ }_{\operatorname{Fun}(K, \mathcal{D})}\) \(\operatorname{Fun}\left(K^{\triangleright}, \mathcal{D}\right)\). It follows from Proposition 7.1.4.19, that \(\bar{f}\) is \(U^{\prime \prime}\)-initial (when regarded as an object of \(\left.\{f\} \times_{\text {Fun }(K, \mathcal{C})} \operatorname{Fun}\left(K^{\triangleright}, \mathcal{C}\right)\right)\) if and only if it is \(U^{\prime}\)-initial (when viewed as an object of \(\operatorname{Fun}\left(K^{\triangleright}, \mathcal{C}\right)\) ).

Remark 7.1.6.4. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories and let \(\bar{f}: K^{\triangleright} \rightarrow \mathcal{C}\) be a morphism of simplicial sets having restriction \(f=\left.\bar{f}\right|_{K}\). Proposition 7.1.6.3 asserts that \(\bar{f}\) is a \(U\)-colimit diagram if and only if, for every diagram \(\bar{g}: K^{\triangleright} \rightarrow \mathcal{C}\) having restriction \(g=\left.\bar{g}\right|_{K}\), the diagram of Kan complexes

is a homotopy pullback square. However, it suffices to verify this condition in the special case where \(\bar{g}\) is a constant diagram: that is the content of Proposition 7.1.5.12,

Corollary 7.1.6.5. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(K\) be a simplicial set, and let
\[
U: \operatorname{Fun}\left(K^{\triangleright}, \mathcal{C}\right) \rightarrow \operatorname{Fun}(K, \mathcal{C})
\]
denote the restriction map. Then a morphism of simplicial sets \(\bar{f}: K^{\triangleright} \rightarrow \mathcal{C}\) is a colimit diagram if and only if it is \(U\)-initial when viewed as an object of the \(\infty\)-category \(\operatorname{Fun}\left(K^{\triangleright}, \mathcal{C}\right)\).

Proof. Apply Proposition 7.1.6.3 in the special case \(\mathcal{D}=\Delta^{0}\).

02XE Corollary 7.1.6.6. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories, let \(B\) and \(K\) be simplicial sets, and let \(A \subseteq B\) be a simplicial subset which contains every vertex of \(B\). Suppose we are given a lifting problem

which satisfies the following condition:
(*) Let \(\sigma: \Delta^{n} \rightarrow B\) be an n-simplex which does not belong to \(A\), and let \(a=\sigma(0)\) be the initial vertex. Then the restriction
\[
f_{a}=\left.f\right|_{\{a\} \times K^{\triangleright}}: K^{\triangleright} \rightarrow \mathcal{C}
\]
is a \(U\)-colimit diagram.
Then the lifting problem (7.4) admits a solution \(\bar{f}: B \times K^{\triangleright} \rightarrow \mathcal{C}\).
Proof. Set \(\mathcal{C}^{\prime}=\operatorname{Fun}\left(K^{\triangleright}, \mathcal{C}\right)\) and \(\mathcal{D}^{\prime}=\operatorname{Fun}(K, \mathcal{C}) \times_{\operatorname{Fun}(K, \mathcal{D})} \operatorname{Fun}\left(K^{\triangleright}, \mathcal{D}\right)\), so that \(U\) induces an inner fibration \(U^{\prime}: \mathcal{C}^{\prime} \rightarrow \mathcal{D}^{\prime}\) (Proposition 4.1.4.1). We can then rewrite 7.4) as a lifting problem

Let \(P\) be the partially ordered set of pairs \(\left(A^{\prime}, g^{\prime}\right)\), where \(A^{\prime} \subseteq B\) is a simplicial subset containing \(A\), and \(g^{\prime}: A^{\prime} \rightarrow \mathcal{C}^{\prime}\) is a morphism satisfying \(\left.g^{\prime}\right|_{A}=g\) and \(U^{\prime} \circ g^{\prime}=\left.g_{0}\right|_{A^{\prime}}\). The partially ordered set \(P\) satisfies the hypotheses of Zorn's lemma and therefore contains a maximal element ( \(A_{\max }, g_{\max }\) ). To complete the proof, it will suffice to show that \(A_{\max }=B\). Assume otherwise: then there exists some \(n\)-simplex \(\sigma: \Delta^{n} \rightarrow B\) which is not contained in \(A_{\max }\). Choose \(n\) as small as possible, so that \(\sigma\) carries the boundary \(\partial \Delta^{n}\) into \(A_{\max }\). Since every vertex of \(A\) is contained in \(B\), we must have \(n>0\). Moreover, it follows from \((*)\) together with Proposition 7.1.6.3 that the vertex \(a=\sigma(0)\) is a \(U^{\prime}\)-initial object of \(\mathcal{C}^{\prime}\).

Applying Corollary 7.1.4.17, we deduce that the lifting problem

has a solution, which contradicts the maximality of \(\left(A_{\max }, g_{\max }\right)\).
Corollary 7.1.6.7. Let \(U: \mathcal{C} \rightarrow \mathcal{D}\) be an inner fibration of \(\infty\)-categories, let \(B\) and \(K\) be 02XG simplicial sets, and suppose we are given a lifting problem

Assume that, for each vertex \(b \in B\), the restriction \(\left.f\right|_{\{b\} \times K}\) can be extended to a \(U\)-colimit diagram \(\bar{f}_{b}: K^{\triangleright} \rightarrow \mathcal{C}\) satisfying \(U \circ \bar{f}_{b}=\left.\bar{g}\right|_{\{b\} \times K \triangleright}\). Then the lifting problem (7.5) admits a solution \(\bar{f}: B \times K^{\triangleright} \rightarrow \mathcal{C}\) satisfying \(\left.\bar{f}\right|_{\{b\} \times K^{\triangleright}}=\bar{f}_{b}\) for each \(b \in B\).

Proof. Apply Corollary 7.1.6.6 in the special case where \(A=\operatorname{sk}_{0}(B)\) is the 0 -skeleton of \(B\).

We can now prove a weak form of Proposition 7.1.6.1:
Corollary 7.1.6.8. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(B\) be a simplicial set, and let \(f: K \rightarrow 02 \mathrm{XJ}\) \(\operatorname{Fun}(B, \mathcal{C})\) be a diagram. Assume that, for every vertex \(b \in B\), the diagram
\[
K \xrightarrow{f} \operatorname{Fun}(B, \mathcal{C}) \xrightarrow{\mathrm{ev}_{b}} \mathcal{C}
\]
has a colimit in \(\mathcal{C}\). Then \(f\) can be extended to a morphism \(\bar{f}: K^{\triangleright} \rightarrow \operatorname{Fun}(B, \mathcal{C})\) having the property that each composition \(K^{\triangleright} \xrightarrow{\bar{f}} \operatorname{Fun}(B, \mathcal{C}) \xrightarrow{\mathrm{ev}_{b}} \mathcal{C}\) is a colimit diagram in \(\mathcal{C}\).

Proof. Apply Corollary 7.1.6.7 in the special case \(\mathcal{D}=\Delta^{0}\).
To complete the proof of Proposition 7.1.6.1. we must show that the morphism \(\bar{f}: K^{\triangleright} \rightarrow\) Fun \((B, \mathcal{C})\) appearing in the statement of Corollary 7.1 .6 .8 is a colimit diagram. As above, it will be convenient to deduce this from a stronger assertion about relative colimit diagrams.

02XK Proposition 7.1.6.9. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories. Let \(B\) be a simplicial set and let \(A\) be a simplicial subset, so that \(F\) induces a functor
\[
F^{\prime}: \operatorname{Fun}(B, \mathcal{C}) \rightarrow \operatorname{Fun}(A, \mathcal{C}) \times \times_{\operatorname{Fun}(A, \mathcal{D})} \operatorname{Fun}(B, \mathcal{D}) .
\]

Suppose we are given a diagram \(\bar{f}: K^{\triangleright} \rightarrow \operatorname{Fun}(B, \mathcal{C})\) satisfying the following condition:
(*) Let \(\sigma: \Delta^{n} \rightarrow B\) be an n-simplex of \(B\) which is not contained in \(A\) and set \(b=\sigma(0)\). Then the composite map \(K^{\triangleright} \xrightarrow{\bar{f}} \operatorname{Fun}(B, \mathcal{C}) \xrightarrow{\mathrm{ev}_{b}} \mathcal{C}\) is an \(F\)-colimit diagram in the \(\infty\)-category \(\mathcal{C}\).

Then \(\bar{f}\) is an \(F^{\prime}\)-colimit diagram in the \(\infty\)-category \(\operatorname{Fun}(B, \mathcal{C})\).
Proof. As in the proof of Corollary 7.1.6.6, we can replace \(F\) by the restriction functor
\[
\operatorname{Fun}\left(K^{\triangleright}, \mathcal{C}\right) \rightarrow \operatorname{Fun}(K, \mathcal{C}) \times_{\operatorname{Fun}(K, \mathcal{D})} \operatorname{Fun}\left(K^{\triangleright}, \mathcal{D}\right)
\]
and thereby reduce to the special case \(K=\emptyset\) (Proposition 7.1.6.3). In this case, we view \(\bar{f}\) as an object of the \(\infty\)-category \(\operatorname{Fun}(B, \mathcal{C})\), and we wish to show that this object is \(F^{\prime}\)-initial.

Using Proposition 4.1.3.2, we can factor \(F\) as a composition \(\mathcal{C} \xrightarrow{G} \mathcal{E} \xrightarrow{U} \mathcal{D}\), where \(U\) is an inner fibration (so that \(\mathcal{E}\) is an \(\infty\)-category) and \(G\) is inner anodyne (and therefore an equivalence of \(\infty\)-categories). Note that we have a commutative diagram

where the vertical maps on the left and right are equivalences of \(\infty\)-categories (Remark 4.5.1.16). Since the square on the right is a pullback diagram and the right horizontal maps are isofibrations (Corollary 4.4.5.3), it follows that the vertical map in the middle is also an equivalence of \(\infty\)-categories (Corollary 4.5.2.29). Consequently, to show that \(\bar{f}\) is \(F^{\prime}\)-initial, it will suffice to show that \(G \circ \bar{f}\) is \(U^{\prime}\)-initial when viewed as an object of \(\operatorname{Fun}(B, \mathcal{E})\) (Remark 7.1.4.9). Since \(U^{\prime}\) is an inner fibration (Proposition 4.1.4.1), it will suffice to verify that \(\bar{f}\) satisfies the criterion of Corollary 7.1.4.17 every lifting problem

has a solution, provided that \(n>0\) and \(\sigma_{0}(0)=\bar{f}\). Unwinding the definitions, we can rewrite (7.6) as a lifting problem

Since \(n>0\), every vertex of the simplicial set \(\Delta^{n} \times B\) is contained in \(\partial \Delta^{n} \times B\). Moreover, if \(\tau: \Delta^{m} \rightarrow \Delta^{n} \times B\) is an \(m\)-simplex which does not belong to \(\left(\partial \Delta^{n} \times B\right) \amalg_{\left(\partial \Delta^{n} \times A\right)}\left(\Delta^{n} \times B\right)\), then condition \((*)\) (and Remark 7.1.4.9) guarantee that \(g\) carries \(\tau(0)\) to a \(U^{\prime}\)-initial vertex of \(\mathcal{E}\). The existence of the desired solution now follows from Corollary 7.1.6.6 (applied in the special case \(K=\emptyset\) ).

Corollary 7.1.6.10. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(B\) be a simplicial set, let \(A \subseteq B\) be 02XM a simplicial subset, and let \(U: \operatorname{Fun}(B, \mathcal{C}) \rightarrow \operatorname{Fun}(A, \mathcal{C})\) be the restriction functor. Let \(\bar{f}: K^{\triangleright} \rightarrow \operatorname{Fun}(B, \mathcal{C})\) be a diagram satisfying the following condition:
(*) Let \(\sigma: \Delta^{n} \rightarrow B\) be an n-simplex of \(B\) which is not contained in \(A\) and set \(b=\sigma(0)\). Then the composite map \(K^{\triangleright} \xrightarrow{\bar{f}} \operatorname{Fun}(B, \mathcal{C}) \xrightarrow{\text { eve }_{b}} \mathcal{C}\) is a colimit diagram in the \(\infty\)-category \(\mathcal{C}\).

Then \(\bar{f}\) is a \(U\)-colimit diagram in the \(\infty\)-category \(\operatorname{Fun}(B, \mathcal{C})\).
Proof. Apply Proposition 7.1.6.9 in the special case \(\mathcal{D}=\Delta^{0}\).
Corollary 7.1.6.11. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, let \(B\) be a simplicial set, 02 XN and let \(F^{\prime}: \operatorname{Fun}(B, \mathcal{C}) \rightarrow \operatorname{Fun}(B, \mathcal{D})\) be given by composition with \(F\). Let \(\bar{f}: K^{\triangleright} \rightarrow \operatorname{Fun}(B, \mathcal{C})\) be a diagram. Assume that, for every vertex \(b \in B\), the composition
\[
K^{\triangleright} \rightarrow \operatorname{Fun}(B, \mathcal{C}) \xrightarrow{\operatorname{ev}_{b}} \mathcal{C}
\]
is an \(F\)-colimit diagram in the \(\infty\)-category \(\mathcal{C}\). Then \(\bar{f}\) is an \(F^{\prime}\)-colimit diagram in the \(\infty\)-category \(\operatorname{Fun}(B, \mathcal{C})\).

Proof. Apply Proposition 7.1.6.9 in the special case \(A=\emptyset\).
Corollary 7.1.6.12. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(B\) be a simplicial set, and let \(\bar{f}: K^{\triangleright} \rightarrow 02 \mathrm{XP}\)
\(\operatorname{Fun}(B, \mathcal{C})\) be a diagram. Assume that, for each vertex \(b \in B\), the composite map \(K^{\triangleright} \xrightarrow{\bar{f}}\) \(\operatorname{Fun}(B, \mathcal{C}) \xrightarrow{\mathrm{ev}_{b}} \mathcal{C}\) is a colimit diagram in \(\mathcal{C}\). Then \(\bar{f}\) is a colimit diagram in \(\operatorname{Fun}(B, \mathcal{C})\).

Proof. Apply Corollary 7.1.6.11 in the special case \(\mathcal{D}=\Delta^{0}\) (or Corollary 7.1.6.10) in the special case \(A=\emptyset\).

Proof of Proposition 7.1.6.1. Let \(\mathcal{C}\) be an \(\infty\)-category, let \(B\) be a simplicial set, and let \(f: K \rightarrow \operatorname{Fun}(B, \mathcal{C})\) be a diagram. Assume that, for every vertex \(b \in B\), the composite diagram
\[
K \xrightarrow{f} \operatorname{Fun}(B, \mathcal{C}) \xrightarrow{\mathrm{ev}_{b}} \mathcal{C}
\]
admits a colimit in the \(\infty\)-category \(\mathcal{C}\). Applying Corollary 7.1.6.8, we see that \(f\) admits an extension \(\bar{f}: K^{\triangleright} \rightarrow \operatorname{Fun}(B, \mathcal{C})\) with the property that, for every vertex \(b \in B\), the composition \(\mathrm{ev}_{b} \circ \bar{f}\) is a colimit diagram in \(\mathcal{C}\). Applying Corollary 7.1.6.12, we see any such extension is a colimit diagram in \(\operatorname{Fun}(B, \mathcal{C})\). To complete the proof, it will suffice to show the converse: if \(\bar{f}^{\prime}: K^{\triangleright} \rightarrow \operatorname{Fun}(B, \mathcal{C})\) is any colimit diagram extending \(f\) and \(b \in B\) is a vertex, then \(\mathrm{ev}_{b} \circ \bar{f}^{\prime}\) is also a colimit diagram in \(\mathcal{C}\). In this case, the extension \(\bar{f}^{\prime}\) is isomorphic to \(\bar{f}\) as an object of the \(\infty\)-category \(\operatorname{Fun}\left(K^{\triangleright}, \operatorname{Fun}(B, \mathcal{C})\right)\). It follows that \(\mathrm{ev}_{b} \circ \bar{f}^{\prime}\) is isomorphic to \(\mathrm{ev}_{b} \circ \bar{f}\) as an object of the \(\infty\)-category \(\operatorname{Fun}\left(K^{\triangleright}, \mathcal{C}\right)\) and therefore a colimit diagram by virtue of Corollary 7.1.2.14

\subsection*{7.2 Cofinality}

02MZ Let \(\mathcal{C}\) be an \(\infty\)-category and let \(f: B \rightarrow \mathcal{C}\) be a diagram in \(\mathcal{C}\) indexed by a simplicial set \(B\). In \(\S 7.1\), we introduced the definition of a \(\operatorname{limit} \lim (f)\) and colimit \(\underset{\leftrightarrows}{\lim }(f)\) of the diagram \(f\) (Definition 7.1.1.11). In practice, it is often convenient to replace \(f\) by a simpler diagram having the same limit (or colimit). The primary goal of this section is to introduce a general formalism which will allow us to make replacements of this sort.

We begin in \(\S 7.2 .1\) by introducing the notions of left cofinal and right cofinal morphisms of simplicial sets (Definition 7.2.1.1). Roughly speaking, one can regard left cofinality as a homotopy-invariant replacement for the notion of left anodyne morphism introduced in Definition 4.2.4.1. More precisely, the collection of left cofinal morphisms of simplicial sets is uniquely determined by the following assertions:
- A monomorphism of simplicial sets \(f: A \hookrightarrow B\) is left cofinal if and only if it is left anodyne (Proposition 7.2.1.3).
- Suppose we are given a commutative diagram of simplicial sets

where the vertical maps are categorical equivalences. Then \(f\) is left cofinal if and only if \(f^{\prime}\) is left cofinal (Corollary 7.2.1.22).

In \(\S 7.2 .2\), we connect the notion of cofinality with the theory of limits and colimits developed in \(\S 7.1\). Let \(\mathcal{C}\) be an \(\infty\)-category, and let \(g: B \rightarrow \mathcal{C}\) be a diagram in \(\mathcal{C}\). We will show that if \(f: A \rightarrow B\) is a left cofinal morphism of simplicial sets, then the limit of the diagram \(g\) (if it exists) can be identified with with the limit of the composite diagram \((g \circ f): A \rightarrow \mathcal{C}\) (Corollary 7.2.2.11). Similarly, if \(f\) is right cofinal, then the colimit of \(g\) can be identified with the colimit of \(g \circ f\). Consequently, cofinality is a very useful tool for computing (or verifying the existence of) limits and colimits.

In \(\$ 7.2 .3\), we specialize to the study of cofinal functors between \(\infty\)-categories. Our main result asserts that a functor \(F: \mathcal{C} \rightarrow \mathcal{D}\) is right cofinal if and only if, for every object \(D \in \mathcal{D}\), the \(\infty\)-category \(\mathcal{C} \times{ }_{\mathcal{D}} \mathcal{D}_{D /}\) is weakly contractible (Theorem 7.2.3.1). In particular, the weak contractibility of each slice \(\mathcal{C} \times_{\mathcal{D}} \mathcal{D}_{/ D}\) guarantees that \(F\) is a weak homotopy equivalence of simplicial sets: this is an \(\infty\)-categorical generalization of Quillen's "Theorem A" (see Example 7.2.3.3). We will deduce Theorem 7.2.3.1 from a general fact about the stability of right cofinality with respect to pullback along cocartesian fibrations (Proposition 7.2.3.12), which is of independent interest.

We devote the second half of this section to studying properties of \(\infty\)-categories which are closely related to the notion of cofinality. We say that an \(\infty\)-category \(\mathcal{C}\) is filtered if, for every finite simplicial set \(K\) and every diagram \(f: K \rightarrow \mathcal{C}\), the coslice \(\infty\)-category \(\mathcal{C}_{f /}\) is nonempty (Definition 7.2.4.3). In \(\$ 7.2 .4\) we show that if this property is satisfied for every finite simplicial set \(K\), then one can say more: every such coslice \(\infty\)-category \(\mathcal{C}_{f /}\) is weakly contractible. It follows that \(\mathcal{C}\) is filtered if and only if the diagonal map \(\mathcal{C} \rightarrow \operatorname{Fun}(K, \mathcal{C})\) is right cofinal for every finite simplicial set \(K\) (Proposition 7.2.4.10).

To show that an \(\infty\)-category \(\mathcal{C}\) is filtered, it is not necessary to show that the coslice \(\infty\)-category \(\mathcal{C}_{f /}\) is nonempty for every finite diagram \(f: K \rightarrow \mathcal{C}\). In \(\$ 7.2 .5\), we show that it suffices to verify this condition in the case where \(K=\partial \Delta^{n}\) is the boundary of a standard simplex, for each \(n \geq 0\) (Lemma 7.2.5.13). Using this observation, we show that the condition that an \(\infty\)-category \(\mathcal{C}\) is filtered can be formulated entirely at the level of the homotopy category hC, viewed as an hKan-enriched category (Theorem 7.2.5.5). As an application, we show that our notion of filtered \(\infty\)-category generalizes the classical notion of a filtered category: that is, an ordinary category \(\mathcal{C}\) is filtered if and only if the nerve \(\mathrm{N}_{\bullet}(\mathcal{C})\) is a filtered \(\infty\)-category (Corollary 7.2.5.8). We also formulate a counterpart of this result for the homotopy coherent nerve of a locally Kan simplicial category (Corollary 7.2.5.10).

Our primary interest in the notion of filtered \(\infty\)-category stems from the exactness properties enjoyed by filtered colimits. We will see later that a small \(\infty\)-category \(\mathcal{C}\) is filtered if and only if the colimit functor \(\underset{\longrightarrow}{\lim }: \operatorname{Fun}(\mathcal{C}, \mathcal{S}) \rightarrow \mathcal{S}\) preserves finite limits (Theorem [?]). In \(\$ 7.2 .6\) we establish a version of this statement, which reformulates the condition
that \(\mathcal{C}\) is filtered in terms of fiber products of \(\infty\)-categories which are left-fibered over \(\mathcal{C}\) (Corollary 7.2.6.3). As a consequence, we show that if \(F: \mathcal{C}^{\prime} \rightarrow \mathcal{C}\) is a right cofinal functor of \(\infty\)-categories where \(\mathcal{C}^{\prime}\) is filtered, then \(\mathcal{C}\) is also filtered (Proposition 7.2.7.1). In \(\S 7.2 .7\), we establish a partial converse to this assertion: if \(\mathcal{C}\) is a filtered \(\infty\)-category, then there exists a directed partially ordered set \((A, \leq)\) and a right cofinal functor \(\mathrm{N}_{\bullet}(A) \rightarrow \mathcal{C}\) (Theorem 7.2.7.2.

For many applications, it will be useful to consider a generalization of the notion of filtered \(\infty\)-category. In \(\S 7.2 .8\), we introduce the larger class of sifted simplicial sets. We say that a simplicial set \(K\) is sifted if, for every finite set \(I\), the diagonal map \(\delta: K \rightarrow K^{I}\) is right cofinal (Definition 7.2.8.1). Equivalently, a simplicial set \(K\) is sifted if it is weakly contractible and the diagonal \(K \hookrightarrow K \times K\) is right cofinal (Proposition 7.2.8.8). Every filtered \(\infty\)-category is sifted (Example 7.2.8.4), but the converse is false: for example, the \(\infty\)-category \(\mathrm{N}_{\bullet}(\boldsymbol{\Delta})^{\text {op }}\) is sifted (Proposition 7.2.8.10), but is not filtered.

\subsection*{7.2.1 Cofinal Morphisms of Simplicial Sets}

02NO Recall that a morphism of simplicial sets \(f: A \rightarrow B\) is left anodyne if, for every left fibration \(q: X \rightarrow S\), every lifting problem

admits a solution (Proposition 4.2.4.5). Beware that this condition can only be satisfied if \(f\) is a monomorphism of simplicial sets, and is therefore not invariant under categorical equivalence. Our goal in this section is to introduce an enlargement of the collection of left anodyne morphisms which does not suffer from this defect.

02N1 Definition 7.2.1.1 (Joyal). Let \(f: A \rightarrow B\) be a morphism of simplicial sets. We say that \(f\) is left cofinal if, for every left fibration \(q: \widetilde{B} \rightarrow B\), precomposition with \(f\) induces a homotopy equivalence of Kan complexes \(\operatorname{Fun}_{/ B}(B, \widetilde{B}) \rightarrow \operatorname{Fun}_{{ }^{\prime}}(\widetilde{B}(A, \widetilde{B})\) (see Corollary 4.4.2.5. We say that \(f\) is right cofinal if, for every right fibration \(q: \widetilde{B} \rightarrow B\), precomposition with \(f\) induces a homotopy equivalence of Kan complexes Fun \({ }_{/ B}(B, \widetilde{B}) \rightarrow \operatorname{Fun}_{/ B}(A, \widetilde{B})\).

02N2 Remark 7.2.1.2. Let \(f: A \rightarrow B\) be a morphism of simplicial sets. Then \(f\) is left cofinal if and only if the opposite morphism \(f^{\mathrm{op}}: A^{\mathrm{op}} \rightarrow B^{\mathrm{op}}\) is right cofinal.

02N3 Proposition 7.2.1.3. Let \(f: A \rightarrow B\) be a morphism of simplicial sets. Then \(f\) is left anodyne if and only if it is a left cofinal monomorphism. Similarly, \(f\) is right anodyne if and only if it is a right cofinal monomorphism.

Proof. We will prove the first assertion; the second follows by a similar argument. Assume first that \(f\) is left anodyne. Then \(f\) is a monomorphism (Remark 4.2.4.4). For every left fibration of simplicial sets \(\widetilde{B} \rightarrow B\), the restriction map \(\theta: \operatorname{Fun}_{/ B}(B, \widetilde{B}) \rightarrow \operatorname{Fun}_{/ B}(A, \widetilde{B})\) is a pullback of the map
\[
\operatorname{Fun}(B, \widetilde{B}) \rightarrow \operatorname{Fun}(B, B) \times_{\operatorname{Fun}(A, B)} \operatorname{Fun}(A, \widetilde{B}),
\]
and is therefore a trivial Kan fibration (Proposition 4.2.5.4). In particular, \(u\) is a homotopy equivalence (Proposition 3.1.6.10). Allowing \(\widetilde{B}\) to vary, we conclude that \(f\) is left cofinal.

We now prove the converse. Assume that \(f\) is a left cofinal monomorphism; we wish to show that \(f\) is left anodyne. By virtue of Proposition 4.2.4.5, it will suffice to show that every lifting problem

admits a solution, provided that \(q\) is a left fibration of simplicial sets. Let us regard the morphism \(g\) as fixed, and consider the restriction map
\[
\theta: \operatorname{Fun}_{/ B}\left(B, X \times_{S} B\right) \rightarrow \operatorname{Fun}_{/ B}\left(A, X \times_{S} B\right) .
\]

Since \(f\) is a monomorphism, the morphism \(\theta\) is a left fibration (Proposition 4.2.5.1). Since the target simplicial set Fun \({ }_{B}\left(A, X \times_{S} B\right)\) is a Kan complex (Corollary 4.4.2.5), it follows that \(\theta\) is a Kan fibration (Corollary 4.4.3.8). Our assumption that \(f\) is left cofinal guarantees that \(\theta\) is a homotopy equivalence, and therefore a trivial Kan fibration (Proposition 3.2.7.2). In particular, it is surjective at the level of vertices, which guarantees that 7.7 admits a solution.

Example 7.2.1.4. Let \(\mathcal{C}\) be an \(\infty\)-category and let \(X\) be an object of \(\mathcal{C}\). Then the inclusion map \(\{X\} \hookrightarrow \mathcal{C}\) is right cofinal if and only if \(X\) is a final object of \(\mathcal{C}\). This follows by combining Proposition 7.2.1.3 with Corollary 4.6.7.24. Similarly, the inclusion map \(\{X\} \hookrightarrow \mathcal{C}\) is left cofinal if and only if \(X\) is an initial object of \(\mathcal{C}\).

Proposition 7.2.1.5. Let \(f: A \rightarrow B\) be a morphism of simplicial sets. Then:
(1) If \(f\) is either left cofinal or right cofinal, then it is a weak homotopy equivalence.
(2) If \(f\) is a weak homotopy equivalence and \(B\) is a Kan complex, then \(f\) is left and right cofinal.

Proof. We first prove (1). Let \(X\) be a Kan complex. Then the projection map \(X \times B \rightarrow B\) is a Kan fibration (Remark 3.1.1.6), and therefore both a left and a right fibration (Example 4.2.1.5. Consequently, if \(f\) is either left cofinal or right cofinal, the induced map
\[
\operatorname{Fun}^{(B, X) \simeq \operatorname{Fun}_{/ B}(B, X \times B) \rightarrow \operatorname{Fun}_{/ B}(A, X \times B) \simeq \operatorname{Fun}(A, X)}
\]
is a homotopy equivalence of Kan complexes. Allowing \(X\) to vary, we conclude that \(f\) is a weak homotopy equivalence.

We now prove (2). Assume that \(B\) is a Kan complex and that \(f\) is a weak homotopy equivalence; we will show that \(f\) is left cofinal (the proof that \(f\) is right cofinal is similar). Let \(q: \widetilde{B} \rightarrow B\) be a left fibration. Since \(B\) is a Kan complex, \(q\) is a Kan fibration (Corollary 4.4.3.8; in particular, \(\widetilde{B}\) is a Kan complex. Applying Corollary 3.1.3.4 we obtain a commutative diagram of Kan complexes

where the vertical maps are Kan fibrations (Corollary 3.1.3.2). Our assumption that \(f\) is a weak homotopy equivalence guarantees that the horizontal maps are homotopy equivalences (Proposition 3.1.6.17). Applying Proposition 3.2.8.1, we deduce that the map \(\operatorname{Fun}_{/ B}(B, \widetilde{B}) \rightarrow \operatorname{Fun}_{/ B}(A, \widetilde{B})\) is also a homotopy equivalence.

02N6 Proposition 7.2.1.6. Let \(f: A \rightarrow B\) and \(g: B \rightarrow C\) be morphisms of simplicial sets, and suppose that \(f\) is left cofinal. Then \(g\) is left cofinal if and only if the composite map \(g \circ f\) is left cofinal. In particular, the collection of left cofinal morphisms is closed under composition.

Proof. Let \(q: \widetilde{C} \rightarrow C\) be a left fibration of simplicial sets, and let
\[
\operatorname{Fun}_{/ C}(C, \widetilde{C}) \xrightarrow{g^{*}} \operatorname{Fun}_{/ C}(B, \widetilde{C}) \xrightarrow{f^{*}} \operatorname{Fun}_{/ C}(A, \widetilde{C})
\]
be the morphisms given by precomposition with \(g\) and \(f\). Our assumption that \(f\) is left cofinal guarantees that \(f^{*}\) is a homotopy equivalence. It follows that \(g^{*}\) is a homotopy equivalence if and only if \(f^{*} \circ g^{*}\) is a homotopy equivalence (Remark 3.1.6.7).

02N7 Corollary 7.2.1.7. Let \(f: A \hookrightarrow B\) and \(g: B \hookrightarrow C\) be monomorphisms of simplicial sets. If both \(f\) and \(g \circ f\) are left anodyne, then \(g\) is left anodyne. If \(f\) and \(g \circ f\) are right anodyne, then \(g\) is right anodyne.

Proof. Combine Propositions 7.2.1.6 and 7.2.1.3.
Warning 7.2.1.8. Let \(g: \Delta^{1} \rightarrow \Delta^{0}\) be the projection map and let \(f:\{1\} \hookrightarrow \Delta^{1}\) be the
02N8 inclusion. Then \(g\) and \(g \circ f\) are left cofinal (Proposition 7.2.1.5). However, the morphism \(f\) is not left cofinal, since it is not left anodyne (see Example 4.2.4.7. Consequently, the collection of left cofinal morphisms does not satisfy the two-out-of-three property.

Corollary 7.2.1.9. Let \(F: \mathcal{C} \rightarrow \mathcal{D}\) be a functor of \(\infty\)-categories, and let \(X\) be an initial 043E object of \(\mathcal{C}\). Then \(F\) is left cofinal if and only if \(F(X)\) is an initial object of \(\mathcal{D}\).

Proof. Combine Proposition 7.2.1.6 with Example 7.2.1.4
Proposition 7.2.1.10. Let \(A\) be a simplicial set, let \(W\) be a collection of edges of \(A\), and let \(f: A \rightarrow B\) be a morphism of simplicial sets which exhibits \(B\) as a localization of \(A\) with respect to \(W\) (see Definition 6.3.1.9). Then \(f\) is both left and right cofinal.

Proof. We will show that \(f\) is left cofinal; the proof that \(f\) is right cofinal is similar. Let \(q: \widetilde{B} \rightarrow B\) be a left fibration; we wish to show that composition with \(f\) induces a homotopy equivalence \(f^{*}: \operatorname{Fun}_{/ B}(B, \widetilde{B}) \rightarrow \operatorname{Fun}_{/ B}(A, \widetilde{B})\). Applying Corollary 5.6.7.3 (and Remark 5.6.7.4, we deduce that there exists a pullback diagram of simplicial sets

where \(Q\) is a left fibration of \(\infty\)-categories. Let \(\operatorname{Fun}\left(A\left[W^{-1}\right], \mathcal{C}\right)\) denote the full subcategory of \(\operatorname{Fun}(A, \mathcal{C})\) spanned by those diagrams which carry each edge of \(W\) to an isomorphism in \(\mathcal{C}\) (Notation 6.3.1.1 , and define \(\operatorname{Fun}\left(A\left[W^{-1}\right], \widetilde{\mathcal{C}}\right)\) similarly. We have a commutative diagram of \(\infty\)-categories

where the vertical maps on both sides are left fibrations (Corollary 4.2.5.2. Since \(Q\) is a left fibration of \(\infty\)-categories, it is conservative (Proposition 4.4.2.11), so the right side of the diagram is a pullback square. In particular, the vertical map in the middle is also
a left fibration. Our assumption that \(f\) exhibits \(B\) as a localization of \(A\) with respect to \(W\) guarantees that the left horizontal maps are equivalences of \(\infty\)-categories. Applying Corollary 4.5.2.32, we conclude that the map of fibers
\[
\begin{aligned}
\operatorname{Fun}_{/ B}(B, \widetilde{B}) \simeq\{g\} \times_{\operatorname{Fun}(B, \mathcal{C})} \operatorname{Fun}(B, \widetilde{\mathcal{C}}) & \rightarrow\{g \circ f\} \times_{\operatorname{Fun}\left(A\left[W^{-1}\right], \mathcal{C}\right)} \operatorname{Fun}\left(A\left[W^{-1}\right], \widetilde{\mathcal{C}}\right) \\
& =\{g \circ f\} \times_{\operatorname{Fun}(A, \mathcal{C})} \operatorname{Fun}(A, \widetilde{\mathcal{C}}) \\
& \simeq \operatorname{Fun}_{/ B}(A, \widetilde{B})
\end{aligned}
\]
is an equivalence of \(\infty\)-categories, and therefore a homotopy equivalence of Kan complexes (Example 4.5.1.13).

02NA Corollary 7.2.1.11. Let \(f: A \rightarrow B\) be a universally localizing morphism of simplicial sets (see Definition 6.3.6.1). Then \(f\) is both left and right cofinal.

02NB Corollary 7.2.1.12. Let \(\mathcal{C}\) be a simplicial set. Then there exists a partially ordered set \((A, \leq)\) and a morphism of simplicial sets \(F: \mathrm{N}_{\bullet}(A) \rightarrow \mathcal{C}\) which is both left and right cofinal. Moreover, if the simplicial set \(\mathcal{C}\) is finite, then we can arrange that the partially ordered set \((A, \leq)\) is finite.

Proof. Combine Theorem 6.3.7.1 (and Variant 6.3.7.17) with Corollary 7.2.1.11.
02NC Corollary 7.2.1.13. Let \(f: A \rightarrow B\) be a categorical equivalence of simplicial sets. Then \(f\) is left cofinal and right cofinal.

Proof. Combine Proposition 7.2.1.10 with Example 6.3.1.12
02ND Corollary 7.2.1.14. Let \(q: X \rightarrow S\) be a morphism of simplicial sets. The following conditions are equivalent:
(1) The morphism \(q\) is left cofinal and a left fibration.
(2) The morphism \(q\) is right cofinal and a right fibration.
(3) The morphism \(q\) is a trivial Kan fibration.

Proof. If \(q\) is a trivial Kan fibration, then it is both a left fibration and a right fibration (Example 4.2.1.5). Moreover, \(q\) is also a categorical equivalence of simplicial sets (Proposition 4.5.3.11, hence left and right cofinal by virtue of Corollary 7.2.1.13. This proves the implications \((3) \Rightarrow(1)\) and (3) \(\Rightarrow(2)\).

We will complete the proof by showing that \((1) \Rightarrow(3)\) (the proof of the implication \((2) \Rightarrow(3)\) is similar). Assume that \(q\) is a left cofinal left fibration. Then composition with \(q\) induces a homotopy equivalence of Kan complexes \(\operatorname{Fun}_{/ S}(S, X) \rightarrow \operatorname{Fun}_{/ S}(X, X)\). In particular, the morphism \(q\) admits a section \(f: S \rightarrow X\) such that id \(X_{X}\) and \(f \circ q\) belong to the
same connected component of \(\operatorname{Fun}_{/ S}(X, X)\). For each vertex \(s \in S\), let \(X_{s}=\{s\} \times_{S} X\) be the fiber of \(q\) over \(s\). Then the identity map id : \(X_{s} \rightarrow X_{s}\) is homotopic to the constant map \(X_{s} \rightarrow\{f(s)\} \hookrightarrow X_{s}\). It follows that the Kan complex \(X_{s}\) is contractible. Allowing \(s\) to vary, we conclude that the left fibration \(q\) is a trivial Kan fibration (Proposition 4.4.2.14).

Corollary 7.2.1.15. Let \(f: X \rightarrow Z\) be a morphism of simplicial sets. Then \(f\) is left cofinal 02NE if and only if it factors as a composition \(X \xrightarrow{f^{\prime}} Y \xrightarrow{f^{\prime \prime}} Z\), where \(f^{\prime}\) is left anodyne and \(f^{\prime \prime}\) is a trivial Kan fibration.

Proof. Suppose first that we can write \(f=f^{\prime \prime} \circ f^{\prime}\), where \(f^{\prime}\) is left anodyne and \(f^{\prime \prime}\) is a trivial Kan fibration. Proposition 7.2.1.3 guarantees that \(f^{\prime}\) is left cofinal, and Proposition 7.2.1.5 guarantees that \(f^{\prime \prime}\) is left cofinal. Applying Proposition 7.2.1.6, we conclude that \(f\) is also left cofinal.

We now prove the converse. Assume that \(f: X \rightarrow Z\) is left cofinal. Applying Proposition 4.2.4.8, we can write \(f\) as a composition \(X \xrightarrow{f^{\prime}} Y \xrightarrow{f^{\prime \prime}} Z\), where \(f^{\prime}\) is left anodyne and \(f^{\prime \prime}\) is a left fibration. Then \(f^{\prime}\) is also left cofinal (Proposition 7.2.1.3). Applying Proposition 7.2.1.6, we deduce that \(f^{\prime \prime}\) is left cofinal. It then follows from Corollary 7.2.1.14 that \(f^{\prime \prime}\) is a trivial Kan fibration.

Corollary 7.2.1.16. Suppose we are given a categorical pushout diagram of simplicial sets 02NF

02NG

If \(f\) is left cofinal, then \(f^{\prime}\) is also left cofinal.
Proof. By virtue of Corollary 7.2.1.15, we may assume that \(f\) factors as a composition \(X \xrightarrow{g} Y \xrightarrow{h} Z\), where \(g\) is left anodyne and \(h\) is a trivial Kan fibration. Setting \(Y^{\prime}=Y \coprod_{X} X^{\prime}\), we can expand 7.8 to a commutative diagram
